| #                    | If the first character of the command is a # , then<br>this command deletes this # and each # that<br>follows a newline. Otherwise, sends the line<br>after inserting a # in front of each line in the<br>command. Useful for causing the current line to<br>be inserted in the history as a comment and<br>removing comments from previous comment<br>commands in the history file. |
| =                    | List the file names that match the current word if<br>an asterisk were appended it.                                                                                                                                                                                                                                                                                                  |
| @<br><i>letter</i>   | Your alias list is searched for an alias by the name<br><code>_ <i>letter</i></code> and if an alias of this name is defined,<br>its value will be inserted on the input queue<br>for processing.                                                                                                                                                                                    |

**Special Commands**

The following *simple-commands* are executed in the shell process. Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is 0 . Commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

\* : [ *arg* ... ]

The command only expands parameters.

\* `. file [ arg ... ]`

Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.

\*\* `alias [-tx] [ name [= value] ] ...`

`alias` with no arguments prints the list of aliases in the form *name=value* on standard output. An *alias* is defined for each *name* whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The `-t` flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value becomes undefined when the value of `PATH` is reset but the aliases remained tracked. Without the `-t` flag, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The `-x` flag is used to set or print *exported aliases*. An *exported alias* is defined for scripts invoked by name. The exit status is non-zero if a *name* is given, but no *value*, and no alias has been defined for the *name*.

`bg [ % job ... ]`

This command is only on systems that support job control. Puts each specified *job* into the background. The current job is put in the background if *job* is not specified. See "JOBS" section above for a description of the format of *job*.

\* `break [ n ]`

Exit from the enclosed `for`, `while`, `until`, or `select` loop, if any. If *n* is specified then `break n` levels.

\* `continue [ n ]`

Resume the next iteration of the enclosed `for`, `while`, `until`, or `select` loop. If *n* is specified then resume at the *n*-th enclosed loop.

`cd [ arg ]`

`cd old new`

This command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is `-` the directory is changed to the previous directory. The shell variable `HOME` is the default *arg*. The variable `PWD` is set to the current directory. The shell variable `CDPATH` defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (`:`). The default path is null (specifying the current directory). Note that the current directory is specified by a null path name, which can

appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a / then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of `cd` substitutes the string *new* for the string *old* in the current directory name, `PWD` and tries to change to this new directory. The `cd` command may not be executed by `rksh`.

```
command [-p] [command_name] [argument ...]
```

```
command [-v -v] command_name
```

The `command` utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup. The `-p` flag performs the command search using a default value for `PATH` that is guaranteed to find all of the standard utilities. The `-v` flag writes a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment, to invoke *command\_name*. The `-v` flag writes a string to standard output that indicates how the name given in the *command\_name* operand will be interpreted by the shell, in the current shell execution environment.

```
echo [arg ...]
```

See `echo(1)` for usage and description.

```
* eval [arg ...]
```

The arguments are read as input to the shell and the resulting command(s) executed.

```
* exec [arg ...]
```

If *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

```
* exit [n]
```

Causes the calling shell or shell script to exit with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the exit status is that of the last command executed. When `exit` occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An EOF will also cause the shell to exit except for a shell which has the `ignoreeof` option (See `set` below) turned on.

```
** export [name [= value]] ...
```

The given *name*s are marked for automatic export to the environment of subsequently-executed commands.

```
fc [-e ename] [-n|r] [first [last]]
```

```
fc -e - [old = new] [command]
```

In the first form, a range of commands from *first* to *last* is selected from the last HISTSIZE commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the *-1* flag is selected, the commands are listed on standard output. Otherwise, the editor program *ename* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable FCEDIT (default /bin/ed) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified then it will be set to *first*. If *first* is not specified the default is the previous command for editing and *-16* for listing. The flag *-r* reverses the order of the commands and the flag *-n* suppresses command numbers when listing. In the second form the *command* is re-executed after the substitution *old* = *new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

```
fg [% job ...]
```

This command is only on systems that support job control. Each *job* specified is brought to the foreground. Otherwise, the current job is brought into the foreground. See "Jobs" section above for a description of the format of *job*.

```
getopts optstring name [arg ...]
```

Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument - ends the options. *optstring* contains the letters that *getopts* recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.

*getopts* places the next option letter it finds inside variable *name* each time it is invoked with a + prepended when *arg* begins with a +. The index of the next *arg* is stored in OPTIND. The option argument, if any, gets stored in OPTARG.

A leading : in *optstring* causes *getopts* to store the letter of an invalid option in OPTARG, and to set *name* to ? for an unknown option and to : when a required option is missing. Otherwise, *getopts* prints an error message. The exit status is non-zero when there are no more options. See *getoptcvt(1)* for usage and description.

```
hash [name ...]
```

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The *-r* option causes

the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk ( \* ) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

`jobs [-lnp] [% job ... ]`

Lists information about each given job; or all active jobs if *job* is omitted.

The `-l` flag lists process ids in addition to the normal information. The `-n` flag displays only jobs that have stopped or exited since last notified. The `-p` flag causes only the process group to be listed. See "Jobs" section above and `jobs(1)` for a description of the format of *job*.

`kill [-sig] % job ...`

`kill [-sig] pid ...`

`kill -l`

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal(3HEAD)` stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD ). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See Jobs for a description of the format of *job*. In the second form, `kill -l`, the signal numbers and names are listed.

`let arg ...`

Each *arg* is a separate *arithmetic expression* to be evaluated. See the Arithmetic Evaluation section above, for a description of arithmetic expression evaluation.

The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

`login argument ...`

Equivalent to 'exec login argument ....' See `login(1)` for usage and description.

\* `newgrp [ arg ... ]`

Equivalent to `exec /bin/newgrp arg ....`

`print [-Rnprsu [n ] ] [ arg ... ]`

The shell output mechanism. With no flags or with flag `-o` or `-`, the arguments are printed on standard output as described by `echo(1)`. The exit status is 0, unless the output file is not open for writing.

`-n` Suppress NEWLINE from being added to the output.

`-R` Raw mode. Ignore the escape conventions of `echo`.  
`| -r` The `-R` option will print all subsequent arguments and options other than `-n`.

`-p` Write the arguments to the pipe of the process spawned with `|&` instead of standard output.

`-s` Write the arguments to the history file instead of standard output.

`-u` Specify a one digit file descriptor unit number *n* on which  
`[ n` the output will be placed. The default is 1.  
`]`

`pwd`

Equivalent to `print -r - $PWD`.

`read [-prsu [n]] [name ? prompt] [name ...]`

The shell input mechanism. One line is read and is broken up into fields using the characters in `IFS` as separators. The escape character, `(\)`, is used to remove any special meaning for the next character and for line continuation. In raw mode, `-r`, the `\` character is not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, etc., with leftover fields assigned to the last *name*. The `-p` option causes the input line to be taken from the input pipe of a process spawned by the shell using `|&`. If the `-s` flag is present, the input will be saved as a command in the history file. The flag `-u` can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the `exec` special command. The default value of *n* is 0. If *name* is omitted then `REPLY` is used as the default *name*. The exit status is 0 unless the input file is not open for reading or an EOF is encountered. An EOF with the `-p` option causes cleanup for this process so that another can be spawned. If the first argument contains a `?`, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is 0 unless an EOF is encountered.

\*\* `readonly [name [= value]] ...`

The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.

\* `return [ n ]`

Causes a shell function or `'.'` script to return to the invoking script with the return status specified by `n`. The value will be the least significant 8 bits of the specified status. If `n` is omitted then the return status is that of the last command executed. If `return` is invoked while not in a function or a `'.'` script, then it is the same as an `exit`.

`set [ \261abCefhkmpstuvx ] [ \261o option ]... [ \261A name ] [ arg... ]`

The flags for this command have meaning as follows:

- A     Array assignment. Unset the variable `name` and assign values sequentially from the list `arg`. If `+A` is used, the variable `name` is not unset first.
- a     All subsequent variables that are defined are automatically exported.
- b     Causes the shell to notify the user asynchronously of background job completions. The following message will be written to standard error:

```
"[%d]%c %s%s\ ", <job-number>, <current>, <status>, <job-name>
```

where the fields are as follows:

`<current>`           The character `+` identifies the job that would be used as a default for the `fg` or `bg` utilities; this job can also be specified using the `job_id %+` or `%%`. The character `-` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the `job_id %-`. For other jobs, this field is a space character. At most one job can be identified with `+` and at most one job can be identified with `-`. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.

`<job-number>`        A number that can be used to identify the process group to the `wait`, `fg`, `bg`, and `kill` utilities. Using these utilities, the job can be identified by prefixing the job number with `%`.

`<status>` Unspecified.

`<job-name>` Unspecified.

When the shell notifies the user a job has been completed, it may remove the job's process ID from the list of those known in the current shell execution environment. Asynchronous notification will not be enabled by default.

- C Prevent existing files from being overwritten by the shell's > redirection operator; the >| redirection operator will override this `noclobber` option for an individual file.
- e If a command has a non-zero exit status, execute the `ERR` trap, if set, and exit. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o The following argument can be one of the following option names:
  - `allexport` Same as `-a`.
  - `errexit` Same as `-e`.
  - `bgnice` All background jobs are run at a lower priority. This is the default mode.
  - `emacs` Puts you in an `emacs` style in-line editor for command entry.

|                         |                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gmacs</code>      | Puts you in a <code>gmacs</code> style in-line editor for command entry.                                                                                                    |
| <code>ignoreeof</code>  | The shell will not exit on <code>EOF</code> . The command <code>exit</code> must be used.                                                                                   |
| <code>keyword</code>    | Same as <code>-k</code> .                                                                                                                                                   |
| <code>markdirs</code>   | All directory names resulting from file name generation have a trailing <code>/</code> appended.                                                                            |
| <code>monitor</code>    | Same as <code>-m</code> .                                                                                                                                                   |
| <code>noclobber</code>  | Prevents redirection <code>&gt;</code> from truncating existing files. Require <code>&gt; </code> to truncate a file when turned on. Equivalent to <code>-C</code> .        |
| <code>noexec</code>     | Same as <code>-n</code> .                                                                                                                                                   |
| <code>noglob</code>     | Same as <code>-f</code> .                                                                                                                                                   |
| <code>nolog</code>      | Do not save function definitions in history file.                                                                                                                           |
| <code>notify</code>     | Equivalent to <code>-b</code> .                                                                                                                                             |
| <code>nounset</code>    | Same as <code>-u</code> .                                                                                                                                                   |
| <code>privileged</code> | Same as <code>-p</code> .                                                                                                                                                   |
| <code>verbose</code>    | Same as <code>-v</code> .                                                                                                                                                   |
| <code>trackall</code>   | Same as <code>-h</code> .                                                                                                                                                   |
| <code>vi</code>         | Puts you in insert mode of a <code>vi</code> style in-line editor until you hit escape character <code>033</code> . This puts you in control mode. A return sends the line. |

viraw            Each character is processed as it is typed  
in vi mode.

xtrace          Same as -x .

If no option name is supplied, the current option settings are printed.

-p            Disables processing of the \$HOME/.profile file and uses the file /etc/suid\_profile instead of the ENV file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.

-s            Sort the positional parameters lexicographically.

-t            Exit after reading and executing one command.

-u            Treat unset parameters as an error when substituting.

-v            Print shell input lines as they are read.

-x            Print commands and their arguments as they are executed.

-            Turns off -x and -v flags and stops examining arguments for flags.

--           Do not change any of the flags; useful in setting \$1 to a value beginning with - . If no arguments follow this flag then the positional parameters are unset.

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$- . Unless -A is specified, the remaining arguments are positional parameters and are assigned, in order, to \$1 \$2 .... If no arguments are given, the names and values of all variables are printed on the standard output.

\* shift [ n ]

The positional parameters from \$ n +1 \$ n +1 . . . are renamed \$1 . . . , default n is 1. The parameter n can be any arithmetic expression that evaluates to a non-negative number less than or equal to \$# .

`stop %jobid . . .`

`stop pid ...`

`stop` stops the execution of a background job(s) by using its *jobid* , or of any process by using its *pid* . (see `ps(1)` ).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`test expression`

Evaluate conditional expressions. See Conditional Expressions section above and `test(1)` for usage and description.

\* `times`

Print the accumulated user and system times for the shell and for processes run from the shell.

\* `trap [ arg sig ... ]`

*arg* is a command to be read and executed when the shell receives signal(s) *sig* . *arg* is scanned once when the trap is set and once when the trap is taken. *sig* can be specified as a signal number or signal name. `trap` commands are executed in order of signal number. Any attempt to set a trap on a signal number that was ignored on entry to the current shell is ineffective.

If *arg* is - , the shell will reset each *sig* to the default value. If *arg* is null ( ' ' ), the shell will ignore each specified *sig* if it arises. Otherwise, *arg* will be read and executed by the shell when one of the corresponding *sigs* arises. The action of the trap will override a previous action (either default action or one explicitly set). The value of \$? after the trap action completes will be the value it had before the trap was invoked.

*sig* can be `EXIT` , 0 (equivalent to `EXIT`) or a signal specified using a symbolic name, without the `SIG` prefix, for example, `HUP` , `INT` , `QUIT` , `TERM` . If *sig* is 0 or `EXIT` and the `trap` statement is executed inside the body of a function, then the command *arg* is executed after the function completes. If *sig* is 0 or `EXIT` for a `trap` set outside any function, the command *arg* is executed on exit from the shell. If *sig* is `ERR` , *arg* will be executed whenever a command has a non-zero exit status. If *sig* is `DEBUG` , *arg* will be executed after each command.

The environment in which the shell executes a trap on `EXIT` will be identical to the environment immediately after the last command executed before the trap on `EXIT` was taken.

Each time the trap is invoked, *arg* will be processed in a manner equivalent to:

```
eval "$arg"
```

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps will remain in place for a given shell until explicitly changed with another `trap` command.

When a subshell is entered, traps are set to the default args. This does not imply that the `trap` command cannot be used within the subshell to set new traps.

The `trap` command with no arguments will write to standard output a list of commands associated with each sig. The format is:

```
trap -- %s %s ... <arg> , <sig> ...
```

The shell will format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$(trap)
...
eval "$save_traps"
```

If the trap name or number is invalid, a non-zero exit status will be returned; otherwise, 0 will be returned. For both interactive and non-interactive shells, invalid signal names or numbers will not be considered a syntax error and will not cause the shell to abort.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on `CHLD` won't be executed until the foreground job terminates.

```
type name ...
```

For each *name*, indicate how it would be interpreted if used as a command name.

```
** typeset [\\261HLRZfilrtux [n]] [name [= value]] ...
```

Sets attributes and values for shell variables and functions. When `typeset` is invoked inside a function, a new instance of the variables *name* is created. The variables *value* and `type` are restored when the function completes. The following list of attributes may be specified:

- H This flag provides UNIX to host-name file mapping on non-UNIX machines.
- L Left justify and remove leading blanks from *value*. If *n* is non-zero it defines the width of the field; otherwise, it is determined by

- the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the `-z` flag is also set. The `-R` flag is turned off.
- `-R` Right justify and fill with leading blanks. If *n* is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The `-L` flag is turned off.
  - `-Z` Right justify and fill with leading zeros if the first non-blank character is a digit and the `-L` flag has not been set. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.
  - `-f` The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are `-t`, `-u`, and `-x`. The flag `-t` turns on execution tracing for this function. The flag `-u` causes this function to be marked undefined. The `FPATH` variable will be searched to find the function definition when the function is referenced. The flag `-x` allows the function definition to remain in effect across shell procedures invoked by name.
  - `-i` Parameter is an integer. This makes arithmetic faster. If *n* is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.
  - `-l` All upper-case characters are converted to lower-case. The upper-case flag, `-u` is turned off.
  - `-r` The given *name* s are marked `readonly` and these names cannot be changed by subsequent assignment.
  - `-t` Tags the variables. Tags are user definable and have no special meaning to the shell.
  - `-u` All lower-case characters are converted to upper-case characters. The lower-case flag, `-l` is turned off.
  - `-x` The given *name* s are marked for automatic export to the `environment` of subsequently-executed commands.

The `-i` attribute can not be specified along with `-R`, `-L`, `-Z`, or `-f`.

Using `+` rather than `-` causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using `+`

rather than `-` keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

`ulimit [-HSacdfnstv] [limit]`

Set or display a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `H` and `S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `H` or `S` options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case the soft limit is printed unless `H` is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- `-a` Lists all of the current resource limits.
- `-c` The number of 512-byte blocks on the size of core dumps.
- `-d` The number of K-bytes on the size of the data area.
- `-f` The number of 512-byte blocks on files written by child processes (files of any size may be read).
- `-n` The number of file descriptors plus 1.
- `-s` The number of K-bytes on the size of the stack area.
- `-t` The number of seconds to be used by each process.
- `-v` The number of K-bytes for virtual memory.

If no option is given, `-f` is assumed.

`umask [-S] [mask]`

The user file-creation mask is set to *mask* (see `umask(2)`). *mask* can either be an octal number or a symbolic value as described in `chmod(1)`. If a symbolic value is given, the new `umask` value is the complement of the result of applying *mask* to the complement of the previous `umask` value.

If *mask* is omitted, the current value of the mask is printed. The `-S` flag produces symbolic output.

`unalias name ...`

The *alias* es given by the list of *name* s are removed from the *alias* list.

`unset [-f ] name ...`

The variables given by the list of *name* s are unassigned, that is, their values and attributes are erased. `readonly` variables cannot be unset. If the `-f` flag is set, then the names refer to *function* names. Unsetting `ERRNO` , `LINENO` , `MAILCHECK` , `OPTARG` , `OPTIND` , `RANDOM` , `SECONDS` , `TMOU` , and `_` removes their special meaning even if they are subsequently assigned to.

\* `wait [ job ]`

Wait for the specified *job* and report its termination status. If *job* is not given then all currently active child processes are waited for. The exit status from this command is that of the process waited for. See `Jobs` for a description of the format of *job* .

`whence [-pv ] name ...`

For each *name* , indicate how it would be interpreted if used as a command name.

The `-v` flag produces a more verbose report.

The `-p` flag does a path search for *name* even if *name* is an alias, a function, or a reserved word.

#### Invocation

If the shell is invoked by `exec(2)` , and the first character of argument zero (`$0` ) is `-` , then the shell is assumed to be a `login` shell and commands are read from `/etc/profile` and then from either `.profile` in the current directory or `$HOME/.profile` , if either file exists. Next, commands are read from the file named by performing parameter substitution on the value of the environment variable `ENV` if the file exists. If the `-s` flag is not present and *arg* is, then a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have read permission and any `setuid` and `setgid` settings will be ignored. If the script is not found on the path, *arg* is processed as if it named a builtin command or function. Commands are then read as described below; the following flags are interpreted by the shell when it is invoked:

`-c` Read commands from the *command\_string* operand. Set the value of special parameter `0` from the value of the *command\_name* operand and the positional parameters (`$1` , `$2` , and so on) in sequence from the remaining *arg* operands. No commands will be read from the standard input.

`-s` If the `-s` flag is present or if no arguments remain, commands are read from the standard input. Shell output, except for the output of the `Special Commands` listed above, is written to file descriptor `2`.

- i If the `-i` flag is present or if the shell input and output are attached to a terminal (as told by `ioctl(2)`), then this shell is *interactive*. In this case, `TERM` is ignored (so that `kill 0` does not kill an interactive shell) and `INTR` is caught and ignored (so that `wait` is interruptible). In all cases, `QUIT` is ignored by the shell.
- r If the `-r` flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the `set` command above.

#### rksh Only

`rksh` is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of `rksh` are identical to those of `ksh`, except that the following are disallowed:

- changing directory (see `cd(1)`)
- setting the value of `SHELL`, `ENV`, or `PATH`
- specifying path or command names containing `/`
- redirecting output (`>`, `>|`, `<>`, and `>>`)
- changing group (see `newgrp(1)`).

The restrictions above are enforced after `.profile` and the `ENV` files are interpreted.

When a command to be executed is found to be a shell procedure, `rksh` invokes `ksh` to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the `.profile` has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, `/usr/rbin`) that can be safely invoked by `rksh`.

#### ERRORS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above). If the shell is being used non-interactively then execution of the shell file is abandoned. Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets (`[ ]`) after the command or function name.

For a non-interactive shell, an error condition encountered by a special built-in or other type of utility will cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

| Error                                          | Special Built-in | Other Utilities |
|------------------------------------------------|------------------|-----------------|
| Shell language syntax error                    | will exit        | will exit       |
| Utility syntax error (option or operand error) | will exit        | will not exit   |
| Redirection error                              | will exit        | will not exit   |
| Variable assignment error                      | will exit        | will not exit   |
| Expansion error                                | will exit        | will exit       |
| Command not found                              | n/a              | may exit        |
| Dot script not found                           | will exit        | n/a             |

An expansion error is one that occurs when the shell expansions are carried out (for example,  $\${x!y}$ , because `!` is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as "will (may) exit" occur in a subshell, the subshell will (may) exit with a non-zero status, but the script containing the subshell will not exit because of the error.

In all of the cases shown in the table, an interactive shell will write a diagnostic message to standard error without exiting.

#### USAGE

See `largefile(5)` for the description of the behavior of `ksh` and `rksh` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

#### EXIT STATUS

Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status will be 127. If the command name is found, but it is not an executable utility, the exit status will be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status will be greater than zero.

When reporting the exit status with the special parameter `?`, the shell will report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal will be reported as greater than 128.

**WARNINGS**

The use of `setuid` shell scripts is *strongly* discouraged.

**NOTES**

If a command which is a *tracked alias* is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to `exec` the original command. Use the `-t` option of the `alias` command to correct this situation.

Some very old shell scripts contain a `^` as a synonym for the pipe character `|`.

Using the `fc` built-in command within a compound command will cause the whole command to disappear from the history file.

The built-in command `. file` reads the whole file before any commands are executed. Therefore, `alias` and `unalias` commands in the file will not apply to any functions defined in the file.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

| <b>NAME</b>        | ksrvtgt – fetch and store Kerberos ticket-granting ticket using a service key                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <code>/usr/bin/ksrvtgt name instance [[realm] srvtab ]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>ksrvtgt retrieves a ticket-granting ticket with a lifetime of five minutes for the principal <code>name.instance@realm</code> (or <code>name.instance@localrealm</code> if <code>realm</code> is not supplied on the command line), decrypts the response using the service key found in the file <code>srvtab</code> (or in <code>/etc/srvtab</code> if <code>srvtab</code> is not specified on the command line), and stores the ticket in the standard ticket cache.</p> <p>This command is intended primarily for use in shell scripts and other batch-type facilities.</p> |                |                 |              |         |
| <b>DIAGNOSTICS</b> | Generic <code>kerberos failure</code> ( <code>kfailure</code> ) can indicate a whole range of problems, the most common of which is the inability to read the service key file.                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>FILES</b>       | <p><code>/etc/krb.conf</code> to get the name of the local realm.</p> <p><code>/tmp/tktuid</code> The default ticket file.</p> <p><code>/etc/srvtab</code> The default service key file.</p>                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
|                    | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                        | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu |

| <b>DESCRIPTION</b>                              | The <code>ktutil</code> command is an interactive command-line interface utility for managing the keylist in keytab files. You must read in a keytab's keylist before you can manage it. Also, the user running the <code>ktutil</code> command must have read/write permissions on the keytab. For example, if a keytab is owned by root, which it typically is, <code>ktutil</code> must be run as root to have the appropriate permissions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <b>COMMANDS</b>                                 | <table border="0"> <tr> <td><code>clear_list, clear</code></td> <td>Clears the current keylist.</td> </tr> <tr> <td><code>read_kt file, rkt file</code></td> <td>Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.</td> </tr> <tr> <td><code>write_kt file, wkt file</code></td> <td>Writes the current keylist to a keytab <i>file</i>. You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.</td> </tr> <tr> <td><code>delete_entry number, delent number</code></td> <td>Deletes an entry from the current keylist. Specify the entry by the keylist slot number.</td> </tr> <tr> <td><code>list, l</code></td> <td>Lists the current keylist.</td> </tr> <tr> <td><code>list_request, lr</code></td> <td>Lists available requests (commands).</td> </tr> <tr> <td><code>quit, exit, q</code></td> <td>Exits utility.</td> </tr> </table> | <code>clear_list, clear</code> | Clears the current keylist. | <code>read_kt file, rkt file</code> | Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read. | <code>write_kt file, wkt file</code> | Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file. | <code>delete_entry number, delent number</code> | Deletes an entry from the current keylist. Specify the entry by the keylist slot number. | <code>list, l</code> | Lists the current keylist. | <code>list_request, lr</code> | Lists available requests (commands). | <code>quit, exit, q</code> | Exits utility. |
| <code>clear_list, clear</code>                  | Clears the current keylist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>read_kt file, rkt file</code>             | Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>write_kt file, wkt file</code>            | Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |
| <code>delete_entry number, delent number</code> | Deletes an entry from the current keylist. Specify the entry by the keylist slot number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |

| <b>EXAMPLES</b>                                 | <p><b>EXAMPLE 1</b> Deleting a principal from a file</p> <p>The following example deletes the <code>host/denver@ACME.com</code> principal from the <code>/etc/krb5/krb5.keytab</code> file. Notice that if you want to delete an entry from an existing keytab, you must first write the keylist to a temporary keytab and then overwrite the existing keytab with the the temporary keytab. This is because the <code>wkt</code> command actually appends the current keylist to an existing keytab, so you can't use it to overwrite a keytab.</p> <pre> example# /usr/krb5/bin/ktutil ktutil: rkt /etc/krb5/krb5.keytab ktutil: list slot KVNO Principal ----- 1      8 host/vail@ACME.COM 2      5 host/denver@ACME.COM ktutil:delent 2 ktutil:l slot KVNO Principal ----- 1      8 host/vail@ACME.COM </pre>                                                                                                                                                     |                                |                             |                                     |                                                                                         |                                      |                                                                                                                                                                                               |                                                 |                                                                                          |                      |                            |                               |                                      |                            |                |

| <b>NAME</b>                        | last – display login and logout information about users and terminals                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |    |                                           |                    |                                                                                                  |                                    |                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>                    | <b>last</b> [-a] [-n <i>number</i>   -number ][-f <i>filename</i> ] [ <i>name</i>   <i>tty</i> ]...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |    |                                           |                    |                                                                                                  |                                    |                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b>                 | <p>The <code>last</code> command looks in the <code>/var/adm/wtmpx</code> file, which records all logins and logouts, for information about a user, a terminal, or any group of users and terminals. Arguments specify names of users or terminals of interest. If multiple arguments are given, the information applicable to any of the arguments is printed. For example, <code>last root console</code> lists all of root's sessions, as well as all sessions on the console terminal. <code>last</code> displays the sessions of the specified users and terminals, most recent first, indicating the times at which the session began, the duration of the session, and the terminal on which the session took place. <code>last</code> also indicates whether the session is continuing or was cut short by a reboot.</p> <p>The pseudo-user <code>reboot</code> logs in when the system reboots. Thus,</p> <pre>last reboot</pre> <p>will give an indication of mean time between reboots.</p> <p><code>last</code> with no arguments displays a record of all logins and logouts, in reverse order.</p> <p>If <code>last</code> is interrupted, it indicates how far the search has progressed in <code>/var/adm/wtmpx</code>. If interrupted with a quit signal (generated by a CTRL-<code>\</code>), <code>last</code> indicates how far the search has progressed, and then continues the search.</p> |    |                                           |                    |                                                                                                  |                                    |                                                                                                                                                                                                                   |
| <b>OPTIONS</b>                     | <p>The following options are supported:</p> <table border="0"> <tr> <td style="vertical-align: top;">-a</td> <td>Displays the hostname in the last column.</td> </tr> <tr> <td style="vertical-align: top;">-f <i>filename</i></td> <td>Uses <i>filename</i> as the name of the accounting file instead of <code>/var/adm/wtmpx</code>.</td> </tr> <tr> <td style="vertical-align: top;">-n <i>number</i>   -<i>number</i></td> <td>Limits the number of entries displayed to that specified by <i>number</i>. These options are identical; the -<i>number</i> option is provided as a transition tool only and will be removed in future releases.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | -a | Displays the hostname in the last column. | -f <i>filename</i> | Uses <i>filename</i> as the name of the accounting file instead of <code>/var/adm/wtmpx</code> . | -n <i>number</i>   - <i>number</i> | Limits the number of entries displayed to that specified by <i>number</i> . These options are identical; the - <i>number</i> option is provided as a transition tool only and will be removed in future releases. |
| -a                                 | Displays the hostname in the last column.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |    |                                           |                    |                                                                                                  |                                    |                                                                                                                                                                                                                   |
| -f <i>filename</i>                 | Uses <i>filename</i> as the name of the accounting file instead of <code>/var/adm/wtmpx</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |    |                                           |                    |                                                                                                  |                                    |                                                                                                                                                                                                                   |

**NAME** ld – link-editor for object files

**SYNOPSIS** `/usr/ccs/bin/ld` [-a | -r ][-b] [-c *name*] [-G] [-i] [-m] [-s] [-t] [-V] [-B dynamic | static ] [-B group] [-B local] [-B eliminate] [-B reduce] [-B symbolic] [-d y | n ] [-D *token*] [-e *epsym*] [-F *name* | -f *name*] [-h *name*] [-I *name*] [-L *path*] [-l *x*] [-M *mapfile*] [-N *string*] [-o *outfile*] [-p *auditlib*] [-P *auditlib*] [-Q y | n ] [-R *path*] [-S *supportlib*] [-u *symname*] [-Y *P,dirlist*] [-z allextact | defaultextract | weakextract ] [-z combrelloc] [-z defs | nodefs ] [-z endfiltee] [-z ignore | record ] [-z lazyload | nolazyload ] [-z initfirst] [-z loadfltr] [-z muldefs] [-z nodelete] [-z nodefaultlib] [-z nodlopen] [-z nodump] [-z nopartial] [-z noversion] [-z now] [-z origin] [-z redlocsymb] [-z text | textwarn | textoff ] *filename...*

**DESCRIPTION**

The `ld` command combines relocatable object files, performs relocation, and resolves external symbols. `ld` operates in two modes, static or dynamic, as governed by the `-d` option. In static mode, `-dn`, relocatable object files given as arguments are combined to produce an executable object file. If the `-r` option is specified, relocatable object files are combined to produce one relocatable object file. In dynamic mode, `-dy`, the default, relocatable object files given as arguments are combined to produce an executable object file that will be linked at execution with any shared object files given as arguments. If the `-G` option is specified, relocatable object files are combined to produce a shared object. In all cases, the output of `ld` is left in `a.out` by default.

If any argument is a library, `ld` searches exactly once at the point it encounters the library in the argument list. The library may be either a relocatable archive or a shared object. For an archive library, `ld` loads only those routines that define an unresolved external reference. `ld` searches the archive library symbol table sequentially with as many passes as are necessary to resolve external references that can be satisfied by library members. See `ar(3HEAD)`. Thus, the order of members in the library is functionally unimportant, unless multiple library members exist that define the same external symbol.

A shared object consists of an indivisible, whole unit, that has been generated by a previous link-edit of one or more input files. When the link-editor processes a shared object, the entire contents of the shared object become a logical part of the resulting output file image. The shared object is not physically copied during the link-edit as its actual inclusion is deferred until process execution. This logical inclusion means that all symbol entries defined in the shared object are made available to the link-editing process.

**OPTIONS**

There is no specific option that tells `ld` to link 64-bit objects; the class of the first object that gets processed by `ld` determines whether it is to perform a 32-bit or a 64-bit link edit.

The following options are supported:

`-a`

In static mode only, produces an executable object file; gives errors for undefined references. This is the default behavior for static mode. `-a` may not be used with the `-r` option.

`-b`

In dynamic mode only, when creating an executable, does not do special processing for relocations that reference symbols in shared objects. Without the `-b` option, the link-editor creates special position-independent relocations for references to functions defined in shared objects and arranges for data objects defined in shared objects to be copied into the memory image of the executable by the runtime linker. With the `-b` option, the output code may be more efficient, but it will be less sharable.

`-B dynamic | static`

Options governing library inclusion. `-B dynamic` is valid in dynamic mode only. These options may be specified any number of times on the command line as toggles: if the `-B static` option is given, no shared objects will be accepted until `-B dynamic` is seen. See also the `-l` option.

`-B eliminate`

Causes any global symbols not assigned to a version definition to be eliminated from the symbol table. This option achieves the same symbol elimination as the *auto-elimination* directive available as part of a *mapfile* version definition.

`-B group`

Establishes a shared object and its dependencies as a group. Objects within the group will be bound to other members of the group at runtime. The runtime processing of an object containing this flag mimics that which occurs if the object is added to a process using `dlopen(3DL)` with the `RTLD_GROUP` mode. As the group must be self contained, use of the `-B group` option also asserts the `-z defs` option.

`-B local`

Causes any global symbols, not assigned to a version definition, to be reduced to local. Version definitions can be supplied via a *mapfile* and indicate the global symbols that should remain visible in the generated object. This option achieves the same symbol reduction as the *auto-reduction* directive available as part of a *mapfile* version definition and may be useful when combining versioned and non-versioned relocatable objects.

**-B reduce**

When generating a relocatable object, causes the reduction of symbolic information defined by any version definitions. Version definitions can be supplied via a *mapfile* to indicate the global symbols that should remain visible in the generated object. When a relocatable object is generated, by default version definitions are only recorded in the output image. The actual reduction of symbolic information will be carried out when the object itself is used in the construction of a dynamic executable or shared object. This option is applied automatically when dynamic executable or shared object is created.

**-B symbolic**

In dynamic mode only. When building a shared object, binds references to global symbols to their definitions, if available, within the object. Normally, references to global symbols within shared objects are not bound until runtime, even if definitions are available, so that definitions of the same symbol in an executable or other shared object can override the object's own definition. `ld` will issue warnings for undefined symbols unless `-z defs` overrides.

**-c name**

Records the configuration file *name* for use at runtime. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternative object dependencies. See `crle(1)`.

**-d y | n**

When `-d y`, the default, is specified, `ld` uses dynamic linking; when `-d n` is specified, `ld` uses static linking. See also `-B dynamic|static`.

**-D token,token,...**

Prints debugging information, as specified by each *token*, to the standard error. The special token `help` indicates the full list of tokens available.

**-e epsym**

Sets the entry point address for the output file to be that of the symbol *epsym*.

**-f name**

Useful only when building a shared object. Specifies that the symbol table of the shared object is used as an auxiliary filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option may not be combined with the `-F` option.

**-F name**

Useful only when building a shared object. Specifies that the symbol table of the shared object is used as a filter on the symbol table of the shared object

specified by *name*. Multiple instances of this option are allowed. This option may not be combined with the `-f` option.

`-G`

In dynamic mode only, produces a shared object. Undefined symbols are allowed.

`-h name`

In dynamic mode only, when building a shared object, records *name* in the object's dynamic section. *name* will be recorded in executables that are linked with this object rather than the object's UNIX System file name. Accordingly, *name* will be used by the runtime linker as the name of the shared object to search for at runtime.

`-i`

Ignores `LD_LIBRARY_PATH`. This option is useful when an `LD_LIBRARY_PATH` setting is in effect to influence the runtime library search, which would interfere with the link-editing being performed.

`-I name`

When building an executable, uses *name* as the path name of the interpreter to be written into the program header. The default in static mode is no interpreter; in dynamic mode, the default is the name of the runtime linker, `ld.so.1(1)`. Either case may be overridden by `-I name`. `exec(2)` will load this interpreter when it loads `a.out` and will pass control to the interpreter rather than to `a.out` directly.

`-l x`

Searches a library `libx.so` or `libx.a`, the conventional names for shared object and archive libraries, respectively. In dynamic mode, unless the `-B static` option is in effect, `ld` searches each directory specified in the library search path for a `libx.so` or `libx.a` file. The directory search stops at the first directory containing either. `ld` chooses the file ending in `.so` if `-lx` expands to two files with names of the form `libx.so` and `libx.a`. If no `libx.so` is found, then `ld` accepts `libx.a`. In static mode, or when the `-B static` option is in effect, `ld` selects only the file ending in `.a`. `ld` searches a library when it encounters its name, so the placement of `-l` is significant.

`-L path`

Adds *path* to the library search directories. `ld` searches for libraries first in any directories specified by the `-L` options and then in the standard directories. This option is useful only if it precedes the `-l` options to which it applies on the command line. The environment variable `LD_LIBRARY_PATH` may be used to supplement the library search path (see `LD_LIBRARY_PATH` below).

`-m`

Produces a memory map or listing of the input/output sections, together with any non-fatal multiply defined symbols, on the standard output.

**-M** *mapfile*

Reads *mapfile* as a text file of directives to `ld`. This option may be specified multiple times. If *mapfile* is a directory, then all regular files, as defined by `stat(2)`, within the directory will be processed. See *Linker and Libraries Guide* for a description of mapfiles. There are mapfiles in `/usr/lib/ld` that show the default layout of programs as well as mapfiles for linking 64-bit programs above or below 4 gigabytes. See the FILES section below.

**-N** *string*

This option causes a `DT_NEEDED` entry to be added to the `.dynamic` section of the object being built. The value of the `DT_NEEDED` string will be the *string* specified on the command line. This option is position dependent, and the `DT_NEEDED` `.dynamic` entry will be relative to the other dynamic dependencies discovered on the link-edit line.

**-o** *outfile*

Produces an output object file named *outfile*. The name of the default object file is `a.out`.

**-p** *auditlib*

Identifies an audit library, *auditlib*, that is used to audit this object at runtime. Any shared object identified as requiring auditing of itself has this requirement inherited by any object specifying this shared object as a dependency (see `-P` option).

**-P** *auditlib*

Identifies an audit library, *auditlib*, that is used to audit this object's dependencies at runtime. Dependency auditing can also be inherited from dependencies identified as requiring auditing (see `-p` option).

**-Q** *y* | *n*

Under `-Q y`, an `ident` string is added to the `.comment` section of the output file to identify the version of the link-editor used to create the file. This results in multiple `ld ident`s when there have been multiple linking steps, such as when using `ld -r`. This is identical with the default action of the `cc` command. `-Q n` suppresses version identification.

**-r**

Combines relocatable object files to produce one relocatable object file. `ld` will not complain about unresolved references. This option cannot be used in dynamic mode or with `-a`.

**-R** *path*

A colon-separated list of directories used to specify library search directories to the runtime linker. If present and not NULL, it is recorded in the output object file and passed to the runtime linker. Multiple instances of this option are concatenated together with each *path* separated by a colon.

-s

Strips symbolic information from the output file. Any debugging information, that is *.debug*, *.line*, and *.stab* sections, and their associated relocation entries will be removed. Except for relocatable files or shared objects, the symbol table and string table sections will also be removed from the output object file.

-S *supportlib*

The shared object *supportlib* is loaded with the link-editor and given information regarding the linking process. Support shared objects may also be supplied using the `SGS_SUPPORT` environment variable. See *Linker and Libraries Guide* for more details.

-t

Turns off the warning about multiply defined symbols that are not the same size.

-u *symname*

Enters *symname* as an undefined symbol in the symbol table. This is useful for loading entirely from an archive library, since initially the symbol table is empty, and an unresolved reference is needed to force the loading of the first routine. The placement of this option on the command line is significant; it must be placed before the library that will define the symbol.

-V

Outputs a message giving information about the version of `ld` being used.

-Y *P*, *dirlist*

Changes the default directories used for finding libraries. *dirlist* is a colon-separated path list.

-z *allextract* | *defaultextract* | *weakextract*

Alters the extraction criteria of objects from any archives that follow. By default, archive members are extracted to satisfy undefined references and to promote tentative definitions with data definitions. Weak symbol references do not trigger extraction. Under `-z allextract`, all archive members are extracted from the archive. Under `-z weakextract`, weak references trigger archive extraction. `-z defaultextract` provides a means of returning to the default following use of the former extract options.

-z *combrelloc*

Combines multiple relocation sections. Reduces overhead when objects are loaded into memory.

`-z defs`

Forces a fatal error if any undefined symbols remain at the end of the link. This is the default when an executable is built. It is also useful when building a shared object to assure that the object is self-contained, that is, that all its symbolic references are resolved internally.

`-z endfiltee`

Marks a filtee so that when processed by a filter it terminates any further filtee searches by the filter.

`-z ignore | record`

Ignores, or records, dynamic dependencies that are not referenced as part of the link-edit. By default, `-z record` is in effect.

`-z initfirst`

Marks the object so that its runtime initialization occurs before the runtime initialization of any other objects brought into the process at the same time. In addition, the object runtime finalization will occur after the runtime finalization of any other objects removed from the process at the same time. This option is only meaningful when building a shared object.

`-z lazyload | nolazyload`

Enables or disables the marking of dynamic dependencies to be lazily loaded. Dynamic dependencies which are marked `lazyload` will not be loaded at initial process startup, but instead will be delayed until the first binding to the object is made.

`-z loadfltr`

Marks the object to require that when building a filter, its filtees be processed immediately at runtime. Normally, filter processing is delayed until a symbol reference is bound to the filter. The runtime processing of an object that contains this flag mimics that which occurs if the `LD_LOADFLTR` environment variable is in effect. See `ld.so.1(1)`.

`-z muldefs`

Allows multiple symbol definitions. By default, multiple symbol definitions that occur between relocatable objects will result in a fatal error condition. This option suppresses the error condition and allows the first symbol definition to be taken.

`-z nodefs`

Allows undefined symbols. This is the default when a shared object is built. When used with executables, the behavior of references to such undefined symbols is unspecified.

- `-z nodelete`  
Marks the object as non-deletable at runtime. The runtime processing of an object that contains this flag mimics that which occurs if the object is added to a process using `dlopen(3DL)` with the `RTLD_NODELETE` mode.
- `-z nodefaultlib`  
Marks the object so that the runtime default library search path (used after any `LD_LIBRARY_PATH` or *runpaths*) is ignored. This option implies that all dependencies of the object can be satisfied from its *runpath*.
- `-z nodlopen`  
Marks the object as not available to `dlopen(3DL)`, either as the object specified by the `dlopen( )`, or as any form of dependency required by the object specified by the `dlopen( )`. This option is only meaningful when building a shared object.
- `-z nodump`  
Marks the object as not available to `dldump(3DL)`.
- `-z nopartial`  
If there are any partially initialized symbols in the input relocatable object files, the partially initialized symbols are expanded when the output file is generated.
- `-z noversion`  
Does not record any versioning sections. Any version sections or associated *.dynamic* section entries will not be generated in the output image.
- `-z now`  
Marks the object to override the runtime linker's default mode and require non-lazy runtime binding. This is similar to adding the object to the process by using `dlopen(3DL)` with the `RTLD_NOW` mode, or setting the `LD_BIND_NOW` environment variable in effect. See `ld.so.1(1)`.
- `-z origin`  
Marks the object as requiring immediate `$ORIGIN` processing at runtime.
- `-z redlocsym`  
Eliminates all local symbols except for the `SECT` symbols from the symbol table `SHT_SYMTAB`. All relocations that refer to local symbols will be updated to refer to the corresponding `SECT` symbol.
- `-z text`  
In dynamic mode only, forces a fatal error if any relocations against non-writable, allocatable sections remain.
- `-z textoff`

ENVIRONMENT  
VARIABLES

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | In dynamic mode only, allows relocations against all allocatable sections, including non-writable ones. This is the default when building a shared object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-z textwarn</code>        | In dynamic mode only, lists a warning if any relocations against non-writable, allocatable sections remain. This is the default when building an executable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>LD_LIBRARY_PATH</code>    | <p>A list of directories in which to search for libraries specified with the <code>-l</code> option. Multiple directories are separated by a colon. In the most general case, it will contain two directory lists separated by a semicolon:</p> <p><i>dirlist1 ; dirlist2</i></p> <p>If <code>ld</code> is called with any number of occurrences of <code>-L</code>, as in:</p> <p><code>ld ... -Lpath1 ... -Lpathn ...</code></p> <p>then the search path ordering is:</p> <p><i>dirlist1 path1 ... pathn dirlist2 LIBPATH</i></p> <p>When the list of directories does not contain a semicolon, it is interpreted as <i>dirlist2</i>.</p> <p>The <code>LD_LIBRARY_PATH</code> environment variable also effects the runtime linkers searching for dynamic dependencies.</p> |
| <code>LD_LIBRARY_PATH_64</code> | Similar to the <code>LD_LIBRARY_PATH</code> environment variable. Overrides <code>LD_LIBRARY_PATH</code> when searching for 64-bit dependencies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>LD_OPTIONS</code>         | <p>A default set of options to <code>ld</code>. <code>LD_OPTIONS</code> is interpreted by <code>ld</code> just as though its value had been placed on the command line, immediately following the name used to invoke <code>ld</code>, as in:</p> <p><code>ld \$LD_OPTIONS . . . other-arguments ...</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>LD_RUN_PATH</code>        | An alternative mechanism for specifying a runpath to the link-editor (see <code>-R</code> option). If both                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

`LD_RUN_PATH` and the `-R` option are specified, `-R` supersedes.

`SGS_SUPPORT`

Provides a colon separated list of shared objects that are loaded with the link-editor and given information regarding the linking process. See also the `-S` option.

Note that environment variable-names beginning with the characters `'LD_'` are reserved for possible future enhancements to `ld` and `ld.so.1(1)`.

## FILES

`libX.so` libraries

`libX.a` libraries

`a.out` output file

`LIBPATH` usually `/usr/lib` or `/usr/lib/sparcv9` for 64-bit SPARCV9 libraries.

`/usr/lib/ld/map.default`

mapfile showing default layout of 32-bit programs

`/usr/lib/ld/sparcv9/map.default`

mapfile showing default layout of 64-bit SPARCV9 programs

`/usr/lib/ld/sparcv9/map.above4G`

mapfile showing suggested layout above 4 gigabytes of 64-bit SPARCV9 programs

`/usr/lib/ld/sparcv9/map.below4G`

mapfile showing suggested layout below 4 gigabytes of 64-bit SPARCV9 programs

*Linker and Libraries Guide Binary Compatibility Guide*

**NAME** | ld – link editor, dynamic link editor

**SYNOPSIS** | `/usr/ucb/ld [options]`

**DESCRIPTION** | `/usr/ucb/ld` is the link editor for the BSD Compatibility Package.  
`/usr/ucb/ld` is identical to `/usr/bin/ld` (see `ld(1)`) except that BSD libraries and routines are included *before* the base libraries and routines.

**OPTIONS** | `/usr/ucb/ld` accepts the same options as `/usr/bin/ld`, with the following exceptions:

–`Ldir` | Add *dir* to the list of directories searched for libraries by `/usr/bin/ld`. Directories specified with this option are searched before `/usr/ucb/lib` and `/usr/lib`.

–`Y LU,dir` | Change the default directory used for finding libraries.  
Warning: This option may have unexpected results, and should not be used.

**FILES** | `/usr/lib`  
`/usr/lib/libx.a`  
`/usr/ucb/lib`  
`/usr/ucb/lib/libx.a`

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| <b>NAME</b>        | ldap – LDAP as a naming repository                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>LDAP refers to Lightweight Directory Access Protocol, which is emerging as an industry standard for accessing directory servers. By using the keyword <code>ldap</code> in the name service switch file, <code>/etc/nsswitch.conf</code>, Solaris clients can obtain naming information from an LDAP server. Information such as usernames, hostnames, and passwords are stored on the LDAP server in the form of a tree called Directory Information Tree or DIT. The DIT consists of entries which in turn are composed of attributes. Each attribute has a type and one or more values.</p> <p>Solaris LDAP clients use LDAP v3 protocol to access naming information from LDAP servers. The LDAP server must support the object classes and attributes defined in RFC2307bis (draft), which maps the Naming Information Service model onto LDAP. Refer to the Solaris Naming Administration Guide for more details.</p> <p>The <code>ldapclient(1M)</code> utility can make a Solaris machine an ldap client by setting up the appropriate directories and configuration information. The LDAP clients cache this configuration information in local cache files. This configuration information is accessed through the <code>ldap_cachemgr(1M)</code> daemon. This daemon also refreshes the information in the configuration files from the LDAP server, providing better performance and security.</p> <p>A client Profile is stored in the LDAP server and is used by the <code>ldapclient</code> utility to initialize an LDAP client. Using the client profile is the easiest way to configure a client machine. See <code>ldapclient(1M)</code>.</p> <p>There are two types of configuration information: client and domain.</p> <p>Domain information contains server-specific parameters that are required by all clients to locate the servers for the desired LDAP domain. This information could be the server's IP address and the search base DN, for instance, and is configured on the client (from the default profile, for example) during client initialization and is periodically updated by the <code>ldap_cachemgr</code> daemon when the expiration time has elapsed.</p> <p>Client information contains client-specific parameters that are used only by a client. This information could be the Bind DN of the client and the password. These parameters are defined during the initialization either manually through <code>ldapclient(1M)</code> or by having been stored in the client profile on the LDAP server.</p> <p>The Naming information is stored in <i>containers</i> on the LDAP server. A container is a non-leaf entry in the Directory Information Tree (DIT) that contains naming service information. Containers are similar to maps in NIS and tables in NIS+. A mapping between the Network Information Service (NIS) databases and the containers in LDAP is presented below:</p> |

| Database             | Object Class                  | Container             |
|----------------------|-------------------------------|-----------------------|
| passwd               | posixAccount<br>shadowAccount | shadowAccount         |
| group                | posixGroup                    | ou=Group,dc=...       |
| services             | ipService                     | ou=Services,dc=...    |
| protocols            | ipProtocol                    | ou=Protocols,dc=...   |
| rpc                  | oncRpc                        | ou=Rpc,dc=...         |
| hosts<br>ipnodes     | ipHost                        | ou=Hosts,dc=...       |
| ethers               | ieee802Device                 | ou=Ethers,dc=...      |
| bootparams           | bootableDevice                | ou=Ethers,dc=...      |
| networks<br>netmasks | ipNetwork                     | ou=Networks,dc=...    |
| netgroup             | nisNetgroup                   | ou=Netgroup,dc=...    |
| alias                | mailGroup                     | ou=Aliases,dc=...     |
| generic              | nisObject                     | nisMapName=...,dc=... |

Clients can authenticate to the LDAP server using three types of authentication mechanisms: Anonymous, Simple, and CRAM-MD5. More protection is provided in the form of access control, allowing the server to grant access for certain containers and/or entries. Access control is specified in the form of access control lists (ACLs). Each ACL specifies one or more directory objects (for example, the `cn` attribute in a specific container), one or more clients you grant or deny access, and one or more access rights that determine what the clients can do to or with the objects. Clients could be users or applications. Access rights could be specified as read and write, for example. Refer to the Solaris Naming Administration Guide for some restrictions on ACLs when using ldap as a Naming repository.

A new `nsswitch.conf(4)` file named `nsswitch.ldap` is available when riding the `ldapclient` utility. This file uses ldap as a repository for the different databases in the `nsswitch.conf` file.

The following is a list of the user commands related to ldap:

|                             |                                             |
|-----------------------------|---------------------------------------------|
| <code>ldapclient(1M)</code> | Intialize ldap clients.                     |
| <code>ldaplist(1)</code>    | List the contents of the ldap naming space. |

|              |                                          |                                                                                                                                                                                    |
|--------------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FILES</b> | <code>/var/ldap/ldap_client_cache</code> | contains a list of servers, their transport addresses, and the security method used to access them.                                                                                |
|              | <code>/var/ldap/ldap_client_cred</code>  | contains Bind Distinguished Name and the encrypted password. This file is normally only readable by root (uid 0) and is only modified and read by <code>ldap_cachemgr(1M)</code> . |
|              | <code>/etc/nsswitch.conf</code>          | configuration file for the name-service switch                                                                                                                                     |
|              | <code>/etc/nsswitch.ldap</code>          | configuration file for the name-service switch configured with ldap                                                                                                                |

| <b>NAME</b>        | ldapdelete – ldap delete entry tool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |       |   |         |   |           |    |         |     |                |
| <b>SYNOPSIS</b>    | <b>ldapdelete</b> [-n] [-v] [-c] [-d <i>debuglevel</i> ] [-f <i>file</i> ] [-D <i>binddn</i> ] [-w <i>passwd</i> ]<br>[-h <i>ldaphost</i> ] [-M <i>authentication</i> ] [-p <i>ldapport</i> ] [ <i>dn...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |       |   |         |   |           |    |         |     |                |
| <b>DESCRIPTION</b> | <code>ldapdelete</code> opens a connection to an LDAP server, binds, and deletes one or more entries. If one or more <i>dn</i> arguments are provided, entries with those distinguished names are deleted. If no <i>dn</i> arguments are provided, a list of DN's is read from <i>file</i> , if the <code>-f</code> option is specified, or from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |   |       |   |         |   |           |    |         |     |                |
| <b>OPTIONS</b>     | <p><code>-n</code> Show what would be done, but don't actually delete entries. Useful in conjunction with <code>-v</code> and <code>-d</code> for debugging.</p> <p><code>-v</code> Use verbose mode, with diagnostics written to standard output.</p> <p><code>-c</code> Continuous operation mode. Errors are reported, but <code>ldapdelete</code> will continue with deletions. The default is to exit after reporting an error.</p> <p><code>-d <i>debuglevel</i></code> Set the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are:</p> <table border="0" style="margin-left: 40px;"> <tr><td>1</td><td>Trace</td></tr> <tr><td>2</td><td>Packets</td></tr> <tr><td>4</td><td>Arguments</td></tr> <tr><td>32</td><td>Filters</td></tr> <tr><td>128</td><td>Access control</td></tr> </table> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <code>debuglevel</code> of 33.</p> <p><code>-f <i>file</i></code> Read the entry deletion information from <i>file</i> instead of from standard input.</p> <p><code>-D <i>binddn</i></code> Use the distinguished name <i>binddn</i> to bind to the directory.</p> <p><code>-w <i>passwd</i></code> Use <i>passwd</i> as the password for authentication to the directory.</p> | 1 | Trace | 2 | Packets | 4 | Arguments | 32 | Filters | 128 | Access control |
| 1                  | Trace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |       |   |         |   |           |    |         |     |                |

- `-h ldaphost` Specify an alternate host on which the slapd server is running.
- `-M authentication` Specifies the authentication mechanism used to bind to the directory. This option can have the value `CRAM-MD5`. The bind DN and bind password are mandatory with this option.
- `-p ldapport` Specify an alternate TCP port where the slapd server is listening.
- `dn` Specifies one or several distinguished names of entries to delete.

**EXAMPLES**

**EXAMPLE 1** To delete the entry named with commonName "Delete Me" directly below the XYZ Corporation organizational entry, use following command:  
`example% ldapdelete "cn=Delete Me, o=XYZ, c=US" -D "cn=Administrator, o=XYZ, c=US" -w password`

**ATTRIBUTES**

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE                         |
|-----------------|-----------------------------------------|
| Availability    | SUNWldap (32-bit)<br>SUNWldapx (64-bit) |
| Stability Level | Evolving                                |

**SEE ALSO**

`ldapadd(1)`, `ldapmodify(1)`, `ldapmodrdn(1)`, `ldapsearch(1)`

**DIAGNOSTICS**

Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message is written to standard error.

**NAME** | ldaplist – search and list naming information from a LDAP directory service

**SYNOPSIS** | `/usr/bin/ldaplist [-dlv] [database[key] ... ]`

`/usr/bin/ldaplist -h`

**DESCRIPTION**

The `ldaplist` utility searches for and lists the naming information from the LDAP directory service defined in the `/var/ldap/LDAP_CLIENT_CACHE` file generated by `ldapclient(1M)` during the client initialization phase.

The database is either a container name or a database name as defined in `nsswitch.conf(4)`. A container is a non-leaf entry in the Directory Information Tree (DIT) that contains naming service information. The container name is the LDAP Relative Distinguished Name (RDN) of the container relative to the search baseDN defined in the `LDAP_CLIENT_CACHE` file. For example, for a container named "ou=people", the database name is the database specified in `nsswitch.conf`. This database is mapped to a container (for example, "passwd" maps to "ou=people"). If an invalid database is specified, it will be mapped to a generic container (for example, "nisMapName=name").

The key is the attribute value to be searched in the database. You can specify more than one key to be searched in the same database. The key can be specified in either of two forms: *attribute=value* or *value*. In the first case, `ldaplist` passes the search key to the server. In the latter case, an attribute is assigned depending on how the database is specified. If the database is a container name, then the "cn" attribute type is used. If it is a valid database name as defined in the `nsswitch.conf`, then a predefined attribute type is used (see table below). If it is an invalid database name, then "cn" is used as the attribute type.

The `ldaplist` utility relies on the Schema defined in the RFC 2307 (with new extension). The data stored on the LDAP server must be stored based on this Schema. The following table lists the mapping from the database names to the container, the LDAP object class, and the attribute type used if not defined in the key:

| Database   | Objectclass    | Attr Type | Container              |
|------------|----------------|-----------|------------------------|
| aliases    | mailGroup      | cn        | ou=Aliases             |
| automount  | nisObject      | cn        | nisMapName=auto_*<br>1 |
| bootparams | bootableDevice | cn        | ou=Ethers              |
| ethers     | ieee802Device  | cn        | ou=Ethers              |
| group      | posixgroup     | cn        | ou=Group               |
| hosts      | ipHost         | cn        | ou=Hosts               |
| ipnodes    | ipHost         | cn        | ou=Hosts               |

| Database  | Objectclass  | Attr Type       | Container    |
|-----------|--------------|-----------------|--------------|
| netgroup  | ipNetgroup   | cn              | ou=Netgroup  |
| netmasks  | ipNetwork    | ipnetworknumber | ou=Networks  |
| networks  | ipNetwork    | ipnetworknumber | ou=Networks  |
| passwd    | posixAccount | uid             | ou=People    |
| protocols | ipProtocol   | cn              | ou=Protocols |
| publickey | nisKeyObject | uidnumber       | ou=People 2  |
|           |              | cn              | ou=Hosts 3   |
| rpc       | oncRpc       | cn              | ou=Rpc       |
| services  | ipService    | cn              | ou=Services  |

The following notes correspond to the numerals in the far right-hand column.

- 1 auto\_\* represents auto\_home, auto\_direct, ...
- 2 If the key starts with a digit, it will be interpreted as an uid number.
- 3 If the key starts with a non-digit, it will be interpreted as a host name.

The `ldaplist` utility supports substring search by using the wildcard "\*" in the key. For example, "my\*" will match any strings that starts with "my". In some shell environments, keys containing the wildcard may need to be quoted.

If the key is not specified, all the containers in the current search baseDN will be listed.

## OPTIONS

The following options are supported:

- d List the attributes for the specified database, rather than the entries. By default, the entries are listed.
- h List the database mapping.
- l List all the attributes for each entry matching the search criteria. By default, `ldaplist` lists only the Distinguished Name of the entries found.
- v Set verbose mode. The `ldaplist` utility will also print the filter used to search for the entry. The filter will be prefixed with "+++".

## EXAMPLES

**EXAMPLE 1** List all entries in the `hosts` database.

```
example% ldaplist hosts
```

**EXAMPLE 2** List all entries in a non-standard database `ou=new`.

```
example% ldaplist ou=new
```

**EXAMPLE 3** Find "user1" in the `passwd` database.

```
example% ldaplist passwd user1
```

**EXAMPLE 4** Find the entry with service port of 4045 in the `services` database.

```
example% ldaplist services ipserviceport=4045
```

**EXAMPLE 5** Find all users with username starting with "new" in the `passwd` database.

```
example% ldaplist passwd 'new*'
```

**EXAMPLE 6** List the attributes for the `hosts` database.

```
example% ldaplist -d hosts
```

## EXIT STATUS

The following exit values are returned:

- 0 Successfully matched some entries.
- 1 Successfully searched the table and no matches were found.
- 2 An error occurred. An error message is output.

## FILES

`/var/ldap/ldap_client_cache` contains a list of servers, their transport addresses, and the security method used to access them.

`/var/ldap/ldap_client_cred` This file contains Bind Distinguished Name and the encrypted password. This file is normally readable only by root (uid 0) and is modified and read only by `ldap_cachemgr(1M)`.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

## SEE ALSO

`ldap(1)`, `ldap_cachemgr(1M)`, `ldapclient(1M)`, `attributes(5)`

## NOTES

RFC 2307 is an IETF experimental document that defines an approach for using LDAP as a Network Information Service. An extension to the RFC 2307 draft is pending.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>        | ldapmodify, ldapadd – ldap entry addition and modification tools                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <p><b>ldapmodify</b> [-a] [-b] [-c] [-r] [-n] [-v] [-F] [-d <i>debuglevel</i>] [-D <i>binddn</i>]<br/>         [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-M <i>authentication</i>] [-p <i>ldapport</i>] [-f <i>file</i>] [-l<br/> <i>nb-ldap-connections</i>]</p> <p><b>/opt/SUNWconn/ldap/bin/ldapadd</b> [-b] [-c] [-n] [-v] [-F] [-d <i>debuglevel</i>]<br/>         [-D <i>binddn</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-p <i>ldapport</i>] [-f <i>file</i>] [-l<br/> <i>nb-ldap-connections</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>ldapmodify opens a connection to an LDAP server, binds, and modifies or adds entries. The entry information is read from standard input or from <i>file</i>, specified using the -f option. ldapadd is implemented as a hard link to the ldapmodify tool. When invoked as ldapadd the -a (add new entry) option is turned on automatically.</p> <p>Both ldapadd and ldapmodify reject duplicate attribute-name/value pairs for the same entry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>-a Add new entries. The default for ldapmodify is to modify existing entries. If invoked as ldapadd, this option is always set.</p> <p>-b Assume that any value that starts with a / is the pathname of a file containing the actual attribute value. This is useful for attribute values in binary format.</p> <p>-c Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.</p> <p>-r Replace existing value with the specified value. This is the default for ldapmodify. When ldapadd is called, or if the -a option is specified, the -r option is ignored.</p> <p>-n Preview modifications, but make no changes to entries. Useful in conjunction with -v and -d for debugging.</p> <p>-v Use verbose mode, with diagnostics written to standard output.</p> <p>-F Force application of all changes regardless of the content of input lines that begin <i>replica: .</i> By default, replica: lines are compared against the</p> |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          | LDAP server host and port in use to decide whether a relog record should be applied.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-d</code><br><i>debuglevel</i>     | Set the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are: <ul style="list-style-type: none"> <li>1      Trace</li> <li>2      Packets</li> <li>4      Arguments</li> <li>32     Filters</li> <li>128    Access control</li> </ul> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <code>debuglevel</code> of 33.</p> |
| <code>-f</code><br><i>file</i>           | Read the entry modification information from <code>file</code> instead of from standard input.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-D</code><br><i>binddn</i>         | Use the distinguished name <i>binddn</i> to bind to the directory.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-w</code><br><i>passwd</i>         | Use <code>passwd</code> as the password for authentication to the directory.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-h</code><br><i>ldaphost</i>       | Specify an alternate host on which the slapd server is running.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-M</code><br><i>authentication</i> | Specifies the authentication mechanism used to bind to the directory. This option can have the value <code>CRAM-MD5</code> . The bind DN and bind password are mandatory with this option.                                                                                                                                                                                                                                                                                  |

- `-p`  
*ldapport* Specify an alternate TCP port where the slapd server is listening.
- `-l`  
*nb-ldap-connections* Specifies the number of LDAP connections that ldapadd or ldapmodify will open to process the modifications in the directory. The default is one connection.

**EXAMPLES**

**EXAMPLE 1** The format of the content of *file* (or standard input if no `-f` option is specified) is illustrated in the examples below.

1. The file `/tmp/entrymods` contains the following modification instructions:

```
dn: cn=Modify Me, o=XYZ, c=US
changetype: modify
replace: mail
mail: modme@atlanta.xyz.com
-
add: title
title: System Manager
-
add: jpegPhoto
jpegPhoto: /tmp/modme.jpeg
-
delete: description
-
```

The command:

```
example% ldapmodify -b -r -f /tmp/entrymods
```

modifies the "Modify Me" entry as follows:

- a. The current value of the `mail` attribute is replaced with the value "modme@atlanta.xyz.com"
- b. A `title` attribute with the value "System Manager" is added
- c. A `jpegPhoto` attribute is added, using the contents of the file `/tmp/modme.jpeg` as the attribute value
- d. The `description` attribute is removed

**EXAMPLE 2** The file `/tmp/newentry` contains the following information for creating a new entry:

```
dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones
```

The command:

```
example% ldapad -f /tmp/newentry
```

adds a new entry for Ann Jones, using the information in the file.

**EXAMPLE 3** The file /tmp/badentry contains the following information about an entry to be deleted:

```
dn: cn=Ann Jones, o=XYZ, c=US
changetype: delete
```

the command:

```
example% ldapmodify -f /tmp/badentry
```

removes Ann Jones' entry.

## ATTRIBUTES

See [attributes\(5\)](#) for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE                         |
|-----------------|-----------------------------------------|
| Availability    | SUNWldap (32-bit)<br>SUNWldapx (64-bit) |
| Stability Level | Evolving                                |

| <b>DESCRIPTION</b> | ldapmodrdn opens a connection to an LDAP server, binds, and modifies the RDN of entries. The entry information is read from standard input, from <i>file</i> through the use of the -f option, or from the command-line pair <i>dn</i> and <i>rdn</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |       |   |         |   |           |    |         |     |                |
| <b>OPTIONS</b>     | <p>-r Remove old RDN values from the entry. By default, old values are kept.</p> <p>-n Show what would be done, but don't actually change entries. Useful in conjunction with -v for debugging.</p> <p>-v Use verbose mode, with diagnostics written to standard output.</p> <p>-c Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.</p> <p>-d <i>debuglevel</i> Set the LDAP debugging level. Useful values of debuglevel for ldapmodrdn are:</p> <table border="0" style="margin-left: 40px;"> <tr><td>1</td><td>Trace</td></tr> <tr><td>2</td><td>Packets</td></tr> <tr><td>4</td><td>Arguments</td></tr> <tr><td>32</td><td>Filters</td></tr> <tr><td>128</td><td>Access control</td></tr> </table> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a debuglevel of 33.</p> <p>-f <i>file</i> Read the entry modification information from <i>file</i> instead of from standard input or the command-line.</p> <p>-D <i>binddn</i> Use the distinguished name <i>binddn</i> to bind to the directory.</p> | 1 | Trace | 2 | Packets | 4 | Arguments | 32 | Filters | 128 | Access control |
| 1                  | Trace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |   |       |   |         |   |           |    |         |     |                |

- `-w passwd` Use `passwd` as the password for authentication to the directory.
- `-h ldaphost` Specify an alternate host on which the slapd server is running.
- `-M authentication` Specifies the authentication mechanism used to bind to the directory. This option can have the value `CRAM-MD5`. The bind DN and bind password are mandatory with this option.
- `-p ldapport` Specify an alternate TCP port where the slapd server is listening.

**Input Format**

If the command-line arguments `dn` and `rdn` are given, `rdn` replaces the RDN of the entry specified by the DN, `dn`.

Otherwise, the contents of `file` (or standard input if the `-f` option is not specified) must consist of one or more pair of lines:

```
Distinguished Name (DN)
Relative Distinguished Name (RDN)
```

Use one or more blank lines to separate each DN/RDN pair.

**EXAMPLES**

The file `/tmp/entrymods` contains:

```
cn=Modify Me, o=XYZ, c=US
cn=The New Me
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

changes the RDN of the "Modify Me" entry from "Modify Me" to "The New Me" and the old cn, "Modify Me" is removed.

**ATTRIBUTES**

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE                         |
|-----------------|-----------------------------------------|
| Availability    | SUNWldap (32-bit)<br>SUNWldapx (64-bit) |
| Stability Level | Evolving                                |

**SEE ALSO**

`ldapadd(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapsearch(1)`

**DIAGNOSTICS**

Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | ldapsearch – ldap search tool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>ldapsearch</b> [-n] [-u] [-v] [-t] [-A] [-B] [-L] [-R] [-d <i>debuglevel</i> ] [-F <i>sep</i> ]<br>[-S <i>attr</i> ] [-f <i>file</i> ] [-D <i>binddn</i> ] [-w <i>passwd</i> ] [-h <i>ldaphost</i> ] [-M <i>authentication</i> ]<br>[-p <i>ldapport</i> ] [-b <i>searchbase</i> ] [-s <i>scope</i> ] [-a <i>deref</i> ] [-l <i>time limit</i> ] [-z <i>size limit</i> ] <i>filter</i> [ <i>attrs ....</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | ldapsearch opens a connection to an LDAP server, binds, and performs a search using the filter <i>filter</i> .<br><br>If ldapsearch finds one or more entries, the attributes specified by <i>attrs</i> are retrieved and the entries and values are printed to standard output. If no <i>attrs</i> are listed, all attributes are returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | -n Show what would be done, but don't actually perform the search. Useful in conjunction with -v and -d for debugging.<br>-u Include the user-friendly form of the Distinguished Name (DN) in the output.<br>-v Run in verbose mode, with diagnostics written to standard output.<br>-t Write retrieved values to a set of temporary files. This is useful for dealing with non-ASCII values such as jpegPhoto or audio.<br>-A Retrieve attributes only (no values). This is useful when you just want to see whether an attribute is present in an entry and are not interested in the specific value.<br>-B Do not suppress display of non-ASCII values. This is useful when dealing with values that appear in alternate character sets such as ISO-8859.1. This option is automatically set by the -L option.<br>-L Display search results in a modified format. This option also turns on the -B option, and causes the -F option to be ignored.<br>-R Do not automatically follow referrals returned while searching.<br>-F <i>sep</i> Use <i>sep</i> as the field separator between attribute names and values. The default separator is '='. |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | If <code>-L</code> option has been specified, this option is ignored.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-S attribute</code>      | Sort the entries returned based on <i>attribute</i> . If <i>attribute</i> is a zero-length string (""), the entries are sorted by the components of their Distinguished Name. Note that <code>ldapsearch</code> normally prints out entries as it receives them. The use of the <code>-S</code> option causes all entries to be retrieved, then sorted, then printed. The default is not to sort entries returned.                                    |
| <code>-d debuglevel</code>     | Set the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are: <ul style="list-style-type: none"> <li>1 Trace</li> <li>2 Packets</li> <li>4 Arguments</li> <li>32 Filters</li> <li>128 Access control</li> </ul> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <code>debuglevel</code> of 33.</p> |
| <code>-f file</code>           | Read a series of lines from <i>file</i> , performing one LDAP search for each line. In this case, the <i>filter</i> given on the command line is treated as a pattern where the first occurrence of <code>%s</code> is replaced with a line from <i>file</i> . If <i>file</i> is a single - character, then the lines are read from standard input.                                                                                                   |
| <code>-D binddn</code>         | Use the distinguished name <i>binddn</i> to bind to the directory.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-w passwd</code>         | Use <i>passwd</i> as the password for authentication to the directory.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-h ldaphost</code>       | Specify an alternate host on which the <code>slapd</code> server is running.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-M authentication</code> | Specifies the authentication mechanism used to bind to the directory. This option can have                                                                                                                                                                                                                                                                                                                                                            |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | the value <code>CRAM-MD5</code> . The bind DN and bind password are mandatory with this option.                                                                                                                                                                                                                                                                                                         |
| <code>-p <i>ldapport</i></code>   | Specify an alternate TCP port where the slapd server is listening.                                                                                                                                                                                                                                                                                                                                      |
| <code>-b <i>searchbase</i></code> | Use <i>searchbase</i> as the starting point for the search instead of the default.                                                                                                                                                                                                                                                                                                                      |
| <code>-s <i>scope</i></code>      | Specify the scope of the search. The possible values of <i>scope</i> are <code>base</code> , <code>one</code> , or <code>sub</code> to specify respectively a base object, one-level, or subtree search. The default is <code>sub</code> .                                                                                                                                                              |
| <code>-a <i>deref</i></code>      | Specify how aliases dereferencing is done. The possible values for <i>deref</i> are <code>never</code> , <code>always</code> , <code>search</code> , or <code>find</code> to specify respectively that aliases are never dereferenced, always dereferenced, dereferenced when searching, or dereferenced only when finding the base object for the search. The default is to never dereference aliases. |
| <code>-l <i>timelimit</i></code>  | Wait at most <i>timelimit</i> seconds for a search to complete.                                                                                                                                                                                                                                                                                                                                         |
| <code>-z <i>sizelimit</i></code>  | Retrieve at most <i>sizelimit</i> entries for a search to complete.                                                                                                                                                                                                                                                                                                                                     |

**Output Format**

If one or more entries are found, each entry is written to standard output in the form:

```
Distinguished Name (DN)
User Friendly Name (if the -u option is used)
attributename=value
attributename=value
attributename=value
...
```

Multiple entries are separated with a single blank line. If the `-F` option is used to specify a different separator character, this character will be used instead of the '=' character. If the `-t` option is used, the name of a temporary file is returned in place of the actual value. If the `-A` option is given, only the "attributename" is returned and not the attribute value.

**EXAMPLES**

1. The following command:

```
example% ldapsearch "cn=mark smith" cn telephoneNumber
```

performs a subtree search (using the default search base) for entries with a commonName of "mark smith". The commonName and telephoneNumber values will be retrieved and printed to standard output. The output might look something like this:

```
cn=Mark D Smith, ou=Sales, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark David Smith
cn=Mark D Smith 1
cn=Mark D Smith
telephoneNumber=+1 123 456-7890
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark C Smith 1
cn=Mark C Smith
telephoneNumber=+1 123 456-9999
```

## 2. The command:

```
example% ldapsearch -u -t "uid=mcs" jpegPhoto audio
```

will perform a subtree search using the default search base for entries with user id of "mcs". The user-friendly form of the entry's DN will be output after the line that contains the DN itself, and the jpegPhoto and audio values will be retrieved and written to temporary files. The output might look like this if one entry with one value for each of the requested attributes is found:

```
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
Mark C Smith, Distribution, Atlanta, People, XYZ, US
audio=/tmp/ldapsearch-audio-a19924
jpegPhoto=/tmp/ldapsearch-jpegPhoto-a19924
```

## 3. The command:

```
example% ldapsearch -L -s one -b "c=US" "o=XY*" o description
```

performs a one-level search at the c=US level for all organizations whose organizationName begins with XY. Search results are displayed in the LDIF format. The organizationName and description attribute values will be retrieved and printed to standard output, resulting in output similar to this:

```
dn: o=XYZ, c=US
o: XYZ
description: XYZ Corporation
dn: o="XY Trading Company", c=US
o: XY Trading Company
description: Import and export specialists

dn: o=XYInternational, c=US
o: XYInternational
o: XYI
o: XY International
```

**ATTRIBUTES**

See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE                          |
|-----------------|------------------------------------------|
| Availability    | SUNWlldap (32-bit)<br>SUNWldapx (64-bit) |
| Stability Level | Evolving                                 |

**SEE ALSO**

`ldapadd(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapmodrdn(1)`

**DIAGNOSTICS**

Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>        | ldd – list dynamic dependencies of executable files or shared objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>ldd</b> [-d   -r ][-c] [-f] [-i] [-L] [-l] [-s] [-v] <i>filename</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The <code>ldd</code> utility lists the dynamic dependencies of executable files or shared objects. <code>ldd</code> uses the runtime linker, <code>ld.so.1</code>, to generate the diagnostics, as it takes the object being inspected and prepares it as it would in a running process. By default, <code>ldd</code> triggers the loading of any lazy dependencies.</p> <p>If <i>filename</i> is an executable file, <code>ldd</code> lists the path names of all shared objects that would be loaded when <i>filename</i> is loaded.</p> <p>If <i>filename</i> is a shared object, <code>ldd</code> lists the path names of all shared objects that would be loaded when <i>filename</i> is loaded. <code>ldd</code> expects shared objects to have execute permission, and if this is not the case, <code>ldd</code> will issue a warning before attempting to process the file.</p> <p><code>ldd</code> processes its input one file at a time. For each input file, <code>ldd</code> performs one of the following:</p> <ul style="list-style-type: none"> <li>■ Lists the object dependencies if they exist</li> <li>■ Succeeds quietly if dependencies do not exist</li> <li>■ Prints an error message if processing fails</li> </ul>                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | <p><code>ldd</code> can also check the compatibility of <i>filename</i> with the shared objects it uses. With each of the following options, <code>ldd</code> prints warnings for any unresolved symbol references that would occur if <i>filename</i> were executed.</p> <p>-d Checks references to data objects.</p> <p>-r Checks references to both data objects and functions.</p> <p>Only one of the above options may be given during any single invocation of <code>ldd</code>.</p> <p>-c Disable any configuration file use. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternative object dependencies. See <code>crle(1)</code>.</p> <p>-f Forces <code>ldd</code> to check for an executable file that is not secure. When <code>ldd</code> is invoked by a super-user, by default, it will not process any executable that it finds not secure. An executable is not considered secure if the interpreter it specifies does not reside under <code>/usr/lib</code> or <code>/etc/lib</code>, or if the interpreter cannot be determined.</p> <p>-i Displays the order of execution of initialization sections.</p> <p>-L Enables lazy loading. This is the default mode of operation when the object under inspection is loaded as part of a process. In this case, any lazy dependencies, or filters, are only loaded into the process when reference is made to a symbol that is defined within the lazy object.</p> |

The `-d` or `-r` options, together with the `-L` option, may be used to inspect the dependencies and their order of loading as it will occur in a running process.

- `-l` Forces the immediate processing of any filters so that all filtees, and their dependencies, are listed. The immediate processing of filters is now the default mode of operation for `ldd`. However, under this default any auxiliary filtees that cannot be found are silently ignored. Under the `-l` option, missing auxiliary filtees generate an error message.
- `-s` Displays the search path used to locate shared object dependencies.
- `-v` Displays all dependency relationships incurred when processing *filename*. This option also displays any dependency version requirements. See `pvs(1)`.

A super-user should use the `-f` option only if the executable to be examined is known to be trustworthy, because use of `-f` on an untrustworthy executable while super-user may compromise system security. If it is unknown whether or not the executable to be examined is trustworthy, it is suggested that a super-user temporarily become a regular user and invoke `ldd` as that regular user.

Untrustworthy objects can be safely examined with `dump(1)` and with `adb(1)`, as long as the `:r` subcommand is not used. In addition, a non-super-user can use either the `:r` subcommand of `adb` or `truss(1)` to examine an untrustworthy executable without too much risk of compromise. To minimize risk when using `ldd`, `adb :r`, or `truss` on an untrustworthy executable, use the user id "nobody".

Objects that employ lazy loading techniques, either through directly specified lazy dependencies or through filters, may experience variations in `ldd` output due to the options they use. If an object expresses all its dependencies as lazy, the default operation of `ldd` will list all dependencies in the order in which they are recorded in that object:

```
example% ldd main
libelf.so.1 => /usr/lib/libelf.so.1
libnsl.so.1 => /usr/lib/libnsl.so.1
libc.so.1 => /usr/lib/libc.so.1
```

The lazy loading behavior that occurs when this object is used at runtime may be enabled using the `-L` option. In this mode, lazy dependencies are loaded when reference is made to a symbol that is defined within the lazy object. Therefore, combining the `-L` option with use of the `-d` and `-r` options will reveal the dependencies needed to satisfy the data and function references respectively:

```
example% ldd -L main
example% ldd -d main
 libc.so.1 => /usr/lib/libc.so.1
example% ldd -r main
 libc.so.1 => /usr/lib/libc.so.1
 libelf.so.1 => /usr/lib/libelf.so.1
```

Note that in this example, the order of the dependencies listed is not the same as displayed from `ldd` with no options, and even with the `-r` option, the function reference to dependencies may not occur in the same order as it will in a running program.

Observing lazy loading may also reveal objects that are not required to satisfy any references. These objects (in this example, `libnsl.so.1`) are candidates for removal from the link-line used to build the object being inspected.

Users that prefer a more static analysis of object files may inspect dependencies using tools such as `dump(1)` and `elfdump(1)`.

**FILES** `/usr/lib/lddstub` Fake executable loaded to check the dependencies of shared objects.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

**SEE ALSO** `adb(1)`, `crle(1)`, `dump(1)`, `elfdump(1)`, `ld(1)`, `ld.so.1(1)`, `pvs(1)`, `truss(1)`, `dlopen(3DL)`, `attributes(5)`

*Linker and Libraries Guide*

**DIAGNOSTICS** `ldd` prints the record of shared object path names to `stdout`. The optional list of symbol resolution problems is printed to `stderr`. If *filename* is not an executable file or a shared object, or if it cannot be opened for reading, a non-zero exit status is returned.

**NOTES** `ldd` does not list shared objects explicitly attached using `dlopen(3DL)`.

Using the `-d` or `-r` option with shared objects can give misleading results. `ldd` does a "worst case" analysis of the shared objects. However, in practice some or all of the symbols reported as unresolved can be resolved by the executable file referencing the shared object. The runtime linker preloading mechanism (see `LD_PRELOAD`) may be employed to add dependencies to the object being inspected.

`ldd` uses the same algorithm as the runtime linker to locate shared objects.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | ld.so.1 – runtime linker for dynamic objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre><b>/usr/lib/ld.so.1</b> <b>/etc/lib/ld.so.1</b></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>Dynamic applications consist of one or more dynamic objects. They are typically a dynamic executable and its shared object dependencies. As part of the initialization and execution of a dynamic application, an <i>interpreter</i> is called to complete the binding of the application to its shared object dependencies. In Solaris this interpreter is referred to as the runtime linker.</p> <p>During the link-editing of a dynamic executable, a special <i>.interp</i> section, together with an associated program header, is created. This section contains a pathname specifying the program's interpreter. The pathname to the interpreter can be specified when the executable is being constructed by the <code>-I</code> option to <code>ld(1)</code> the link-editor. The default name supplied by the link-editor is that of the runtime linker, <code>/usr/lib/ld.so.1</code>.</p> <p>During the process of executing a dynamic executable the kernel maps the file and locates the required interpreter. See <code>exec(2)</code> and <code>mmap(2)</code>. The kernel maps this interpreter and transfers control to it, passing sufficient information to allow the interpreter to continue binding the application and then run it.</p> <p>In addition to initializing an application, the runtime linker provides services that allow the application to extend its address space by mapping additional shared objects and binding to symbols within them.</p> <p>The runtime linker performs the following functions:</p> <ul style="list-style-type: none"> <li>■ It opens and processes any applicable configuration file. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternative object dependencies. See <code>crle(1)</code>. By default the configuration file <code>/var/ld/ld.config</code> is used for 32-bit objects and <code>/var/ld/64/ld.config</code> for 64-bit objects. Alternative configuration files can be specified with the <code>LD_CONFIG</code> environment variable, or encoded within a dynamic executable using the <code>-c</code> option of <code>ld(1)</code>.</li> <li>■ It analyzes the application's dynamic information section (<i>.dynamic</i>) and determines which shared object dependencies are required.</li> <li>■ It locates and maps in these dependencies, and then it analyzes their dynamic information sections to determine if any additional shared object dependencies are required.</li> <li>■ Once all shared object dependencies are located and mapped, the runtime linker performs any necessary relocations to bind these shared objects in preparation for process execution.</li> </ul> |

- It calls any initialization functions provided by the shared object dependencies. By default these are called in the reverse order of the topologically sorted dependencies. Should cyclic dependencies exist, the initialization functions are called using the sorted order with the cycle removed. `ldd(1)` can be used to display the initialization order of shared object dependencies. See also `LD_BREADTH`.
- It passes control to the application.
- During the application's execution, the runtime linker can be called upon to perform any delayed function binding.
- It calls any finalization functions on deletion of shared objects from the process. By default these are called in the order of the topologically sorted dependencies.
- The application can also call upon the runtime linker's services to acquire additional shared objects by `dlopen(3DL)` and bind to symbols within these objects with `dlsym(3DL)`

Further details on each of the above topics may be found in the *Linker and Libraries Guide*

The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. The default search paths are the `runpath` recorded in the object, followed by `/usr/lib` for 32-bit objects or `/usr/lib/64` for 64-bit objects. This latter component can be modified using a configuration file created with `crle(1)`. The `runpath` is specified when the dynamic object is constructed using the `-R` option to `ld(1)`. `LD_LIBRARY_PATH` can be used to indicate directories to be searched before the default directories.

## ENVIRONMENT VARIABLES

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LD_AUDIT</code>    | A colon separated list of objects that will be loaded by the runtime linker. As each object is loaded, it will be examined for <i>Link-Auditing</i> interfaces; the routines that are present will be called as specified in the <i>Link-Auditing</i> interface described in the <i>Linker and Libraries Guide</i> . Also see the <code>-p</code> and <code>-P</code> options of <code>ld(1)</code> .                      |
| <code>LD_BIND_NOW</code> | The runtime linker's default mode of performing lazy binding can be overridden by setting the environment variable <code>LD_BIND_NOW</code> to any non-null value. This setting causes the runtime linker to perform both data reference and function reference relocations during process initialization, before transferring control to the application. Also see the <code>-z now</code> option of <code>ld(1)</code> . |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LD_BREADTH         | Any initialization functions are called reverse breadth-first order. Any finalization functions are called in breadth-first order.                                                                                                                                                                                                                                                                                                                               |
| LD_CONFIG          | Provides an alternative configuration file. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternate object dependencies. See <code>crle(1)</code> .                                                                                                                                                                                                                                                   |
| LD_DEBUG           | Provides a comma-separated list of tokens to cause the runtime linker to print debugging information to the standard error. The special token <code>help</code> indicates the full list of tokens available. The environment variable <code>LD_DEBUG_OUTPUT</code> may also be supplied to specify a file to which the debugging information is sent. The filename will be suffixed with the process id of the application generating the debugging information. |
| LD_FLAGS           | Can take the values <code>nolazyload</code> or <code>nodirect</code> , which disable the lazy loading and direct binding of an object's dependencies for those objects that use these features.                                                                                                                                                                                                                                                                  |
| LD_LIBRARY_PATH    | The <code>LD_LIBRARY_PATH</code> environment variable, if set, is used to enhance the search path that the runtime linker uses to find dynamic dependencies. <code>LD_LIBRARY_PATH</code> specifies a colon-separated list of directories that are to be searched before the default directories. Also note that <code>LD_LIBRARY_PATH</code> adds additional semantics to <code>ld(1)</code> .                                                                  |
| LD_LIBRARY_PATH_64 | Similar to the <code>LD_LIBRARY_PATH</code> environment variable. Overrides <code>LD_LIBRARY_PATH</code> for 64-bit dependencies.                                                                                                                                                                                                                                                                                                                                |
| LD_LOADFLTR        | Filters are a form of shared object. They allow an alternative shared object to be selected at runtime and provide the implementation for any symbols defined within the filter. See the <code>-f</code> and <code>-F</code> options of <code>ld(1)</code> . By default the alternative shared object processing is deferred until symbol resolution occurs against the filter.                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | <p>When <code>LD_LOADFLTR</code> is set to any non-null value, the runtime linker will process filters immediately when they are loaded. Also see the <code>-z loadfltr</code> option of <code>ld(1)</code>.</p>                                                                                                                                                                               |
| <code>LD_NOAUXFLTR</code>   | <p>Auxiliary filters are a form of shared object. They allow an alternative shared object to be selected at runtime which provides the implementation for any symbols defined within the filter. See the <code>-f</code> option of <code>ld(1)</code>. When <code>LD_NOAUXFLTR</code> is set to any non-null value, the runtime linker will disable this alternative shared object lookup.</p> |
| <code>LD_NOCONFIG</code>    | <p>By default the runtime linker attempts to open and process a configuration file. When <code>LD_NOCONFIG</code> is set to any non-null value, the runtime linker will disable this configuration file processing.</p>                                                                                                                                                                        |
| <code>LD_NODIRCONFIG</code> | <p>Provides a subset of <code>LD_NOCONFIG</code> in that any directory cache information provided in a configuration file is ignored.</p>                                                                                                                                                                                                                                                      |
| <code>LD_NOOBJALTER</code>  | <p>Provides a subset of <code>LD_NOCONFIG</code> in that any alternative object dependencies provided in a configuration file are ignored.</p>                                                                                                                                                                                                                                                 |
| <code>LD_NOVERSION</code>   | <p>By default the runtime linker verifies version dependencies for the primary executable and all of its dependencies. When <code>LD_NOVERSION</code> is set to any non-null value, the runtime linker will disable this version checking.</p>                                                                                                                                                 |
| <code>LD_ORIGIN</code>      | <p>The immediate processing of <code>\$ORIGIN</code> can be triggered by setting the environment variable <code>LD_ORIGIN</code> to any non-null value. This may be useful for applications that invoke <code>chdir(2)</code> prior to locating dependencies that employ the <code>\$ORIGIN</code> string token.</p>                                                                           |
| <code>LD_PRELOAD</code>     | <p>Provides a whitespace-separated list of shared objects that are to be interpreted by the runtime linker. The specified shared objects are linked after the program is executed but before any other shared objects that the program references.</p>                                                                                                                                         |

LD\_PROFILE

Defines a shared object that will be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file is the name of the shared object being profiled with a `.profile` extension. By default this buffer is placed under `/var/tmp`. The environment variable `LD_ORIGIN_OUTPUT` may also be supplied to indicate an alternative directory in which to place the profiling buffer. This buffer contains `profil(2)` and call count information similar to the `gmon.out` information generated by programs that have been linked with the `-xpg` option of `cc`. Any applications that use the named shared object and run while this environment variable is set will accumulate data in the profile buffer. The profile buffer information may be examined using `gprof(1)`. Note that this profiling technique is an alternative to any that may be provided by the compilation system. The shared object being profiled does not have to be instrumented in any way, and `LD_PROFILE` should not be combined with a profile-instrumented application.

Note that environment variable names beginning with the characters `'LD_'` are reserved for possible future enhancements to `ld(1)` and `ld.so.1`.

**SECURITY**

To prevent malicious dependency substitution or symbol interposition, some restrictions may apply to the evaluation of the dependencies of secure processes.

The runtime linker categorizes a process as secure if the user is not a super-user, and either the real user and effective user identifiers are not equal, or the real group and effective group identifiers are not equal. See `getuid(2)`, `geteuid(2)`, `getgid(2)`, and `getegid(2)`.

If an `LD_LIBRARY_PATH` environment variable is in effect for a secure process, then only the trusted directories specified by this variable will be used to augment the runtime linker's search rules. Presently, the only trusted directory known to the runtime linker is `/usr/lib/secure`, or `/usr/lib/secure/sparcv9` for 64-bit SPARCV9 objects.

In a secure process, any `runpath` specifications provided by the application or any of its dependencies will be used, provided they are full pathnames, that is, the pathname starts with a `'/'`.

Additional objects may be loaded with a secure process using the `LD_PRELOAD` environment variable, provided the objects are specified as simple file names,

with no '/' in the name. These objects will be located subject to the search path restrictions previously described.

**FILES**

|                                        |                                                                            |
|----------------------------------------|----------------------------------------------------------------------------|
| <code>/usr/lib/ld.so.1</code>          | Default runtime linker.                                                    |
| <code>/etc/lib/ld.so.1</code>          | Alternate runtime linker.                                                  |
| <code>/usr/lib/libc.so.1</code>        | Alternate interpreter for SVID ABI compatibility.                          |
| <code>/usr/lib/ld.so</code>            | AOUT(BCP) runtime linker.                                                  |
| <code>/usr/lib/0@0.so.1</code>         | Null character pointer compatibility library. See NOTES.                   |
| <code>/usr/lib/secure</code>           | LD_PRELOAD location for secure applications.                               |
| <code>/usr/lib/secure/sparcv9</code>   | LD_PRELOAD location for secure SPARCV9 applications.                       |
| <code>/usr/lib/sparcv9/ld.so.1</code>  | Default runtime linker for the SPARCV9 architecture.                       |
| <code>/usr/lib/sparcv9/0@0.so.1</code> | Null character pointer compatibility library for the SPARCV9 architecture. |
| <code>/var/ld/ld.config</code>         | Default configuration file for 32-bit applications..                       |
| <code>/var/ld/sparcv9/ld.config</code> | Default configuration file for SPARCV9 applications.                       |

*Linker and Libraries Guide*

**NOTES**

The user compatibility library `/usr/lib/0@0.so.1` provides a mechanism that establishes a value of 0 at location 0. Some applications exist that erroneously assume a null character pointer should be treated the same as a pointer to a null string. A segmentation violation will occur in these applications when a null character pointer is accessed. If this library is added to such an application at

runtime using `LD_PRELOAD`, it provides an environment that is sympathetic to this errant behavior. However, the user compatibility library is intended neither to enable the generation of such applications, nor to endorse this particular programming practice.

**NAME** | let – shell built-in function to evaluate one or more arithmetic expressions

**SYNOPSIS**

**ksh** | **let** *arg...*

**DESCRIPTION**

**ksh** | Each *arg* is a separate "arithmetic expression" to be evaluated.

**EXIT STATUS**

The following exit values are returned:

- 0       The value of the last expression is non-zero.
- 1       The value of the last expression is zero.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | lex - generate programs for lexical tasks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>lex</b> [-cntv] [-e   -w ][-v -Q [y   n ] ] [ <i>file...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | The <code>lex</code> utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to <code>yacc</code> . The C programs are generated from <code>lex</code> source code and conform to the ISO C standard. Usually, the <code>lex</code> utility writes the program it generates to the file <code>lex.yy.c</code> ; the state of this file is unspecified if <code>lex</code> exits with a non-zero exit status. See <b>EXTENDED DESCRIPTION</b> for a complete description of the <code>lex</code> input language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-c Indicate C-language action (default option).</li> <li>-e Generate a program that can handle EUC characters (cannot be used with the <code>-w</code> option). <code>yytext[ ]</code> is of type <code>unsigned char[ ]</code>.</li> <li>-n Suppress the summary of statistics usually written with the <code>-v</code> option. If no table sizes are specified in the <code>lex</code> source code and the <code>-v</code> option is not specified, then <code>-n</code> is implied.</li> <li>-t Write the resulting program to standard output instead of <code>lex.yy.c</code>.</li> <li>-v Write a summary of <code>lex</code> statistics to the standard error. (See the discussion of <code>lex</code> table sizes under the heading <b>Definitions in lex</b>.) If table sizes are specified in the <code>lex</code> source code, and if the <code>-n</code> option is not specified, the <code>-v</code> option may be enabled.</li> <li>-w Generate a program that can handle EUC characters (cannot be used with the <code>-e</code> option). Unlike the <code>-e</code> option, <code>yytext[ ]</code> is of type <code>wchar_t[ ]</code>.</li> <li>-V Print out version information on standard error.</li> <li>-Q[y n] Print out version information to output file <code>lex.yy.c</code> by using <code>-Qy</code>. The <code>-Qn</code> option does not print out version information and is the default.</li> </ul> |
| <b>OPERANDS</b>    | The following operand is supported: <ul style="list-style-type: none"> <li><code>file</code> A pathname of an input file. If more than one such <code>file</code> is specified, all files will be concatenated to produce a single <code>lex</code> program. If no <code>file</code> operands are specified, or if a <code>file</code> operand is <code>-</code>, the standard input will be used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OUTPUT</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Stdout** If the `-t` option is specified, the text file of C source code output of `lex` will be written to standard output.

**Stderr** If the `-t` option is specified informational, error and warning messages concerning the contents of `lex` source code input will be written to the standard error.

If the `-t` option is not specified:

1. Informational error and warning messages concerning the contents of `lex` source code input will be written to either the standard output or standard error.
2. If the `-v` option is specified and the `-n` option is not specified, `lex` statistics will also be written to standard error. These statistics may also be generated if table sizes are specified with a `%` operator in the `Definitions` in `lex` section (see `EXTENDED DESCRIPTION`), as long as the `-n` option is not specified.

**Output Files** A text file containing C source code will be written to `lex.yy.c`, or to the standard output if the `-t` option is present.

## EXTENDED DESCRIPTION

Each input file contains `lex` source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.

When `lex.yy.c` is compiled and linked with the `lex` library (using the `-l 1` operand with `c89` or `cc`), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.

When an expression is matched, these actions will occur:

- The input string that was matched is left in `ytext` as a null-terminated string; `ytext` is either an external character array or a pointer to a character string. As explained in `Definitions` in `lex`, the type can be explicitly selected using the `%array` or `%pointer` declarations, but the default is `%array`.
- The external `int yyleng` is set to the length of the matching string.
- The expression's corresponding program fragment, or action, is executed.

During pattern matching, `lex` searches the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first will be chosen.

The general format of `lex` source is:

```
Definitions
%%
Rules
%%
```

*User Subroutines*

The first %% is required to mark the beginning of the rules (regular expressions and actions); the second %% is required only if user subroutines follow.

Any line in the `Definitions` in `lex` section beginning with a blank character will be assumed to be a C program fragment and will be copied to the external definition area of the `lex.yy.c` file. Similarly, anything in the `Definitions` in `lex` section included between delimiter lines containing only %{} will also be copied unchanged to the external definition area of the `lex.yy.c` file.

Any such input (beginning with a blank character or within %{} delimiter lines) appearing at the beginning of the `Rules` section before any rules are specified will be written to `lex.yy.c` after the declarations of variables for the `yylex` function and before the first line of code in `yylex`. Thus, user variables local to `yylex` can be declared here, as well as application code to execute upon entry to `yylex`.

The action taken by `lex` when encountering any input beginning with a blank character or within %{} delimiter lines appearing in the `Rules` section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the `yylex` function.

**Definitions in lex**

`Definitions` in `lex` appear before the first %% delimiter. Any line in this section not contained between %{} lines and not beginning with a blank character is assumed to define a `lex` substitution string. The format of these lines is:

*name substitute*

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* will replace the string { *name* } when it is used in a rule. The *name* string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the `Definitions` in `lex` section, any line beginning with a % (percent sign) character and followed by an alphanumeric word beginning with either `s` or `S` defines a set of start conditions. Any line beginning with a % followed by a word beginning with either `x` or `X` defines a set of exclusive start conditions. When the generated scanner is in a %`s` state, patterns with no state specified will be also active; in a %`x` state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular

expressions to one or more states as described in Regular expressions in lex.

Implementations accept either of the following two mutually exclusive declarations in the Definitions in lex section:

`%array`        Declare the type of `yytext` to be a null-terminated character array.

`%pointer`       Declare the type of `yytext` to be a pointer to a null-terminated character string.

Note: When using the `%pointer` option, you may not also use the `yyless` function to alter `yytext`.

`%array` is the default. If `%array` is specified (or neither `%array` nor `%pointer` is specified), then the correct way to make an external reference to `yytext` is with a declaration of the form:

```
extern char yytext[]
```

If `%pointer` is specified, then the correct external reference is of the form:

```
extern char *yytext;
```

lex will accept declarations in the Definitions in lex section for setting certain internal table sizes. The declarations are shown in the following table.

Table Size Declaration in lex

| Declaration       | Description                        | Default |
|-------------------|------------------------------------|---------|
| <code>%pn</code>  | Number of positions                | 2500    |
| <code>%nn</code>  | Number of states                   | 500     |
| <code>%a n</code> | Number of transitions              | 2000    |
| <code>%en</code>  | Number of parse tree nodes         | 1000    |
| <code>%kn</code>  | Number of packed character classes | 10000   |
| <code>%on</code>  | Size of the output array           | 3000    |

Programs generated by lex need either the `-e` or `-w` option to handle input that contains EUC characters from supplementary codesets. If neither of these options is specified, `yytext` is of the type `char[ ]`, and the generated program can handle only ASCII characters.

When the `-e` option is used, `yytext` is of the type `unsigned char[ ]` and `yylen` gives the total number of *bytes* in the matched string. With this option, the macros `input( )`, `unput( c)`, and `output( c)` should do a byte-based I/O in the same way as with the regular ASCII `lex`. Two more variables are available with the `-e` option, `yywtext` and `yywlen`, which behave the same as `yytext` and `yylen` would under the `-w` option.

When the `-w` option is used, `yytext` is of the type `wchar_t[ ]` and `yylen` gives the total number of *characters* in the matched string. If you supply your own `input( )`, `unput( c)`, or `output( c)` macros with this option, they must return or accept EUC characters in the form of wide character (`wchar_t`). This allows a different interface between your program and the `lex` internals, to expedite some programs.

#### Rules in lex

The `Rules` in `lex` source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

```
ERE action
ERE action
...
```

The extended regular expression (ERE) portion of a row will be separated from *action* by one or more blank characters. A regular expression containing blank characters is recognized under one of the following conditions:

- The entire expression appears within double-quotes.
- The blank characters appear within double-quotes or square brackets.
- Each blank character is preceded by a backslash character.

#### User Subroutines in lex

Anything in the user subroutines section will be copied to `lex.yy.c` following `yylex`.

#### Regular Expressions in lex

The `lex` utility supports the set of Extended Regular Expressions (EREs) described on `regex(5)` with the following additions and exceptions to the syntax:

```
...
```

Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, `"\01"1"` represents a single string: the octal value 1 followed by the character 1.

```
<state>r
<state1, state2, ...>r
```

The regular expression *r* will be matched only when the program is in one of the start conditions indicated by *state*, *state1*, and so forth; for more information see *Actions in lex* (As an exception to the typographical conventions of the rest of this document, in this case *<state>* does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition is recognized as such only at the beginning of a regular expression.

*r/x*

The regular expression *r* will be matched only if it is followed by an occurrence of regular expression *x*. The token returned in *yytext* will only match *r*. If the trailing portion of *r* matches the beginning of *x*, the result is unspecified. The *r* expression cannot include further trailing context or the \$ (match-end-of-line) operator; *x* cannot include the ^ (match-beginning-of-line) operator, nor trailing context, nor the \$ operator. That is, only one occurrence of trailing context is allowed in a *lex* regular expression, and the ^ operator only can be used at the beginning of such an expression. A further restriction is that the trailing-context operator / (slash) cannot be grouped within parentheses.

{*name*}

When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, will be replaced by the *substitute* value. The *substitute* value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if {*name*} occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character (\\, \a, \b, \f, \n, \r, \t, \v) is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.

A literal newline character cannot occur within an ERE; the escape sequence \n can be used to represent a newline character. A newline character cannot be matched by a period operator.

Escape Sequences in *lex*

| Escape Sequences in lex |                                                                                                                                                                                                                                |                                                                                                                                                                                                                                     |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Escape Sequence         | Description                                                                                                                                                                                                                    | Meaning                                                                                                                                                                                                                             |
| <code>\digits</code>    | A backslash character followed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.          | The character whose encoding is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <code>\</code> for each byte. |
| <code>\xdigits</code>   | A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.          | The character whose encoding is represented by the hexadecimal integer.                                                                                                                                                             |
| <code>\c</code>         | A backslash character followed by any character not described in this table. ( <code>\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ). | The character <code>c</code> , unchanged.                                                                                                                                                                                           |

The order of precedence given to extended regular expressions for `lex` is as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

| ERE Precedence in lex                    |                                         |
|------------------------------------------|-----------------------------------------|
| <i>collation-related bracket symbols</i> | <code>[ = ] [ : : ] [ . . ]</code>      |
| <i>escaped characters</i>                | <code>\&lt;special character&gt;</code> |
| <i>bracket expression</i>                | <code>[ ]</code>                        |
| <i>quoting</i>                           | <code>" . . . "</code>                  |
| <i>grouping</i>                          | <code>( )</code>                        |
| <i>definition</i>                        | <code>{ name }</code>                   |
| <i>single-character RE duplication</i>   | <code>* + ?</code>                      |

| ERE Precedence in lex |         |
|-----------------------|---------|
| concatenation         |         |
| interval expression   | { m,n } |
| alternation           |         |

The ERE anchoring operators ( `^` and `$` ) do not appear in the table. With `lex` regular expressions, these operators are restricted in their use: the `^` operator can only be used at the beginning of an entire regular expression, and the `$` operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern `(^abc) | (def$)` is undefined; it can instead be written as two separate rules, one with the regular expression `^abc` and one with `def$`, which share a common action via the special `|` action (see below). If the pattern were written `^abc|def$`, it would match either of `abc` or `def` on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical `lex` implementations. An example of embedded anchoring would be for patterns such as `(^)foo($)` to match `foo` when it exists as a complete word. This functionality can be obtained using existing `lex` features:

```
^foo/[\n]|
" foo"/[\n] /* found foo as a separate word */
```

Note also that `$` is a form of trailing context (it is equivalent to `/\n` and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator `/` (slash) can be used as an ordinary character if presented within double-quotes, `" / "`; preceded by a backslash, `\ /`; or within a bracket expression, `[ / ]`. The start-condition `<` and `>` operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between `lex` regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form `r/x`, the string matching `r` is always returned; confusion may arise when the beginning of `x` matches the trailing portion of `r`. For example, given the regular expression `a*b/cc` and the input `aaabcc`, `yytext` would contain the string `aaab` on this match. But given the regular expression `x*/xy` and the input `xxxxy`, the token `xxx`, not `xx`, is returned by some implementations because `xxx` matches `x*`.

**Actions in lex**

In the rule `ab*/bc`, the `b*` at the end of `r` will extend `r`'s match into the beginning of the trailing context, so the result is unspecified. If this rule were `ab/bc`, however, the rule matches the text `ab` when it is followed by the text `bc`. In this latter case, the matching of `r` cannot extend into the beginning of `x`, so the result is specified.

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement `;` is a valid action; any string in the `lex.yy.c` input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action `lex` takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
program statement }
```

The default action when a string in the input to a `lex.yy.c` program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by `lex` is to read the input and copy it to the output, a minimal `lex` source program that has just `%%` generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

```
| ECHO; REJECT; BEGIN
```

| The action `|` means that the action for the next rule is the action for this rule. Unlike the other three actions, `|` cannot be enclosed in braces or be semicolon-terminated; it must be specified alone, with no other actions.

```
ECHO; Write the contents of the string yytext on the output.
```

```
REJECT; Usually only a single expression is matched by a given string
in the input. REJECT means "continue to the next expression
that matches the current input," and causes whatever rule
was the second choice after the current rule to be executed
for the same input. Thus, multiple rules can be matched and
executed for one input string or overlapping input strings.
For example, given the regular expressions xyz and xy and
the input xyz, usually only the regular expression xyz
would match. The next attempted match would start after z.
If the last action in the xyz rule is REJECT, both this rule
```

and the `xy` rule would be executed. The `REJECT` action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a `goto` to another part of `yylex`. The use of `REJECT` may result in somewhat larger and slower scanners.

`BEGIN`

The action:

```
BEGIN newstate;
```

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the `Definitions in lex` section, the results are unspecified. The initial state is indicated by the digit 0 or the token `INITIAL`.

The functions or macros described below are accessible to user code included in the `lex` input. It is unspecified whether they appear in the C code output of `lex`, or are accessible only through the `-l 1` operand to `c89` or `cc` (the `lex` library).

|                                |                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>int yylex(void)</code>   | Performs lexical analysis on the input; this is the primary function generated by the <code>lex</code> utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.                                                                                                                     |
| <code>int yymore(void)</code>  | When called, indicates that when the next input string is recognized, it is to be appended to the current value of <code>yytext</code> rather than replacing it; the value in <code>yyleng</code> is adjusted accordingly.                                                                                                                                                                 |
| <code>int yyless(int n)</code> | Retains <i>n</i> initial characters in <code>yytext</code> , NUL-terminated, and treats the remaining characters as if they had not been read; the value in <code>yyleng</code> is adjusted accordingly.                                                                                                                                                                                   |
| <code>int input(void)</code>   | Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer <code>yyin</code> , although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of <code>yyin</code> is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner. |

```
int unput(int c) Returns the character c to the input; yytext and
 yytext and yytext are undefined until the next expression
 is matched. The result of using unput for more
 characters than have been input is unspecified.
```

The following functions appear only in the `lex` library accessible through the `-l` operand; they can therefore be redefined by a portable application:

```
int yywrap(void)
 Called by yylex at end-of-file; the default yywrap always will return 1.
 If the application requires yylex to continue processing with another
 source of input, then the application can include a function yywrap, which
 associates another file with the external variable FILE *yyin and will return
 a value of zero.
```

```
int main(int argc, char *argv[])
 Calls yylex to perform lexical analysis, then exits. The user code can
 contain main to perform application-specific operations, calling yylex
 as applicable.
```

The reason for breaking these functions into two lists is that only those functions in `libl.a` can be reliably redefined by a portable application.

Except for `input`, `unput` and `main`, all external and static names generated by `lex` begin with the prefix `yy` or `YY`.

## USAGE

Portable applications are warned that in the `Rules in lex` section, an ERE without an action is not acceptable, but need not be detected as erroneous by `lex`. This may result in compilation or run-time errors.

The purpose of `input` is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The `lex` utility is not fully internationalized in its treatment of regular expressions in the `lex` source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the `lex` source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current `lex` technology. Furthermore, the very nature of the lexical analyzers produced by `lex` must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)

## EXAMPLES

**EXAMPLE 1** Using `lex`

The following is an example of a `lex` program that implements a rudimentary scanner for a Pascal-like syntax:

```

%{
/* need this for the call to atof() below */
#include <math.h>
/* need this for printf(), fopen() and stdin below */
#include <stdio.h>
}%

DIGIT [0-9]
ID [a-z][a-z0-9]*
%%

{DIGIT}+ {
 printf("An integer: %s (%d)\n", yytext,
 atoi(yytext));
 }

{DIGIT}+"."{DIGIT}* {
 printf("A float: %s (%g)\n", yytext,
 atof(yytext));
 }

if|then|begin|end|procedure|function {
 printf("A keyword: %s\n", yytext);
 }

{ID} printf("An identifier: %s\n", yytext);

"+"|"-"|"*"|"/" printf("An operator: %s\n", yytext);

{"^[^\\n]*"} /* eat up one-line comments */

[\t\n]+ /* eat up white space */

. printf("Unrecognized character: %s\n", yytext);

%%

int main(int argc, char *argv[])
{
 ++argv, --argc; /* skip over program name */
 if (argc > 0)
yyin = fopen(argv[0], "r");
 else
yyin = stdin;

 yylex();
}

```

## ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of lex: LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

## EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

## SEE ALSO

`yacc(1)`, `attributes(5)`, `environ(5)`, `regex(5)`

## NOTES

If routines such as `yyback()`, `yywrap()`, and `yylock()` in `.l` (ell) files are to be external C functions, the command line to compile a C++ program must define the `__EXTERN_C__` macro. For example:

```
example% CC -D__EXTERN_C__ . . . file
```

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <code>/usr/bin/ulimit</code> | The <code>ulimit</code> utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>sh</b>                    | The Bourne shell built-in function, <code>ulimit</code> , prints or sets hard or soft resource limits. These limits are described in <code>getrlimit(2)</code> .<br><br>If <code>limit</code> is not present, <code>ulimit</code> prints the specified limits. Any number of limits may be printed at one time. The <code>-a</code> option prints all limits.<br><br>If <code>limit</code> is present, <code>ulimit</code> sets the specified limit to <code>limit</code> . The string <code>unlimited</code> requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see <code>su(1M)</code> .<br><br>The <code>-H</code> option specifies a hard limit. The <code>-S</code> option specifies a soft limit. If neither option is specified, <code>ulimit</code> will set both limits and print the soft limit.<br><br>The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.<br><ul style="list-style-type: none"> <li><code>-c</code> maximum core file size (in 512-byte blocks)</li> <li><code>-d</code> maximum size of data segment or heap (in kbytes)</li> <li><code>-f</code> maximum file size (in 512-byte blocks)</li> <li><code>-n</code> maximum file descriptor plus 1</li> <li><code>-s</code> maximum size of stack segment (in kbytes)</li> <li><code>-t</code> maximum CPU time (in seconds)</li> <li><code>-v</code> maximum size of virtual memory (in kbytes)</li> </ul> |
| <b>csh</b>                   | The C-shell built-in function, <code>limit</code> , limits the consumption by the current process or any process it spawns, each not to exceed <code>limit</code> on the specified                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

*resource*. If *limit* is omitted, print the current limit; if *resource* is omitted, display all limits. (Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).

`-h` Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

*resource* is one of:

`cputime` Maximum CPU seconds per process.

`filesize` Largest single file allowed; limited to the size of the filesystem (see `df(1M)`).

`datasize` The maximum size of a process's heap in kilobytes.

`stacksize` Maximum stack size for the process (see `swap(1M)`).

`coredumpsize` Maximum size of a core dump (file). This is limited to the size of the filesystem.

`descriptors` Maximum number of file descriptors (run `sysdef()`).

`memorysize` Maximum size of virtual memory.

*limit* is a number, with an optional scaling factor, as follows:

*n* Hours (for `cputime`).

*h*

*n* *n* kilobytes. This is the default for all but `cputime`.

*k*

*n* *n* megabytes or minutes (for `cputime`).

*m*

*mm* Minutes and seconds (for `cputime`).

*:*

*ss*

`unlimit` removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.

`-h` Remove corresponding hard limits. Only the privileged user may do this.

**ksh** The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with

each resource, or the value `unlimited`. The `-H` and `-S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `-H` or `-S` options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless `-H` is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- `-a` Lists all of the current resource limits.
- `-c` The number of 512-byte blocks on the size of core dumps.
- `-d` The number of K-bytes on the size of the data area.
- `-f` The number of 512-byte blocks on files written by child processes (files of any size may be read).
- `-n` The number of file descriptors plus 1.
- `-s` The number of K-bytes on the size of the stack area.
- `-t` The number of seconds (CPU time) to be used by each process.
- `-v` The number of K-bytes for virtual memory.

If no option is given, `-f` is assumed.

#### OPTIONS

The following option is supported by `ulimit`:

- `-f` Set (or report, if no *blocks* operand is present), the file size limit in blocks. The `-f` option is also the default case.

#### OPERANDS

The following operand is supported by `ulimit`:

- blocks* The number of 512-byte blocks to use as the new file size limit.

#### EXAMPLES

`/usr/bin/ulimit`

**EXAMPLE 1** Limiting the stack size

To limit the stack size to 512 kilobytes:

```
% ulimit -s 512
% ulimit -a
% time(seconds) unlimited
file(blocks) 100
data(kbytes) 523256
```

```

stack(kbytes) 512
coredump(blocks) 200
nofiles(descriptors) 64
memory(kbytes) unlimited

```

**sh/ksh**    **EXAMPLE 2**    Limiting the number of file descriptors

To limit the number of file descriptors to 12:

```

$ ulimit -n 12
$ ulimit -a
time(seconds) unlimited
file(blocks) 41943
data(kbytes) 523256
stack(kbytes) 8192
coredump(blocks) 200
nofiles(descriptors) 12
vmemory(kbytes) unlimited

```

**cs**    **EXAMPLE 3**    Limiting the core dump file size

To limit the size of a core dump file size to 0 kilobytes:

```

% limit coredumpsize 0
% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize 0 kbytes
descriptors 64
memorysize unlimited

```

**CODE EXAMPLE 1**    Removing the limitation for core file size

To remove the above limitation for the core file size:

```

% unlimit coredumpsize
% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize unlimited
descriptors 64
memorysize unlimited

```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ulimit`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned by `ulimit`:

0        Successful completion.

>0 A request for a higher limit was rejected or an error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`bc(1)`, `cs(1)`, `ksh(1)`, `sh(1)`, `df(1M)`, `su(1M)`, `swap(1M)`, `sysdef(1M)`, `getrlimit(2)`, `attributes(5)`, `environ(5)`

**NAME** | line – read one line

**SYNOPSIS** | **line**

**DESCRIPTION** | The `line` utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's terminal.

**EXIT STATUS** | Exit status is:  
 0       Successful completion  
 >0      End-of-file on input.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `sh(1)`, `read(2)`, `attributes(5)`

| <b>NAME</b>                      | lint – C program verifier                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                               |             |                            |           |                              |                                              |                           |                                           |                                  |                             |                                 |                                    |                              |                                      |
| <b>SYNOPSIS</b>                  | <code>/usr/ucb/lint</code> [ <i>options</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                               |             |                            |           |                              |                                              |                           |                                           |                                  |                             |                                 |                                    |                              |                                      |
| <b>DESCRIPTION</b>               | <p><code>/usr/ucb/lint</code> is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link <code>/usr/ccs/bin/ucblint</code> to the C program verifier. <code>/usr/ccs/bin/ucblint</code> is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code>. <code>/usr/ucb/lint</code> is identical to <code>/usr/ccs/bin/ucblint</code>, except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/lint.1</code> man page is available only with the SPROcc package.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |                               |             |                            |           |                              |                                              |                           |                                           |                                  |                             |                                 |                                    |                              |                                      |
| <b>OPTIONS</b>                   | <p><code>/usr/ucb/lint</code> accepts the same options as <code>/usr/ccs/bin/ucblint</code>, with the following exceptions:</p> <p><code>-I dir</code> Search <i>dir</i> for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple <code>-I</code> options are searched in the order specified. The preprocessor first searches for <code>#include</code> files in the directory containing <i>sourcefile</i>, and then in directories named with <code>-I</code> options (if any), then <code>/usr/ucbinclude</code>, and finally, in <code>/usr/include</code>.</p> <p><code>-L dir</code> Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ucblint</code>. This option is passed to <code>/usr/ccs/bin/ld</code>. Directories specified with this option are searched before <code>/usr/ucb/lib</code> and <code>/usr/lib</code>.</p> <p><code>-Y P, dir</code> Change the default directory used for finding libraries.</p> |                               |             |                            |           |                              |                                              |                           |                                           |                                  |                             |                                 |                                    |                              |                                      |
| <b>EXIT STATUS</b>               | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>&gt;0 An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                               |             |                            |           |                              |                                              |                           |                                           |                                  |                             |                                 |                                    |                              |                                      |

**NAME** listusers – list user login information

**SYNOPSIS** **listusers** [-g *groups*] [-l *logins*]

**DESCRIPTION** Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by `/etc/nsswitch.conf`.

**OPTIONS** The following options are supported:

- g *groups* Lists all user logins belonging to *group*, sorted by login. Multiple groups can be specified as a comma-separated list.
- l *logins* Lists the user login or logins specified by *logins*, sorted by login. Multiple logins can be specified as a comma-separated list.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `nsswitch.conf(4)`, `attributes(5)`

**NOTES** A user login is one that has a UID of 100 or greater. The -l and -g options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.

| <b>NAME</b>        | llc2_autoconfig – generate LLC2 configuration files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/lib/llc2/llc2_autoconfig [-f]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>llc2_autoconfig</code> utility is used to generate LLC2 configuration files (<code>/etc/llc2/default/llc2.*</code>). If there is no configuration file in <code>/etc/llc2_default/</code>, it detects all the available interfaces in the system and generates corresponding default configuration files.</p> <p>If there are existing configuration files in <code>/etc/llc2_default/</code>, it will check if those interfaces defined in the files still exist. If they do not exist in the system, it will set <code>llc2_on</code> in those files to 0. After this, it will detect if there are new interfaces in the system. If there are, it will generate configuration files for them.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <p><code>-f</code> Erases all configuration files in <code>/etc/llc2/default/</code>. Then detects all the available interfaces in the system and generates corresponding default configuration files. Use this option with caution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/llc2/default/llc2.*</code> LLC2 configuration files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |

**NAME** llc\_config – configure LLC2 interface parameters

**SYNOPSIS** `/usr/lib/llc2/llc2_config [-P | -U | -d | -q | -i ppa | -r ppa ]`

**DESCRIPTION** The `llc2_config` utility is used to start/stop the LLC2 subsystem and to configure LLC2 interface parameters.

**OPTIONS** The following options are supported:

- `-d` Turns on debug mode. Extra debugging information will be printed out.
- `-i ppa` Initializes the corresponding interface using the file `/etc/llc2/default/llc2.ppa`.
- `-P` Reads in all `/etc/llc2/default/llc2.*` configuration files, opens those devices defined in the files, and sets up the streams needed for LLC2 to use those devices. Before doing this, `llc2_config -q` will not show anything.
- `-q` Queries the LLC2 subsystem. Information similar to the following example will be printed out for all PPAs (Physical Point of Attachment) available under the LLC2 module:

| PPA | State | ID   | MACAddr      | Type     | MaxSDU | MinSDU | Mode |
|-----|-------|------|--------------|----------|--------|--------|------|
| 0   | up    | 0000 | 0800208a217e | ethernet | 1500   | 0      | 3    |

The fields displayed are described below:

|             |                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PPA         | The relative logical position of the interface.                                                                                                                                                                                                                    |
| State       | The state of the interface:                                                                                                                                                                                                                                        |
| <i>up</i>   | The interface is initialized and operational.                                                                                                                                                                                                                      |
| <i>down</i> | The interface was "discovered" by the LLC2 driver, has passed its bootup diagnostics, and is awaiting initialization.                                                                                                                                              |
| <i>bad</i>  | The interface is known to the LLC2 driver, but failed one or more of the integrity checks performed at boot time. This might include detecting Interrupt Request and shared memory conflicts or failures detected during the execution of the level 0 diagnostics. |

- ID The interface ID.
- MACAddr The MAC address currently in effect for the interface.
- Type The MAC type. Current types supported include:
- csma/cd 10 Megabit Ethernet
  - ethernet Ethernet type device
  - tkn-ring 4/16 Megabit Token Ring
  - fddi 100 Megabit Fiber Distributed Data Interface
- MaxSDU The Maximum Service Data Unit size transmitted on this interface.
- Mode The Service Modes supported by this interface. This field consists of the bitwise logical-ORing of the supported modes, also defined in `/usr/include/sys/dlpi.h`.
- `-r ppa` Uninitializes the corresponding interface. By using this option, and then using the `-i` option, the parameters associated with an interface can be changed.
- `-U` Destroys all streams used by the LLC2 subsystem. This is the reverse of the `-P` option. After this is executed, `llc2_config -q` will not show anything.

**FILES**

`/etc/llc2/default/llc2.*` LLC2 configuration files

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWllc         |

**SEE ALSO**

`llc2_autoconfig(1)`, `llc2(4)`, `attributes(5)`, `llc2(7D)`

**NAME** llc2\_stats – LLC2 Station, SAP, and Connection Statistics

**SYNOPSIS** **llc2\_stats** *ppa* [-r] [-s *sap*] [-c *connection*]

**DESCRIPTION** The `llc2_stats` command is used to retrieve statistical information from the Host-based Logical Link Control Class 2 component of the LLC2 Driver. Statistics are kept for the station, SAP (Service Access Point), and connection components.

**OPTIONS** The following options are supported:

`-c connection` Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.

`-r` Resets the specified counters to zero after reading them. This option is only valid if the `root` user is executing the command.

`-s sap` Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS `sap`, 240 (0xf0) would be entered as: `-s f0`.

**OPERANDS** The following operand is supported:

`ppa` The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.

**EXAMPLES**

**EXAMPLE 1** Station Statistics

The following command will display the station statistics for PPA 4. After the example, a brief description of each field is presented.

```
example% /usr/lib/llc2/llc2_stats 4

Station values received:
ppa = 0x00000004 clearFlag = 0x00
of saps (hex) = 0x0002
saps (hex) = 02 aa
state = 0x01
nullSapXidCmdRcvd = 0x00000000
nullSapXidRspSent = 0x00000000
nullSapTestCmdRcvd = 0x00000000
nullSapTestRspSent = 0x00000000
outOfState = 0x00000000
allocFail = 0x00000000
protocolError = 0x00000000
```

The fields are described as follows:

`ppa` The logical number used to address the adapter.

|                    |                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| clearFlag          | This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0). |
| # of saps          | The number of SAPs currently bound on this station.                                                                                   |
| saps               | The array of the station's Service Access Point (SAP) logical interface values between the LLC and its adjacent layers.               |
| state              | A number indicating the current state of the station component (0 = down, 1 = up).                                                    |
| nullSapXidCmdRcvd  | The number of XID command Protocol Data Units (PDUs) received for the NULL SAP address (sap = 0x00).                                  |
| nullSapXidRspSent  | The number of XID response PDUs sent in response to XID command PDUs received for the null SAP address.                               |
| nullSapTestCmdRcvd | The number of TEST command PDUs received for the null SAP address.                                                                    |
| nullSapTestRspSent | The number of TEST response PDUs sent in response to TEST command PDUs received for the null SAP address.                             |
| outOfState         | The number of events received in an invalid state.                                                                                    |
| allocFail          | The number of buffer allocation failures.                                                                                             |
| protocolError      | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.        |

**EXAMPLE 2** SAP Statistics

In the above display, there are two active SAPs, 0x02 and 0xaa. The following is an example of a command for retrieving the statistics for SAP 02 and a brief explanation of each field presented.

```
example% /usr/lib/llc2/llc2_stats 4 -s 02
```

```
Sap values received:
ppa = 0x00000004 clearFlag = 0x00
sap = 0x02
state = 0x01
of cons (hex) = 0x0000000a
connections (hex) = 0000 0001 0002 0003 0004 0005 0006 0007 0008 0009
xidCmdSent = 0x00000000
```

```

xidCmdRcvd = 0x00000000
xidRspSent = 0x00000000
xidRspRcvd = 0x00000000
testCmdSent = 0x00000000
testCmdRcvd = 0x00000000
testRspSent = 0x00000000
testRspRcvd = 0x00000000
uiSent = 0x00000000
uiRcvd = 0x00000000
outOfState = 0x00000000
allocFail = 0x00000000
protocolError = 0x00000000

```

The fields are described as follows:

|             |                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------|
| ppa         | The logical number used to address the adapter.                                                                                       |
| clearFlag   | This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0). |
| sap         | The specified Service Access Point (SAP) logical interface value for the station.                                                     |
| state       | A number indicating the current state of the SAP component (0 = inactive, 1 = active).                                                |
| # of cons   | The number of active connections on this SAP.                                                                                         |
| connections | The array of active connection indexes.                                                                                               |
| xidCmdSent  | The number of XID command PDUs sent (Source SAP = this sap).                                                                          |
| xidCmdRcvd  | The number of XID command PDUs received (Destination SAP = this sap).                                                                 |
| xidRspSent  | The number of XID response PDUs sent (Source SAP = this sap).                                                                         |
| xidRspRcvd  | The number of XID response PDUs received (Source SAP = this sap).                                                                     |
| testCmdSent | The number of TEST command PDUs sent (Source SAP = this sap).                                                                         |
| testCmdRcvd | The number of TEST command PDUs received (Destination SAP = this sap).                                                                |
| testRspSent | The number of TEST response PDUs sent (Source SAP = this sap).                                                                        |

|               |                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| testRspRcvd   | The number of TEST response PDUs received (Source SAP = this sap).                                                             |
| uiSent        | The number of Unnumbered Information Frames sent.                                                                              |
| uiRcvd        | The number of Unnumbered Information Frames received.                                                                          |
| outOfState    | The number of events received in an invalid state.                                                                             |
| allocFail     | The number of buffer allocation failures.                                                                                      |
| protocolError | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |

**EXAMPLE 3** Connection Statistics

Ten established connections are associated with this SAP. To retrieve the statistics for connection 1, enter the following command:

```
example% /usr/lib/llc2/llc2_stats 4 -s 2 -c 1
Connection values received:
ppa = 0x0004 clearFlag = 0x00
sap = 0x02 con = 0x0001 sid = 0x0201
stateOldest = 0x00 stateOlder = 0x00 stateOld = 0x01

```

|           |                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| ppa       | The logical number used to address the adapter.                                                                                       |
| clearFlag | This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0). |

|             |                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sap         | The specified Service Access Point (SAP) logical interface value for the station.                                                                                  |
| con         | The specified connection index value for the SAP.                                                                                                                  |
| stateOldest | A number representing the state of the connection component prior to stateOlder.                                                                                   |
| stateOlder  | A number representing the state of the connection component prior to stateOld.                                                                                     |
| stateOld    | A number representing the state of the connection component prior to state.                                                                                        |
| state       | A number representing the most current state of the connection component. See Table 1.                                                                             |
| sid         | The Station Identifier composed of the SAP (upper byte) and connection index (lower byte).                                                                         |
| dl_nodeaddr | The Data Link Node Address. This is the destination node's MAC address.                                                                                            |
| dl_sap      | The destination node's SAP.                                                                                                                                        |
| flag        | The connection component processing flag. See Table 3.                                                                                                             |
| dataFlag    | A number representing the status of the data units from received I-frame PDUs (0 = not discarded, 1 = discarded, 2 = busy state entered with REJ PDU outstanding). |
| timerOn     | A number representing the timer activity flag, with each bit representing an active timer for this connection. See Table 2 for timer definitions.                  |
| vs          | The sequence number of the next I-frame PDU to send.                                                                                                               |
| vr          | The expected sequence number of the next I-frame PDU to be received.                                                                                               |
| nrRcvd      | The sequence number plus 1 of the last sent I-frame PDU acknowledged by the remote node.                                                                           |
| k           | The transmit window size.                                                                                                                                          |
| retryCount  | The <code>retryCount</code> is incremented whenever a timer expiration occurs. These timers protect outbound frames.                                               |

|              |                                                                              |
|--------------|------------------------------------------------------------------------------|
| numToBeAcked | The number of outbound I-frames awaiting acknowledgement.                    |
| numToResend  | The number of outbound I-frames to be retransmitted.                         |
| macOutSave   | No longer used.                                                              |
| macOutDump   | No longer used.                                                              |
| iSent        | The number of I-frames sent.                                                 |
| iRcvd        | The number of I-frames received.                                             |
| frmrSent     | The number of Frame Reject PDUs (FRMR) sent.                                 |
| frmrRcvd     | The number of Frame Reject PDUs (FRMR) received.                             |
| rrSent       | The number of Receiver Ready PDUs (RR) sent.                                 |
| rrRcvd       | The number of Receiver Ready PDUs (RR) received.                             |
| rnrSent      | The number of Receiver Not Ready PDUs (RNR) sent.                            |
| rnrRcvd      | The number of Receiver Not Ready PDUs (RNR) received.                        |
| rejSent      | The number of Reject PDUs (REJ) sent.                                        |
| rejRcvd      | The number of Reject PDUs (REJ) received.                                    |
| sabmeSent    | The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) sent.     |
| sabmeRcvd    | The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) received. |
| uaSent       | The number of Unnumbered Acknowledgment PDUs (UA) sent.                      |
| uaRcvd       | The number of Unnumbered Acknowledgment PDUs (UA) received.                  |
| discSent     | The number of Disconnect PDUs (DISC) sent.                                   |
| outOfState   | The number of events received in an invalid state.                           |
| allocFail    | The number of buffer allocation failures.                                    |

|                 |                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------|
| protocolError   | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |
| localBusy       | The number of times this component was in local busy state and could not accept I-frames.                                      |
| remoteBusy      | The number of times the remote connection component was busy and could not accept I-frames.                                    |
| maxRetryFail    | The number of failures that occurred because maxRetry was reached.                                                             |
| ackTimerExp     | The number of expirations of the Acknowledgement timer.                                                                        |
| pollTimerExp    | The number of expirations of the Poll timer.                                                                                   |
| rejTimerExp     | The number of expirations of the Reject timer.                                                                                 |
| remBusyTimerExp | The number of expirations of the Remote Busy timer.                                                                            |
| inactTimerExp   | The number of expirations of the Inactivity timer.                                                                             |
| sendAckTimerExp | The number of expirations of the Send Acknowledgement timer.                                                                   |

**Table 1:** LLC2 States

|                   |      |
|-------------------|------|

| <b>NAME</b>        | ln – make hard or symbolic links to files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre> /usr/bin/ln [-fns] source_file [target] /usr/bin/ln [-fns] source_file... target /usr/xpg4/bin/ln [-fs] source_file [target] /usr/xpg/bin/ln [-fs] source_file... target </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>In the first synopsis form, the <code>ln</code> utility creates a new directory entry (link) for the file specified by <i>source_file</i>, at the destination path specified by <i>target</i>. If <i>target</i> is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.</p> <p>In the second synopsis form, the <code>ln</code> utility creates a new directory entry for each file specified by a <i>source_file</i> operand, at a destination path in the existing directory named by <i>target</i>.</p> <p>The <code>ln</code> utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.</p> <p><code>ln</code> by default creates hard links. <i>source_file</i> is linked to <i>target</i>. If <i>target</i> is a directory, another file named <i>source_file</i> is created in <i>target</i> and linked to the original <i>source_file</i>.</p> <p><b>/usr/bin/ln</b> If <i>target</i> is a file, its contents are overwritten. If <code>/usr/bin/ln</code> determines that the mode of <i>target</i> forbids writing, it will print the mode (see <code>chmod(1)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the link occurs, if permissible; otherwise, the command exits.</p> <p><b>/usr/xpg4/bin/ln</b> If <i>target</i> is a file and the <code>-f</code> option is not specified, <code>/usr/xpg4/bin/ln</code> will write a diagnostic message to standard error, do nothing more with the current <i>source_file</i>, and go on to any remaining <i>source_files</i>.</p> <p>A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.</p> <p>When creating a hard link, and the source file is itself a symbolic link, then the target will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (<i>source_file</i>).</p> <p>File permissions for <i>target</i> may be different from those displayed with a <code>-l</code> listing of the <code>ls(1)</code> command. To display the permissions of <i>target</i> use <code>ls -lL</code>. See <code>stat(2)</code> for more information.</p> |

**OPTIONS**

The following options are supported for both `/usr/bin/ln` and `/usr/xpg4/bin/ln`:

`-f` Link files without questioning the user, even if the mode of *target* forbids writing. This is the default if the standard input is not a terminal.

`-s` Create a symbolic link.

If the `-s` option is used with two arguments, *target* may be an existing directory or a non-existent file. If *target* already exists and is not a directory, an error is returned. *source\_file* may be any path name and need not exist. If it exists, it may be a file or directory and may reside on a different file system from *target*. If *target* is an existing directory, a file is created in directory *target* whose name is *source\_file* or the last component of *source\_file*. This file is a symbolic link that references *source\_file*. If *target* does not exist, a file with name *target* is created and it is a symbolic link that references *source\_file*.

If the `-s` option is used with more than two arguments, *target* must be an existing directory or an error will be returned. For each *source\_file*, a link is created in *target* whose name is the last component of *source\_file*; each new *source\_file* is a symbolic link to the original *source\_file*. The files and *target* may reside on different file systems.

**/usr/bin/ln**

The following options are supported for `/usr/bin/ln` only:

`-n` If the link is an existing file, do not overwrite the contents of the file. The `-f` option overrides this option. This is the default behavior for `/usr/xpg4/bin/ln`, and is silently ignored.

**OPERANDS**

The following operands are supported:

*source\_file* A path name of a file to be linked. This can be either a regular or special file. If the `-s` option is specified, *source\_file* can also be a directory.

*target* The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.

**USAGE**

See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ln`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

0 All the specified files were linked successfully

>0 An error occurred.

**ATTRIBUTES**  
/usr/bin/ln

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

## /usr/xpg4/bin/ln

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |
| CSI            | Enabled         |

**NOTES**

A symbolic link to a directory behaves differently than you might expect in certain cases. While an `ls(1)` on such a link displays the files in the pointed-to directory, an `'ls -l'` displays information about the link itself:

```
example% ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user 7 Jan 11 23:27 link -> dir
```

When you `cd(1)` to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is `/usr` and not `/home/user/linktest`.

```
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd ..
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

| <b>NAME</b>        | ln - make hard or symbolic links to files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>/usr/ucb/ln [-fs] filename [linkname] /usr/ucb/ln [-fs] pathname... directory</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>/usr/ucb/ln</code> utility creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc.</p> <p><i>filename</i> is the name of the original file or directory. <i>linkname</i> is the new name to associate with the file or filename. If <i>linkname</i> is omitted, the last component of <i>filename</i> is used as the name of the link.</p> <p>If the last argument is the name of a directory, symbolic links are made in that directory for each <i>pathname</i> argument; <code>/usr/ucb/ln</code> uses the last component of each <i>pathname</i> as the name of each link in the named <i>directory</i>.</p> <p>A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.</p> <p>A symbolic link, made with the <code>-s</code> option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.</p> <p>A symbolic link to a directory behaves differently than you might expect in certain cases. While an <code>ls(1)</code> on such a link displays the files in the pointed-to directory, an <code>'ls -l'</code> displays information about the link itself:</p> <pre>example% /usr/ucb/ln -s dir link example% ls link file1 file2 file3 file4 example% ls -l link lrwxrwxrwx  1 user          7 Jan 11 23:27 link -&gt; dir</pre> <p>When you use <code>cd(1)</code> to change to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is <code>/usr</code> and not <code>/home/user/linktest</code>.</p> |

```

example% pwd
/home/user/linktest
example% /usr/ucb/ln -s /var/tmp symlink
example% cd symlink
example% cd ..
example% pwd
/usr

```

C shell user's can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

**OPTIONS**

- f Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.
- s Create a symbolic link or links.

**USAGE**

See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES**

**EXAMPLE 1** The `/usr/ucb/ln` command

The commands below illustrate the effects of the different forms of the `/usr/ucb/ln` command:

```

example% /usr/ucb/ln file link
example% ls -F file link
file link
example% /usr/ucb/ln -s file symlink
example% ls -F file symlink
file symlink@
example% ls -li file link symlink
 10606 -rw-r--r-- 2 user 0 Jan 12 00:06 file
 10606 -rw-r--r-- 2 user 0 Jan 12 00:06 link
 10607 lrwxrwxrwx 1 user 4 Jan 12 00:06 symlink -> file
example% /usr/ucb/ln -s nonesuch devoid
example% ls -F devoid
devoid@
example% cat devoid
devoid: No such file or directory
example% /usr/ucb/ln -s /proto/bin/* /tmp/bin
example% ls -F /proto/bin /tmp/bin
/proto/bin:
x* y* z*

/tmp/bin:
x@ y@ z@

```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO**

cp(1), ls(1), mv(1), rm(1), link(2), readlink(2), stat(2), symlink(2),  
attributes(5), largefile(5)

**NOTES**

When the last argument is a directory, simple basenames should not be used for *pathname* arguments. If a basename is used, the resulting symbolic link points to itself:

```
example% /usr/ucb/ln -s file /tmp
example% ls -l /tmp/file
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file -> file
example% cat /tmp/file
/tmp/file: Too many levels of symbolic links
```

To avoid this problem, use full pathnames, or prepend a reference to the `PWD` variable to files in the working directory:

```
example% rm /tmp/file
example% /usr/ucb/ln -s $PWD/file /tmp
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file ->
/home/user/subdir/file
```

| <b>NAME</b>         | loadkeys, dumpkeys – load and dump keyboard translation tables                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |                     |          |

| <b>DESCRIPTION</b>  | <p>loadkeys reads the file specified by <i>filename</i>, and modifies the keyboard streams module's translation tables. If no file is specified, loadkeys loads the file: <code>/usr/share/lib/keytables/type_ <i>tt</i> /layout_ <i>dd</i></code>, where <i>tt</i> is the value returned by the <code>KIOCTYPE ioctl</code>, and <i>dd</i> is the value returned by the <code>KIOCLAYOUT ioctl</code> (see <code>kb(7M)</code>). These keytable files specify only the entries that change between the specified layout and the default layout for the particular keyboard type. On self-identifying keyboards, the value returned by the <code>KIOCLAYOUT ioctl</code> is set from the DIP switches.</p> <p>dumpkeys writes the current contents of the keyboard streams module's translation tables, in the format specified by <code>keytables(4)</code>, to the standard output.</p> |                |                 |              |         |                     |          |
| <b>FILES</b>        | <code>/usr/share/lib/keytables/layout_ <i>dd</i></code> default keytable files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |                     |          |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |                     |          |

| <b>SYNOPSIS</b>    | <b>locale</b> [-a   -m ]<br><b>locale</b> [-ck] <i>name...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>locale</code> utility writes information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a <i>public locale</i> is one provided by the implementation that is accessible to the application.</p> <p>When <code>locale</code> is invoked without any arguments, it summarizes the current locale environment for each locale category as determined by the settings of the environment variables.</p> <p>When invoked with operands, it writes values that have been assigned to the keywords in the locale categories, as follows:</p> <ul style="list-style-type: none"> <li>■ Specifying a keyword name selects the named keyword and the category containing that keyword.</li> <li>■ Specifying a category name selects the named category and all keywords in that category.</li> </ul> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a Write information about all available public locales. The available locales include <code>POSIX</code>, representing the <code>POSIX</code> locale.</p> <p>-c Write the names of selected locale categories. The <code>-c</code> option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the <code>-k</code> option.</p> <p>-k Write the names and values of selected keywords. The implementation may omit values for some keywords; see <code>OPERANDS</code>.</p> <p>-m Write names of available charmaps; see <code>localedef(1)</code>.</p>                                                                                                                                                          |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>name</i> The name of a locale category, the name of a keyword in a locale category, or the reserved name <code>charmap</code>. The named category or keyword will be selected for output. If a single <i>name</i> represents both a locale category name and a keyword name in the current locale, the results are unspecified; otherwise, both category and keyword names can be specified as <i>name</i> operands, in any sequence.</p>                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of the <code>locale</code> utility.</p> <p>In the following examples, the assumption is that locale environment variables are set as follows:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

```
LANG=locale_x LC_COLLATE=locale_y
```

The command `locale` would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_NUMERIC="locale_x"
LC_TIME="locale_x"
LC_COLLATE=locale_y
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The command `LC_ALL=POSIX locale -ck decimal_point` would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of `locale` to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | /usr/xpg4/bin/grep -Eq\
 "${locale yesexpr}"
then
 affirmative processing goes here
else
 non-affirmative processing goes here
fi
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for the descriptions of `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The `LANG`, `LC_*`, and `NLSPATH` environment variables must specify the current locale environment to be written out; they will be used if the `-a` option is not specified.

**EXIT STATUS**

The following exit values are returned:

- 0 All the requested information was found and output successfully.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |
| CSI            | Enabled         |

**SEE ALSO**

localedef(1), attributes(5), charmap(5), environ(5), locale(5)

**NOTES**

If LC\_CTYPE or keywords in the category LC\_CTYPE are specified, only the values in the range 0x00-0x7f are written out.

If LC\_COLLATE or keywords in the category LC\_COLLATE are specified, no actual values are written out.

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |

| <b>DESCRIPTION</b>                      | <p>The <code>localedef</code> utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables; see <code>environ(5)</code>.</p> <p>The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the <code>-i</code> option (if specified) or from standard input.</p> <p>Each category source definition is identified by the corresponding environment variable name and terminated by an <code>END <i>category-name</i></code> statement. The following categories are supported.</p> <table border="0"> <tr> <td style="padding-right: 20px;">LC_CTYPE</td> <td>Defines character classification and case conversion.</td> </tr> <tr> <td>LC_COLLATE</td> <td>Defines collation rules.</td> </tr> <tr> <td>LC_MONETARY</td> <td>Defines the format and symbols used in formatting of monetary information.</td> </tr> <tr> <td>LC_NUMERIC</td> <td>Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.</td> </tr> <tr> <td>LC_TIME</td> <td>Defines the format and content of date and time information.</td> </tr> <tr> <td>LC_MESSAGES</td> <td>Defines the format and values of affirmative and negative responses.</td> </tr> </table> | LC_CTYPE        | Defines character classification and case conversion.               | LC_COLLATE                              | Defines collation rules.                                                                                                                                                                                                                                | LC_MONETARY                    | Defines the format and symbols used in formatting of monetary information.                                                                                                              | LC_NUMERIC | Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing. | LC_TIME | Defines the format and content of date and time information. | LC_MESSAGES | Defines the format and values of affirmative and negative responses. |
| LC_CTYPE                                | Defines character classification and case conversion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |
| LC_COLLATE                              | Defines collation rules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |
| LC_MONETARY                             | Defines the format and symbols used in formatting of monetary information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |
| LC_NUMERIC                              | Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |
| LC_TIME                                 | Defines the format and content of date and time information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |
| LC_MESSAGES                             | Defines the format and values of affirmative and negative responses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                 |                                                                     |                                         |                                                                                                                                                                                                                                                         |                                |                                                                                                                                                                                         |            |                                                                                               |         |                                                              |             |                                                                      |

|                                 | (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-i sourcefile</code>      | The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-L linker_options</code>  | Passes the <i>linker_options</i> to the C compiler ( <code>cc</code> ) that follows the C source filename. If more than one option is specified, then the options must be enclosed in quotes (" ").                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                 | This is an old option. Use the <code>-W cc,arg</code> option instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-m model</code>           | Specifies whether <code>localedef</code> will generate a 64-bit or a 32-bit locale object.<br><br>Specify <i>model</i> as <code>ilp32</code> to generate a 32-bit locale object. Specify <code>lp64</code> to generate a 64-bit locale object. If the <code>-m</code> option is not specified, <code>localedef</code> generates a 32-bit locale object. And if no other options than <code>-c</code> , <code>-f</code> , and <code>-i</code> options are specified and if the system running <code>localedef</code> supports the 64-bit environment, <code>localedef</code> additionally generates a 64-bit locale object. |
| <code>-W cc,arg</code>          | Passes <i>arg</i> options to the C compiler. Each argument must be separated from the preceding by only a comma. (A comma can be part of an argument by escaping it by an immediately preceding backslash character; the backslash is removed from the resulting argument.)<br><br>Use this option instead of the <code>-C</code> and <code>-L</code> options.                                                                                                                                                                                                                                                             |
| <code>-x extensions_file</code> | Specifies the name of an extension file where various <code>localedef</code> options are listed. See <code>locale(5)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**OPERANDS**

The following operand is supported:

|                   |                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>localename</i> | Identifies the locale. If the name contains one or more slash characters, <i>localename</i> will be interpreted as a path name where the created locale definitions will be stored. |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one *localename*, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

**OUTPUT**

localedef creates a temporary C source file that represents the locale's data. localedef then calls the C compiler to compile this C source file into a shared object.

If the `-m ilp32` option is specified, localedef calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If the `-m lp64` option is specified, localedef calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If the `-m` option is not specified, localedef calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If no other options than `-c`, `-f`, and `-i` options are specified and if the system running localedef supports the 64-bit environment, localedef additionally calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If no option to the C compiler is explicitly specified using the `-w`, `-C`, or `-L` options, localedef calls the C compiler with appropriate C compiler options to generate a locale object or objects.

If the `-m ilp32` option is specified, localedef generates a 32-bit locale object named:

*localename.so.version\_number*

If the `-m lp64` option is specified, localedef generates a 64-bit locale object named:

*localename.so.version\_number*

If the `-m` option is not specified, localedef generates a 32-bit locale object named:

*localename.so.version\_number*

and, if appropriate, generates a 64-bit locale object named:

*64-bit\_architecture\_name/localename.so.version\_number*

The shared object for the 32-bit environment must be moved to:

*/usr/lib/locale/ localename/ localename.so.version\_number*

The shared object for the 64-bit environment on SPARC must be moved to:

*/usr/lib/locale/ localename/ sparcv9/ localename.so.version\_number*

`localedef` also generates a text file named *localename* that is used for information only.

## ENVIRONMENT VARIABLES

See `environ(5)` for definitions of the following environment variables that affect the execution of `localedef`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

## EXIT STATUS

The following exit values are returned:

- 0 No errors occurred and the locales were successfully created.
- 1 Warnings occurred and the locales were successfully created.
- 2 The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
- 3 The capability to create new locales is not supported by the implementation.
- >3 Warnings or errors occurred and no output was created.

If an error is detected, no permanent output will be created.

## FILES

*/usr/lib/localedef/extensions/generic\_eucbc.x*

Describes what a generic EUC locale uses in the system. This file is used by default.

*/usr/lib/localedef/extensions/single\_byte.x*

Describes a generic single-byte file used in the system.

*/usr/lib/locale/ localename/ localename.so.version\_number*

The shared object for the 32-bit environment.

*/usr/lib/locale/ localename/ sparcv9/ localename.so.version\_number*

The shared object for the 64-bit environment on SPARC.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

## SEE ALSO

`locale(1)`, `nl_langinfo(3C)`, `strftime(3C)`, `attributes(5)`, `charmap(5)`, `environ(5)`, `extensions(5)`, `locale(5)`

**WARNINGS**

If warnings occur, permanent output will be created if the `-c` option was specified. The following conditions will cause warning messages to be issued:

- If a symbolic name not found in the *charmap* file is used for the descriptions of the `LC_CTYPE` or `LC_COLLATE` categories (for other categories, this will be an error conditions).
- If optional keywords not supported by the implementation are present in the source.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | logger – add entries to the system log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>logger</b> [-i] [-f <i>file</i> ] [-p <i>priority</i> ] [-t <i>tag</i> ] [ <i>message</i> ] ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | The <code>logger</code> command provides a method for adding one-line entries to the system log file from the command line. One or more <i>message</i> arguments can be given on the command line, in which case each is logged immediately. If this is unspecified, either the file indicated with <code>-f</code> or the standard input is added to the log. Otherwise, a <i>file</i> can be specified, in which case each line in the file is logged. If neither is specified, <code>logger</code> reads and logs messages on a line-by-line basis from the standard input.                                                                                                |
| <b>OPTIONS</b>     | The following options are supported:<br><code>-ffile</code> Use the contents of <i>file</i> as the message to log.<br><code>-i</code> Log the process ID of the <code>logger</code> process with each line.<br><code>-ppriority</code> Enter the message with the specified <i>priority</i> . The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, ' <code>-p local3.info</code> ' assigns the message priority to the <code>info</code> level in the <code>local3</code> facility. The default priority is <code>user.notice</code> .<br><code>-ttag</code> Mark each line added to the log with the specified <i>tag</i> .   |
| <b>OPERANDS</b>    | The following operand is supported:<br><i>message</i> One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> Examples of the <code>logger</code> command.<br>The following example:<br><pre>example% logger System rebooted</pre> logs the message 'System rebooted' to the default priority level <code>notice</code> to be treated by <code>syslogd</code> as are other messages to the facility <code>user</code> .<br>The next example:<br><pre>example% logger -p local0.notice -t HOSTIDM -f /dev/idmc</pre> reads from the file <code>/dev/idmc</code> and logs each line in that file as a message with the tag 'HOSTIDM' at priority level <code>notice</code> to be treated by <code>syslogd</code> as are other messages to the facility <code>local0</code> . |

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `logger`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

0       Successful completion.

>0      An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>        | logger – add entries to the system log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/logger [-f filename] [-i] [-p priority] [-t tag] mm[message] ...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | The <code>logger</code> utility provides a method for adding one-line entries to the system log file from the command line. One or more <i>message</i> arguments can be given on the command line, in which case each is logged immediately. If <i>message</i> is unspecified, either the file indicated with <code>-f</code> or the standard input is added to the log. Otherwise, a <i>filename</i> can be specified, in which case each line in the file is logged. If neither is specified, <code>logger</code> reads and logs messages on a line-by-line basis from the standard input.                                                                                                                        |
| <b>OPTIONS</b>     | The following options are supported:<br><code>-i</code> Log the process ID of the <code>logger</code> process with each line.<br><code>-f filename</code> Use the contents of <i>filename</i> as the message to log.<br><code>-p priority</code> Enter the message with the specified <i>priority</i> . The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, <code>'-p local3.info'</code> assigns the message priority to the <code>info</code> level in the <code>local3</code> facility. The default priority is <code>user.notice</code> .<br><code>-t tag</code> Mark each line added to the log with the specified <i>tag</i> .                                |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Logging a message</p> <p>The command:</p> <pre>example% logger System rebooted</pre> <p>will log the message 'System rebooted' to the facility at priority <code>notice</code> to be treated by <code>syslogd</code> as other messages to the facility <code>notice</code> are.</p> <p><b>EXAMPLE 2</b> Logging messages from a file</p> <p>The command:</p> <pre>example% logger -p local0.notice -t HOSTIDM -f /dev/idmc</pre> <p>will read from the file <code>/dev/idmc</code> and will log each line in that file as a message with the tag 'HOSTIDM' at priority <code>notice</code> to be treated by <code>syslogd</code> as other messages to the facility <code>local0</code> are.</p> |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | login – sign on to the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>login</b> [-p] [-d <i>device</i> ] [-h <i>hostname</i>   [ <i>terminal</i> ]   -r <i>hostname</i> ][ <i>name</i> [ <i>environ</i> ] ... ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>login</code> command is used at the beginning of each terminal session to identify oneself to the system. <code>login</code> is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the <code>exit</code> command.</p> <p>If <code>login</code> is invoked as a command, it must replace the initial command interpreter. To invoke <code>login</code> in this fashion, type:</p> <pre>exec login</pre> <p>from the initial shell. The C shell and Korn shell have their own builtins of <code>login</code>. See <code>ksh(1)</code> and <code>csh(1)</code> for descriptions of <code>login</code> builtins and usage.</p> <p><code>login</code> asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.</p> <p>If you make any mistake in the login procedure, the message:</p> <pre>Login incorrect</pre> <p>is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in <code>/var/adm/loginlog</code>, if it exists. The TTY line will be dropped.</p> <p>If password aging is turned on and the password has "aged" (see <code>passwd(1)</code> for more information), the user is forced to change the password. In this case the <code>/etc/nsswitch.conf</code> file is consulted to determine password repositories (see <code>nsswitch.conf(4)</code>). The password update configurations supported are limited to the following five cases.</p> <ul style="list-style-type: none"> <li>■ <code>passwd: files</code></li> <li>■ <code>passwd: files nis</code></li> <li>■ <code>passwd: files nisplus</code></li> <li>■ <code>passwd: compat (==&gt; files nis)</code></li> <li>■ <code>passwd: compat (==&gt; files nisplus)</code></li> </ul> <pre>passwd_compat: nisplus</pre> |

Failure to comply with the configurations will prevent the user from logging onto the system because `passwd(1)` will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.

After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the `/etc/logindevperm` file, and the time you last logged in is printed (see `logindevperm(4)`).

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually `ksh`) is started.

The basic *environment* is initialized to:

```
HOME=your-login-directory
LOGNAME=your-login-name
PATH=/usr/bin:
SHELL=last-field-of-passwd-entry
MAIL=/var/mail/TZ=timezone-specification
```

For Bourne shell and Korn shell logins, the shell executes `/etc/profile` and `$HOME/.profile`, if it exists. For C shell logins, the shell executes `/etc/.login`, `$HOME/.cshrc`, and `$HOME/.login`. The default `/etc/profile` and `/etc/.login` files check quotas (see `quota(1M)`), print `/etc/motd`, and check for mail. None of the messages are printed if the file `$HOME/.hushlogin` exists. The name of the command interpreter is set to `-` (dash), followed by the last component of the interpreter's path name, for example, `-sh`.

If the `login-shell` field in the password file (see `passwd(4)`) is empty, then the default command interpreter, `/usr/bin/sh`, is used. If this field is `*` (asterisk), then the named directory becomes the root directory. At that point, `login` is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to `login`, either at execution time or when `login` requests your login name. The arguments may take either the form `xxx` or `xxx=yyy`. Arguments without an `=` (equal sign) are placed in the environment as:

```
Ln=xxx
```

where *n* is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an `=` (equal sign) are placed in the

environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables `PATH` and `SHELL` cannot be changed. This prevents people logged into restricted shell environments from spawning secondary shells that are not restricted. `login` understands simple single-character quoting conventions. Typing a `\` (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the `-p` flag to `login`. This flag indicates that all currently defined environment variables should be passed, if possible, to the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the `login` line take precedence, if a variable is passed by both methods.

To enable remote logins by root, edit the `/etc/default/login` file by inserting a `#` (pound sign) before the `CONSOLE=/dev/console` entry. See `FILES`.

## SECURITY

The `login` command uses `pam(3PAM)` for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `login`. Here is a partial `pam.conf` file with entries for the `login` command using the UNIX authentication, account management, session management, and password management module.

```
login auth required /usr/lib/security/pam_unix.so.1
login account required /usr/lib/security/pam_unix.so.1
login session required /usr/lib/security/pam_unix.so.1
login password required /usr/lib/security/pam_unix.so.1
```

If there are no entries for the `login` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

When `login` is invoked through `rlogind` or `telnetd`, the service name used by PAM is `rlogin` or `telnet` respectively.

## OPTIONS

The following options are supported:

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d device</code>                | <code>login</code> accepts a device option, <i>device</i> . <i>device</i> is taken to be the path name of the TTY port <code>login</code> is to operate on. The use of the device option can be expected to improve <code>login</code> performance, since <code>login</code> will not need to call <code>ttynam(3C)</code> . The <code>-d</code> option is available only to users whose UID and effective UID are root. Any other attempt to use <code>-d</code> will cause <code>login</code> to quietly exit. |
| <code>-h hostname [ terminal ]</code> | Used by <code>in.telnetd(1M)</code> to pass information about the remote host and terminal type.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-p</code>                       | Used to pass environment variables to the <code>login</code> shell.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-r hostname</code>              | Used by <code>in.rlogind(1M)</code> to pass information about the remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**EXIT STATUS**

The following exit values are returned:

|          |                       |
|----------|-----------------------|
| 0        | Successful operation. |
| non-zero | Error.                |

**FILES**

|                                |                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------|
| <code>\$HOME/.cshrc</code>     | initial commands for each <code>cs</code>                                           |

| <code>/etc/default/login</code>         | Default value can be set for the following flags in <code>/etc/default/login</code> . For example:<br>TIMEZONE=EST5EDT<br><br>TIMEZONE<br>Sets the TZ environment variable of the shell (see <code>environ(5)</code> ).<br><br>HZ<br>Sets the HZ environment variable of the shell.<br><br>ULIMIT<br>Sets the file size limit for the login. Units are disk blocks. Default is zero (no limit).<br><br>CONSOLE<br>If set, root can login on that device only. This will not prevent execution of remote commands with <code>rsh(1)</code> . Comment out this line to allow login by root.<br><br>PASSREQ<br>Determines if login requires a non-null password.<br><br>ALTSHELL<br>Determines if login should set the SHELL environment variable.<br><br>PATH<br>Sets the initial shell PATH variable.<br><br>SUPATH |

Sets the initial shell `PATH` variable for root.

**TIMEOUT**

Sets the number of seconds (between 0 and 900) to wait before abandoning a login session.

**UMASK**

Sets the initial shell file creation mode mask.  
See `umask(1)`.

**SYSLOG**

Determines whether the `syslog(3C)` `LOG_AUTH` facility should be used to log all root logins at level `LOG_NOTICE` and multiple failed login attempts at `LOG_CRIT`.

**SLEEPTIME**

If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

**RETRIES**

Sets the number of retries for logging in (see `pam(3PAM)`). The default is 5.

**SYSLOG\_FAILED\_LOGINS**

Used to determine how many failed login attempts will be allowed by the system before a failed login message is logged, using the `syslog(3C)` `LOG_NOTICE` facility. For example, if the variable is set to 0, `login` will log *all* failed login attempts.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**DIAGNOSTICS**

Login incorrect

The user name or the password cannot be matched.

Not on system console

Root login denied. Check the `CONSOLE` setting in `/etc/default/login`.

No directory! Logging in with `home=/`

The user's home directory named in the `passwd(4)` database cannot be found or has the wrong permissions. Contact your system administrator.

No shell

Cannot execute the shell named in the `passwd(4)` database. Contact your system administrator.

NO LOGINS: System going down in *N* minutes

The machine is in the process of being shut down and logins have been disabled.

**WARNINGS**

Users with a UID greater than 76695844 are not subject to password aging, and the system does not record their last login time.

If you use the `CONSOLE` setting to disable root logins, you should arrange that remote command execution by root is also disabled. See `rsh(1)`, `rcmd(3SOCKET)`, and `hosts.equiv(4)` for further details.

| <b>NAME</b>                  | logname – return user’s login name                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>              | <b>logname</b>                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b>           | The logname utility will write the user’s login name to standard output. The login name is the string that would be returned by the <code>getlogin(3C)</code> function. Under the conditions where <code>getlogin( )</code> would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status. |                |                 |              |         |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of logname: <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                 |                |                 |              |         |
| <b>EXIT STATUS</b>           | The following error values are returned:<br>0        Successful completion.<br>>0      An error occurred.                                                                                                                                                                                                                               |                |                 |              |         |
| <b>FILES</b>                 | <code>/etc/profile</code> environment for user at login time<br><code>/var/adm/utmp</code> user and accounting information                                                                                                                                                                                                              |                |                 |              |         |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                            |                |                 |              |         |

| <b>NAME</b>        | look – find words in the system dictionary or lines in a sorted list                                                                                                                                                                                                                                                                                                |                |                 |              |         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <code>/usr/bin/look [-d] [-f] [-tc] string [filename]</code>                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>look</code> command consults a sorted <i>filename</i> and prints all lines that begin with <i>string</i>.</p> <p>If no <i>filename</i> is specified, <code>look</code> uses <code>/usr/share/lib/dict/words</code> with collating sequence <code>-df</code>.</p> <p><code>look</code> limits the length of a word to search for to 256 characters.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-d</code> Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons.</p> <p><code>-f</code> Fold case. Upper case letters are not distinguished from lower case in comparisons.</p> <p><code>-tc</code> Set termination character. All characters to the right of <i>c</i> in <i>string</i> are ignored.</p>                |                |                 |              |         |
| <b>FILES</b>       | <code>/usr/share/lib/dict/words</code> spelling list                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

**NAME** | lookbib – find references in a bibliographic database

**SYNOPSIS** | **lookbib** *database*

**DESCRIPTION** | A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a '%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with '%'.  
 The lookbib utility uses an inverted index made by indxbib to find sets of bibliographic references. It reads keywords typed after the '>' prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another '>' prompt.

The lookbib utility uses an inverted index made by indxbib to find sets of bibliographic references. It reads keywords typed after the '>' prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another '>' prompt.

It is possible to search multiple databases, as long as they have a common index made by indxbib(1). In that case, only the first argument given to indxbib is specified to lookbib.

If lookbib does not find the index files (the .i[abc] files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a .ig suffix, suitable for use with fgrep (see grep(1)). lookbib then uses this fgrep file to find references. This method is simpler to use, but the .ig file is slower to use than the .i[abc] files, and does not allow the use of multiple reference files.

**FILES** |  
 x.ia  
 x.ib  
 x.ic index files  
 x.ig reference file

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**SEE ALSO** | addbib(1), grep(1), indxbib(1), refer(1), roffbib(1), sortbib(1), attributes(5)

**BUGS** | Probably all dates should be indexed, since many disciplines refer to literature written in the 1800s or earlier.

| <b>NAME</b>        | lorder – find ordering relation for an object or library archive                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |                |                 |        |                                                                                                                                                                      |

| <b>SYNOPSIS</b>    | <b>lorder</b> <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |                |                 |        |                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The input is one or more object or library archive <i>filenames</i> (see <code>ar(1)</code>). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by <code>tsort(1)</code> to find an ordering of a library suitable for one-pass access by <code>ld</code>. Note that the link editor <code>ld</code> is capable of multiple passes over an archive in the portable archive format (see <code>ar(3HEAD)</code>) and does not require that <code>lorder</code> be used when building an archive. The usage of the <code>lorder</code> command may, however, allow for a more efficient access of the archive during the link edit process.</p> <p>The following example builds a new library from existing <code>.o</code> files.</p> <pre>ar -cr library `lorder *.o   tsort `</pre> |                |                 |                |                 |        |                                                                                                                                                                      |

| <b>DESCRIPTION</b> | <p>lp submits print requests to a destination. There are two formats of the lp command.</p> <p>The first form of lp prints files (<i>file</i>) and associated information (collectively called a <i>print request</i>). If <i>file</i> is not specified, lp assumes the standard input. Use a hyphen ('-') with <i>file</i> to specify the standard input. Files are printed in the order in which they appear on the command line.</p> <p>The second form of lp changes print request options. This form of lp can only be used on a Solaris 2.6 Operating Environment or compatible versions of the LP print server. The print request identified by <i>request-ID</i> is changed according to the printing options specified. The printing options available are the same as those with the first form of the lp. If the request has finished printing when the lp command is executed, the change is rejected. If the request is in the process of printing, it will be stopped and restarted from the beginning (unless the -P option has been given).</p> <p>The print client commands locate destination information in a very specific order. See printers(4) and printers.conf(4) for details.</p> |
| <b>OPTIONS</b>     | <p>Printers that have a 4.x or BSD-based print server are not configured to handle BSD protocol extensions. lp handles print requests sent to such destinations differently (see NOTES).</p> <p>The following options are supported:</p> <p>-c      Copies <i>file</i> before printing.</p> <p>        Unless -c is specified, users should not remove any <i>file</i> before the print request has completely printed. Changes made to <i>file</i> after the print request is made but before it is printed will be reflected in the printed output. <i>file</i> will be linked (as opposed to copied).</p> <p>-d <i>destination</i>                      Prints <i>file</i> on a specific destination. Destination can be either a printer or a class of printers, (see lpadmin(1M)). Specify <i>destination</i> using atomic,</p>                                                                                                                                                                                                                                                                                                                                                                        |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                   |                                                                                                                                                                                                                                    |                     |                                                                                                                                                       |

Other print requests will go ahead of a request that has been put on hold ( <i>held print request</i> ) until the print request is resumed.                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |                                                                                                                                                                                                                                    |                     |                                                                                                                                                       |
| <code>resume</code>              | Resume a held print request. If the print request had begun to print when held, it will be the next print request printed, unless it is superseded by                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                   |                                                                                                                                                                                                                                    |                     |                                                                                                                                                       |

|                        |                        |                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                        | an <i>immediate</i> print request.                                                                                                                                                                                                                                                                                                                                                                     |
|                        | <code>immediate</code> | Print the print request next. If more than one print request is assigned, the most recent print request is printed next. If a print request is currently printing on the desired printer, a <code>hold</code> request must be issued to allow the <code>immediate</code> request to print. The <code>immediate</code> request is only available to LP administrators.                                  |
| <code>-m</code>        |                        | Sends mail after <code>file</code> has printed (see <code>mail(1)</code> ). By default, no mail is sent upon normal completion of a print request.                                                                                                                                                                                                                                                     |
| <code>-n number</code> |                        | Prints a specific number of copies of <code>file</code> . Specify <code>number</code> as a digit. The default for <code>number</code> is 1.                                                                                                                                                                                                                                                            |
| <code>-o option</code> |                        | Specify printer-dependent <i>options</i> . Specify several options by specifying <code>-o option</code> multiple times. ( <code>-o option -o option -o option</code> ). Printer-dependent options may also be specified using the <code>-o</code> keyletter once, followed by a list of options enclosed in double quotes ( <code>-o "option option option"</code> ). The following options are valid: |
|                        | <code>nobanner</code>  |                                                                                                                                                                                                                                                                                                                                                                                                        |

Do not print a banner page with the request. This option can be disallowed by the LP administrator.

`nofilebreak`

Prints multiple files without inserting a form feed between them.

`length=numberi | numberc | number`

Prints the print request with pages of a specific length. Specify `length` in inches, centimeters, or number of lines. Use `number` to specify the number of inches, centimeters or lines. Indicate inches or centimeters by appending the letter `i` for inches, `c` for centimeters to `number`. Indicate the the number of lines by specifying `number` alone. `length=66` indicates a page length of 66 lines. `length=11i` indicates a page length of 11 inches. `length=27.94c` indicates a page length of 27.94 centimeters.

This option may not be used with the `-f` option.

`width=numberi | numberc | number`

Prints the print request with with pages of a specific width. Specify `width` in inches, centimeters, or number of columns. Use `number` to specify the number of inches, centimeters or lines. Indicate inches or centimeters by appending the letter `i` for inches, `c` for centimeters to `number`. Indicate the the number of lines by specifying `number` alone. `width=65` indicates a page width of 65 columns. `width=6.5i`

indicates a page width of 6.5 inches. `width=10c` indicates a page width of 10 centimeters.

This option may not be used with the `-f` option.

`lpi=number`

Prints the print request with the line pitch set to *number* lines in an inch. Use *number* to specify the number of lines in an inch.

This option may not be used with the `-f` option.

`cpi=n|pica|elite|compressed`

Prints the print request with the character pitch set to *number* characters in an inch. Use *number* to specify the number of characters in an inch. Use `pica` to set character pitch to `pica` (10 characters per inch), or `elite` to set character pitch to `elite` (12 characters per inch) Use `compressed` to set character pitch to as many characters as the printer can handle. There is no standard number of characters per inch for all printers; see the `terminfo` database (see `terminfo(4)`) for the default character pitch for your printer. This option may not be used with the `-f` option.

`stty=stty-option-list`

Prints the request using a list of options valid for the `stty` command (see `stty(1)`). Enclose

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | the list in single quotes ( ' ' ) if it contains blanks.                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-P page-list</code>                 | Prints the pages specified in <i>page-list</i> in ascending order. Specify <i>page-list</i> as a of range of numbers, single page number, or a combination of both.                                                                                                                                                                                                                                                           |
|                                           | <code>-P</code> can only be used if there is a filter available to handle it; otherwise, the print request will be rejected.                                                                                                                                                                                                                                                                                                  |
| <code>-P</code>                           | Enables notification on completion of the print request. Delivery of the notification is dependent on additional software.                                                                                                                                                                                                                                                                                                    |
| <code>-q priority-level</code>            | Assigns the print request a priority in the print queue. Specify <i>priority-level</i> as an integer between from 0 and 39. Use 0 to indicate the highest priority; 39 to indicate the lowest priority. If no priority is specified, the default priority for a print service is assigned by the LP administrator. The LP administrator may also assign a default priority to individual users.                               |
| <code>-s</code>                           | Suppresses the display of messages sent from <code>lp</code> .                                                                                                                                                                                                                                                                                                                                                                |
| <code>-S character-set print-wheel</code> | Prints the request using the <i>character-set</i> or <i>print-wheel</i> . If a form was requested and requires a character set or print wheel other than the one specified with the <code>-S</code> option, the request is rejected. Printers using mountable print wheels or font cartridges use the print wheel or font cartridge mounted at the time of the print request, unless the <code>-S</code> option is specified. |
|                                           | Printers Using Print Wheels: If <i>print wheel</i> is not one listed by the LP administrator as acceptable for the                                                                                                                                                                                                                                                                                                            |

printer the request is rejected unless the print wheel is already mounted on the printer.

Printers Using Selectable or Programmable Character Sets: If the `-S` option is not specified, `lp` uses the standard character set. If *character-set* is not defined in the `terminfo` database for the printer (see `terminfo(4)`), or is not an alias defined by the LP administrator, the request is rejected.

- `-t title` Prints a title on the banner page of the output. Enclose *title* in quotes if it contains blanks. If *title* is not specified, the name of the file is printed on the banner page.
- `-T content-type [-r]` Prints the request on a printer that can support the specified *content-type*. If no printer accepts this type directly, a filter will be used to convert the content into an acceptable type. If the `-r` option is specified, a filter will not be used. If `-r` is specified, and no printer accepts the *content-type* directly, the request is rejected. If the *content-type* is not acceptable to any printer, either directly or with a filter, the request is rejected.
- `-w` Writes a message on the user's terminal after the *files* have been printed. If the user is not logged in, then mail will be sent instead.
- `-y mode-list` Prints the request according to the printing modes listed in *mode-list*. The allowed values for *mode-list* are locally defined.
- This option may be used only if there is a filter available to handle it; otherwise, the print request will be rejected.

## OPERANDS

The following operands are supported:

- `file` The name of the file to be printed. Specify *file* as a pathname or as a hyphen ('-') to indicate the standard input. If *file* is not specified, `lp` uses the standard input.

**USAGE** See `largefile(5)` for the description of the behavior of `lp` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES**

`/var/spool/lp/*` LP print queue.

`$HOME/.printers` User-configurable printer database.

`/etc/printers.conf` System printer configuration database.

`printers.conf.byname` NIS version of `/etc/printers.conf`.

`fns.ctx_dir.domain` NIS+ version of `/etc/printers.conf`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE     |
|----------------|---------------------|
| Availability   | SUNWpcu             |
| CSI            | Enabled (see NOTES) |

**SEE ALSO** `cancel(1)`, `enable(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `mail(1)`, `postprint(1)`, `pr(1)`, `stty(1)`, `accept(1M)`, `lpadmin(1M)`, `lpfilter(1M)`, `lpforms(1M)`, `lpsched(1M)`, `lpshut(1M)`, `lpssystem(1M)`, `lpusers(1M)`, `printers(4)`, `printers.conf(4)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** CSI-capability assumes that printer names are composed of ASCII characters.

Printers that have a 4.x or BSD-based print server. are not configured to handle BSD protocol extensions. `lp` handles print requests sent to such printers in the following ways:

1. Print requests with more than 52 filenames will be truncated to 52 files. `lp` displays a warning message.
2. The `-f`, `-H`, `-o`, `-P`, `-p`, `-q`, `-S`, `-T`, and `-y` options may require a protocol extension to pass to a print server. If `lp` cannot handle the print request, it displays a warning message.

LP administrators enable protocol extensions by setting a printer's `bsdaddr` entry in `/etc/printers.conf`. Changing the `bsdaddr` entry in `/etc/printers.conf` to:

*destination:bsdaddr=server,destination,Solaris*

generates a set of BSD print protocol extensions that can be processed by a Solaris print server. `lp` supports only Solaris protocol extensions at this time.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | lpc – line printer control program                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lpc [command [parameter... ] ]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The <code>lpc</code> utility controls the operation of local printers.</p> <p>Use <code>lpc</code> to perform the following functions:</p> <ul style="list-style-type: none"> <li>■ start or stop a printer,</li> <li>■ disable or enable a printer's spooling queue,</li> <li>■ rearrange the order of jobs in a print queue, or</li> <li>■ display the status of a printer print queue and printer daemon.</li> </ul> <p><code>lpc</code> can be run from the command line or interactively. Specifying <code>lpc</code> with the optional <i>command</i> and <i>parameter</i> arguments causes <code>lpc</code> to interpret the first argument as an <code>lpc</code> command, and all other arguments as parameters to that command. Specifying <code>lpc</code> without arguments causes it to run interactively, prompting the user for <code>lpc</code> commands with <code>lpc&gt;</code>. By redirecting the standard input, <code>lpc</code> can read commands from a file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>USAGE</b>       | <p><code>lpc</code> commands may be typed in their entirety or abbreviated to an unambiguous substring. Some <code>lpc</code> commands are available to all users; others are available only to super-users.</p> <p>All users may execute the following <code>lpc</code> commands:</p> <p><code>? [command ...]   help [command ...]</code><br/> Displays a short description of <i>command</i>. <i>command</i> is an <code>lpc</code> command. If <i>command</i> is not specified, displays a list of <code>lpc</code> commands.</p> <p><code>exit   quit</code><br/> Exits from <code>lpc</code>.</p> <p><code>status [all   printer ...]</code><br/> Displays the status of print daemons and print queues. <i>all</i> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> <p>Only a super-user may execute the following <code>lpc</code> commands:</p> <p><code>abort [all   printer ...]</code><br/> Terminates an active spooling daemon. Disables printing (by preventing new daemons from being started by <code>lpr(1B)</code>) for <i>printer</i>. <i>all</i> specifies this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> |

`clean [all | printer ...]`

Removes files created in the print spool directory by the print daemon from *printer*'s print queue. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`disable [all | printer ...]`

Turns off the print queue for *printer*. Prevents new printer jobs from being entered into the print queue for *printer* by `lpr(1B)`. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`down [all | printer ...] [message]`

Turns the queue for *printer* off and disables printing on *printer*. Inserts *message* in the printer status file. *message* does not need to be quoted; multiple arguments to *message* are treated as arguments are to `echo(1)`. Use `down` to take a printer down and inform users. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`enable [all | printer ...]`

Enables `lpr(1B)` to add new jobs in the spool queue. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`restart [all | printer ...]`

Attempts to start a new printer daemon. `restart` is useful when a print daemon dies unexpectedly and leaves jobs in the print queue. *all* specifies that this command is performed on all locally attached printers. *printer* indicates that this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`start [all | printer ...]`

Enables printing. Starts a spooling daemon for the *printer*. *all* specifies that this command is performed on all locally attached printers. *printer* indicates the command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`stop [all | printer ...]`

Stops a spooling daemon after the current job is complete. Disables printing at that time. `all` specifies that this command is performed on all locally attached printers. `printer` indicates this command is performed on specific printers. Specify `printer` as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`topq printer [request-ID ...] [user ...]`

Moves `request-ID` or print jobs belonging to `user` on `printer` to the beginning of the print queue. Specify `user` as a user's login name. Specify `printer` as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`up [all | printer ...]`

Turns the queue for `printer` on and enables printing on `printer`. Deletes the message in the printer status file (inserted by `down`). Use `up` to undo the effects of `down`. `all` specifies that this command is performed on all locally attached printers. `printer` indicates this command is performed on specific printers. Specify `printer` as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

#### EXIT STATUS

The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

#### FILES

`/var/spool/lp/*` LP print queue.

`/var/spool/lp/system/pstatus` Printer status information file.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscplp       |

#### SEE ALSO

`echo(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `lpsched(1M)`, `lpshut(1M)`, `printers.conf(4)`, `attributes(5)`

#### DIAGNOSTICS

Ambiguous command

Indicates that the `lpc` command or abbreviation matches more than one command.

?Invalid command

Indicates that the `lpc` command or abbreviation is not recognized.

?Privileged command

Indicates that the `lpc` command or abbreviation can be executed only by a super-user.

`lpc: printer:` unknown printer to the print service

Indicates that *printer* does not exist in the LP database. Check that *printer* was correctly specified. Use `lpstat -p` or the status command (see `lpstat(1)` or `USAGE`) to check the status of printers.

`lpc: error on opening queue to spooler`

Indicates that the connection to `lpsched` failed. Usually means that the printer server has died or is hung. Use `/usr/lib/lp/lpsched` to check if the printer spooler daemon is running.

`lpc: Can't send message to LP print service`

`lpc: Can't receive message from LP print service`

Indicates that the LP print service stopped. Contact the LP administrator.

`lpc: Received unexpected message from LP print service`

Indicates a problem with the software. Contact the LP administrator.

| <b>NAME</b>        | lpq – display the content of a print queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lpq [-P <i>destination</i>] [-l] [+ [<i>interval</i>] ] [<i>request-ID...</i>] [<i>user...</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>lpq</code> utility displays the information about the contents of a print queue. A print queue is comprised of print requests that are waiting in the process of being printed.</p> <p><code>lpq</code> displays the following information to the standard output:</p> <ul style="list-style-type: none"> <li>■ the username of the person associated with a print request,</li> <li>■ the position of a print request in the print queue,</li> <li>■ the name of file or files comprising a print request,</li> <li>■ the job number of a print request, and</li> <li>■ the size of the file requested by a print request. File size is reported in bytes.</li> </ul> <p>Normally, only as much information as will fit on one line is displayed. If the name of the input file associated with a print request is not available, the input file field indicates the standard input.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-P <i>destination</i></code>      Displays information about printer or class of printers (see <code>lpadmin(1M)</code>) . Specify <i>destination</i> using atomic, POSIX-style (<i>server: destination</i>), or Federated Naming Service (FNS) (<i>.../service/printer/...</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><code>-l</code>                      Displays information in long format. Long format includes the name of the host from which a print request originated in the display.</p> <p><code>+ [<i>interval</i>]</code>        Displays information at specific time intervals. Stops displaying information when the print queue is empty. Clears the screen before reporting displaying the print queue. Specify <i>interval</i> as the number of seconds between displays. If <i>interval</i> is not specified only executes once.</p>                                                                          |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>request-ID</i>            The job number associated with a print request.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

*user*            The name of the user about whose jobs `lpq` reports information. Specify *user* as a valid username.

**EXIT STATUS**

The following exit values are returned:

0                Successful completion.

non-zero        An error occurred.

**FILES**

`/var/spool/print/[cd]f*`            Spooling directory and request files for jobs awaiting transfer.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscplp       |

| <b>DESCRIPTION</b> | <p>The <code>lpr</code> utility submits print requests to a destination. <code>lpr</code> prints files (<i>file</i>) and associated information, collectively called a <i>print request</i>. If <i>file</i> is not specified, <code>lpr</code> assumes the standard input.</p> <p>The print client commands locate destination information in a very specific order. See <code>printers(4)</code> and <code>printers.conf(4)</code> for details.</p> <p>Print requests with more than 52 <i>files</i> specified will be truncated to 52 files. <code>lpr</code> displays a warning message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-P destination</code> Prints <i>file</i> on a specific printer or class of printers(see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<code>../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><code>-# number</code> Prints a specific number of copies. Specify <i>number</i> as a positive integer. The default for <i>number</i> is 1.</p> <p><code>-C class</code> Prints <i>class</i> as the job classification on the banner page of the output. Enclose <i>class</i> in double quotes if it contains blanks. If <i>class</i> is not specified, the name of the system (as returned by <code>hostname</code>) is printed as the job classification. See <code>hostname(1)</code>.</p> <p><code>-J job</code> Prints <i>job</i> as the <i>job name</i> on the banner page of the output. Enclose <i>job</i> in double quotes if it contains blanks. If <i>job</i> is not specified, <i>file</i> (or in the case of multiple files, the first <i>file</i> specified on the command line) is printed as the job name on the banner page of the output.</p> <p><code>-T title</code> Prints a title on the banner page of the output. Enclose <i>title</i> in double quotes if it contains blanks. If <i>title</i> is not specified, <i>file</i> is printed on the banner page.</p> |

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                                                                   |                |                                                    |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-------------------------------------------------------------------|----------------|----------------------------------------------------|
| <code>-i <i>indent</i></code>              | Indents the output a specific number of <code>SPACE</code> characters. Use <i>indent</i> to indicate the number of <code>SPACE</code> characters to be indented. Specify <i>indent</i> as a positive integer. Eight <code>SPACE</code> characters is the default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                                                   |                |                                                    |
| <code>-l   -2   -3   -4 <i>font</i></code> | Mounts the specified font in the font position 1, 2, 3, or 4. Specify <i>font</i> as a valid font name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                                                   |                |                                                    |
| <code>-w <i>cols</i></code>                | Prints <i>file</i> with pages of a specific width. <i>cols</i> indicates the number of columns wide.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                                                                   |                |                                                    |
| <code>-m</code>                            | Sends mail after <i>file</i> has printed. See <code>mail(1)</code> . By default, no mail is sent upon normal completion of a print request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                                                   |                |                                                    |
| <code>-h</code>                            | Suppresses printing of the banner page of the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                                                   |                |                                                    |
| <code>-s</code>                            | Uses full pathnames (as opposed to symbolic links) to <i>file</i> rather than trying to copy them. This means <i>file</i> should not be modified or removed until it has completed printing. Option <code>-s</code> only prevents copies of local files from being made on the local machine. Option <code>-s</code> only works with specified <i>files</i> . If the <code>lpr</code> command is at the end of a pipeline, <i>file</i> is copied to the spool.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                                                   |                |                                                    |
| <code>- <i>filter_option</i></code>        | <p>Notifies the print spooler that <i>file</i> is not a standard text file. Enables the spooling daemon to use the appropriate filters to print <i>file</i>.</p> <p><i>filter_options</i> offer a standard user interface. All options may not be available for, or applicable to, all printers.</p> <p>Specify <i>filter_option</i> as a single character.</p> <p>If <i>filter_option</i> is not specified and the printer can interpret PostScript®, inserting ‘%!’ as the first two characters of <i>file</i> causes <i>file</i> to be interpreted as PostScript.</p> <p>The following <i>filter_options</i> are supported:</p> <table> <tr> <td><code>p</code></td> <td>Use <code>pr</code> to format the files. See <code>pr(1)</code>.</td> </tr> <tr> <td><code>l</code></td> <td>Print control characters and suppress page breaks.</td> </tr> </table> | <code>p</code> | Use <code>pr</code> to format the files. See <code>pr(1)</code> . | <code>l</code> | Print control characters and suppress page breaks. |
| <code>p</code>                             | Use <code>pr</code> to format the files. See <code>pr(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                                                   |                |                                                    |
| <code>l</code>                             | Print control characters and suppress page breaks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                                                                   |                |                                                    |

- t *file* contains troff (cat phototypesetter) binary data.
- n *file* contains ditroff data from device independent troff.
- d *file* contains tex data from in DVI format from Stanford.
- g *file* contains standard plot data produced by plot(1B) routines.
- v *file* contains a raster image. *printer* must support an appropriate imaging model such as PostScript in order to print the image.
- c *file* contains data produced by cifplot.
- f Interprets the first character of each line as a standard FORTRAN carriage control character.

**OPERANDS**

The following operands are supported:

*file* The name of the file to be printed. Specify *file* as a pathname. If *file* is not specified, lpr uses the standard input.

**USAGE**

See largefile(5) for the description of the behavior of lpr when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.  
non-zero An error occurred.

**FILES**

/var/spool/print/.seq File containing the sequence numbers for job ID assignment.  
/var/spool/print/[cd]f\* Spooling directories and files.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE     |
|----------------|---------------------|
| Availability   | SUNWscplp           |
| CSI            | Enabled (see NOTES) |

**SEE ALSO**

hostname(1), lp(1), lpc(1B), lpq(1B), lprm(1B), lpstat(1), mail(1), plot(1B), pr(1), troff(1), lpadmin(1M), printers(4), printers.conf(4), attributes(5), largefile(5), standards(5)

**DIAGNOSTICS**

lpr: *destination* |: unknown destination  
*destination* was not found in the LP configuration database. Usually this is a typing mistake; however, it may indicate that the destination does not exist on the system. Use `lpstat -p` to display information about the status of the print service.

**NOTES**

lpr is CSI-enabled except for the *printer* name.

| <b>NAME</b>        | lprm – remove print requests from the print queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/lprm [-P <i>destination</i>] [-] [<i>request-ID</i> ...] [<i>user</i>...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>lprm</code> utility removes print requests (<i>request-ID</i>) from the print queue.</p> <p>Without arguments, <code>lprm</code> deletes the current print request. <code>lprm</code> reports the name of the file associated with print requests that it removes. <code>lprm</code> is silent if there are no applicable print requests to remove.</p> <p>Users can only remove print requests associated with their user name. See NOTES. If a super-user executes <code>lprm</code> and specifies the <i>user</i> operand, <code>lprm</code> removes all print requests belonging to the specified user.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-P <i>destination</i></code>     The name of the printer or class of printers (see <code>lpadmin(1M)</code>) from which to remove print requests. Specify <i>destination</i> using atomic, POSIX-style (<code>server:destination</code>), or Federated Naming Service (FNS) (<code>.../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p>–                         If a user specifies this option, removes all print requests owned by that user. If a super-user specifies this option, removes all requests in the print queue. Job ownership is determined by the user’s login name and host name on the machine from which <code>lpr</code> was executed. See NOTES.</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported.</p> <p><i>user</i>                    Removes print requests associated with a specific user. Specify <i>user</i> as a valid user name. This option can only be used by a super-user.</p> <p><i>request-ID</i>            Removes a specific print request. Specify <i>request-ID</i> as the job number (Job) associated with a print request and reported by <code>lpq</code>. See <code>lpq(1B)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Removing a print request</p> <p>The following example removes request-ID 385 from destination <code>killtree</code>:</p> <pre>example% lprm -P killtree 385</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**EXIT STATUS**

The following exit values are returned:  
 0 Successful completion.  
 non-zero An error occurred.

**FILES**

/var/spool/print/[cd]f\* Spooling directories and files.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscplp       |

**SEE ALSO**

**NOTES**

Users can only remove print requests associated with their user name. By default, users can only remove print requests on the host from which the print request was submitted. If a super-user has set `user-equivalence=true` in `/etc/printers.conf` on the print server, users can remove print requests associated with their user name on any host. Super-users can remove print requests on the host from which the print request was submitted. Super-users can also remove print requests from the print server.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | lpstat - print information about the status of the print service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>lpstat</b> [-d] [-r] [-R] [-s] [-t] [-a [ <i>list</i> ]] [-c [ <i>list</i> ]] [-f [ <i>list</i> ] [-1]] [-o [ <i>list</i> ]] [-p [ <i>list</i> ] [-D] [-1]] [-S [ <i>list</i> ] [-1]] [-u [ <i>login-ID -list</i> ]] [-v [ <i>list</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>lpstat displays information about the current status of the LP print service to standard output.</p> <p>If no options are given, lpstat prints the status of all the user's print requests made by lp. (see lp(1)). Any arguments that are not <i>options</i> are assumed to be <i>request-IDs</i> as returned by lp. The lpstat command prints the status of such requests. <i>options</i> may appear in any order and may be repeated and intermixed with other arguments. Some key letters may be followed by an optional <i>list</i> that can be in one of two forms: a list of items separated from one another by a comma, or a list of items separated from one another by spaces enclosed in quotes. For example:</p> <pre>example% lpstat -u "user1 user2 user3"</pre> <p>Specifying <i>all</i> after any key letter that takes <i>list</i> as an argument causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o all</pre> <p>prints the status of all output requests.</p> <p>The omission of a <i>list</i> following such key letters causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o</pre> <p>prints the status of all output requests.</p> <p>The print client commands locate printer information in a very specific order. See printers.conf(4) and printers(4) for details.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported on all platforms.</p> <p>-d                   Print the default destination for output requests.</p> <p>-o [<i>list</i>]           Print the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter -o may be omitted. Specify printer and class names using atomic, POSIX-style (<i>server: destination</i>), or Federated Naming Service (FNS) (.../service/printer/...) names. See</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- `printers.conf(4)` for information regarding the naming conventions for atomic and FNS names, and `standards(5)` for information regarding POSIX.
- `-r` Print the status of the LP request scheduler.
- `-R` Print a number showing the position of each request in the print queue.
- `-s` Print a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.
- `-t` Print all status information. This includes all the information obtained with the `-s` option, plus the acceptance and idle/busy status of all printers.
- `-u [login-ID-list]` Print the status of output requests for users. The *login-ID-list* argument may include any or all of the following constructs:
- login-ID*  
a user on any system
- system\_name!login-ID*  
a user on system *system\_name*
- system\_name!all*  
all users on system *system\_name*
- all!login-ID*  
a user on all systems
- all*  
all users on all systems
- `-v [list]` Print the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.

The following options return accurate results only if they are issued from a Solaris 2.6 Operating Environment or compatible version of the LP print server.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a [ <i>list</i> ]           | Reports whether print destinations are accepting requests. <i>list</i> is a list of intermixed printer names and class names.                                                                                                                                                                                                                                                                                                                                                                                           |
| -c [ <i>list</i> ]           | Print name of all classes and their members. <i>list</i> is a list of class names.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -f [ <i>list</i> ] [-1]      | Print a verification that the forms in <i>list</i> are recognized by the LP print service. <i>list</i> is a list of forms; the default is <code>all</code> . The <code>-1</code> option will list the form descriptions.                                                                                                                                                                                                                                                                                                |
| -p [ <i>list</i> ] [-D] [-1] | Print the status of printers. <i>list</i> is a list of printer names. If the <code>-D</code> option is given, a brief description is printed for each printer in <i>list</i> . If the <code>-1</code> option is given and the printer is on the local machine, a full description of each printer's configuration is returned, including the form mounted, the acceptable content and printer types, a printer description, and the interface used.                                                                     |
| -s [ <i>list</i> ] [-1]      | Print a verification that the character sets or the print wheels specified in <i>list</i> are recognized by the LP print service. Items in <i>list</i> can be character sets or print wheels; the default for the list is <code>all</code> . If the <code>-1</code> option is given, each line is appended by a list of printers that can handle the print wheel or character set. The list also shows whether the print wheel or character set is mounted, or specifies the built-in character set into which it maps. |
| -d                           | Print the default destination for output requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -o [ <i>list</i> ]           | Print the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and <i>request-IDs</i> . The key letter <code>-o</code> may be omitted.                                                                                                                                                                                                                                                                                                                                            |
| -r                           | Print the status of the LP request scheduler.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| -R                           | Print a number showing the position of each request in the print queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -s                           | Print a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms                                                                                                                                                                                                                                                                                                          |

currently mounted, and a list of all recognized character sets and print wheels.

**-t** Print all status information. This includes all the information obtained with the **-s** option, plus the acceptance and idle/busy status of all printers.

**-u** [*login-ID-list*] Print the status of output requests for users. The *login-ID-list* argument may include any or all of the following constructs:

*login-ID*  
a user on any system

*system\_name!**login-ID*  
a user on system *system\_name*

*system\_name!*all  
all users on system *system\_name*

all!*login-ID*  
a user on all systems

all  
all users on all systems

**-v** [*list*] Print the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES**

*/var/spool/print/\** LP print queue.

*\$HOME/.printers* User-configurable printer database.

*/etc/printers.conf* System configuration database.

| <b>SYNOPSIS</b>    | <code>/usr/ucb/lptest [length [count] ]</code>                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>The <code>lptest</code> utility writes the traditional <i>ripple test</i> pattern to the standard output. In 96 lines, the ripple test pattern prints all 96 printable ASCII characters in each position. The ripple test pattern was originally created to test printers. It is also useful for testing terminals, driving terminal ports, debugging, and performing tasks that require a quick supply of random data.</p> <p>This command is obsolete.</p> |                |                 |              |           |
| <b>OPTIONS</b>     | <p><i>length</i>                Specifies the length of the output line in characters. 79 characters is the default.</p> <p><i>count</i>                 Specifies the number of output lines. 200 lines is the default. If <i>count</i> is specified, <i>length</i> must also be specified.</p>                                                                                                                                                                |                |                 |              |           |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                        Successful completion.</p> <p>non-zero                An error occurred.</p>                                                                                                                                                                                                                                                                                                         |                |                 |              |           |

| <b>NAME</b>        | ls – list contents of directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/ls [-aAbcCdFgILMnoprRstux1] [file...]</pre> <pre>/usr/xpg4/bin/ls [-aAbcCdFgILMnoprRstux1] [file...]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>For each <i>file</i> that is a directory, <code>ls</code> lists the contents of the directory; for each <i>file</i> that is an ordinary file, <code>ls</code> repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.</p> <p>There are three major listing formats. The default format for output directed to a terminal is multi-column with entries sorted down the columns. The <code>-l</code> option allows single column output and <code>-m</code> enables stream output format. In order to determine output formats for the <code>-C</code>, <code>-x</code>, and <code>-m</code> options, <code>ls</code> uses an environment variable, <code>COLUMNS</code>, to determine the number of character positions available on one output line. If this variable is not set, the <code>terminfo(4)</code> database is used to determine the number of columns, based on the environment variable <code>TERM</code>. If this information cannot be obtained, 80 columns are assumed.</p> <p>The mode printed under the <code>-l</code> option consists of ten characters. The first character may be one of the following:</p> <ul style="list-style-type: none"> <li>d       the entry is a directory;</li> <li>D       the entry is a door;</li> <li>l       the entry is a symbolic link;</li> <li>b       the entry is a block special file;</li> <li>c       the entry is a character special file;</li> <li>p       the entry is a fifo (or “named pipe”) special file;</li> <li>s       the entry is an <code>AF_UNIX</code> address family socket;</li> <li>–       the entry is an ordinary file;</li> </ul> <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner’s permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, “execute” permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is ACL indication. A plus sign is displayed if there is an ACL associated with the file. Nothing is displayed if there are just permissions.</p> <p><code>ls -l</code> (the long list) prints its output as follows for the POSIX locale:</p> |

```
-rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2
```

Reading from right to left, you see that the current directory holds one file, named `part2`. Next, the last time that file's contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group `dev` (perhaps indicating "development"), and his or her login name is `smith`. The number, in this case 1, indicates the number of links to file `part2`; see `cp(1)`. The plus sign indicates that there is an ACL associated with the file. Finally, the dash and letters tell you that user, group, and others have permissions to read, write, and execute `part2`.

The execute (`x`) symbol here occupies the third position of the three-character sequence. A `-` in the third position would have indicated a denial of execution permissions.

The permissions are indicated as follows:

|                                 |                                                                                                                                   |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| r                               | the file is readable                                                                                                              |
| w                               | the file is writable                                                                                                              |
| x                               | the file is executable                                                                                                            |
| -                               | the indicated permission is <i>not</i> granted                                                                                    |
| s                               | the <code>set-user-ID</code> or <code>set-group-ID</code> bit is on, and the corresponding user or group execution bit is also on |
| S                               | undefined bit-state (the <code>set-user-ID</code> bit is on and the user execution bit is off)                                    |
| t                               | the 1000 (octal) bit, or sticky bit, is on (see <code>chmod(1)</code> ), and execution is on                                      |
| T                               | the 1000 bit is turned on, and execution is off (undefined bit-state)                                                             |
| <code>/usr/bin/ls</code> 1      | mandatory locking occurs during access (the <code>set-group-ID</code> bit is on and the group execution bit is off)               |
| <code>/usr/xpg4/bin/ls</code> L | mandatory locking occurs during access (the <code>set-group-ID</code> bit is on and the group execution bit is off)               |

For user and group permissions, the third position is sometimes occupied by a character other than `x` or `-`. `s` also may occupy this position, referring to the state of the `set-ID` bit, whether it be the user's or the group's. The ability to assume the same ID as the user during execution is, for example, used during login when you begin as root but need to assume the identity of the user you login as.

In the case of the sequence of group permissions, `l` may occupy the third position. `l` refers to mandatory file and record locking. This permission

describes a file's ability to allow other files to lock its reading or writing permissions during access.

For others permissions, the third position may be occupied by `t` or `T`. These refer to the state of the sticky bit and execution permissions.

## OPTIONS

The following options are supported:

- a Lists all entries, including those that begin with a dot (`.`), which are normally not listed.
- A Lists all entries, including those that begin with a dot (`.`), with the exception of the working directory (`.`) and the parent directory (`..`).
- b Forces printing of non-printable characters to be in the octal `\ddd` notation.
- c Uses time of last modification of the i-node (file created, mode changed, and so forth) for sorting (`-t`) or printing (`-l` or `-n`).
- C Multi-column output with entries sorted down the columns. This is the default output format.
- d If an argument is a directory, lists only its name (not its contents); often used with `-l` to get the status of a directory.
- f Forces each argument to be interpreted as a directory and list the name found in each slot. This option turns off `-l`, `-t`, `-s`, and `-r`, and turns on `-a`; the order is the order in which entries appear in the directory.
- F Marks directories with a trailing slash (`/`), doors with a trailing greater-than sign (`>`), executable files with a trailing asterisk (`*`), FIFOs with a trailing vertical bar (`|`), symbolic links with a trailing at-sign (`@`), and `AF_UNIX` address family sockets with a trailing equals sign (`=`).
- g The same as `-l`, except that the owner is not printed.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format 'month date year' for the POSIX locale. When the `LC_TIME` locale category is not set to the POSIX locale, a different format of the time field may be used. Files modified within six months show 'month date time'. If the file is a symbolic link, the filename is printed followed by "`→`" and the path name of the referenced file.

- L If an argument is a symbolic link, lists the file or directory the link references rather than the link itself.
- m Streams output format; files are listed across the page, separated by commas.
- n The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
- o The same as -l, except that the group is not printed.
- P Puts a slash (/) after each filename if the file is a directory.
- q Forces printing of non-printable characters in file names as the character question mark (?).
- r Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- R Recursively lists subdirectories encountered.
- s Gives size in blocks, including indirect blocks, for each entry.
- t Sorts by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)
- u Uses time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).
- x Multi-column output with entries sorted across rather than down the page.
- 1 Prints one entry per line of output.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (one), -c and -u. The last option specified in each pair determines the output format.

**/usr/bin/ls**

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell). The -l option overrides the other option specified in each pair.

**/usr/xpg4/bin/ls**

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell). The last option specified in each pair determines the output format.

**OPERANDS**

The following operand is supported:

*file* A path name of a file to be written. If the file specified is not found, a diagnostic message will be output on standard error.

**USAGE**

See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES****EXAMPLE 1** File permissions

An example of a file's permissions is:

```
-rwxr--r--
```

This describes a file that is readable, writable, and executable by the user and readable by the group and others.

Another example of a file's permissions is:

```
-rwsr-xr-x
```

This describes a file that is readable, writable, and executable by the user, readable and executable by the group and others, and allows its user-ID to be assumed, during execution, by the user presently executing it.

Another example of a file's permissions is:

```
-rw-rwl---
```

This describes a file that is readable and writable only by the user and the group and can be locked during access.

**EXAMPLE 2** Printing the names of all files

This command prints the names of all files in the current directory, including those that begin with a dot (.), which normally do not print:

```
example% ls -a
```

**EXAMPLE 3** Providing file information

Another example of a command line is:

```
example% ls -aisn
```

This command provides information on all files, including those that begin with a dot (a), the *i*-number—the memory address of the *i*-node associated with the file—printed in the left-hand column (*i*); the *size* (in blocks) of the files, printed in the column to the right of the *i*-numbers (*s*); finally, the report is displayed in the numeric version of the long list, printing the *UID* (instead of user name) and *gid* (instead of group name) numbers associated with the files.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ls`: `LC_COLLATE`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TZ`.

**COLUMNS** Determine the user's preferred column position width for writing multiple text-column output. If this variable

contains a string representing a decimal integer, the `ls` utility calculates how many path name text columns to write (see `-C`) based on the width provided. If `COLUMNS` is not set or is invalid, 80 is used. The column width chosen to write the names of files in any given directory will be constant. File names will not be truncated to fit into the multiple text-column output.

**EXIT STATUS**

0 All information was written successfully.

>0 An error occurred.

**FILES**

`/etc/group` group IDs for `ls -l` and `ls -g`

`/etc/passwd` user IDs for `ls -l` and `ls -o`

`/usr/share/lib/terminfo/?/*` terminal information database

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/ls`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

`/usr/xpg4/bin/ls`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |
| CSI            | Enabled         |

**SEE ALSO**

`chmod(1)`, `cp(1)`, `setfacl(1)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

**NOTES**

Unprintable characters in file names may confuse the columnar output options.

The total block count will be incorrect if there are hard links among the files.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>              | ls – list the contents of a directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>          | <code>/usr/ucb/ls [-aAcCdFFgillLqrRstu1] filename...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>       | For each <i>filename</i> which is a directory, <code>ls</code> lists the contents of the directory; for each <i>filename</i> which is a file, <code>ls</code> repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Permissions Field</b> | <p>The mode printed under the <code>-l</code> option contains 10 characters interpreted as follows. If the first character is:</p> <ul style="list-style-type: none"> <li>d entry is a directory;</li> <li>b entry is a block-type special file;</li> <li>c entry is a character-type special file;</li> <li>l entry is a symbolic link;</li> <li>p entry is a FIFO (also known as “named pipe”) special file;</li> <li>s entry is an <code>AF_UNIX</code> address family socket, or</li> <li>– entry is a plain file.</li> </ul> <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to owner permissions; the next refers to permissions to others in the same user-group; and the last refers to all others. Within each set the three characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, “execute” permission is interpreted to mean permission to search the directory. The permissions are indicated as follows:</p> <ul style="list-style-type: none"> <li>r the file is readable;</li> <li>w the file is writable;</li> <li>x the file is executable;</li> <li>– the indicated permission is not granted.</li> </ul> <p>The group-execute permission character is given as <code>s</code> if the file has the set-group-id bit set; likewise the owner-execute permission character is given as <code>s</code> if the file has the set-user-id bit set.</p> <p>The last character of the mode (normally <code>x</code> or <code>'-</code>) is <code>true</code> if the 1000 bit of the mode is on. See <code>chmod(1)</code> for the meaning of this mode. The indications of set-ID and 1000 bits of the mode are capitalized (<code>S</code> and <code>T</code> respectively) if the corresponding execute permission is <i>not</i> set.</p> |

**OPTIONS**

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks is printed.

- a List all entries; in the absence of this option, entries whose names begin with a '.' are *not* listed (except for the privileged user, for whom `ls` normally prints even files that begin with a '.').
- A Same as `-a`, except that '.' and '..' are not listed.
- c Use time of last edit (or last mode change) for sorting or printing.
- C Force multi-column output, with entries sorted down the columns; for `ls`, this is the default when output is to a terminal.
- d If argument is a directory, list only its name (not its contents); often used with `-l` to get the status of a directory.
- f Force each argument to be interpreted as a directory and list the name found in each slot. This option turns off `-l`, `-t`, `-s`, and `-r`, and turns on `-a`; the order is the order in which entries appear in the directory.
- F Mark directories with a trailing slash ('/'), executable files with a trailing asterisk (\*), symbolic links with a trailing at-sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=).
- g For `ls`, show the group ownership of the file in a long output.
- i For each file, print the i-node number in the first column of the report.
- l List in long format, giving mode, number of links, owner, size in bytes, and time of last modification for each file. If the file is a special file the size field will instead contain the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format '*month date year*'; files modified within six months show '*month date time*'. If the file is a symbolic link the pathname of the linked-to file is printed preceded by '->'.  
If argument is a symbolic link, list the file or directory the link references rather than the link itself.

- q            Display non-graphic characters in filenames as the character ?; for `ls`, this is the default when output is to a terminal.
- r            Reverse the order of sort to get reverse alphabetic or oldest first as appropriate.
- R            Recursively list subdirectories encountered.
- s            Give size of each file, including any indirect blocks used to map the file, in kilobytes.
- t            Sort by time modified (latest first) instead of by name.
- u            Use time of last access instead of last modification for sorting (with the `-t` option) and/or printing (with the `-l` option).
- l            Force one entry per line output format; this is the default when output is not to a terminal.

**USAGE**

See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**FILES**

`/etc/group`                    to get group ID for '`ls -g`'  
`/etc/passwd`                   to get user ID's for '`ls -l`' and '`ls -o`'

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO**

`ls(1)`, `attributes(5)`, `largefile(5)`

**NOTES**

NEWLINE and TAB are considered printing characters in filenames.

The output device is assumed to be 80 columns wide.

The option setting based on whether the output is a teletype is undesirable as '`ls -s`' is much different than '`ls -s | lpr`'. On the other hand, not doing this setting would make old shell scripts which used `ls` almost certain losers.

Unprintable characters in file names may confuse the columnar output options.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>DESCRIPTION</b>      | <p>The m4 utility is a macro processor intended as a front end for C, assembler, and other languages. Each of the argument files is processed in order; if there are no files, or if a file is -, the standard input is read. The processed text is written on the standard output.</p>                                                                                                                                                                                                                                                                                                                                            |
| <b>Macro Syntax</b>     | <p>Macro calls have the form:</p> <pre>name( arg1, arg2, ..., argn )</pre> <p>The ( must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphanumeric characters and underscore (_), where the first character is not a digit.</p> <p>Leading unquoted blanks, TABs, and NEWLINEs are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes.</p>                              |
| <b>Macro Processing</b> | <p>When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be NULL. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses that happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned.</p>                                                              |
| <b>OPTIONS</b>          | <p>The options and their effects are as follows:</p> <ul style="list-style-type: none"> <li>-e Operate interactively. Interrupts are ignored and the output is unbuffered.</li> <li>-s Enable line sync output for the C preprocessor (#line ...)</li> <li>-Bint Change the size of the push-back and argument collection buffers from the default of 4,096.</li> <li>-Hint Change the size of the symbol table hash array from the default of 199. The size should be prime.</li> <li>-Sint Change the size of the call stack from the default of 100slots. Macros take three slots, and non-macro arguments take one.</li> </ul> |

`-Tint` Change the size of the token buffer from the default of 512bytes.

To be effective, the above flags must appear before any file names and before any `-D` or `-U` flags:

`-D name[=val]` Defines `name` to `val` or to `NULL` in `val`'s absence.

`-Uname` Undefines `name`.

## OPERANDS

The following operand is supported:

`file` A path name of a text file to be processed. If no `file` is given, or if it is `-`, the standard input is read.

## USAGE

The `m4` utility makes available the following built-in macros. These macros may be redefined, but once this is done the original meaning is lost. Their values are `NULL` unless otherwise stated.

`changequote` Change quote symbols to the first and second arguments. The symbols may be up to five characters long. `changequote` without arguments restores the original values (that is, `' '`).

`changecom` Change left and right comment markers from the default `#` and `NEWLINE`. With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes `NEWLINE`. With two arguments, both markers are affected. Comment markers may be up to five characters long.

`decr` Returns the value of its argument decremented by 1.

`define` The second argument is installed as the value of the macro whose name is the first argument. Each occurrence of `$n` in the replacement text, where `n` is a digit, is replaced by the `n`-th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; `$#` is replaced by the number of arguments; `$*` is replaced by a list of all the arguments separated by commas; `$@` is like `$*`, but each argument is quoted (with the current quotes).

`defn` Returns the quoted definition of its argument(s). It is useful for renaming macros, especially built-ins.

|                               |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | <code>divert</code>   | m4 maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The <code>divert</code> macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.                                                                                                                                                                                                                                                                                                                                                                                                               |
|                               | <code>divnum</code>   | Returns the value of the current output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                               | <code>dnl</code>      | Reads and discards characters up to and including the next NEWLINE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                               | <code>dumpdef</code>  | Prints current names and definitions, for the named items, or for all if no arguments are given.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                               | <code>errprint</code> | Prints its argument on the diagnostic output file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>/usr/ccs/bin/m4</code>  | <code>eval</code>     | Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , relationals, bitwise <code>&amp;</code> , <code> </code> , <code>&amp;&amp;</code> , and <code>  </code> . Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.                                                                                                |
| <code>/usr/xpg4/bin/m4</code> | <code>eval</code>     | Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , <code>&lt;&lt;</code> , <code>&gt;&gt;</code> , relationals, bitwise <code>&amp;</code> , <code> </code> , <code>&amp;&amp;</code> , and <code>  </code> . Precedence and associativity are as in C. Octal and hex numbers may also be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result. |
|                               | <code>ifdef</code>    | If the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is <code>NULL</code> . The word <code>unix</code> is predefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                               | <code>ifelse</code>   | This macro has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is either the fourth string, or, if it is not present, <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                  |
|                               | <code>include</code>  | Returns the contents of the file named in the argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                       |                                                                                                                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>incr</code>     | Returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.                                                                                                                       |
| <code>index</code>    | Returns the position in its first argument where the second argument begins (zero origin), or -1 if the second argument does not occur.                                                                                                                                        |
| <code>len</code>      | Returns the number of characters in its argument.                                                                                                                                                                                                                              |
| <code>m4exit</code>   | This macro causes immediate exit from m4. Argument 1, if given, is the exit code; the default is 0.                                                                                                                                                                            |
| <code>m4wrap</code>   | Argument 1 will be pushed back at final EOF; example:<br><code>m4wrap('cleanup( )')</code>                                                                                                                                                                                     |
| <code>maketemp</code> | Fills in a string of "x" characters in its argument with the current process ID.                                                                                                                                                                                               |
| <code>popdef</code>   | Removes current definition of its argument(s), exposing the previous one, if any.                                                                                                                                                                                              |
| <code>pushdef</code>  | Like <code>define</code> , but saves any previous definition.                                                                                                                                                                                                                  |
| <code>shift</code>    | Returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.                                                                             |
| <code>sinclude</code> | This macro is identical to <code>include</code> , except that it says nothing if the file is inaccessible.                                                                                                                                                                     |
| <code>substr</code>   | Returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string. |
| <code>syscmd</code>   | This macro executes the command given in the first argument. No value is returned.                                                                                                                                                                                             |
| <code>sysval</code>   | This macro is the return code from the last call to <code>syscmd</code> .                                                                                                                                                                                                      |
| <code>translit</code> | Transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.                                                                                                                   |
| <code>traceon</code>  | This macro with no arguments, turns on tracing for all macros (including built-ins). Otherwise, turns on tracing for named macros.                                                                                                                                             |

`traceoff` Turns off trace globally and for any macros specified. Macros specifically traced by `traceon` can be untraced only by specific calls to `traceoff`.

`undefine` Removes the definition of the macro named in its argument.

`undivert` This macro causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.

**EXAMPLES****EXAMPLE 1** Examples of m4 files.

An example of a single m4 input file capable of generating two output files follows. The file `file1.m4` could contain lines such as:

```
if(VER, 1, do_something)
if(VER, 2, do_something)
```

The makefile for the program might include:

```
file1.1.c : file1.m4
 m4 -D VER=1 file1.m4 > file1.1.c
 ...
file1.2.c : file1.m4
 m4 -D VER=2 file1.m4 > file1.2.c
 ...
```

The `-U` option can be used to undefine `VER`. If `file1.m4` contains:

```
if(VER, 1, do_something)
if(VER, 2, do_something)
ifndef(VER, do_something)
```

then the makefile would contain:

```
file1.0.c : file1.m4
 m4 -U VER file1.m4 > file1.0.c
 ...
file1.1.c : file1.m4
 m4 -D VER=1 file1.m4 > file1.1.c
 ...
file1.2.c : file1.m4
 m4 -D VER=2 file1.m4 > file1.2.c
 ...
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of m4: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

>0 An error occurred

If the `m4exit` macro is used, the exit value can be specified by the input file.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

#### `/usr/ccs/bin/m4`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

#### `/usr/xpg4/bin/m4`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

### SEE ALSO

`as(1)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

**NAME** mach – display the processor type of the current host

**SYNOPSIS** mach

**DESCRIPTION** The mach command displays the processor-type of the current host.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** arch(1), uname(1), attributes(5)

**NOTES** mach and uname -p return equivalent values; therefore, Independent Software Vendors (ISV) and others who need to ascertain processor type are encouraged to use uname with the -p option instead of the mach command. The mach command is provided for compatibility with previous releases, but generally its use is discouraged.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**NAME** mailcompat – provide SunOS compatibility for Solaris mailbox format

**DESCRIPTION** mailcompat is a program to provide SunOS 4.x compatibility for the Solaris mailbox format. You would typically run mailcompat to be able to read mail on a workstation running SunOS 4.x when your mail server is running Solaris.

Enabling mailcompat creates an entry in your .forward file, if it exists. If this file does not exist, mailcompat will create it. Disabling mailcompat will remove the entry from the .forward file, and if this was the only entry, will remove the entire file.

To execute mailcompat, log onto the Solaris mail server and enter mailcompat on the command line. Answer the queries provided by the program.

**USAGE** See largefile(5) for the description of the behavior of mailcompat when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**EXAMPLES** **EXAMPLE 1** Examples of the mailcompat feature.

The following example enables the mailcompat feature for the user "john".

```
example% mailcompat
This program can be used to store your mail in a format
that you can read with SunOS 4.X based mail readers
To enable the mailcompat feature a ".forward" file is created.
Would you like to enable the mailcompat feature? Y
Mailcompat feature ENABLED.Run mailcompat with no arguments to remove it
example%
```

The following example disables the mailcompat feature for the user "john".

```
example% mailcompat
This program can be used to store your mail in a format
that you can read with SunOS 4.X based mail readers
You have a .forward file in your home directory containing:
"|usr/bin/mailcompat johns"
Would you like to remove it and disable the mailcompat feature? y
Back to normal reception of mail.
example%
```

**FILES** ~/.forward list of recipients for forwarding messages

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | mailp, digestp, filep, newsp, filofaxp, franklinp, timemanp, timesysp – frontends to the mp PostScript pretty printer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <p><b>mailp</b> [<i>options</i>] <i>filename...</i></p> <p><b>newsp</b> [<i>options</i>] <i>filename...</i></p> <p><b>digestp</b> [<i>options</i>] <i>filename...</i></p> <p><b>filep</b> [<i>options</i>] <i>filename...</i></p> <p><b>filofaxp</b> [<i>options</i>] <i>filename...</i></p> <p><b>franklinp</b> [<i>options</i>] <i>filename...</i></p> <p><b>timemanp</b> [<i>options</i>] <i>filename...</i></p> <p><b>timesysp</b> [<i>options</i>] <i>filename...</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The mailp utility is a frontend to the mp(1) Postscript pretty printer program. It uses different names to provide various mp options:</p> <p>mailp            Prints out mail messages.</p> <p>newsp            Prints out USENET news articles.</p> <p>digestp          Prints out USENET digest files.</p> <p>filep            Prints out ordinary ASCII files.</p> <p>filofaxp         Prints out in Filofax personal organiser format.</p> <p>franklinp        Prints out in Franklin Planner personal organiser format.</p> <p>timemanp         Prints out in Time Manager personal organiser format.</p> <p>timesysp         Prints out in Time/System International personal organiser format.</p> <p>mailp and the associated programs read each <i>filename</i> in sequence and generate a prettified version of the contents in PostScript format. If no filename arguments are provided, mailp reads the standard input.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-d                Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable, <i>printer</i></p> <p>-F                Instead of printing who the mail article is for, the top header will contain who the mail article is from. This is a useful option for people with their own personal printer.</p> <p>-h                Banner printing is disabled. Most of the information that typically appears on the banner sheet is output in the mp banners.</p>                                                                                                                                                                                                                                                                                                                                                                      |

- l            Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
- P  
*printer*    Sends output to the named printer. Otherwise, sends output to the printer named in the `PRINTER` environment variable.
- s  
*subject*    Uses *subject* as the new subject for the printout. If you are printing ordinary ASCII files which have been specified on the command line, the subject will default to the name of each of these files.

**OPERANDS**

The following operand is supported:  
*filename*        The name of the file to be read.

**ENVIRONMENT VARIABLES**

`mailp` uses the `PRINTER` environment variable to determine the printer to which the output from the `mp(1)` program is sent. If this environment variable is not found, then it defaults to the `ps` printer.

**EXIT STATUS**

The following exit values are returned:

- 0            Successful completion.
- 1            An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <code>/usr/bin/mailq [-q <i>Xstring</i>] [-v]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>mailq displays a summary of the mail messages queued for future delivery.</p> <p>The first line displayed for each mail message shows the internal identifier used on this host for the message, the size of the message in bytes, the date and time the message was accepted into the queue, and the envelope sender of the message. The second line of the display shows the error message that caused this message to be retained in the queue. This line will not be displayed if the message is being processed for the first time.</p> <p>The mailq utility is identical to <code>sendmail -bp</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |           |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-q <i>Xstring</i></code>      Run the queue once, limiting the jobs to those matching <i>Xstring</i>. The <i>Xstring</i> argument consists of a key letter (<i>X</i>) followed by <i>string</i>. The key letter <i>X</i> can be an <code>I</code>, <code>R</code> or <code>S</code>. Use <code>I</code> to limit based on queue identifier. Use <code>R</code> to limit based on recipient. Use <code>S</code> to limit based on sender. A particular queued job is accepted if one of the corresponding addresses contains the specified <i>string</i>.</p> <p><code>-v</code>                      Print verbose information. This adds the priority of the message and a single character indicator (+ or blank) indicating whether a warning message has been sent on the first line of the message. Additionally, extra lines may be intermixed with the recipients indicating the "controlling user" information; this shows who will own any programs that are executed on behalf of this message and the name of the alias this command is expanded from, if any.</p> |                |                 |              |           |
| <b>EXIT STATUS</b> | <p>0                      Successful completion.</p> <p>&gt;0                     An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |           |

| <b>SYNOPSIS</b>                       | <b>mailstats</b> [-o] [-c <i>configfile</i> ] [-f <i>statisticsfile</i> ] <i>file</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                   |                                                       |                                       |                                                    |                 |                                                     |        |                                   |          |                       |         |                                            |          |                                             |        |                         |
| <b>DESCRIPTION</b>                    | <p>The <code>mailstats</code> utility prints out the statistics collected by the <code>sendmail(1M)</code> program on mailer usage. These statistics are collected if the file indicated by the <code>S</code> configuration option of <code>sendmail</code> (defined in <code>/etc/mail/sendmail.cf</code>) exists. The default statistics file is <code>/etc/mail/sendmail.st</code>.</p> <p><code>mailstats</code> first prints the time that the statistics file was created and the last time it was modified. Then, the statistics for each mailer are displayed on a single line, each with the following whitespace-separated fields:</p> <table border="0"> <tr> <td style="padding-right: 2em;">M</td> <td>The mailer number.</td> </tr> <tr> <td>msgsfr</td> <td>Number of messages from the mailer.</td> </tr> <tr> <td>bytes_from</td> <td>Kbytes from the mailer.</td> </tr> <tr> <td>msgsto</td> <td>Number of messages to the mailer.</td> </tr> <tr> <td>bytes_to</td> <td>Kbytes to the mailer.</td> </tr> <tr> <td>msgsrej</td> <td>Number of messages rejected by the mailer.</td> </tr> <tr> <td>msgsdisc</td> <td>Number of messages discarded by the mailer.</td> </tr> <tr> <td>Mailer</td> <td>The name of the mailer.</td> </tr> </table> <p>After this display, a line totaling the values for all of the mailers is displayed, separated from the previous information by a line containing only equal sign (=) characters.</p> <p>You might want to add an entry to <code>/var/spool/cron/crontabs/root</code> to reinitialize the statistics file once a night. Copy <code>/dev/null</code> into the statistics file or otherwise truncate it to reset the counters.</p> | M                                 | The mailer number.                                    | msgsfr                                | Number of messages from the mailer.                | bytes_from      | Kbytes from the mailer.                             | msgsto | Number of messages to the mailer. | bytes_to | Kbytes to the mailer. | msgsrej | Number of messages rejected by the mailer. | msgsdisc | Number of messages discarded by the mailer. | Mailer | The name of the mailer. |

| <b>NAME</b>        | mailx, mail – interactive message processing system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <p><b>mailx</b> [-BdeHiInNURvV~] [-f <i>file</i>   <i>+folder</i> ] [-T <i>file</i>] [-u <i>user</i>]</p> <p><b>mailx</b> [-BdFintUv~] [-b <i>bcc</i>] [-c <i>cc</i>] [-h <i>number</i>] [-r <i>address</i>] [-s <i>subject</i>]<br/> <i>recipient...</i></p> <p><b>/usr/ucb/mail</b> ...</p> <p><b>/usr/ucb/Mail</b> ...</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The mail utilities listed above provide a comfortable, flexible environment for sending and receiving mail messages electronically.</p> <p>When reading mail, the mail utilities provide commands to facilitate saving, deleting, and responding to messages. When sending mail, the mail utilities allow editing, reviewing and other modification of the message as it is entered.</p> <p>Incoming mail is stored in a standard file for each user, called the <code>mailbox</code> for that user. When the mail utilities are called to read messages, the <code>mailbox</code> is the default place to find them. As messages are read, they are marked to be moved to a secondary file for storage, unless specific action is taken, so that the messages need not be seen again. This secondary file is called the <code>mbox</code> and is normally located in the user's HOME directory (see <code>MBOX</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file). Messages can be saved in other secondary files named by the user. Messages remain in a secondary file until forcibly removed.</p> <p>The user can access a secondary file by using the <code>-f</code> option. Messages in the secondary file can then be read or otherwise processed using the same Commands as in the primary <code>mailbox</code>. This gives rise within these pages to the notion of a current <code>mailbox</code>.</p> |
| <b>OPTIONS</b>     | <p>On the command line options start with a dash (-). Any other arguments are taken to be destinations (recipients). If no recipients are specified, <code>mailx</code> attempts to read messages from the <code>mailbox</code>.</p> <p><code>-B</code> Do not buffer standard input or standard output.</p> <p><code>-b</code> Set the blind carbon copy list to <code>bcc</code>. <code>bcc</code> should be enclosed in quotes if it contains more than one name.</p> <p><code>-c</code> Set the carbon copy list to <code>cc</code>. <code>cc</code> should be enclosed in quotes if it contains more than one name.</p> <p><code>-d</code> Turn on debugging output. (Neither particularly interesting nor recommended.)</p> <p><code>-e</code> Test for the presence of mail. <code>mailx</code> prints nothing and exits with a successful return code if there is mail to read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                 |                                                                                                                                                                                    |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -F                              | Record the message in a file named after the first recipient. Overrides the <code>record</code> variable, if set (see <code>Internal Variables</code> ).                           |
| -f<br>[<br><i>file</i><br>]     | Read messages from <i>file</i> instead of <code>mailbox</code> . If no <i>file</i> is specified, the <code>mbox</code> is used.                                                    |
| -f<br>[ +<br><i>folder</i><br>] | Use the file <i>folder</i> in the folder directory (same as the <code>fold</code> er command). The name of this directory is listed in the <code>folder</code> variable.           |
| -H                              | Print header summary only.                                                                                                                                                         |
| -h<br><i>number</i>             | The number of network "hops" made so far. This is provided for network software to avoid infinite delivery loops. This option and its argument are passed to the delivery program. |
| -I                              | Include the newsgroup and article-id header lines when printing mail messages. This option requires the <code>-f</code> option to be specified.                                    |
| -i                              | Ignore interrupts. See also <code>ignore</code> in <code>Internal Variables</code> .                                                                                               |
| -N                              | Do not print initial header summary.                                                                                                                                               |
| -n                              | Do not initialize from the system default <code>mailx.rc</code> or <code>Mail.rc</code> file. See <code>USAGE</code> .                                                             |
| -r<br><i>address</i>            | Use <i>address</i> as the return address when invoking the delivery program. All tilde commands are disabled. This option and its argument is passed to the delivery program.      |
| -s<br><i>subject</i>            | Set the Subject header field to <i>subject</i> . <i>subject</i> should be enclosed in quotes if it contains embedded white space.                                                  |
| -T<br><i>file</i>               | Message-id and article-id header lines are recorded in <i>file</i> after the message is read. This option also sets the <code>-I</code> option.                                    |
| -t                              | Scan the input for <code>To:</code> , <code>Cc:</code> , and <code>Bcc:</code> fields. Any recipients on the command line will be ignored.                                         |
| -U                              | Convert UUCP-style addresses to internet standards. Overrides the <code>conv</code> environment variable.                                                                          |
| -u<br><i>user</i>               | Read <i>user</i> 's <code>mailbox</code> . This is only effective if <i>user</i> 's <code>mailbox</code> is not read protected.                                                    |

-V            Print the mailx version number and exit.  
 -v            Pass the -v flag to sendmail(1M) .  
 --            Interpret tilde escapes in the input even if not reading  
               from a tty.

**OPERANDS**

The following operands are supported:  
*recipient*        Addressee of message.

**USAGE****Starting Mail**

At startup time, mailx executes the system startup file `/etc/mail/mailx.rc` . If invoked as `mail` or `Mail` , the system startup file `/etc/mail/Mail.rc` is used instead.

The system startup file sets up initial display options and alias lists and assigns values to some internal variables. These variables are flags and valued parameters which are set and cleared using the `set` and `unset` commands. See `Internal Variables` .

With the following exceptions, regular commands are legal inside startup files: `!` , `C`opy, `e`dit, `f`ollowup, `F`ollowup, `h`old, `m`ail, `p`re serve, `r`epl, `R`epl, `sh`ell, and `v`isual. An error in the startup file causes the remaining lines in the file to be ignored.

After executing the system startup file, the mail utilities execute the optional personal startup file `$HOME/.mailrc` , wherein the user can override the values of the internal variables as set by the system startup file.

If the `-n` option is specified, however, the mail utilities do not execute the system startup file.

Many system administrators include the commands

```
set appenddeadletter
unset replyall
unset pipeignore
```

in the system startup files (to be compatible with past Solaris behavior), but this does not meet standards requirements for mailx . To get standard behavior for mailx , users should use the `-n` option or include the following commands in a personal startup file:

```
unset appenddeadletter
set replyall
set pipeignore
```

When reading mail, the mail utilities are in *command mode*. A header summary of the first several messages is displayed, followed by a prompt indicating the mail utilities can accept regular commands (see `Commands` below). When sending mail, the mail utilities are in *input mode*. If no subject is specified on the command line, and the `asksub` variable is set, a prompt for the subject is printed.

As the message is typed, the mail utilities read the message and store it in a temporary file. Commands may be entered by beginning a line with the tilde (~) escape character followed by a single command letter and optional arguments. See `Tilde Escapes` for a summary of these commands.

### Reading Mail

Each message is assigned a sequential number, and there is at any time the notion of a current message, marked by a right angle bracket (>) in the header summary. Many commands take an optional list of messages (*message-list*) to operate on. In most cases, the current message is set to the highest-numbered message in the list after the command is finished executing.

The default for *message-list* is the current message. A *message-list* is a list of message identifiers separated by spaces, which may include:

|                           |                                                                     |
|---------------------------|---------------------------------------------------------------------|
| <i>n</i>                  | Message number <i>n</i> .                                           |
| .                         | The current message.                                                |
| ^                         | The first undeleted message.                                        |
| \$                        | The last message.                                                   |
| *                         | All messages.                                                       |
| +                         | The next undeleted message.                                         |
| -                         | The previous undeleted message.                                     |
| <i>n</i><br>-<br><i>m</i> | An inclusive range of message numbers.                              |
| <i>user</i>               | All messages from <i>user</i> .                                     |
| <i>/string</i>            | All messages with <i>string</i> in the Subject line (case ignored). |
| :                         | All messages of type <i>c</i> , where <i>c</i> is one of:           |
| <i>c</i>                  |                                                                     |
| d                         | deleted messages                                                    |
| n                         | new messages                                                        |
| o                         | old messages                                                        |
| r                         | read messages                                                       |

u unread messages

Note that the context of the command determines whether this type of message specification makes sense.

Other arguments are usually arbitrary strings whose usage depends on the command involved. Filenames, where expected, are expanded using the normal shell conventions (see `sh(1)`). Special characters are recognized by certain commands and are documented with the commands below.

#### **Sending Mail**

Recipients listed on the command line may be of three types: login names, shell commands, or alias groups. Login names may be any network address, including mixed network addressing. If mail is found to be undeliverable, an attempt is made to return it to the sender's `mailbox`. If the recipient name begins with a pipe symbol ( `|` ), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as `lp(1)` for recording outgoing mail on paper. Alias groups are set by the `alias` command (see Commands below) or in a system startup file (for example, `$HOME/.mailrc`). Aliases are lists of recipients of any type.

#### **Forwarding Mail**

To forward a specific message, include it in a message to the desired recipients with the `~f` or `~m` tilde escapes. See `Tilde Escapes` below. To forward mail automatically, add a comma-separated list of addresses for additional recipients to the `.forward` file in your home directory. This is different from the format of the `alias` command, which takes a space-separated list instead. Note: forwarding addresses must be valid, or the messages will "bounce." You cannot, for instance, reroute your mail to a new host by forwarding it to your new address if it is not yet listed in the NIS aliases domain.

#### **Commands**

Regular commands are of the form

```
[command] [message-list] [arguments]
```

In *input mode*, commands are recognized by the escape character, `tilde(~)`, and lines not treated as commands are taken as input for the message. If no command is specified in *command mode*, `next` is assumed. The following is a complete list of `mailx` commands:

! *shell-command*

Escape to the shell. See `SHELL` in `ENVIRONMENT VARIABLES`.

# *comment*

NULL command (comment). Useful in `mailrc` files.

=

Print the current message number.

?  
Prints a summary of commands.

a *lias alias name ...*

g *roup alias name ...*  
Declare an alias for the given names. The names are substituted when *alias* is used as a recipient. Useful in the *mailrc* file. With no arguments, the command displays the list of defined aliases.

alt *ernates name ...*  
Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alternate names. See also *allnet* in Internal Variables .

cd [*directory* ]

ch *dir [directory ]*  
Change directory. If *directory* is not specified, *\$HOME* is used.

c *opy [file ]*

c *opy [message-list ] file*  
Copy messages to the file without marking the messages as saved. Otherwise equivalent to the *s ave* command.

C *opy [message-list ]*  
Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise equivalent to the *S ave* command.

d *elele [message-list ]*  
Delete messages from the mailbox . If *autoprint* is set, the next message after the last one deleted is printed (see Internal Variables ).

di *scard [header-field ...]*

ig *nore [header-field ...]*  
Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are *Status* and *Received* . The fields are included when the message is saved, unless the *alwaysignore* variable is set. The *Mo re*, *Pa ge*, *P rint*, and *T ype* commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the *undi scard* and *unig nore* commands.

d*p* [*message-list* ]

d*t* [*message-list* ]

Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a `d` elete command followed by a `p` rint command.

`echo string ...`

Echo the given strings (like `echo(1)`).

`edit [message-list]`

Edit the given messages. Each message is placed in a temporary file and the program named by the `EDITOR` variable is invoked to edit it (see `ENVIRONMENT VARIABLES`). Default editor is `ed(1)`.

`exit`

`xit`

Exit from `mailx`, without changing the mailbox. No messages are saved in the `mbox` (see also `quit`).

`field [message-list] header-file`

Display the value of the header field in the specified message.

`file [file]`

`folder [file]`

Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names:

`%` the current mailbox.

`%` the mailbox for `user`.

`user`

`#` the previous mail file.

`&` the current `mbox`.

`+` The named file in the `folder` directory (listed in the `folder` variable).

`file`

With no arguments, print the name of the current mail file, and the number of messages and characters it contains.

`folders`

Print the names of the files in the directory set by the `folder` variable (see `Internal Variables`).

`Followup [message]`

Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. If the `replyall` variable is set, the actions of `Followup` and `followup` are reversed. See also the `followup`, `save`, and `copy` commands and

outfolder in Internal Variables , and the Starting Mail section in USAGE above.

**f**ollowup [*message-list* ]

Respond to the first message in the *message-list* , sending the message to the author of each message in the *message-list* . The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. If the `replyall` variable is set, the actions of `f`ollowup and `F`ollowup are reversed. See also the `F`ollowup, `S`ave, and `C`opy commands and outfolder in Internal Variables , and the Starting Mail section in USAGE above.

**f**rom [*message-list* ]

Print the header summary for the specified messages. If no messages are specified, print the header summary for the current message.

**g**roup *alias name ...*

**a**lias *alias name ...*

Declare an alias for the given names. The names are substituted when `alias` is used as a recipient. Useful in the `mailrc` file.

**h**eaders [*message* ]

Print the page of headers which includes the message specified. The `screen` variable sets the number of headers per page (see Internal Variables ). See also the `z` command.

**h**elp

Print a summary of commands.

**h**old [*message-list* ]

**p**reserve [*message-list* ]

Hold the specified messages in the mailbox .

**i**f *s* | *r* | *t*

*mail-commands*

**e**l **s**e

*mail-commands*

**e**n **d**if

Conditional execution, where *s* executes following *mail-commands* , up to an `e`l `s`e or `e`n `d`if, if the program is in *send* mode, *r* causes the *mail-commands* to be executed only in *receive* mode, and *t* causes the *mail-commands* to be executed only if `mailx` is being run from a terminal. Useful in the `mailrc` file.

**i**nc

Incorporate messages that arrive while you are reading the system mailbox. The new messages are added to the message list in the current mail session.

This command does not commit changes made during the session, and prior messages are not renumbered.

`ignore [header-field ...]`

`discard [header-field ...]`

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are `Status` and `Cc`. All fields are included when the message is saved. The `More`, `Page`, `Print` and `Type` commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

`list`

Print all commands available. No explanation is given.

`load`

`[message] file` The specified message is replaced by the message in the named file. `file` should contain a single mail message including mail headers (as saved by the `save` command).

`mail recipient ...`

Mail a message to the specified recipients.

`Mail recipient`

Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. See also the `Save` and `Copy` commands and `outfolder` in `Internal Variables`.

`mb ox [message-list]`

Arrange for the given messages to end up in the standard `mbox save` file when `mailx` terminates normally. See `MBOX` in `ENVIRONMENT VARIABLES` for a description of this file. See also the `exit` and `quit` commands.

`more [message-list]`

`page [message-list]`

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `print` and `type` commands.

`More [message-list]`

`Page [message-list]`

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `Print` and `Type` commands.

```

ne w [message-list]
N ew [message-list]
unr ead [message-list]
U nread
 [message-list] Take a message list and mark each message as not having
 been read.
n ext [message]
 Go to the next message matching message . If message is not supplied,
 this command finds the next message that was not deleted or saved. A
 message-list may be specified, but in this case the first valid message in the
 list is the only one used. This is useful for jumping to the next message from
 a specific user, since the name would be taken as a command in the absence
 of a real command. See the discussion of message-list above for a description
 of possible message specifications.
pi pe [message-list] [shell-command]
| [message-list] [shell-command]
 Pipe the message through the given shell-command . The message is treated
 as if it were read. If no arguments are given, the current message is piped
 through the command specified by the value of the cmd variable. If the
 page variable is set, a form feed character is inserted after each message
 (see Internal Variables).
pre serve [message-list]
ho ld [message-list]
 Preserve the specified messages in the mailbox .
p rint [message-list]
t ype [message-list]
 Print the specified messages. If crt is set, the messages longer than the
 number of lines specified by the crt variable are paged through the
 command specified by the PAGER variable. The default command is pg(1) or
 if the bsdcompat variable is set, the default is more(1) . See ENVIRONMENT
 VARIABLES . Same as the mo re and pa ge commands.
P rint [message-list]
T ype [message-list]
 Print the specified messages on the screen, including all header fields.
 Overrides suppression of fields by the ig nore command. Same as the Mo
re and Pa ge commands.
pu t [file]
pu t [message-list] file
 Save the specified message in the given file. Use the same conventions as
 the p rint command for which header fields are ignored.

```

`Pu t [file ]`

`Pu t [message-list ] file`

Save the specified message in the given file. Overrides suppression of fields by the `ig nore` command.

`q uit`

Exit from `mailx`, storing messages that were read in `mbox` and unread messages in the `mailbox`. Messages that have been explicitly saved in a file are deleted unless the `keepsave` variable is set.

`r eply [message-list ]`

`r espond [message-list ]`

`replys ender [message-list ]`

Send a response to the author of each message in the `message-list`. The subject line is taken from the first message. If `record` is set to a file, a copy of the reply is added to that file. If the `replyall` variable is set, the actions of `R eply/R espond` and `r eply/r espond` are reversed. The `replys ender` command is not affected by the `replyall` variable, but sends each reply only to the sender of each message. See the `Starting Mail` section in `USAGE` above.

`R eply [message ]`

`R espond [message ]`

`replya ll [message ]`

Reply to the specified message, including all other recipients of that message. If the variable `record` is set to a file, a copy of the reply added to that file. If the `replyall` variable is set, the actions of `R eply/R espond` and `r eply/r espond` are reversed. The `replya ll` command is not affected by the `replyall` variable, but always sends the reply to all recipients of the message. See the `Starting Mail` section in `USAGE` above.

`ret ain`

Add the list of header fields named to the `retained list`. Only the header fields in the `retain list` are shown on your terminal when you print a message. All other header fields are suppressed. The set of retained fields specified by the `ret ain` command overrides any list of ignored fields specified by the `ig nore` command. The `T ype` and `P rint` commands can be used to print a message in its entirety. If `ret ain` is executed with no arguments, it lists the current set of retained fields.

`S ave [message-list ]`

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the `C opy`, `fo llowup`, and `F ollowup` commands and `outfolder` in `Internal Variables`.

`s ave [file ]`

`s ave [message-list ] file`

Save the specified messages in the given file. The file is created if it does not exist. The file defaults to `mbox`. The message is deleted from the mailbox when `mailx` terminates unless `keepsave` is set (see also `Internal Variables` and the `ex it` and `q uit` commands).

`se t`

`se t variable`

`se t variable = string`

`se t variable = number`

Define a *variable*. To assign a *value* to *variable*, separate the variable name from the value by an '=' (there must be no space before or after the '='). A variable may be given a null, string, or numeric *value*. To embed SPACE characters within a *value*, enclose it in quotes.

With no arguments, `se t` displays all defined variables and any values they might have. See `Internal Variables` for a description of all predefined `mail` variables.

`sh ell`

Invoke an interactive shell. See also `SHELL` in `ENVIRONMENT VARIABLES`.

`si ze [message-list ]`

Print the size in characters of the specified messages.

`so urce file`

Read commands from the given file and return to command mode.

`to p [message-list ]`

Print the top few lines of the specified messages. If the `toplines` variable is set, it is taken as the number of lines to print (see `Internal Variables`). The default is 5.

`to uch [message-list ]`

Touch the specified messages. If any message in *message-list* is not specifically saved in a file, it is placed in the `mbox`, or the file specified in the `MBOX` environment variable, upon normal termination. See `ex it` and `q uit`.

`T ype [message-list ]`

`P rint [message-list ]`

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ig nore` command.

`t ype [message-list ]`

`p rint [message-list ]`

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)`. See `ENVIRONMENT VARIABLES`.

`unalias` [*alias*] ...

`unalias` [*alias*] ...

Remove the definitions of the specified aliases.

`undelete` [*message-list*]

Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If `autoprint` is set, the last message of those restored is printed (see `Internal Variables`).

`undiscard` [*header-field* ...]

`undiscard` [*header-field* ...]

Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.

`unretain` [*header-field* ...]

Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.

`unread` [*message-list*]

`unread` [*message-list*] Same as the `new` command.

`unset` *variable* ...

Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within `mailx`.

`version`

Print the current version and release date of the `mailx` utility.

`visual` [*message-list*]

Edit the given messages with a screen editor. Each message is placed in a temporary file and the program named by the `VISUAL` variable is invoked to edit it (see `ENVIRONMENT VARIABLES`). Note that the default visual editor is `vi`.

`write` [*message-list*] *file*

Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the `save` command.

`xit`

`exit`

Exit from `mailx`, without changing the mailbox. No messages are saved in the `mbox` (see also `q uit`).

`z [+ | - ]`

Scroll the header display forward or backward one screen-full. The number of headers displayed is set by the `screen` variable (see `Internal Variables`).

### Tilde Escapes

The following tilde escape commands can be used when composing mail to send. These may be entered only from *input mode*, by beginning a line with the tilde escape character (`~`). See `escape` in `Internal Variables` for changing this special character. The escape character can be entered as text by typing it twice.

`~!` Escape to the shell. If present, run *shell-command*.  
*shell-command*

`~.` Simulate end of file (terminate message input).

`~:`  
*mail-command*

`~_` Perform the command-level request. Valid only when sending a message while reading mail.  
*mail-command*

`~?` Print a summary of tilde escapes.

`~A` Insert the autograph string `Sign` into the message (see `Internal Variables`).

`~a` Insert the autograph string `sign` into the message (see `Internal Variables`).

`~b` Add the *names* to the blind carbon copy (`BCC`) list. This is like the carbon copy (`CC`) list, except that the names in the `BCC` list are not shown in the header of the mail message.  
*name ...*

`~c` Add the *names* to the carbon copy (`CC`) list.  
*name ...*

`~d` Read in the dead-letter file. See `DEAD` in `ENVIRONMENT VARIABLES` for a description of this file.

`~e` Invoke the editor on the partial message. See also `EDITOR` in `ENVIRONMENT VARIABLES`.

`~f` Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are  
*[message-list*  
*]*

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                               | inserted into the message without alteration (as opposed to the <code>~m</code> escape).                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>~F</code><br>[ <i>message-list</i><br>] | Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the <code>ignore</code> command.                                                                                                                                                                                                                                                                                                                                   |
| <code>~h</code>                               | Prompt for <code>Subject</code> line and <code>To</code> , <code>Cc</code> , and <code>Bcc</code> lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.                                                                                                                                                                                                                                                                                                  |
| <code>~i</code><br><i>variable</i>            | Insert the value of the named variable into the text of the message. For example, <code>~A</code> is equivalent to <code>'~i Sign.'</code> Environment variables set and exported in the shell are also accessible by <code>~i</code> .                                                                                                                                                                                                                                                                  |
| <code>~m</code><br>[ <i>message-list</i><br>] | Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line.                                                                                                       |
| <code>~M</code><br>[ <i>message-list</i><br>] | Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line. Overrides the suppression of fields by the <code>ignore</code> command. |
| <code>~p</code>                               | Print the message being entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>~q</code>                               | Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in <code>dead-letter</code> . See <code>DEAD</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file.                                                                                                                                                                                                                                                          |
| <code>~R</code>                               | Mark message for return receipt.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                       |                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ~r<br>file            |                                                                                                                                                                                                                      |
| ~<<br>file            |                                                                                                                                                                                                                      |
| ~< !<br>shell-command | Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message. |
| ~s<br>string ...      | Set the subject line to <i>string</i> .                                                                                                                                                                              |
| ~t<br>name ...        | Add the given <i>name</i> s to the To list.                                                                                                                                                                          |
| ~v                    | Invoke a preferred screen editor on the partial message. The default visual editor is <code>vi(1)</code> . See also <code>VISUAL</code> in <code>ENVIRONMENT VARIABLES</code> .                                      |
| ~w<br>file            | Write the message into the given file, without the header.                                                                                                                                                           |
| ~x                    | Exit as with ~q except the message is not saved in <code>dead-letter</code> .                                                                                                                                        |
| ~ <br>shell-command   | Pipe the body of the message through the given <i>shell-command</i> . If the <i>shell-command</i> returns a successful exit status, the output of the command replaces the message.                                  |

**Internal Variables**

The following variables are internal variables. They may be imported from the execution environment or set using the `set` command at any time. The `unset` command may be used to erase variables.

|              |                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allnet       | All network names whose last component (login name) match are treated as identical. This causes the <i>message-list</i> message specifications to behave similarly. Disabled by default. See also the <code>alternates</code> command and the <code>metoo</code> variable.       |
| alwaysignore | Ignore header fields with <code>ignore</code> everywhere, not just during <code>print</code> or <code>type</code> . Affects the <code>save</code> , <code>Save</code> , <code>copy</code> , <code>Copy</code> , <code>topipe</code> , <code>pipe</code> , and <code>write</code> |

|                  |                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | commands, and the <code>~m</code> and <code>~f</code> tilde escapes. Enabled by default.                                                                                                                                                                                                                                                                                                     |
| append           | Upon termination, append messages to the end of the <code>mbox</code> file instead of prepending them. Although disabled by default, <code>append</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).                                                                                                                           |
| appenddeadletter | Append to the deadletter file rather than overwrite it. Although disabled by default, <code>appenddeadletter</code> is frequently set in the system startup file. See <i>Starting Mail</i> in <i>USAGE</i> above.                                                                                                                                                                            |
| askbcc           | Prompt for the <code>Bcc</code> list after the <code>Subject</code> is entered if it is not specified on the command line with the <code>-b</code> option. Disabled by default.                                                                                                                                                                                                              |
| askcc            | Prompt for the <code>Cc</code> list after the <code>Subject</code> is entered if it is not specified on the command line with the <code>-c</code> option. Disabled by default.                                                                                                                                                                                                               |
| asksub           | Prompt for subject if it is not specified on the command line with the <code>-s</code> option. Enabled by default.                                                                                                                                                                                                                                                                           |
| autoinc          | Automatically incorporate new messages into the current session as they arrive. This has an affect similar to issuing the <code>inc</code> command every time the command prompt is displayed. Disabled by default, but <code>autoinc</code> is set in the default system startup file for <code>mailx</code> ; it is not set for <code>/usr/ucb/mail</code> or <code>/usr/ucb/Mail</code> . |
| autoprint        | Enable automatic printing of messages after <code>d elete</code> and <code>u ndelete</code> commands. Disabled by default.                                                                                                                                                                                                                                                                   |

| crt<br>[=<br><i>number</i><br>] | Pipe messages having more than <i>number</i> lines through the command specified by the value of the <code>PAGER</code> variable ( <code>pg(1)</code> or <code>more(1)</code> by default). If <i>number</i> is not specified,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |          |                                                                                                         |          |                                                                                                                                                                                                                                                                   |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | the current window size is used.<br>Disabled by default.                                                                                                                                                                                                                                                                                                                                             |
| debug                | Enable verbose diagnostics for debugging. Messages are not delivered. Disabled by default.                                                                                                                                                                                                                                                                                                           |
| dot                  | Take a period on a line by itself, or EOF during input from a terminal as end-of-file. Disabled by default, but <code>dot</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).                                                                                                                                                           |
| flipr                | Reverse the effect of the <code>followup/Followup</code> and <code>reply/Reply</code> command pairs. If both <code>flipr</code> and <code>replyall</code> are set, the effect is as if neither was set.                                                                                                                                                                                              |
| from                 | Extract the author listed in the header summary from the <code>From:</code> header instead of the UNIX <code>From</code> line.<br>Enabled by default.                                                                                                                                                                                                                                                |
| escape=<br>c         | Substitute <code>c</code> for the <code>~</code> escape character.<br>Takes effect with next message sent.                                                                                                                                                                                                                                                                                           |
| folder=<br>directory | The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If <code>directory</code> does not start with a slash (/), <code>\$HOME</code> is prepended to it. There is no default for the <code>folder</code> variable. See also <code>outfolder</code> below. |
| header               | Enable printing of the header summary when entering <code>mailx</code> . Enabled by default.                                                                                                                                                                                                                                                                                                         |
| hold                 | Preserve all messages that are read in the <code>mailbox</code> instead of putting them in the standard <code>mbox</code> save file.<br>Disabled by default.                                                                                                                                                                                                                                         |

|                         |                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ignore                  | Ignore interrupts while entering messages. Handy for noisy dial-up lines. Disabled by default.                                                                                                                           |
| ignoreeof               | Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the ~. command. See also dot above. Disabled by default.                                                     |
| indentprefix=<br>string | When indentprefix is set, string is used to mark indented lines from messages included with ~m. The default is a TAB character.                                                                                          |
| keep                    | When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.                                                                                                                       |
| iprompt=<br>string      | The specified prompt string is displayed before each line on input is requested when sending a message.                                                                                                                  |
| keepsave                | Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.                                                                                                          |
| makeremote              | When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822. |
| metoo                   | If your login appears as a recipient, do not delete it from the list. Disabled by default.                                                                                                                               |
| mustbang                | Force all mail addresses to be in bang format.                                                                                                                                                                           |
| onehop                  | When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag            |

|                   |                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default.                                                                                                                      |
| outfolder         | Locate the files used to record outgoing messages in the directory specified by the <code>folder</code> variable unless the path name is absolute. Disabled by default. See <code>folder</code> above and the <code>Save</code> , <code>Copy</code> , <code>Followup</code> , and <code>Followup</code> commands. |
| page              | Used with the <code>pipe</code> command to insert a form feed after each message sent through the pipe. Disabled by default.                                                                                                                                                                                      |
| pipeignore        | Omit ignored header when outputting to the <code>pipe</code> command. Although disabled by default, <code>pipeignore</code> is frequently set in the system startup file. See <code>Starting Mail</code> in <code>USAGE</code> above.                                                                             |
| postmark          | Your "real name" to be included in the <code>From</code> line of messages you send. By default this is derived from the comment field in your <code>passwd(4)</code> file entry.                                                                                                                                  |
| prompt=<br>string | Set the <i>command mode</i> prompt to <i>string</i> . Default is "? ", unless the <code>bsdcompat</code> variable is set, then the default is "& ".                                                                                                                                                               |
| quiet             | Refrain from printing the opening message and version when entering <code>mailx</code> . Disabled by default.                                                                                                                                                                                                     |
| record=<br>file   | Record all outgoing mail in <code>file</code> . Disabled by default. | verbose                    | <p>Invoke <code>sendmail(1M)</code> with the <code>-v</code> flag.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| translate                  | <p>The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order:</p> <ul style="list-style-type: none"> <li>■ the postmark for the sender (see the postmark variable)</li> <li>■ translated mail addresses, one per line, corresponding to the program's arguments. Each translated address will replace the corresponding address in the mail message being sent.</li> <li>■ a line containing only "y" or "n". if the line contains "y" the user will be asked to confirm that the message should be sent.</li> </ul> |

The translate program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.

**Large File Behavior**

See `largefile(5)` for the description of the behavior of `mailx` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `mailx`: `HOME`, `LANG`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TERM`.

**DEAD** The name of the file in which to save partial letters in case of untimely interrupt. Default is `$HOME/dead.letter`.

**EDITOR** The command to run when the `e dit` or `~e` command is used. Default is `ed(1)`.

**LLISTER** The command (and options) to use when listing the contents of the `folder` directory. The default is `ls(1)`.

**MAIL** The name of the initial mailbox file to read (in lieu of the standard system mailbox). The default is `/var/mail/username`.

**MAILRC** The name of the startup file. Default is `$HOME/.mailrc`.

**MAILX\_HEAD** The specified string is included at the beginning of the body of each message that is sent.

**MAILX\_TAIL** The specified string is included at the end of the body of each message that is sent.

**MBOX** The name of the file to save messages which have been read. The `ex it` command overrides this function, as does saving the message explicitly in another file. Default is `$HOME/mbox`.

**PAGER** The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is `pg(1)`, or if the `bsdcompat` variable is set, the default is `more(1)`. See `Internal Variables`.

**SHELL** The name of a preferred command interpreter. Default is `sh(1)`.

**VISUAL** The name of a preferred screen editor. Default is `vi(1)`.

**EXIT STATUS**

When the `-e` option is specified, the following exit values are returned:

0 Mail was found.  
 >0 Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0 Successful completion. Note that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.

>0 An error occurred

## FILES

`$HOME/.mailrc` personal startup file  
`$HOME/mbox` secondary storage file  
`$HOME/.Maillock` lock file to prevent multiple writers of system mailbox  
`/etc/mail/mailx.rc` optional system startup file for mailx only  
`/etc/mail/Mail.rc` BSD compatibility system-wide startup file for `/usr/ucb/mail` and `/usr/ucb/Mail`  
`/tmp/R[emqsx]*` temporary files  
`/usr/share/lib/mailx/mailx.help*` help message files  
`/var/mail/*` post office directory

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

## SEE ALSO

`biff(1B)`, `echo(1)`, `ed(1)`, `ex(1)`, `fmt(1)`, `lp(1)`, `ls(1)`, `mail(1)`, `mail(1B)`, `mailcompat(1)`, `more(1)`, `newaliases(1)`, `pg(1)`, `sh(1)`, `uucp(1C)`, `vacation(1)`, `vi(1)`, `sendmail(1M)`, `aliases(4)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

## NOTES

Where *shell-command* is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be `uns et`.

The full internet addressing is not fully supported by `mailx`. The new standards need some time to settle down.

Replies do not always generate correct return addresses. Try resending the errant reply with `onehop` set.

`mailx` does not lock your record file. So, if you use a record file and send two or more messages simultaneously, lines from the messages may be interleaved in the record file.

The format for the `alias` command is a space-separated list of recipients, while the format for an alias in either the `.forward` or `/etc/aliases` is a comma-separated list.

To read mail on a workstation running Solaris 1.x when your mail server is running Solaris 2.x, first execute the `mailcompat(1)` program.

| <b>DESCRIPTION</b> | <p>The <code>make</code> utility executes a list of shell commands associated with each <i>target</i>, typically to create or update a file of the same name. <i>makefile</i> contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called <i>dependencies</i>. Since each dependency is a target, it may have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that <code>make</code> traces when deciding whether or not to rebuild a <i>target</i>.</p> <p>The <code>make</code> utility recursively checks each <i>target</i> against its dependencies, beginning with the first target entry in <i>makefile</i> if no <i>target</i> argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, <code>make</code> rebuilds it. Optionally with this version of <code>make</code>, a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.</p> <p>To build a given target, <code>make</code> executes the list of commands, called a <i>rule</i>. This rule may be listed explicitly in the target's <i>makefile</i> entry, or it may be supplied implicitly by <code>make</code>.</p> <p>If no <i>target</i> is specified on the command line, <code>make</code> uses the first target defined in <i>makefile</i>.</p> <p>If a <i>target</i> has no <i>makefile</i> entry, or if its entry has no rule, <code>make</code> attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. Each method is described under USAGE below.</p> <ul style="list-style-type: none"> <li>■ Pattern matching rules.</li> <li>■ Implicit rules, read in from a user-supplied <i>makefile</i>.</li> <li>■ Standard implicit rules (also known as suffix rules), typically read in from the file <code>/usr/share/lib/make/make.rules</code>.</li> <li>■ SCCS retrieval. <code>make</code> retrieves the most recent version from the SCCS history file (if any). See the description of the <code>.SCCS_GET:</code> special-function target for details.</li> <li>■ The rule from the <code>.DEFAULT:</code> target entry, if there is such an entry in the <i>makefile</i>.</li> </ul> |

**OPTIONS**

If there is no makefile entry for a *target*, if no rule can be derived for building it, and if no file by that name is present, `make` issues an error message and halts.

The following options are supported:

- `-d` Displays the reasons why `make` chooses to rebuild a target; `make` displays any and all dependencies that are newer. In addition, `make` displays options read in from the `MAKEFLAGS` environment variable.
- `-dd` Displays the dependency check and processing in vast detail.
- `-D` Displays the text of the makefiles read in.
- `-DD` Displays the text of the makefiles, `make.rules` file, the state file, and all hidden-dependency reports.
- `-e` Environment variables override assignments within makefiles.
- `-f makefile` Uses the description file *makefile*. A '-' as the *makefile* argument denotes the standard input. The contents of *makefile*, when present, override the standard set of implicit rules and predefined macros. When more than one '-f *makefile*' argument pair appears, `make` uses the concatenation of those files, in order of appearance.

When no *makefile* is specified, `/usr/ccs/bin/make` tries the following in sequence, except when in POSIX mode (see the `.POSIX` Special-Function Targets in the USAGE section below):

- If there is a file named `makefile` in the working directory, `make` uses that file. If, however, there is an SCCS history file (`SCCS/s.makefile`) which is newer, `make` attempts to retrieve and use the most recent version.
- In the absence of the above file(s), if a file named `Makefile` is present in the working directory, `make` attempts to use it. If there is an SCCS history file (`SCCS/s.Makefile`) that is newer, `make` attempts to retrieve and use the most recent version.

When no *makefile* is specified, `/usr/ccs/bin/make` in POSIX mode and `/usr/xpg4/bin/make` try the following files in sequence:

- `./makefile`, `./Makefile`
- `s.makefile`, `SCCS/s.makefile`
- `s.Makefile`, `SCCS/s.Makefile`

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -i                  | Ignores error codes returned by commands. Equivalent to the special-function target <code>.IGNORE:</code> .                                                                                                                                                                                                                                                                                                                                                                                                      |
| -k                  | When a nonzero error status is returned by a rule, or when <code>make</code> cannot find a rule, abandons work on the current target, but continues with other dependency branches that do not depend on it.                                                                                                                                                                                                                                                                                                     |
| -K <i>statefile</i> | Uses the state file <i>statefile</i> . A <code>'-'</code> as the <i>statefile</i> argument denotes the standard input. The contents of <i>statefile</i> , when present, override the standard set of implicit rules and predefined macros. When more than one <code>'-K statefile'</code> argument pair appears, <code>make</code> uses the concatenation of those files, in order of appearance. (See also <code>.KEEP_STATE</code> and <code>.KEEP_STATE_FILE</code> in the Special-Function Targets section). |
| -n                  | No execution mode. Prints commands, but does not execute them. Even lines beginning with an <code>@</code> are printed. However, if a command line contains a reference to the <code>\$(MAKE)</code> macro, that line is always executed (see the discussion of <code>MAKEFLAGS</code> in Reading Makefiles and the Environment). When in POSIX mode, lines beginning with a <code>+</code> are executed.                                                                                                        |
| -P                  | Prints out the complete set of macro definitions and target descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -P                  | Merely reports dependencies, rather than building them.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -q                  | Question mode. <code>make</code> returns a zero or nonzero status code depending on whether or not the target file is up to date. When in POSIX mode, lines beginning with a <code>+</code> are executed.                                                                                                                                                                                                                                                                                                        |
| -r                  | Does not read in the default makefile<br><code>/usr/share/lib/make/make.rules.</code>                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -s                  | Silent mode. Does not print command lines before executing them. Equivalent to the special-function target <code>.SILENT:</code> .                                                                                                                                                                                                                                                                                                                                                                               |
| -S                  | Undoes the effect of the <code>-k</code> option. Stops processing when a non-zero exit status is returned by a command.                                                                                                                                                                                                                                                                                                                                                                                          |
| -t                  | Touches the target files (bringing them up to date) rather than performing their rules. <i>This can be dangerous when files are maintained by more than one person.</i> When the <code>.KEEP_STATE:</code> target appears in the makefile, this option                                                                                                                                                                                                                                                           |

updates the state file just as if the rules had been performed. When in POSIX mode, lines beginning with a “+” are executed.

-v Puts `make` into SysV mode. Refer to `sysv-make(1)` for respective details.

## OPERANDS

The following operands are supported:

*target* Target names, as defined in `USAGE`.

*macro=value* Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.

## USAGE

### Reading Makefiles and the Environment

When `make` first starts, it reads the `MAKEFLAGS` environment variable to obtain any of the following options specified present in its value: `-d`, `-D`, `-e`, `-i`, `-k`, `-n`, `-p`, `-q`, `-r`, `-s`, `-S`, or `-t`. Due to the implementation of POSIX.2 (see POSIX.2(5)), the `MAKEFLAGS` values will contain a leading ‘-’ character. The `make` utility then reads the command line for additional options, which also take effect.

Next, `make` reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, `make` uses the file `make.rules` in the current directory; otherwise it reads the file `/usr/share/lib/make/make.rules`, which contains the standard definitions and rules. Use the directive:

```
include /usr/share/lib/make/make.rules
```

in your local `make.rules` file to include them.

Next, `make` imports variables from the environment (unless the `-e` option is in effect), and treats them as defined macros. Because `make` uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment variable of the same name. When `-e` is in effect, however, environment variables are read in *after* all makefiles have been read. In that case, the environment variables take precedence over definitions in the makefile.

Next, `make` reads any makefiles you specify with `-f`, or one of `makefile` or `Makefile` as described above and then the state file, in the local directory if it exists. If the makefile contains a `.KEEP_STATE_FILE` target, then it reads the state file that follows the target. Refer to special target `.KEEP_STATE_FILE` for details.

Next (after reading the environment if `-e` is in effect), `make` reads in any macro definitions supplied as command line arguments. These override macro

definitions in the makefile and the environment both, but only for the `make` command itself.

`make` exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.

`make` does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, `make` exports its value as defined on the command line. Unless `-e` is in effect, macro definitions within the makefile take precedence over those imported from the environment.

The macros `MAKEFLAGS`, `MAKE`, `SHELL`, `HOST_ARCH`, `HOST_MACH`, and `TARGET_MACH` are special cases. See *Special-Purpose Macros* below for details.

### Makefile Target Entries

A target entry has the following format:

```
target [:|:] [dependency] ... [; command] ...
 [command]
 . . .
```

The first line contains the name of a target, or a space-separated list of target names, terminated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) may be followed by a *dependency*, or a dependency list. `make` checks this list before building the target. The dependency list may be terminated with a semicolon (`;`), which in turn can be followed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB and contain Bourne shell commands. These commands comprise the rule for building the target.

Shell commands may be continued across input lines by escaping the NEWLINE with a backslash (`\`). The continuing line must also start with a TAB.

To rebuild a target, `make` expands macros, strips off initial TAB characters and either executes the command directly (if it contains no shell metacharacters), or passes each command line to a Bourne shell for execution.

The first *non-empty* line that does not begin with a TAB or `'#'` begins another target or macro definition.

### Special Characters

#### Global

|   |                                                                                                                                                                                                                    |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| # | Start a comment. The comment ends at the next NEWLINE. If the <code>'#'</code> follows the TAB in a command line, that line is passed to the shell (which also treats <code>'#'</code> as the start of a comment). |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Targets and  
Dependencies`include filename`

If the word `include` appears as the first seven letters of a line and is followed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line. `include` files can be nested to a depth of no more than about 16. If *filename* is a macro reference, it is expanded.

:

Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target's complete dependency list.

::

Target terminator for alternate dependencies. When used in place of a ':' the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according the rule in that other entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed.

`target [+ target... ] :`

Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per `make` run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.

%

Pattern matching wild card metacharacter. Like the '\*' shell wild card, '%' matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Note that only one '%' can appear in a target, dependency-name, or pattern-replacement macro reference.

|        |                                      |                                                                                                                                                                                                                                                                                                                                                                           |
|--------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | <code>./pathname</code>              | <code>make</code> ignores the leading <code>./</code> characters from targets with names given as pathnames relative to “dot,” the working directory.                                                                                                                                                                                                                     |
| Macros | <code>=</code>                       | Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the <code>=</code> is implied.                                                                                                                         |
|        | <code>\$</code>                      | Macro reference. The following character, or the parenthesized or bracketed string, is interpreted as a macro reference: <code>make</code> expands the reference (including the <code>\$</code> ) by replacing it with the macro’s value.                                                                                                                                 |
|        | <code>( )</code><br><code>{ }</code> | Macro-reference name delimiters. A parenthesized or bracketed word appended to a <code>\$</code> is taken as the name of the macro being referred to. Without the delimiters, <code>make</code> recognizes only the first character as the macro name.                                                                                                                    |
|        | <code>\$\$</code>                    | A reference to the dollar-sign macro, the value of which is the character <code>'\$'</code> . Used to pass variable expressions beginning with <code>\$</code> to the shell, to refer to environment variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed. |
|        | <code>\\$</code>                     | Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.                                                                                                                                                                                                                                                                                        |
|        | <code>+=</code>                      | When used in place of <code>'=</code> ', appends a string to a macro definition (must be surrounded by white space, unlike <code>'=</code> ').                                                                                                                                                                                                                            |
|        | <code>:=</code>                      | Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.                                                                                                                                                                 |
|        | <code>:sh =</code>                   | Define the value of a macro to be the output of a command (see Command Substitutions below).                                                                                                                                                                                                                                                                              |
|        | <code>:sh</code>                     | In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see Command Substitutions below).                                                                                                                                                                                                               |
| Rules  | <code>+</code>                       | <code>make</code> will always execute the commands preceded by a <code>+</code> , even when <code>-n</code> is specified.                                                                                                                                                                                                                                                 |

- make ignores any nonzero error code returned by a command line for which the first non-TAB character is a '-'. This character is not passed to the shell as part of the command line. make normally terminates when a command returns nonzero status, unless the -i or -k options, or the .IGNORE: special-function target is in effect.
- @ If the first non-TAB character is a @, make does not print the command line before executing it. This character is not passed to the shell.
- ? Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.
- ! Force command-dependency checking. Command-dependency checking is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the '?' dynamic macro (for example, '\$?').  
When any combination of '+', '-', '@', '?', or '!' appear as the first characters after the TAB, all that are present apply. None are passed to the shell.

#### Special-Function Targets

When incorporated in a makefile, the following target names perform special-functions:

- .DEFAULT: If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. make ignores any dependencies for this target.
- .DONE: If defined in the makefile, make processes this target and its dependencies after all other targets are built. This target is also performed when make halts with an error, unless the .FAILED target is defined.
- .FAILED: This target, along with its dependencies, is performed instead of .DONE when defined in the makefile and make halts with an error.
- .GET\_POSIX: This target contains the rule for retrieving the current version of an SCCS file from its history

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | file in the current working directory. <code>make</code> uses this rule when it is running in POSIX mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>.IGNORE:</code>          | Ignore errors. When this target appears in the makefile, <code>make</code> ignores non-zero error codes returned from commands. When used in POSIX mode, <code>.IGNORE</code> could be followed by target names only, for which the errors will be ignored.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>.INIT:</code>            | If defined in the makefile, this target and its dependencies are built before any other targets are processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>.KEEP_STATE:</code>      | If this target is in effect, <code>make</code> updates the state file, <code>.make.state</code> , in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the <code>.KEEP_STATE:</code> target appears in the makefile, or the environment variable <code>KEEP_STATE</code> is set (" <code>setenv KEEP_STATE</code> "), <code>make</code> will rebuild everything in order to collect dependency information, even if all the targets were up to date due to previous <code>make</code> runs. See also the ENVIRONMENT VARIABLES section. This target has no effect if used in POSIX mode. |
| <code>.KEEP_STATE_FILE:</code> | This target has no effect if used in POSIX mode. This target implies <code>.KEEP_STATE</code> . If the target is followed by a filename, <code>make</code> uses it as the state file. If the target is followed by a directory name, <code>make</code> looks for a <code>.make.state</code> file in that directory. If the target is not followed by any name, <code>make</code> looks for <code>.make.state</code> file in the current working directory.                                                                                                                                                                                             |
| <code>.MAKE_VERSION:</code>    | A target-entry of the form: <p style="text-align: center;"><code>Z.MAKE_VERSION: VERSION-number</code></p> enables version checking. If the version of <code>make</code> differs from the version indicated, <code>make</code> issues a warning message.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>.NO_PARALLEL:</code>     | Currently, this target has no effect, it is, however, reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>.PARALLEL:</code>        | Currently of no effect, but reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

- `.POSIX:` This target enables POSIX mode.
- `.PRECIOUS:` List of files not to delete. `make` does not remove any of the files listed as dependencies for this target when interrupted. `make` normally removes the current target when it receives an interrupt. When used in POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.
- `.SCCS_GET:` This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.
- `.SCCS_GET_POSIX:` This target contains the rule for retrieving the current version of an SCCS file from its history file. `make` uses this rule when it is running in POSIX mode.
- `.SILENT:` Run silently. When this target appears in the makefile, `make` does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those will be executed silently.
- `.SUFFIXES:` The suffixes list for selecting implicit rules (see The Suffixes List).
- `.WAIT:` Currently of no effect, but reserved for future use.

*Clearing Special Targets*

In this version of `make`, you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule:

`.DEFAULT`, `.SCCS_GET`, and `.SUFFIXES`

**Command Dependencies**

When the `.KEEP_STATE:` target is effective, `make` checks the command for building a target against the state file. If the command has changed since the last `make` run, `make` rebuilds the target.

**Hidden Dependencies**

When the `.KEEP_STATE:` target is effective, `make` reads reports from `cpp(1)` and other compilation processors for any "hidden" files, such as `#include` files. If the target is out of date with respect to any of these files, `make` rebuilds it.

**Macros**

Entries of the form

*macro=value*

define macros. *macro* is the name of the macro, and *value*, which consists of all characters up to a comment character or unescaped NEWLINE, is the value. `make` strips both leading and trailing white space in accepting the value.

Subsequent references to the macro, of the forms: `$(name)` or `${name}` are replaced by *value*. The parentheses or brackets can be omitted in a reference to a macro with a single-character name.

Macro references can contain references to other macros, in which case nested references are expanded first.

*Suffix Replacement  
Macro References*

Substitutions within macros can be made as follows:

```
$(name: string1=string2)
```

where *string1* is either a suffix, or a word to be replaced in the macro definition, and *string2* is the replacement suffix or word. Words in a macro value are separated by SPACE, TAB, and escaped NEWLINE characters.

*Pattern Replacement  
Macro References*

Pattern matching replacements can also be applied to macros, with a reference of the form:

```
$(name: op%os= np%ns)
```

where *op* is the existing (old) prefix and *os* is the existing (old) suffix, *np* and *ns* are the new prefix and new suffix, respectively, and the pattern matched by `%` (a string of zero or more characters), is carried forward from the value being replaced. For example:

```
PROGRAM=fabricate
DEBUG= $(PROGRAM:%=tmp/%-g)
```

sets the value of `DEBUG` to `tmp/fabricate-g`.

Note that pattern replacement macro references cannot be used in the dependency list of a pattern matching rule; the `%` characters are not evaluated independently. Also, any number of `%` metacharacters can appear after the equal-sign.

*Appending to a Macro*

Words can be appended to macro values as follows:

```
macro += word ...
```

**Special-Purpose  
Macros**

When the `MAKEFLAGS` variable is present in the environment, `make` takes options from it, in combination with options entered on the command line. `make` retains this combined value as the `MAKEFLAGS` macro, and exports it automatically to each command or shell it invokes.

Note that flags passed by way of `MAKEFLAGS` are only displayed when the `-d`, or `-dd` options are in effect.

The `MAKE` macro is another special case. It has the value `make` by default, and temporarily overrides the `-n` option for any line in which it is referred to. This allows nested invocations of `make` written as:

```
$(MAKE) . . .
```

to run recursively, with the `-n` flag in effect for all commands but `make`. This lets you use `'make-n'` to test an entire hierarchy of makefiles.

For compatibility with the 4.2 BSD `make`, the `MFLAGS` macro is set from the `MAKEFLAGS` variable by prepending a `'-'`. `MFLAGS` is not exported automatically.

The `SHELL` macro, when set to a single-word value such as `/usr/bin/csh`, indicates the name of an alternate shell to use. The default is `/bin/sh`. Note that `make` executes commands that contain no shell metacharacters itself. Built-in commands, such as `dirs` in the C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of `-e`. To be sure it is set properly, you must define this macro within every makefile that requires it.

The syntax of the `VPATH` macro is:

```
VPATH = [pathname [: pathname] ...]
```

`VPATH` specifies a list of directories to search for the files, which are targets or dependencies, when `make` is executed. `VPATH` is also used in order to search for the include files mentioned in the particular makefile.

When processing a target or a dependency or an include directive, `make` checks the existence of the file with the same name in the current directory. If the file is found to be missing, `make` will search for this file in the list of directories presented in `VPATH` (like the `PATH` variable in the shell). Unlike the `PATH` variable, `VPATH` is used in order to search for the files with relative pathnames. When `make` attempts to apply implicit rules to the target, it also searches for the dependency files using `VPATH`.

When the file is found using `VPATH`, internal macros `$$`, `@<`, `$$?`, `$$*`, and their alternative forms (with `D` or `F` appended) are set in accordance with the name derived from `VPATH`. For instance, if the target `subdir/foo.o` is found in the directory `/aaa/bbb` using `VPATH`, then the value of the internal macro `$$` for this target will be `/aaa/bbb/subdir/foo.o`.

If a target or a dependency file is found using `VPATH`, then any occurrences of the word that is the same as the target name in the subsequent rules will be replaced with the actual name of the target derived from `VPATH`.

For example:

```
VPATH=./subdir
file.o : file.c
 cc -c file.c -o file.o
```

If `file.c` is found in `./subdir`, then the command

```
cc -c ./subdir/file.c -o file.o
```

will be executed.

The following macros are provided for use with cross-compilation:

**HOST\_ARCH**      The machine architecture of the host system. By default, this is the output of the `arch(1)` command prepended with '-'. Under normal circumstances, this value should never be altered by the user.

**HOST\_MACH**      The machine architecture of the host system. By default, this is the output of the `mach(1)`, prepended with '-'. Under normal circumstances, this value should never be altered by the user.

**TARGET\_ARCH**    The machine architecture of the target system. By default, the output of `mach`, prepended with '-'.

### Dynamic Macros

There are several dynamically maintained macros that are useful as abbreviations within rules. They are shown here as references; if you were to define them, `make` would simply override the definition.

**\$\***      The basename of the current target, derived as if selected for use with an implicit rule.

**\$<**      The name of a dependency file, derived as if selected for use with an implicit rule.

**\$@**      The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form '\$\$@'.)

**\$?**      The list of dependencies that are newer than the target. Command-dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a '?'. See the description of '?', under *Special Character Rules*, above. You can force this check with the `!` command-line prefix.

**\$%**      The name of the library member being processed. (See *Library Maintenance*, below.)

To refer to the `$@` dynamic macro within a dependency list, precede the reference with an additional '\$' character (as in, '\$\$@'). Because `make` assigns `$<` and `$*` as it would for implicit rules (according to the suffixes list and the directory contents), they may be unreliable when used within explicit target entries.

These macros can be modified to apply either to the filename part, or the directory part of the strings they stand for, by adding an upper case `F` or `D`, respectively (and enclosing the resulting name in parentheses or braces). Thus,

'\$(@D)' refers to the directory part of the string '\$@'; if there is no directory part, '.' is assigned. '\$(@F)' refers to the filename part.

**Conditional Macro Definitions**

A macro definition of the form:

*target-list := macro = value*

indicates that when processing any of the targets listed and their dependencies, *macro* is to be set to the *value* supplied. Note that if a conditional macro is referred to in a dependency list, the \$ must be delayed (use \$\$ instead). Also, *target-list* may contain a % pattern, in which case the macro will be conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the *value*.

You can temporarily append to a macro's value with a conditional definition of the form:

*target-list := macro += value*

**Predefined Macros**

make supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by make. If you run make with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If -r is in effect, make does not read the default makefile (./make.rules or /usr/share/lib/make/make.rules) in which these macro definitions are supplied.

**Implicit Rules**

When a target has no entry in the makefile, `make` attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, `make` allows you to define your own, either by pattern, or by suffix.

*Pattern Matching  
Rules*

A target entry of the form:

```
tp%ts: dp%ds
 rule
```

is a pattern matching rule, in which *tp* is a target prefix, *ts* is a target suffix, *dp* is a dependency prefix, and *ds* is a dependency suffix (any of which may be null). The '%' stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When `make` encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the `$$` and `$$<` dynamic macros as placeholders for the target and dependency names. Other, regular dependencies may occur in the dependency list; however, none of the regular dependencies may contain '%'. An entry of the form:

```
tp%ts: [dependency ...] dp%ds [dependency ...]
 rule
```

*Suffix Rules*

is a valid pattern matching rule.

When no pattern matching rule applies, `make` checks the target name to see if it ends with a suffix in the known suffixes list. If so, `make` checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

*DsTs*: *rule*

where *Ts* is the suffix of the target, *Ds* is the suffix of the dependency file, and *rule* is the rule for building a target in the class. Both *Ds* and *Ts* must appear in the suffixes list. (A suffix need not begin with a '.' to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the `.c` rule could be used to build an executable program named `file` from a C source file named `file.c`. If a target with a null suffix has an explicit dependency, `make` omits the search for a suffix rule.

| <i>Table of Standard Implicit (Suffix) Rules for Assembly Files</i> |                                                                                                                |

| <i>Table of Standard Implicit (Suffix) Rules for yacc Files</i> |                     |
|-----------------------------------------------------------------|---------------------|
| <i>Implicit Rule Name</i>                                       | <i>Command Line</i> |
|                                                                 | rm -f y.tab.c       |
|                                                                 | mv y.tab.o \$@      |

make reads in the standard set of implicit rules from the file /usr/share/lib/make/make.rules, unless -r is in effect, or there is a make.rules file in the local directory that does not include that file.

**The Suffixes List**

The suffixes list is given as the list of dependencies for the .SUFFIXES: special-function target. The default list is contained in the SUFFIXES macro (See Table of Predefined Macros for the standard list of suffixes). You can define additional .SUFFIXES: targets; a .SUFFIXES target with no dependencies clears the list of suffixes. Order is significant within the list; make selects a rule that corresponds to the target's suffix and the first dependency-file suffix found in the list. To place suffixes at the head of the list, clear the list and replace it with the new suffixes, followed by the default list:

```
.SUFFIXES:
.SUFFIXES: suffixes $(SUFFIXES)
```

A tilde (~) indicates that if a dependency file with the indicated suffix (minus the ~) is under SCCS its most recent version should be retrieved, if necessary, before the target is processed.

**Library Maintenance**

A target name of the form:

```
lib(member ...)
```

refers to a member, or a space-separated list of members, in an ar(1) library.

The dependency of the library member on the corresponding file must be given as an explicit entry in the makefile. This can be handled by a pattern matching rule of the form:

```
lib(%s): %s
```

where .s is the suffix of the member; this suffix is typically .o for object libraries.

A target name of the form:

```
lib((symbol))
```

refers to the member of a randomized object library that defines the entry point named symbol.

**Command Execution**

Command lines are executed one at a time, each by its own process or shell. Shell commands, notably cd, are ineffectual across an unescaped NEWLINE in the

makefile. A line is printed (after macro expansion) just before being executed. This is suppressed if it starts with a '@', if there is a '.SILENT:' entry in the makefile, or if `make` is run with the `-s` option. Although the `-n` option specifies printing without execution, lines containing the macro `$(MAKE)` are executed regardless, and lines containing the @ special character are printed. The `-t` (touch) option updates the modification date of a file without executing any rules. This can be dangerous when sources are maintained by more than one person.

`make` invokes the shell with the `-e` (exit-on-errors) argument. Thus, with semicolon-separated command sequences, execution of the later commands depends on the success of the former. This behavior can be overridden by starting the command line with a '-', or by writing a shell script that returns a non-zero status only as it finds appropriate.

### Bourne Shell Constructs

To use the Bourne shell `if` control structure for branching, use a command line of the form:

```
if expression ; \
then command ; \
 . . . ; \
else command ; \
 . . . ; \
fi
```

Although composed of several input lines, the escaped NEWLINE characters insure that `make` treats them all as one (shell) command line.

To use the Bourne shell `for` control structure for loops, use a command line of the form:

```
for var in list ; \
do command ; \
 . . . ; \
done
```

To refer to a shell variable, use a double-dollar-sign (\$\$). This prevents expansion of the dollar-sign by `make`.

### Command Substitutions

To incorporate the standard output of a shell command in a macro, use a definition of the form:

```
MACRO :sh =command
```

The command is executed only once, standard error output is discarded, and NEWLINE characters are replaced with SPACES. If the command has a non-zero exit status, `make` halts with an error.

To capture the output of a shell command in a macro reference, use a reference of the form:

```
$(MACRO:sh)
```

where *MACRO* is the name of a macro containing a valid Bourne shell command line. In this case, the command is executed whenever the reference is evaluated. As with shell command substitutions, the reference is replaced with the standard output of the command. If the command has a non-zero exit status, *make* halts with an error.

In contrast to commands in rules, the command is not subject for macro substitution; therefore, a dollar sign (\$) need not be replaced with a double dollar sign (\$\$).

*Signals*

INT, SIGTERM, and QUIT signals received from the keyboard halt *make* and remove the target file being processed unless that target is in the dependency list for *.PRECIOUS:*.

**EXAMPLES**

**EXAMPLE 1** Defining dependencies

This makefile says that *pgm* depends on two files *a.o* and *b.o*, and that they in turn depend on their corresponding source files (*a.c* and *b.c*) along with a common file *incl.h*:

```
pgm: a.o b.o
 $(LINK.c) -o $@a.o b.o
a.o: incl.h a.c
 cc -c a.c
b.o: incl.h b.c
 cc -c b.c
```

**EXAMPLE 2** Using implicit rules

The following makefile uses implicit rules to express the same dependencies:

```
pgm: a.o b.o
 cc a.o b.o -o pgm
a.o b.o: incl.h
```

**ENVIRONMENT VARIABLES**

See *environ(5)* for descriptions of the following environment variables that affect the execution of *make*: *LC\_CTYPE*, *LC\_MESSAGES*, and *NLSPATH*.

**KEEP\_STATE** This environment variable has the same effect as the *.KEEP\_STATE:* special-function target. It enables command dependencies, hidden dependencies and writing of the state file.

**USE\_SVR4\_MAKE** This environment variable causes *make* to invoke the generic System V version of *make* (*/usr/ccs/lib/avr4.make*). See *sysV-make(1)*.

**MAKEFLAGS** This variable is interpreted as a character string representing a series of option characters to be

used as the default options. The implementation will accept both of the following formats (but need not accept them when intermixed):

1. The characters are option letters without the leading hyphens or blank character separation used on a command line.
2. The characters are formatted in a manner similar to a portion of the `make` command line: options are preceded by hyphens and blank-character-separated. The `macro=name` macro definition operands can also be included. The difference between the contents of `MAKEFLAGS` and the command line is that the contents of the variable will not be subjected to the word expansions (see `wordexp(3C)`) associated with parsing the command line values.

When the command-line options `-f` or `-p` are used, they will take effect regardless of whether they also appear in `MAKEFLAGS`. If they otherwise appear in `MAKEFLAGS`, the result is undefined.

The `MAKEFLAGS` variable will be accessed from the environment before the makefile is read. At that time, all of the options (except `-f` and `-p`) and command-line macros not already included in `MAKEFLAGS` are added to the `MAKEFLAGS` macro. The `MAKEFLAGS` macro will be passed into the environment as an environment variable for all child processes. If the `MAKEFLAGS` macro is subsequently set by the makefile, it replaces the `MAKEFLAGS` variable currently found in the environment.

## EXIT STATUS

When the `-q` option is specified, the `make` utility will exit with one of the following values:

- 0 Successful completion.
- 1 The target was not up-to-date.
- >1 An error occurred.

When the `-q` option is not specified, the `make` utility will exit with one of the following values:

- 0 Successful completion
- >0 An error occurred

**FILES**

`makefile`  
`Makefile` current version(s) of `make` description file

`s.makefile`  
`s.Makefile` SCCS history files for the above `makefile(s)` in the current directory

`SCCS/s.makefile`  
`SCCS/s.Makefile` SCCS history files for the above `makefile(s)`

`make.rules` default file for user-defined targets, macros, and implicit rules

`/usr/share/lib/make/make.rules` `makefile` for standard implicit rules and macros (not read if `make.rules` is)

`.make.state` state file in the local directory

**ATTRIBUTES**

`/usr/ccs/bin/make`

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

`/usr/xpg4/bin/make`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4t       |

*OpenWindows Advanced User's Guide*

**DIAGNOSTICS**

Don't know how to make target '`target`'

There is no makefile entry for *target*, and none of *make*'s implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target's suffix is not in the list).

\*\*\* *target* removed.

*make* was interrupted while building *target*. Rather than leaving a partially-completed version that is newer than its dependencies, *make* removes the file named *target*.

\*\*\* *target* not removed.

*make* was interrupted while building *target* and *target* was not present in the directory.

\*\*\* *target* could not be removed, *reason*

*make* was interrupted while building *target*, which was not removed for the indicated reason.

Read of include file '*file*' failed

The makefile indicated in an include directive was not found, or was inaccessible.

Loop detected when expanding macro value '*macro*'

A reference to the macro being defined was found in the definition.

Could not write state file '*file*'

You used the `.KEEP_STATE: target`, but do not have write permission on the state file.

\*\*\* Error code *n*

The previous shell command returned a nonzero error code.

\*\*\* *signal message*

The previous shell command was aborted due to a signal. If '`- core dumped`' appears after the message, a `core` file was created.

Conditional macro conflict encountered

Displayed only when `-d` is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

## BUGS

Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a '`-`'.

Filenames with the characters '`=`', '`:`', or '`@`', do not work.

You cannot build `file.o` from `lib(file.o)`.

Options supplied by `MAKEFLAGS` should be reported for nested `make` commands. Use the `-d` option to find out what options the nested command picks up from `MAKEFLAGS`.

This version of `make` is incompatible in certain respects with previous versions:

- The `-d` option output is much briefer in this version. `-dd` now produces the equivalent voluminous output.
- `make` attempts to derive values for the dynamic macros `'$*'`, `'$<'`, and `'$?'`, while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)
- `make` no longer searches for SCCS history "(s.)" files.
- Suffix replacement in macro references are now applied after the macro is expanded.

There is no guarantee that makefiles created for this version of `make` will work with earlier versions.

If there is no `make.rules` file in the current directory, and the file `/usr/share/lib/make/make.rules` is missing, `make` stops before processing any targets. To force `make` to run anyway, create an empty `make.rules` file in the current directory.

Once a dependency is made, `make` assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors may result.

When hidden dependency checking is in effect, the `$?` macro's value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when `$?` is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of `make` strips a leading `./` from the value of the `'$@'` dynamic macro.

With automatic SCCS retrieval, this version of `make` does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is `$@` (takes the form `'$$@'`).

`make` invokes the shell with the `-e` argument. This cannot be inferred from the syntax of the rule alone.

| <b>DESCRIPTION</b>              | The <b>man</b> command displays information from the reference manuals. It displays complete manual pages that you select by <i>name</i> , or one-line summaries selected either by <i>keyword</i> (-k), or by the name of an associated file (-f). If no manual page is located, <b>man</b> prints an error message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Source Format</b>            | Reference Manual pages are marked up with either <b>nroff</b> (1) or <b>sgml</b> (5) (Standard Generalized Markup Language) tags. The <b>man</b> command recognizes the type of markup and processes the file accordingly. The various source files are kept in separate directories depending on the type of markup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Location of Manual Pages</b> | <p>The online Reference Manual page directories are conventionally located in <code>/usr/share/man</code>. The <b>nroff</b> sources are located in the <code>/usr/share/man/man*</code> directories. The SGML sources are located in the <code>/usr/share/man/sman*</code> directories. Each directory corresponds to a section of the manual. Since these directories are optionally installed, they may not reside on your host; you may have to mount <code>/usr/share/man</code> from a host on which they do reside.</p> <p>If there are preformatted, up-to-date versions in the corresponding <code>cat*</code> or <code>fmt*</code> directories, <b>man</b> simply displays or prints those versions. If the preformatted version of interest is out of date or missing, <b>man</b> reformats it prior to display and will store the preformatted version if <code>cat*</code> or <code>fmt*</code> is writable. The <code>windex</code> database is not updated. See <b>catman</b>(1M). If directories for the preformatted versions are not provided, <b>man</b> reformats a page whenever it is requested; it uses a temporary file to store the formatted text during display.</p> <p>If the standard output is not a terminal, or if the '-' flag is given, <b>man</b> pipes its output through <b>cat</b>(1); otherwise, <b>man</b> pipes its output through <b>more</b>(1) to handle paging and underlining on the screen.</p> |
| <b>OPTIONS</b>                  | <p>The following options are supported:</p> <p>-a                   Shows all manual pages matching <i>name</i> within the <code>MANPATH</code> search path. Manual pages are displayed in the order found.</p> <p>-d                   Debugs. Displays what a section-specifier evaluates to, method used for searching, and paths searched by <b>man</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f <i>file</i> ...    | man attempts to locate manual pages related to any of the given <i>files</i> . It strips the leading path name components from each <i>file</i> , and then prints one-line summaries containing the resulting basename or names. This option also uses the <code>windex</code> database.                                                                                                                                                                                                                                                                                                                                                                              |
| -F                    | Forces man to search all directories specified by <code>MANPATH</code> or the <code>man.cf</code> file, rather than using the <code>windex</code> lookup database. This is useful if the database is not up to date. If the <code>windex</code> database does not exist, this option is assumed.                                                                                                                                                                                                                                                                                                                                                                      |
| -k <i>keyword</i> ... | Prints out one-line summaries from the <code>windex</code> database (table of contents) that contain any of the given <i>keywords</i> . The <code>windex</code> database is created using <code>catman(1M)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -l                    | Lists all manual pages found matching <i>name</i> within the search path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -M <i>path</i>        | Specifies an alternate search path for manual pages. <i>path</i> is a colon-separated list of directories that contain manual page directory subtrees. For example, if <i>path</i> is <code>/usr/share/man:/usr/local/man</code> , man searches for <i>name</i> in the standard location, and then <code>/usr/local/man</code> . When used with the <code>-k</code> or <code>-f</code> options, the <code>-M</code> option must appear first. Each directory in the <i>path</i> is assumed to contain subdirectories of the form <code>man*</code> or <code>sman*</code> , one for each section. This option overrides the <code>MANPATH</code> environment variable. |
| -r                    | Reformats the manual page, but does not display it. This replaces the <code>man -t <i>name</i></code> combination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -s <i>section</i> ... | Specifies sections of the manual for man to search. The directories searched for <i>name</i> are limited to those specified by <i>section</i> . <i>section</i> can be a digit (perhaps followed by one or more letters), a word (for example: <code>local</code> , <code>new</code> , <code>old</code> , <code>public</code> ), or a letter. To specify multiple sections, separate each section with a comma. This option overrides the <code>MANPATH</code> environment variable and the <code>man.cf</code>                                                                                                                                                        |

file. See `Search Path` below for an explanation of how `man` conducts its search.

`-t` `man` arranges for the specified manual pages to be troffed to a suitable raster output device (see `troff(1)`). If both the `-` and `-t` flags are given, `man` updates the troffed versions of each named *name* (if necessary), but does not display them.

`-T macro-package` Formats manual pages using *macro-package* rather than the standard `-man` macros defined in `/usr/share/lib/tmac/an`. See `Search Path` under `USAGE` for a complete explanation of the default search path order.

**OPERANDS**

The following operand is supported:

*name*                    A keyword or the name of a standard utility.

**USAGE****Manual Page Sections**

Entries in the reference manuals are organized into *sections*. A section name consists of a major section name, typically a single digit, optionally followed by a subsection name, typically one or more letters. An unadorned major section name acts as an abbreviation for the section of the same name along with all of its subsections. Each section contains descriptions apropos to a particular reference category, with subsections refining these distinctions. See the `intro` manual pages for an explanation of the classification used in this release.

**Search Path**

Before searching for a given *name*, `man` constructs a list of candidate directories and sections. `man` searches for *name* in the directories specified by the `MANPATH` environment variable. If this variable is not set, `/usr/share/man` is searched by default.

Within the manual page directories, `man` confines its search to the sections specified in the following order:

- *sections* specified on the command line with the `-s` option
- *sections* embedded in the `MANPATH` environment variable
- *sections* specified in the `man.cf` file for each directory specified in the `MANPATH` environment variable

If none of the above exist, `man` searches each directory in the manual page path, and displays the first matching manual page found.

The `man.cf` file has the following format:

MANSECTS=*section*[,*section*]...

Lines beginning with '#' and blank lines are considered comments, and are ignored. Each directory specified in MANPATH can contain a manual page configuration file, specifying the default search order for that directory.

### Formatting Manual Pages

Manual pages are marked up in `nroff(1)` or `sgml(5)`. Nroff manual pages are processed by `nroff(1)` or `troff(1)` with the `-man` macro package. Please refer to `man(5)` for information on macro usage. SGML—tagged manual pages are processed by an SGML parser and passed to the formatter.

### Preprocessing Nroff Manual Pages

When formatting an nroff manual page, `man` examines the first line to determine whether it requires special processing. If the first line is a string of the form:

```
' \ " X
```

where `X` is separated from the `'` by a single SPACE and consists of any combination of characters in the following list, `man` pipes its input to `troff(1)` or `nroff(1)` through the corresponding preprocessors.

```
e eqn(1), or neqn for nroff
r refer(1)
t tbl(1)
v vgrind(1)
```

If `eqn` or `neqn` is invoked, it will automatically read the file `/usr/pub/eqnchar` (see `eqnchar(5)`). If `nroff(1)` is invoked, `col(1)` is automatically used.

### Referring to Other Nroff Manual Pages

If the first line of the nroff manual page is a reference to another manual page entry fitting the pattern:

```
.so man*/sourcefile
```

`man` processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.

When the second or any subsequent line starts with `.so`, `man` ignores it; `troff(1)` or `nroff(1)` processes the request in the usual manner.

### Processing SGML Manual Pages

Manual pages are identified as being marked up in SGML by the presence of the string `<!DOCTYPE`. If the file also contains the string `SHADOW_PAGE`, the file refers to another manual page for the content. The reference is made with a file

entity reference to the manual page that contains the text. This is similar to the `.so` mechanism used in the `nroff` formatted man pages.

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `man`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`MANPATH` A colon-separated list of directories; each directory can be followed by a comma-separated list of sections. If set, its value overrides `/usr/share/man` as the default directory search path, and the `man.cf` file as the default section search path. The `-M` and `-s` flags, in turn, override these values.)

`PAGER` A program to use for interactively delivering `man`'s output to the screen. If not set, `'more -s'` is used. See `more(1)`.

`TCAT` The name of the program to use to display `troffed` manual pages.

`TROFF` The name of the formatter to use when the `-t` flag is given. If not set, `troff(1)` is used.

## EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

## FILES

`/usr/share/man`  
root of the standard manual page directory subtree

`/usr/share/man/man?/*`  
unformatted `nroff` manual entries

`/usr/share/man/sman?/*`  
unformatted SGML manual entries

`/usr/share/man/cat?/*`  
`nroffed` manual entries

`/usr/share/man/fmt?/*`  
`troffed` manual entries

`/usr/share/man/windex`  
table of contents and keyword database

`/usr/share/lib/tmac/an`  
standard `-man` macro package

`/usr/share/lib/sgml/locale/C/dtd/*`  
SGML document type definition files

`/usr/share/lib/sgml/locale/C/solbook/*`

SGML style sheet and entity definitions directories

/usr/share/lib/pub/eqnchar  
standard definitions for eqn and neqn

man.cf  
default search order by section

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE     |
|----------------|---------------------|
| Availability   | SUNWdoc             |
| CSI            | Enabled (see NOTES) |

**SEE ALSO**

apropos(1), cat(1), col(1), eqn(1), more(1), nroff(1), refer(1), tbl(1), troff(1), vgrind(1), whatis(1), catman(1M), attributes(5), environ(5), eqnchar(5), man(5), sgml(5)

**NOTES**

The -f and -k options use the windex database, which is created by catman(1M).

The man command is CSI-capable. However, some utilities invoked by the man command, namely, troff, eqn, neqn, refer, tbl, and vgrind, are not verified to be CSI-capable. Because of this, the man command with the -t option may not handle non-EUC data. Also, using the man command to display man pages that require special processing through eqn, neqn, refer, tbl, or vgrind may not be CSI-capable.

**BUGS**

The manual is supposed to be reproducible either on a phototypesetter or on an ASCII terminal. However, on a terminal some information (indicated by font changes, for instance) is lost.

Some dumb terminals cannot process the vertical motions produced by the e (see eqn(1)) preprocessing flag. To prevent garbled output on these terminals, when you use e, also use t, to invoke col(1) implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts, even on those terminals that can display them. Control-q will clear a terminal that gets confused by eqn(1) output.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | mconnect – connect to SMTP mail server socket                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>mconnect</b> [-p <i>port</i> ] [-r] [ <i>hostname</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | The <code>mconnect</code> utility opens a connection to the mail server on a given host, so that it can be tested independently of all other mail software. If no host is given, the connection is made to the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this connection. Exit by typing the <code>quit</code> command. Typing <code>EOF</code> sends an end of file to the server. An interrupt closes the connection immediately and exits. |
| <b>OPTIONS</b>     | The following options are supported:<br>-p <i>port</i> Specify the port number instead of the default SMTP port (number 25) as the next argument.<br>-r                   "Raw" mode: disable the default line buffering and input handling. This produces an effect similar to <code>telnet(1)</code> to port number 25.                                                                                                                                                           |
| <b>OPERANDS</b>    | The following operand is supported:<br><i>hostname</i> The name of a given host.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>USAGE</b>       | The <code>mconnect</code> command is IPv6-enabled. See <code>ip6(7P)</code> .                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>FILES</b>       | <code>/etc/mail/sendmail.hf</code> help file for SMTP commands                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | mcs – manipulate the comment section of an object file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>mcs</b> {-c   -d   -p   -v   -a <i>string</i>   -n <i>name</i> }... <i>file</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>mcs</code> command is used to manipulate a section, by default the <code>.comment</code> section, in an ELF object file. It is used to add to, delete, print, and compress the contents of a section in an ELF object file, and print only the contents of a section in a COFF object file. <code>mcs</code> cannot add, delete or compress the contents of a section that is contained within a segment.</p> <p>If the input file is an archive (see <code>ar(3HEAD)</code>), the archive is treated as a set of individual files. For example, if the <code>-a</code> option is specified, the string is appended to the comment section of each ELF object file in the archive; if the archive member is not an ELF object file, then it is left unchanged.</p> <p><code>mcs</code> must be given one or more of the options described below. It applies, in order, each of the specified options to each file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p><code>-a <i>string</i></code>      Append <i>string</i> to the comment section of the ELF object files. If <i>string</i> contains embedded blanks, it must be enclosed in quotation marks.</p> <p><code>-c</code>                Compress the contents of the comment section of the ELF object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.</p> <p><code>-d</code>                Delete the contents of the comment section from the ELF object files. The section header for the comment section is also removed.</p> <p><code>-n <i>name</i></code>        Specify the name of the comment section to access if other than <code>.comment</code>. By default, <code>mcs</code> deals with the section named <code>.comment</code>. This option can be used to specify another section. <code>mcs</code> can take multiple <code>-n</code> options to allow for specification of multiple section comments.</p> <p><code>-p</code>                Print the contents of the comment section on the standard output. Each section printed is tagged by the name of the file from which it was extracted, using the format <code>file[<i>member_name</i>]:</code> for archive files and <code>file:</code> for other files.</p> <p><code>-v</code>                Print on standard error the version number of <code>mcs</code>.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b>    Printing a file's comment section</p> <p>The following entry</p> <pre>example% mcs -p elf.file</pre> <p>prints the comment section of the file <code>elf.file</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**EXAMPLE 2** Appending a string to a comment section

The following entry

```
example% mcs -a xyz elf.file
```

appends string `xyz` to `elf.file`'s comment section.

**FILES**

`/tmp/mcs*` temporary files

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**SEE ALSO**

`ar(1)`, `as(1)`, `ld(1)`, `elf(3ELF)`, `tmpnam(3C)`, `a.out(4)`, `ar(3HEAD)`, `attributes(5)`

**NOTES**

When `mcs` deletes a section using the `-d` option, it tries to bind together sections of type `SHT_REL` and target sections pointed to by the `sh_info` section header field. If one is to be deleted, `mcs` attempts to delete the other of the pair.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>SYNOPSIS</b>     | <code>mdb</code> [-kmuwyAFMS] [ $\pm o$ option] [-p pid] [-s distance] [-I path] [-L path] [-P prompt] [-R root] [-V dis-version] [object [core] core   suffix ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Introduction</b> | <p>The <code>mdb</code> utility is an extensible utility for low-level debugging and editing of the live operating system, operating system crash dumps, user processes, user process core dumps, and object files. For a more detailed description of <code>mdb</code> features, refer to the manual, <i>Solaris Modular Debugger Guide</i>.</p> <p>Debugging is the process of analyzing the execution and state of a software program in order to remove defects. Traditional debugging tools provide facilities for execution control so that programmers can re-execute programs in a controlled environment and display the current state of program data or evaluate expressions in the source language used to develop the program.</p> <p>Unfortunately, these techniques are often inappropriate for debugging complex software systems such as an operating system, where bugs may not be reproducible and program state is massive and distributed, for programs that are highly optimized, have had their debug information removed, or are themselves low-level debugging tools, or for customer situations where the developer can only access post-mortem information.</p> <p><code>mdb</code> provides a completely customizable environment for debugging these programs and scenarios, including a dynamic module facility that programmers can use to implement their own debugging commands to perform program-specific analysis. Each <code>mdb</code> module can be used to examine the program in several different contexts, including live and post-mortem.</p> |
| <b>Definitions</b>  | <p>The <i>target</i> is the program being inspected by the debugger. <code>mdb</code> currently provides support for the following types of targets: user processes, user process core files, the live operating system (via <code>/dev/kmem</code> and <code>/dev/ksyms</code>), operating system crash dumps, user process images recorded inside an operating system crash dump, and ELF object files. Each target exports a standard set of properties, including one or more address spaces, one or more symbol tables, a set of load objects, and a set of threads that can be examined using the debugger commands described below.</p> <p>A debugger command, or <i>dcmd</i> (pronounced dee-command) in <code>mdb</code> terminology, is a routine in the debugger that can access any of the properties of the current target. <code>mdb</code> parses commands from standard input, and then executes the corresponding <i>dcmds</i>. Each <i>dcmd</i> can also accept a list of string or numerical arguments, as shown in the syntax description below. <code>mdb</code> contains a set of built-in <i>dcmds</i>, described below, that are always available. You can also extend</p>                                                                                                                                                                                                                                                                                                                                                                                        |

the capabilities of `mdb` itself by writing your own `dcmds`, as described in the *Solaris Modular Debugger Guide*.

A *walker* is a set of routines that describe how to walk, or iterate, through the elements of a particular program data structure. A walker encapsulates the data structure's implementation from `dcmds` and from `mdb` itself. You can use walkers interactively, or use them as a primitive to build other `dcmds` or walkers. As with `dcmds`, you can extend `mdb` by implementing your own walkers as part of a debugger module.

A debugger module, or *dmod* (pronounced dee-mod), is a dynamically loaded library containing a set of `dcmds` and walkers. During initialization, `mdb` will attempt to load `dmods` corresponding to the load objects present in the target. You can subsequently load or unload `dmods` at any time while running `mdb`. `mdb` ships with a set of standard `dmods` for debugging the Solaris kernel. The *Solaris Modular Debugger Guide* contains more information on developing your own debugger modules.

A *macro file* is a text file containing a set of commands to execute. Macro files are typically used to automate the process of displaying a simple data structure. `mdb` provides complete backward compatibility for the execution of macro files written for `adb(1)`, and the Solaris installation includes a set of macro files for debugging the Solaris kernel that may be used with either tool.

#### Syntax

The debugger processes commands from standard input. If standard input is a terminal, `mdb` provides terminal editing capabilities. `mdb` can also process commands from macro files and from `dcmd` pipelines, described below. The language syntax is designed around the concept of computing the value of an expression (typically a memory address in the target), and then applying a `dcmd` to that address. The current address location is referred to as *dot*, and its value is referenced using `."`.

A *metacharacter* is one of the following characters:

```
[] | ! / \ ? = > $: ; NEWLINE SPACE TAB
```

A *blank* is a `TAB` or a `SPACE`. A *word* is a sequence of characters separated by one or more non-quoted metacharacters. Some of the metacharacters only function as delimiters in certain contexts, as described below. An *identifier* is a sequence of letters, digits, underscores, periods, or backquotes beginning with a letter, underscore, or period. Identifiers are used as the names of symbols, variables, `dcmds`, and walkers. Commands are delimited by a `NEWLINE` or semicolon (`;`).

A *dcmd* is denoted by one of the following words or metacharacters:

```
/ \ ? = > $character :character ::identifier
```

*dcmds* named by metacharacters or prefixed by a single `$` or `:` are provided as builtin operators, and implement complete compatibility with the command set of the legacy `adb(1)` utility. Once a *dcmd* has been parsed, the `/`, `\`, `?`, `=`, `>`, `$`, and `:` characters are no longer recognized as metacharacters until the termination of the argument list.

A *simple-command* is a *dcmd* followed by a sequence or zero or more blank-separated words. The words are passed as arguments to the invoked *dcmd*, except as specified under `Quoting` and `Arithmetic Expansion` below. Each *dcmd* returns an exit status that indicates it was either successful, failed, or was invoked with invalid arguments.

A *pipeline* is a sequence of one or more simple commands separated by `|`. Unlike the shell, *dcmds* in `mdb` pipelines are not executed as separate processes. After the pipeline has been parsed, each *dcmd* is invoked in order from left to right. Each *dcmd*'s output is processed and stored as described under `dcmd Pipelines` below. Once the left-hand *dcmd* is complete, its processed output is used as input for the next *dcmd* in the pipeline. If any *dcmd* does not return a successful exit status, the pipeline is aborted.

An *expression* is a sequence of words that is evaluated to compute a 64-bit unsigned integer value. The words are evaluated using the rules described under `Arithmetic Expansion` below.

## Commands

A *command* is one of the following:

```
pipeline [! word...] [;]
```

A simple-command or pipeline can be optionally suffixed with the `!` character, indicating that the debugger should open a `pipe(2)` and send the standard output of the last *dcmd* in the `mdb` pipeline to an external process created by executing `$SHELL -c` followed by the string formed by concatenating the words after the `!` character. For more details, refer to `Shell Escapes` below.

```
expression pipeline [! word...] [;]
```

A simple-command or pipeline can be prefixed with an expression. Before execution of the pipeline, the value of `dot` (the variable denoted by `."`) is set to the value of the expression.

```
expression , expression pipeline [! word...] [;]
```

A simple-command or pipeline can be prefixed with two expressions. The first is evaluated to determine the new value of dot, and the second is evaluated to determine a repeat count for the first dcmd in the pipeline. This dcmd will be executed *count* times before the next dcmd in the pipeline is executed. The repeat count only applies to the first dcmd in the pipeline.

, *expression pipeline* [! *word ...*] [ ; ]

If the initial expression is omitted, dot is not modified but the first dcmd in the pipeline will be repeated according to the value of the expression.

*expression* [! *word ...*] [ ; ]

A command can consist only of an arithmetic expression. The expression is evaluated and the dot variable is set to its value, and then the previous dcmd and arguments are executed using the new value of dot.

*expression, expression* [! *word ...*] [ ; ]

A command can consist only of a dot expression and repeat count expression. After dot is set to the value of the first expression, the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the second expression.

, *expression* [! *word ...*] [ ; ]

If the initial expression is omitted, dot is not modified but the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the count expression.

! *word ...* [ ; ]

If the command begins with the ! character, no dcmds are executed and the debugger simply executes `$SHELL -c` followed by the string formed by concatenating the words after the ! character.

#### Comments

A word beginning with // causes that word and all the subsequent characters up to a NEWLINE to be ignored.

#### Arithmetic Expansion

Arithmetic expansion is performed when an mdb command is preceded by an optional expression representing a start address, or a start address and a repeat count. Arithmetic expansion can also be performed to compute a numerical argument for a dcmd. An arithmetic expression can appear in an argument list enclosed in square brackets preceded by a dollar sign (`[$[ expression ]`), and will be replaced by the value of the expression.

Expressions may contain any of the following special words:

*integer*

The specified integer value. Integer values may be prefixed with `0i` or `0I` to indicate binary values, `0o` or `0O` to indicate octal values, `0t` or `0T` to indicate decimal values, and `0x` or `0X` to indicate hexadecimal values (the default).

|                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0[rT][0-9]+.[0-9]+                                                                                                                                                                                      | The specified decimal floating point value, converted to its IEEE double-precision floating point representation.                                                                                                                                                             |
| 'cccccccc'                                                                                                                                                                                              | The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte. |
| <identifier                                                                                                                                                                                             | The value of the variable named by <i>identifier</i> .                                                                                                                                                                                                                        |
| identifier                                                                                                                                                                                              | The value of the symbol named by <i>identifier</i> .                                                                                                                                                                                                                          |
| (expression)                                                                                                                                                                                            | The value of <i>expression</i> .                                                                                                                                                                                                                                              |
| .                                                                                                                                                                                                       | The value of dot.                                                                                                                                                                                                                                                             |
| &                                                                                                                                                                                                       | The most recent value of dot used to execute a dcmd.                                                                                                                                                                                                                          |
| +                                                                                                                                                                                                       | The value of dot incremented by the current increment.                                                                                                                                                                                                                        |
| ^                                                                                                                                                                                                       | The value of dot decremented by the current increment.                                                                                                                                                                                                                        |
| The increment is a global variable that stores the total bytes read by the last formatting dcmd. For more information on the increment, refer to the discussion of <code>Formatting dcmds</code> below. |                                                                                                                                                                                                                                                                               |
| Unary operators are right associative and have higher precedence than binary operators. The unary operators are:                                                                                        |                                                                                                                                                                                                                                                                               |
| #expression                                                                                                                                                                                             | Logical negation.                                                                                                                                                                                                                                                             |
| ~expression                                                                                                                                                                                             | Bitwise complement.                                                                                                                                                                                                                                                           |
| -expression                                                                                                                                                                                             | Integer negation.                                                                                                                                                                                                                                                             |
| %expression                                                                                                                                                                                             | The value of a pointer-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.                                                                                                                   |
| %/[csil]/expression                                                                                                                                                                                     | The value of a char, short, int, or long-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.                                                                                                 |
| %/[1248]/expression                                                                                                                                                                                     | The value of a one, two, four, or eight-byte quantity at the object file location corresponding                                                                                                                                                                               |

|                                      | to virtual address <i>expression</i> in the target's virtual address space.                                                         |
| * <i>expression</i>                  | The value of a pointer-sized quantity at virtual address <i>expression</i> in the target's virtual address space.                   |
| */[ <i>csil</i> ]/ <i>expression</i> | The value of a char, short, int, or long-sized quantity at virtual address <i>expression</i> in the target's virtual address space. |
| */[1248]/ <i>expression</i>          | The value of a one, two, four, or eight-byte quantity at virtual address <i>expression</i> in the target's virtual address space.   |

Binary operators are left associative and have lower precedence than unary operators. The binary operators, in order of precedence from highest to lowest, are:

|    |                                                                |
|----|----------------------------------------------------------------|
| *  | Integer multiplication.                                        |
| %  | Integer division.                                              |
| #  | Left-hand side rounded up to next multiple of right-hand side. |
| +  | Integer addition.                                              |
| -  | Integer subtraction.                                           |
| << | Bitwise shift left.                                            |
| >> | Bitwise shift right.                                           |
| == | Logical equality.                                              |
| != | Logical inequality.                                            |
| &  | Bitwise AND.                                                   |
| ^  | Bitwise exclusive OR.                                          |
|    | Bitwise inclusive OR.                                          |

#### Quoting

Each metacharacter described above (see *Syntax*) terminates a word unless quoted. Characters can be quoted (forcing `mdb` to interpret each character as itself without any special significance) by enclosing them in a pair of single (') or double (") quote marks. A single quote cannot appear within single quotes. Inside double quotes, `mdb` recognizes the C programming language character escape sequences.

#### Shell Escapes

The `!` character can be used to create a pipeline between an `mdb` command and the user's shell. If the `$SHELL` environment variable is set, `mdb` will fork and exec this program for shell escapes; otherwise `/bin/sh` is used. The shell is

**Variables**

invoked with the `-c` option followed by a string formed by concatenating the words after the `!` character. The `!` character takes precedence over all other metacharacters, except semicolon (`;`) and `NEWLINE`. Once a shell escape is detected, the remaining characters up to the next semicolon or `NEWLINE` are passed as is to the shell. The output of shell commands may not be piped to `mdb` dcmds. Commands executed by a shell escape have their output sent directly to the terminal, not to `mdb`.

A *variable* is a variable name, a corresponding integer value, and a set of attributes. A variable name is a sequence of letters, digits, underscores, or periods. A variable can be assigned a value using the `> dcmd` or `::typeset dcmd`, and its attributes can be manipulated using the `::typeset dcmd`. Each variable's value is represented as a 64-bit unsigned integer. A variable may have one or more of the following attributes: read-only (cannot be modified by the user), persistent (cannot be unset by the user), and tagged (user-defined indicator).

The following variables are defined as persistent:

- 0 The most recent value printed using the `/`, `\`, `?`, or `=` dcmd.
- 9 The most recent count used with the `$<` dcmd.
- b The virtual address of the base of the data section.
- d The size of the data section in bytes.
- e The virtual address of the entry point.
- m The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet.
- t The size of the text section in bytes.

In addition, the `mdb` kernel and process targets will export the current values of the representative thread's register set as named variables. The names of these variables will depend on the target's platform and instruction set architecture.

**Symbol Name Resolution**

As explained in the `Syntax` description above, a symbol identifier present in an expression context evaluates to the value of this symbol. The value typically denotes the virtual address of the storage associated with the symbol in the target's virtual address space. A target may support multiple symbol tables including, but not limited to, a primary executable symbol table, a primary dynamic symbol table, a run-time link-editor symbol table, and standard and dynamic symbol tables for each of a number of load objects (such as shared libraries in a user process, or kernel modules in the Solaris kernel). The target typically searches the primary executable's symbol tables first, and then one or more of the other symbol tables. Notice that ELF symbol tables only contain

entries for external, global, and static symbols; automatic symbols do not appear in the symbol tables processed by `mdb`.

Additionally, `mdb` provides a private user-defined symbol table that is searched prior to any of the target symbol tables. The private symbol table is initially empty, and can be manipulated using the `::nmadd` and `::nmdelete` commands. The `::nm -P` option can be used to display the contents of the private symbol table. The private symbol table allows the user to create symbol definitions for program functions or data that were either missing from the original program or stripped out. These definitions are then used whenever `mdb` converts a symbolic name to an address, or an address to the nearest symbol.

As targets contain multiple symbol tables, and each symbol table may include symbols from multiple object files, different symbols with the same name may exist. `mdb` uses the backquote ( ``` ) character as a symbol name scoping operator to allow the programmer to obtain the value of the desired symbol in this situation. The programmer can specify the scope used to resolve a symbol name as either: *object`name*, or *file`name*, or *object`file`name*. The object identifier refers to the name of a load object. The file identifier refers to the basename of a source file that has a symbol of type `STT_FILE` in the specified object's symbol table. The object identifier's interpretation depends on the target type.

The `mdb` kernel target expects *object* to specify the basename of a loaded kernel module. For example, the symbol name:

```
specfs`_init
```

evaluates to the value of the `_init` symbol in the `specfs` kernel module.

The `mdb` process target expects *object* to specify the name of the executable or of a loaded shared library. It may take any of the following forms:

1. An exact match (that is, a full pathname): `/usr/lib/libc.so.1`
2. An exact basename match: `libc.so.1`
3. An initial basename match up to a `."` suffix: `libc.so` or `libc`
4. The literal string `a.out` is accepted as an alias for the executable.

In the case of a naming conflict between symbols and hexadecimal integer values, `mdb` will attempt to evaluate an ambiguous token as a symbol first, before evaluating it as an integer value. For example, the token `f` may either refer to the decimal integer value 15 specified in hexadecimal (the default base), or to a global variable named `f` in the target's symbol table. If a symbol with an ambiguous name is present, the integer value can be specified by using an explicit `0x` or `0X` prefix.

**dcmd and Walker  
Name Resolution**

As described earlier, each `mdb` `dmod` provides a set of `dcmds` and `walkers`. `dcmds` and `walkers` are tracked in two distinct, global namespaces. `mdb` also keeps track of a `dcmd` and `walker` namespace associated with each `dmod`. Identically named `dcmds` or `walkers` within a given `dmod` are not allowed: a `dmod` with this type of naming conflict will fail to load. Name conflicts between `dcmds` or `walkers` from different `dmods` are allowed in the global namespace. In the case of a conflict, the first `dcmd` or `walker` with that particular name to be loaded is given precedence in the global namespace. Alternate definitions are kept in a list in load order. The backquote character (```) may be used in a `dcmd` or `walker` name as a scoping operator to select an alternate definition. For example, if `dmods` `m1` and `m2` each provide a `dcmd` `d`, and `m1` is loaded prior to `m2`, then:

```

: :d Executes m1's definition of d.
: :m1 `d Executes m1's definition of d.
: :m2 `d Executes m2's definition of d.

```

If module `m1` were now unloaded, the next `dcmd` on the global definition list (`m2 `d`) would be promoted to global visibility. The current definition of a `dcmd` or `walker` can be determined using the `::which` `dcmd`, described below. The global definition list can be displayed using the `::which -v` option.

**dcmd Pipelines**

`dcmds` can be composed into a pipeline using the `|` operator. The purpose of a pipeline is to pass a list of values, typically virtual addresses, from one `dcmd` or `walker` to another. Pipeline stages might be used to map a pointer from one type of data structure to a pointer to a corresponding data structure, to sort a list of addresses, or to select the addresses of structures with certain properties.

`mdb` executes each `dcmd` in the pipeline in order from left to right. The leftmost `dcmd` is executed using the current value of `dot`, or using the value specified by an explicit expression at the start of the command. When a `|` operator is encountered, `mdb` creates a pipe (a shared buffer) between the output of the `dcmd` to its left and the `mdb` parser, and an empty list of values. As the `dcmd` executes, its standard output is placed in the pipe and then consumed and evaluated by the parser, as if `mdb` were reading this data from standard input. Each line must consist of an arithmetic expression terminated by a `NEWLINE` or semicolon (`;`). The value of the expression is appended to the list of values associated with the pipe. If a syntax error is detected, the pipeline is aborted.

When the `dcmd` to the left of a `|` operator completes, the list of values associated with the pipe is then used to invoke the `dcmd` to the right of the `|` operator. For each value in the list, `dot` is set to this value and the right-hand `dcmd` is executed. Only the rightmost `dcmd` in the pipeline has its output printed to standard output. If any `dcmd` in the pipeline produces output to standard error,

these messages are printed directly to standard error and are not processed as part of the pipeline.

### Signal Handling

The debugger ignores the `PIPE` and `QUIT` signals. The `INT` signal aborts the command that is currently executing. The debugger intercepts and provides special handling for the `ILL`, `TRAP`, `EMT`, `FPE`, `BUS`, and `SEGV` signals. If any of these signals are generated asynchronously (that is, delivered from another process using `kill(2)`), `mdb` will restore the signal to its default disposition and dump core. However, if any of these signals are generated synchronously by the debugger process itself and a `dcmd` from an externally loaded `dmod` is currently executing, and standard input is a terminal, `mdb` will provide a menu of choices allowing the user to force a core dump, quit without producing a core dump, stop for attach by a debugger, or attempt to resume. The resume option will abort all active commands and unload the `dmod` whose `dcmd` was active at the time the fault occurred. It can then be subsequently re-loaded by the user. The resume option provides limited protection against buggy `dcmds`. Refer to `WARNINGS`, `Use of the Error Recovery Mechanism`, below for information about the risks associated with the resume option.

### Command Re-entry

The text of the last `HISTSIZE` (default 128) commands entered from a terminal device are saved in memory. The in-line editing facility, described next, provides key mappings for searching and fetching elements from the history list.

### In-line Editing

If standard input is a terminal device, `mdb` provides some simple emacs-style facilities for editing the command line. The `search`, `previous`, and `next` commands in edit mode provide access to the history list. Only strings, not patterns, are matched when searching. In the table below, the notation for control characters is caret (^) followed by a character shown in upper case. The notation for escape sequences is `M-` followed by a character. For example, `M-f` (pronounced meta-eff) is entered by depressing `ESC` followed by `'f'`, or by depressing `Meta` followed by `'f'` on keyboards that support a `Meta` key. A command line is committed and executed using `RETURN` or `NEWLINE`. The edit commands are:

|                  |                                            |
|------------------|--------------------------------------------|
| <code>^F</code>  | Move cursor forward (right) one character. |
| <code>M-f</code> | Move cursor forward one word.              |
| <code>^B</code>  | Move cursor backward (left) one character. |
| <code>M-b</code> | Move cursor backward one word.             |
| <code>^A</code>  | Move cursor to start of line.              |
| <code>^E</code>  | Move cursor to end of line.                |

|                         |                                                                                                                                                                                                                                                         |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>^D</code>         | Delete current character, if the current line is not empty. If the current line is empty, <code>^D</code> denotes EOF and the debugger will exit.                                                                                                       |
| <code>^K</code>         | Delete from the cursor to the end of the line.                                                                                                                                                                                                          |
| <code>^L</code>         | Reprint the current line.                                                                                                                                                                                                                               |
| <code>^T</code>         | Transpose current character with next character.                                                                                                                                                                                                        |
| <code>^N</code>         | Fetch the next command from the history. Each time <code>^N</code> is entered, the next command forward in time is retrieved.                                                                                                                           |
| <code>^P</code>         | Fetch the previous command from the history. Each time <code>^P</code> is entered, the next command backward in time is retrieved.                                                                                                                      |
| <code>^R[string]</code> | Search backward in the history for a previous command line containing <i>string</i> . The string should be terminated by a RETURN or NEWLINE. If <i>string</i> is omitted, the previous history element containing the most recent string is retrieved. |

The editing mode also interprets the following user-defined sequences as editing commands. User defined sequences can be read or modified using the `stty(1)` command.

|                      |                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------|
| <code>erase</code>   | User defined erase character (usually <code>^H</code> or <code>^?</code> ). Delete previous character.         |
| <code>intr</code>    | User defined interrupt character (usually <code>^C</code> ). Abort the current command and print a new prompt. |
| <code>kill</code>    | User defined kill character (usually <code>^U</code> ). Kill the entire current command line.                  |
| <code>quit</code>    | User defined quit character (usually <code>^\</code> ). Quit the debugger.                                     |
| <code>suspend</code> | User defined suspend character (usually <code>^Z</code> ). Suspend the debugger.                               |

On keyboards that support an extended keypad with arrow keys, `mdb` will interpret these keystrokes as editing commands:

|                          |                                                                         |
|--------------------------|-------------------------------------------------------------------------|
| <code>up-arrow</code>    | Fetch the previous command from the history (same as <code>^P</code> ). |
| <code>down-arrow</code>  | Fetch the next command from the history (same as <code>^N</code> ).     |
| <code>left-arrow</code>  | Move cursor backward one character (same as <code>^B</code> ).          |
| <code>right-arrow</code> | Move cursor forward one character (same as <code>^F</code> ).           |

**Output Pager**

mdb provides a built-in output pager. The output pager is enabled if the debugger's standard output is a terminal device. Each time a command is executed, mdb will pause after one screenful of output is produced and will display a pager prompt:

```
>> More [<space>, <cr>, q, n, c, a] ?
```

The following key sequences are recognized by the pager:

|                       |                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------|
| SPACE                 | Display the next screenful of output.                                                                         |
| a, A                  | Abort the current top-level command and return to the prompt.                                                 |
| c, C                  | Continue displaying output without pausing at each screenful until the current top-level command is complete. |
| n, N, NEWLINE, RETURN | Display the next line of output.                                                                              |
| q, Q, ^C, ^\          | Quit (abort) the current dcmd only.                                                                           |

**Formatting dcmds**

The `/`, `\`, `?`, and `=` metacharacters are used to denote the special output formatting dcmds. Each of these dcmds accepts an argument list consisting of one or more format characters, repeat counts, or quoted strings. A format character is one of the ASCII characters shown in the table below. Format characters are used to read and format data from the target. A repeat count is a positive integer preceding the format character that is always interpreted in base 10 (decimal). A repeat count may also be specified as an expression enclosed in square brackets preceded by a dollar sign (`$[ ]`). A string argument must be enclosed in double-quotes (`" "`). No blanks are necessary between format arguments.

The formatting dcmds are:

|                |                                                                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/</code> | Display data from the target's virtual address space starting at the virtual address specified by dot.                                                                     |
| <code>\</code> | Display data from the target's physical address space starting at the physical address specified by dot.                                                                   |
| <code>?</code> | Display data from the target's primary object file starting at the object file location corresponding to the virtual address specified by dot.                             |
| <code>=</code> | Display the value of dot itself in each of the specified data formats. The <code>=</code> dcmd is therefore useful for converting between bases and performing arithmetic. |

In addition to dot, mdb keeps track of another global value called the *increment*. The increment represents the distance between dot and the address following all the data read by the last formatting dcmd. For example, if a formatting dcmd is executed with dot equal to address A, and displays a 4-byte integer, then after

this `dcmd` completes, `dot` is still `A`, but the increment is set to 4. The `+` character (described under `Arithmetic Expansion` above) would now evaluate to the value `A + 4`, and could be used to reset `dot` to the address of the next data object for a subsequent `dcmd`.

Most format characters increase the value of the increment by the number of bytes corresponding to the size of the data format, shown in the table. The table of format characters can be displayed from within `mdb` using the `::formats` `dcmd`. The format characters are:

|                |                                                                              |
|----------------|------------------------------------------------------------------------------|
| <code>+</code> | increment <code>dot</code> by the count (variable size)                      |
| <code>-</code> | decrement <code>dot</code> by the count (variable size)                      |
| <code>B</code> | hexadecimal int (1 byte)                                                     |
| <code>C</code> | character using C character notation (1 byte)                                |
| <code>D</code> | decimal signed int (4 bytes)                                                 |
| <code>E</code> | decimal unsigned long long (8 bytes)                                         |
| <code>F</code> | double (8 bytes)                                                             |
| <code>G</code> | octal unsigned long long (8 bytes)                                           |
| <code>H</code> | swap bytes and shorts (4 bytes)                                              |
| <code>I</code> | address and disassembled instruction (variable size)                         |
| <code>J</code> | hexadecimal long long (8 bytes)                                              |
| <code>K</code> | hexadecimal <code>uintptr_t</code> (4 or 8 bytes)                            |
| <code>O</code> | octal unsigned int (4 bytes)                                                 |
| <code>P</code> | symbol (4 or 8 bytes)                                                        |
| <code>Q</code> | octal signed int (4 bytes)                                                   |
| <code>S</code> | string using C string notation (variable size)                               |
| <code>U</code> | decimal unsigned int (4 bytes)                                               |
| <code>V</code> | decimal unsigned int (1 byte)                                                |
| <code>W</code> | default radix unsigned int (4 bytes)                                         |
| <code>X</code> | hexadecimal int (4 bytes)                                                    |
| <code>Y</code> | decoded <code>time32_t</code> (4 bytes)                                      |
| <code>Z</code> | hexadecimal long long (8 bytes)                                              |
| <code>^</code> | decrement <code>dot</code> by <code>increment * count</code> (variable size) |
| <code>a</code> | <code>dot</code> as <code>symbol+offset</code>                               |

|   |                                          |
|---|------------------------------------------|
| b | octal unsigned int (1 byte)              |
| c | character (1 byte)                       |
| d | decimal signed short (2 bytes)           |
| e | decimal signed long long (8 bytes)       |
| f | float (4 bytes)                          |
| g | octal signed long long (8 bytes)         |
| h | swap bytes (2 bytes)                     |
| i | disassembled instruction (variable size) |
| n | newline                                  |
| o | octal unsigned short (2 bytes)           |
| p | symbol (4 or 8 bytes)                    |
| q | octal signed short (2 bytes)             |
| r | whitespace                               |
| s | raw string (variable size)               |
| t | horizontal tab                           |
| u | decimal unsigned short (2 bytes)         |
| v | decimal signed int (1 byte)              |
| w | default radix unsigned short (2 bytes)   |
| x | hexadecimal short (2 bytes)              |
| y | decoded time64_t (8 bytes)               |

The /, \, and ? formatting dcmds can also be used to write to the target's virtual address space, physical address space, or object file by specifying one of the following modifiers as the first format character, and then specifying a list of words that are either immediate values or expressions enclosed in square brackets preceded by a dollar sign (\$ [ ]).

The write modifiers are:

- v, w Write the lowest 2 bytes of the value of each expression to the target beginning at the location specified by dot.
- W Write the lowest 4 bytes of the value of each expression to the target beginning at the location specified by dot.
- Z Write the complete 8 bytes of the value of each expression to the target beginning at the location specified by dot.

The `/`, `\`, and `?` formatting dcmts can also be used to search for a particular integer value in the target's virtual address space, physical address space, and object file, respectively, by specifying one of the following modifiers as the first format character, and then specifying a value and optional mask. The value and mask are each specified as either immediate values or expressions enclosed in square brackets preceded by a dollar sign. If only a value is specified, `mdb` reads integers of the appropriate size and stops at the address containing the matching value. If a value `V` and mask `M` are specified, `mdb` reads integers of the appropriate size and stops at the address containing a value `X` where  $(X \& M) == V$ . At the completion of the dcmtd, dot is updated to the address containing the match. If no match is found, dot is left at the last address that was read.

The search modifiers are:

- `I` Search for the specified 2-byte value.
- `L` Search for the specified 4-byte value.
- `M` Search for the specified 8-byte value.

Note that for both user and kernel targets, an address space is typically composed of a set of discontinuous segments. It is not legal to read from an address that does not have a corresponding segment. If a search reaches a segment boundary without finding a match, it will abort when the read past the end of the segment boundary fails.

#### Builtin dcmts

`mdb` provides a set of builtin dcmts that are always defined. Some of these dcmts are only applicable to certain targets: if a dcmtd is not applicable to the current target, it will fail and print a message indicating "command is not supported by current target". In many cases, `mdb` provides a mnemonic equivalent (`:::identifier`) for the legacy `adb(1)` dcmtd names. For example, `:::quit` is provided as the equivalent of `$q`. Programmers who are experienced with `adb(1)` or who appreciate brevity or arcana may prefer the `$` or `:` forms of the builtins. Programmers who are new to `mdb` may prefer the more verbose `:::form`. The builtins are shown in alphabetical order. If a `$` or `:` form has a `:::identifier` equivalent, it is shown underneath the `:::identifier` form.

The builtin dcmts are:

`> variable-name`

`>/modifier/ variable-name`

Assign the value of dot to the specified named variable. Some variables are read-only and may not be modified. If the `>` is followed by a modifier character surrounded by `/ /`, then the value is modified as part of the assignment. The modifier characters are:

- `c` unsigned char quantity (1-byte)

- s        unsigned short quantity (2-byte)
- i        unsigned int quantity (4-byte)
- l        unsigned long quantity (4-byte in 32-bit, 8-byte in 64-bit)

Notice that these operators do not perform a cast; they instead fetch the specified number of low-order bytes (on little-endian architectures) or high-order bytes (big-endian architectures). Modifiers are provided for backwards compatibility; the `mdb */modifier/` and `%/modifier/` syntax should be used instead.

`$< macro-name`

Read and execute commands from the specified macro file. The filename may be given as an absolute or relative path. If the filename is a simple name (that is, if it does not contain a '/'), `mdb` will search for it in the macro file include path. If another macro file is currently being processed, this file is closed and replaced with the new file.

`$<< macro-name`

Read and execute commands from the specified macro file (as with `$<`), but do not close the current open macro file.

`$?`

Print the process-ID and current signal of the target if it is a user process or core file, and then print the general register set of the representative thread.

`[ address ] $C [ count ]`

Print a C stack backtrace, including stack frame pointer information. If the `dcmd` is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.

`[ base ] $d`

Get or set the default output radix. If the `dcmd` is preceded by an explicit expression, the default output radix is set to the given *base*; otherwise the current radix is printed in base 10 (decimal). The default radix is base 16 (hexadecimal).

`$e`

Print a list of all known external (global) symbols of type object or function, the value of the symbol, and the first 4 (32-bit `mdb`) or 8 (64-bit `mdb`) bytes stored at this location in the target's virtual address space. The `::nm dcmd` provides more flexible options for displaying symbol tables.

`$P prompt-string`

Set the prompt to the specified *prompt-string*. The default prompt is '>'. The prompt can also be set using `::set -P` or the `-P` command-line option

*distance* \$s

Get or set the symbol matching *distance* for address-to-symbol-name conversions. The symbol matching distance modes are discussed along with the `-s` command-line option under **OPTIONS**, below. The symbol matching distance may also be modified using the `::set -s` option. If no distance is specified, the current setting is displayed.

\$v

Print a list of the named variables that have non-zero values. The `::vars` dcmd provides other options for listing variables.

*width* \$w

Set the output page *width* to the specified value. Typically, this command is not necessary as `mdb` queries the terminal for its width and handles resize events.

\$W

Re-open the target for writing, as if `mdb` had been executed with the `-w` option on the command line. Write mode can also be enabled with the `::set -w` option.

[ *pid* ] ::attach [ *core* | *pid* ]

[ *pid* ] :A [ *core* | *pid* ]

If the user process target is active, attach to and debug the specified process-ID or *core* file. The core file pathname should be specified as a string argument. The process-ID may be specified as the string argument, or as the value of the expression preceding the dcmd. Recall that the default base is hexadecimal, so decimal PIDs obtained using `pgrep(1)` or `ps(1)` should be preceded with "0t" when specified as expressions.

::cat *filename* ...

Concatenate and display files. Each filename may specified as a relative or absolute pathname. The file contents will be printed to standard output, but will not be passed to the output pager. This dcmd is intended to be used with the `|` operator; the programmer can initiate a pipeline using a list of addresses stored in an external file.

*address* ::context

*address* \$p

Context switch to the specified process. A context switch operation is only valid when using the kernel target. The process context is specified using the *address* of its proc structure in the kernel's virtual address space. The special context address "0" is used to denote the context of the kernel itself. `mdb` can only perform a context switch when examining a crash dump if

the dump contains all physical memory pages (as opposed to just kernel pages). The kernel crash dump facility can be configured to dump all pages using `dumpadm(1M)`.

When the user requests a context switch from the kernel target, `mdb` constructs a new target representing the specified user process. Once the switch occurs, the new target interposes its `dcmds` at the global level: thus the `/ dcmd` will now format and display data from the virtual address space of the user process, the `::mappings dcmd` will display the mappings in the address space of the user process, and so on. The kernel target can be restored by executing `0::context`.

`::dcmds`

List the available `dcmds` and print a brief description for each one.

`[ address ] ::dis [ -fw ] [ -n count ] [ address ]`

Disassemble starting at or around the *address* specified by the final argument, or the current value of `dot`. If the address matches the start of a known function, the entire function is disassembled; otherwise a "window" of instructions before and after the specified address is printed in order to provide context. By default, instructions are read from the target's virtual address space; if the `-f` option is present, instructions are read from the target's object file instead. The `-w` option can be used to force "window"-mode, even if the address is the start of a known function. The size of the window defaults to ten instructions; the number of instructions can be specified explicitly using the `-n` option.

`::disasms`

List the available disassembler modes. When a target is initialized, `mdb` will attempt to select the appropriate disassembler mode. The user can change the mode to any of the modes listed using the `::dismode dcmd`.

`::dismode [ mode ]`

`$v [ mode ]`

Get or set the disassembler mode. If no argument is specified, print the current disassembler mode. If a *mode* argument is specified, switch the disassembler to the specified mode. The list of available disassemblers can be displayed using the `::disasms dcmd`.

`::dmods [ -l ] [ module-name ]`

List the loaded debugger modules. If the `-l` option is specified, the list of the `dcmds` and walkers associated with each `dmod` is printed below its name. The output can be restricted to a particular `dmod` by specifying its name as an additional argument.

`::dump`

Print a hexadecimal and ASCII memory dump of the 16-byte aligned region of virtual memory containing the address specified by dot. If a repeat count is specified for `::dump`, this is interpreted as a number of bytes to dump rather than a number of iterations.

`::echo [ string | value ... ]`  
 Print the arguments separated by blanks and terminated by a NEWLINE to standard output. Expressions enclosed in `$( )` will be evaluated to a value and printed in the default base.

`::eval command`  
 Evaluate and execute the specified string as a command. If the command contains metacharacters or whitespace, it should be enclosed in double or single quotes.

`::files`  
`$f`  
 Print a list of the known source files (symbols of type `STT_FILE` present in the various target symbol tables).

`::fpregs`  
`$x, $X, $y, $Y`  
 Print the floating-point register set of the representative thread.

`::formats`  
 List the available output format characters for use with the `/`, `\`, `?`, and `=` formatting dcmds. The formats and their use is described under `Formatting dcmds`, above.

`::grep command`  
 Evaluate the specified command string, and then print the old value of dot if the new value of dot is non-zero. If the *command* contains whitespace or metacharacters, it must be quoted. The `::grep` dcmd can be used in pipelines to filter a list of addresses.

`::help [ dcmd-name ]`  
 With no arguments, the `::help` dcmd prints a brief overview of the help facilities available in `mdb`. If a *dcmd-name* is specified, `mdb` will print a usage summary for that dcmd.

`::load module-name`  
 Load the specified dmod. The module name may be given as an absolute or relative path. If *module-name* is a simple name (that is, does not contain a `'/'`), `mdb` will search for it in the module library path. Modules with conflicting names may not be loaded; the existing module must be unloaded first.

`::log [ -d | [ -e ] filename ]`

\$> [ *filename* ]

Enable or disable the output log. `mdb` provides an interactive logging facility where both the input commands and standard output can be logged to a file while still interacting with the user. The `-e` option enables logging to the specified file, or re-enables logging to the previous log file if no filename is given. The `-d` option disables logging. If the `$> dcmd` is used, logging is enabled if a filename argument is specified; otherwise, logging is disabled. If the specified log file already exists, `mdb` appends any new log output to the file.

`::map command`

Map the value of `dot` to a corresponding value using the *command* specified as a string argument, and then print the new value of `dot`. If the command contains whitespace or metacharacters, it must be quoted. The `::map dcmd` can be used in pipelines to transform the list of addresses into a new list of addresses.

[ *address* ] `::mappings` [ *name* ]

[ *address* ] `$m` [ *name* ]

Print a list of each mapping in the target's virtual address space, including the address, size, and description of each mapping. If the `dcmd` is preceded by an *address*, `mdb` will only show the mapping that contains the given address. If a string *name* argument is given, `mdb` will only show the mapping matching that description.

`::nm` [ `-DPdghnopuvx` ] [ *object* ]

Print the symbol tables associated with the current target. If an *object* name argument is specified, only the symbol table for this load object is displayed. The `::nm dcmd` also recognizes the following options:

- `-D` Print `.dynsym` (dynamic symbol table) instead of `.symtab`.
- `-P` Print the private symbol table instead of `.symtab`.
- `-d` Print value and size fields in decimal.
- `-g` Print only global symbols.
- `-h` Suppress the header line.
- `-n` Sort symbols by name.
- `-o` Print value and size fields in octal.
- `-p` Print symbols as a series of `::nmadd` commands. This option can be used with `-P` to produce a macro file that can be subsequently read into the debugger with `$<`.

```

-u Print only undefined symbols.
-v Sort symbols by value.
-x Print value and size fields in hexadecimal.
value ::nmadd [-fo] [-e end] [-s size] name
Add the specified symbol name to the private symbol table. mdb provides
a private, configurable symbol table that can be used to interpose on the
target's symbol table, as described under Symbol Name Resolution above.
The ::nmadd cmd also recognizes the following options:

-e Set the size of the symbol to end - value.
-f Set the type of the symbol to STT_FUNC.
-o Set the type of the symbol to STT_OBJECT.
-s Set the size of the symbol to size.

::nmdel name
Delete the specified symbol name from the private symbol table.

::objects
Print a map of the target's virtual address space, showing only those
mappings that correspond to the primary mapping (usually the text section)
of each of the known load objects.

::quit
$g
Quit the debugger.

::regs
$r
Print the general-purpose register set of the representative thread.

::release
:R
Release the previously attached process or core file.

::set [-wF] [+/-o option] [-s distance]
[-I path] [-L path] [-P prompt]
Get or set miscellaneous debugger properties. If no options are specified,
the current set of debugger properties is displayed. The ::set cmd
recognizes the following options:

```

- F Forcibly take over the next user process that `::attach` is applied to, as if `mdb` had been executed with the `-F` option on the command line.
- I Set the default path for locating macro files. The path argument may contain any of the special tokens described for the `-I` command-line option under `OPTIONS` below.
- L Set the default path for locating debugger modules. The path argument may contain any of the special tokens described for the `-I` command-line option under `OPTIONS` below.
- o Enable the specified debugger option. If the `+o` form is used, the option is disabled. The option strings are described along with the `-o` command-line option under `OPTIONS` below.
- P Set the command prompt to the specified prompt string.
- s Set the symbol matching distance to the specified distance. Refer to the description of the `-s` command-line option under `OPTIONS` below for more information.
- w Re-open the target for writing, as if `mdb` had been executed with the `-w` option on the command line.

`[ address ] ::stack [ count ]`

`[ address ] $c [ count ]`

Print a C stack backtrace. If the `dcmd` is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.

`::status`

Print a summary of information related to the current target.

`::typeset [+/-t] variable-name ...`

Set attributes for named variables. If one or more variable names are specified, they are defined and set to the value of `.`. If the `-t` option is present, the user-defined tag associated with each variable is set. If the `+t` option is present, the tag is cleared. If no variable names are specified, the list of variables and their values is printed.

`::unload module-name`

Unload the specified `dmod`. The list of active `dmods` may be printed using the `::dmods` `dcmd`. Builtin modules may not be unloaded. Modules that are busy (that is, provide `dcmds` that are currently executing) may not be unloaded.

```

::unset variable-name ...
 Unset (remove) the specified variable(s) from the list of defined variables.
 Some variables are exported by mdb are marked as persistent, and may
 not be unset by the user.

::vars [-npt]
 Print a listing of named variables. If the -n option is present, the output is
 restricted to variables that currently have non-zero values. If the -p option
 is present, the variables are printed in a form suitable for re-processing by
 the debugger using the $< dcmd. This option can be used to record the
 variables to a macro file and then restore these values later. If the -t option
 is present, only the tagged variables are printed. Variables can be tagged
 using the -t option of the ::typeset dcmd.

::version
 Print the debugger version number.

address ::vtop
 Print the physical address mapping for the specified virtual address, if
 possible. The ::vtop dcmd is only available when examining a kernel
 target, or when examining a user process inside a kernel crash dump (after a
 ::context dcmd has been issued).

[address] ::walk walker-name [variable-name]
 Walk through the elements of a data structure using the specified walker.
 The available walkers can be listed using the ::walkers dcmd. Some
 walkers operate on a global data structure and do not require a starting
 address. For example, walk the list of proc structures in the kernel. Other
 walkers operate on a specific data structure whose address must be specified
 explicitly. For example, given a pointer to an address space, walk the list of
 segments. When used interactively, the ::walk dcmd will print the address
 of each element of the data structure in the default base. The dcmd can also
 be used to provide a list of addresses for a pipeline. The walker name may
 use the backquote (`) scoping operator described under dcmd and Walker
 Name Resolution, above. If the optional variable-name is specified, the
 specified variable will be assigned the value returned at each step of the
 walk when mdb invokes the next stage of the pipeline.

::walkers
 List the available walkers and print a brief description for each one.

::whence [-v] name ...
::which [-v] name ...
 Print the dmod that exports the specified dcmds and walkers. These dcmds
 can be used to determine which dmod is currently providing the global
 definition of the given dcmd or walker. Refer to the section on dcmd

```

and Walker Name Resolution above for more information on global name resolution. The `-v` option will cause the `dcmd` to print the alternate definitions of each `dcmd` and walker in order of precedence.

`::xdata`

List the external data buffers exported by the current target. External data buffers represent information associated with the target that can not be accessed through standard target facilities (that is, an address space, symbol table, or register set). These buffers may be consumed by `dcmds`; for more information, refer to the *Solaris Modular Debugger Guide*.

## OPTIONS

The following options are supported:

- `-A` Disables automatic loading of `mdb` modules. By default, `mdb` will attempt to load debugger modules corresponding to the active shared libraries in a user process or core file, or to the loaded kernel modules in the live operating system or an operating system crash dump.
- `-F` Forcibly takes over the specified user process, if necessary. By default, `mdb` will refuse to attach to a user process that is already under the control of another debugging tool, such as `truss(1)`. With the `-F` option, `mdb` will attach to these processes anyway. This may produce unexpected interactions between `mdb` and the other tools attempting to control the process.
- `-I` Sets default path for locating macro files. Macro files are read using the `$<` or `$<<` `dcmds`. The path is a sequence of directory names delimited by colon (`:`) characters. The `-I` include path and `-L` library path (see below) may also contain any of the following tokens:
  - `%i` Expands to the current instruction set architecture (ISA) name ('sparc', 'sparcv9', or 'i386').
  - `%o` Expands to the old value of the path being modified. This is useful for appending or prepending directories to an existing path.
  - `%p` Expands to the current platform string (either `uname -i` or the platform string stored in the process core file or crash dump).
  - `%r` Expands to the pathname of the root directory. An alternate root directory may be specified using the `-R` option. If no `-R` option is present, the root

directory is derived dynamically from the path to the `mdb` executable itself. For example, if `/bin/mdb` is executed, the root directory will be `.`. If `/net/hostname/bin/mdb` were executed, the root directory would be derived as `/net/hostname`.

`%t` Expands to the name of the current target. This will either be the literal string `'proc'` (a user process or user process core file), or `'kvm'` (a kernel crash dump or the live operating system).

The default include path for 32-bit `mdb` is:

```
%r/usr/platform/%p/lib/adb:%r/usr/lib/adb
```

The default include path for 64-bit `mdb` is:

```
%r/usr/platform/%p/lib/adb/%i:%r/usr/lib/adb/%i
```

`-k` Forces kernel debugging mode. By default, `mdb` will attempt to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The `-k` option forces `mdb` to assume these files are operating system crash dump files. If no object or core operand is specified, but the `-k` option is specified, `mdb` will default to an object file of `/dev/ksyms` and a core file of `/dev/kmem`. Access to `/dev/kmem` is restricted to group `sys`.

`-L` Sets default path for locating debugger modules. Modules are loaded automatically on startup or using the `::load` `dcmd`. The path is a sequence of directory names delimited by colon (`:`) characters. The `-L` library path may also contain any of the tokens shown for `-I` above.

`-m` Disables demand-loading of kernel module symbols. By default, `mdb` will process the list of loaded kernel modules and perform demand loading of per-module symbol tables. If the `-m` option is specified, `mdb` will not attempt to process the kernel module list or provide per-module symbol tables. As a result, `mdb` modules corresponding to active kernel modules will not be loaded on startup.

`-M` Preloads all kernel module symbols. By default, `mdb` performs demand-loading for kernel module symbols: the complete symbol table for a module is read when an address

is that module's text or data section is referenced. With the `-M` option, `mdb` will load the complete symbol table of all kernel modules during startup.

`-o option` Enables the specified debugger option. If the `+o` form of the option is used, the specified option is disabled. Unless noted below, each option is off by default. `mdb` recognizes the following option arguments:

**adb**  
Enable stricter `adb(1)` compatibility. The prompt will be set to the empty string and many `mdb` features, such as the output pager, will be disabled.

**follow\_child**  
The debugger will follow the child process if a `fork(2)` system call occurs. By default, the debugger remains attached to the original target process (the parent).

**ignoreeof**  
The debugger will not exit when an EOF sequence (`^D`) is entered at the terminal. The `::quit` cmd must be used to quit.

**pager**  
The output pager will be enabled (default).

**repeatlast**  
If a `NEWLINE` is entered as the complete command at the terminal, `mdb` will repeat the previous command with the current value of `dot`. This option is implied by `-o adb`.

`-p pid` Attach to and stop the specified process-id. `mdb` will use the `/proc/pid/object/a.out` file as the executable file pathname.

`-P` Sets the command prompt. The default prompt is `'> '`.

`-R` Sets root directory for pathname expansion. By default, the root directory is derived from the pathname of the `mdb` executable itself. The root directory is substituted in place of the `%r` token during pathname expansion.

`-s distance` Sets the symbol matching distance for address-to-symbol-name conversions to the specified *distance*. By default, `mdb` sets the distance to zero, which enables a

- smart-matching mode. Each ELF symbol table entry includes a value *V* and size *S*, representing the size of the function or data object in bytes. In smart mode, `mdb` matches an address *A* with the given symbol if *A* is in the range [ *V*, *V* + *S* ). If any non-zero distance is specified, the same algorithm is used, but *S* in the expression above is always the specified absolute distance and the symbol size is ignored.
- `-S` Suppresses processing of the user's `~/ .mdbrc` file. By default, `mdb` will read and process the macro file `.mdbrc` if one is present in the user's home directory, as defined by `$HOME`. If the `-S` option is present, this file will not be read.
  - `-u` Forces user debugging mode. By default, `mdb` will attempt to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The `-u` option forces `mdb` to assume these files are not operating system crash dump files.
  - `-V` Sets disassembler version. By default, `mdb` will attempt to infer the appropriate disassembler version for the debug target. The disassembler can be set explicitly using the `-V` option. The `::disasms dcmd` lists the available disassembler versions.
  - `-w` Opens the specified object and core files for writing.
  - `-y` Sends explicit terminal initialization sequences for tty mode. Some terminals, such as `cmdtool(1)`, require explicit initialization sequences to switch into a tty mode. Without this initialization sequence, terminal features such as standout mode may not be available to `mdb`.

**OPERANDS**

The following operands are supported:

- object* Specifies an ELF format object file to examine. `mdb` provides the ability to examine and edit ELF format executables (`ET_EXEC`), ELF dynamic library files (`ET_DYN`), ELF relocatable object files (`ET_REL`), and operating system `unix.X` symbol table files.
- core* Specifies an ELF process core file (`ET_CORE`), or an operating system crash dump `vmcore.X` file. If an ELF core file operand is provided without a corresponding object file, `mdb` will attempt to infer the name of the executable file that produced the core using several different algorithms. If no

executable is found, `mdb` will still execute, but some symbol information may be unavailable.

*suffix* Specifies the numerical suffix representing a pair of operating system crash dump files. For example, if the suffix is '3', `mdb` infers that it should examine the files 'unix.3' and 'vmcore.3'. The string of digits will not be interpreted as a suffix if an actual file of the same name is present in the current directory.

## EXIT STATUS

The following exit values are returned:

- 0 Debugger completed execution successfully.
- 1 A fatal error occurred.
- 2 Invalid command line options were specified.

## ENVIRONMENT VARIABLES

*HISTSIZE* This variable is used to determine the maximum length of the command history list. If this variable is not present, the default length is 128.

*HOME* This variable is used to determine the pathname of the user's home directory, where a `.mdbContext` file may reside. If this variable is not present, no `.mdbContext` processing will occur.

*SHELL* This variable is used to determine the pathname of the shell used to process shell escapes requested using the `!` meta-character. If this variable is not present, `/bin/sh` is used.

## FILES

`$HOME/.mdbContext`

User `mdb` initialization file. The `.mdbContext` file, if present, is processed after the debug target has been initialized, but before module auto-loading is performed or any commands have been read from standard input.

`/dev/kmem`

Kernel virtual memory image device. This device special file is used as the core file when examining the live operating system.

`/dev/ksyms`

Kernel symbol table device. This device special file is used as the object file when examining the live operating system.

`/proc/pid/*`

Process information files that are read when examining and controlling user processes.

`/usr/lib/adb`

`/usr/platform/platform-name/lib/adb`

Default directories for macro files that are read with the `$<` and `$<<` dcmts. *platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see `uname(1)`).

`/usr/lib/mdb`

`/usr/platform/platform-name/lib/mdb`

Default directories for debugger modules that are loaded using the `::load` dcmts. *platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see `uname(1)`).

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                     |

*Linker and Libraries Guide*

*Solaris Modular Debugger Guide*

**WARNINGS**

**Use of the Error Recovery Mechanism**

The debugger and its dmods execute in the same address space, and thus it is quite possible that a buggy dmod can cause `mdb` to dump core or otherwise misbehave. The `mdb` resume capability, described above under `Signal Handling`, provides a limited recovery mechanism for these situations. However, it is not possible for `mdb` to know definitively whether the dmod in question has corrupted only its own state, or the debugger's global state. Therefore a resume operation cannot be guaranteed to be safe, or to prevent a subsequent crash of the debugger. The safest course of action following a resume is to save any important debug information, and then quit and restart the debugger.

**Use of the Debugger to Modify the Live Operating System**

The use of the debugger to modify (that is, write to) the address space of live running operating system is extremely dangerous, and may result in a system panic in the event the user damages a kernel data structure.

**NOTES****Limitations on  
Examining Process  
Core Files**

`mdb` does not provide support for examining process core files that were generated by a release of Solaris preceding Solaris 2.6. If a core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) may not be able to initialize. In this case, symbol information for shared libraries will not be available. Furthermore, since shared mappings are not present in user core files, the text section and read-only data of shared libraries may not match the data that was present in the process at the time it dumped core. Core files from Solaris Intel systems may not be examined on Solaris SPARC systems, and vice-versa.

**Limitations on  
Examining Crash  
Dump Files**

Crash dumps from Solaris 7 and earlier releases may only be examined with the aid of the `libkvm` from the corresponding operating system release. If a crash dump from one operating system release is examined using the `dmods` from a different operating system release, changes in the kernel implementation may prevent some `dcmds` or `walkers` from working properly. `mdb` will issue a warning message if it detects this condition. Crash dumps from Solaris Intel systems may not be examined on Solaris SPARC systems, and vice-versa.

**Relationship Between  
32-bit and 64-bit  
Debugger**

`mdb` provides support for debugging both 32-bit and 64-bit programs. Once it has examined the target and determined its data model, `mdb` will automatically re-execute the `mdb` binary that has the same data model as the target, if necessary. This approach simplifies the task of writing debugger modules, because the modules that are loaded will use the same data model as the primary target. Only the 64-bit debugger may be used to debug 64-bit target programs. The 64-bit debugger can only be used on a system that is running the 64-bit operating environment.

**Developer  
Information**

The *Solaris Modular Debugger Guide* provides a more detailed description of `mdb` features, as well as information for debugger module developers.

**NAME** mesg - permit or deny messages

**SYNOPSIS** mesg [-n | -y | n | y]

**DESCRIPTION** The mesg utility will control whether other users are allowed to send messages via write(1), talk(1), or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, mesg reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

**OPTIONS** The following options are supported:  
-n|n Deny permission to other users to send message to the terminal. See write(1).  
-y|y Grant permission to other users to send messages to the terminal.

**ENVIRONMENT VARIABLES** See environ(5) for descriptions of the following environment variables that affect the execution of mesg: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:  
0 if messages are receivable.  
1 if messages are not receivable.  
2 on error.

**FILES** /dev/tty\* terminal devices  
/dev/pts/\* terminal devices

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** talk(1), write(1), attributes(5), environ(5)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | message – puts its arguments on FMLI message line                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>DESCRIPTION</b> | <p>The <code>message</code> command puts <i>string</i> out on the FMLI message line. If there is no <i>string</i>, the <i>stdin</i> input to <code>message</code> will be used. The output of <code>message</code> has a duration (length of time it remains on the message line). The default duration is "transient": it or one of two other durations can be requested with the mutually-exclusive options below.</p> <p>Messages displayed with <code>message -p</code> will replace (change the value of) any message currently displayed or stored via use of the <code>permanentmsg</code> descriptor. Likewise, <code>message -f</code> will replace any message currently displayed or stored via use of the <code>framemsg</code> descriptor. If more than one message in a frame definition file is specified with the <code>-p</code> option, the last one specified will be the permanent duration message.</p> <p>The <i>string</i> argument should always be the last argument.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>-t Explicitly defines a message to have transient duration. Transient messages remain on the message line only until the user presses another key or a CHECKWORLD occurs. The descriptors <code>itemmsg</code>, <code>fieldmsg</code>, <code>invalidmsg</code>, <code>choicemsg</code>, the default-if-not-defined value of <code>oninterrupt</code>, and FMLI generated error messages (that is, from syntax errors) also output transient duration messages. Transient messages take precedence over both frame messages and permanent messages.</p> <p>-f Defines a message to have "frame" duration. Frame messages remain on the message line as long as the frame in which they are defined is current. The descriptor <code>framemsg</code> also outputs a frame duration message. Frame messages take precedence over permanent messages.</p> <p>-p Defines a message to have "permanent" duration. Permanent messages remain on the message line for the length of the FMLI session, unless explicitly replaced by another permanent message or temporarily superseded by a transient message or frame message. A permanent message is not affected by navigating away from, or by closing, the frame which generated the permanent message. The descriptor <code>permanentmsg</code> also outputs a permanent duration message.</p> <p>-b[<i>num</i>] Rings the terminal bell <i>num</i> times, where <i>num</i> is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen will flash <i>num</i> times instead, if possible.</p> |

- o Forces message to duplicate its message to *stdout*.
- w Turns on the working indicator.

**EXAMPLES**

**EXAMPLE 1** A sample output of *message* on the message line:

When a value entered in a field is invalid, ring the bell 3 times and then display Invalid Entry: Try again! on the message line:

```
invalidmsg='message -b 3 "Invalid Entry: Try again!"'
```

Display a message that tells the user what is being done:

```
done='message EDITOR has been set in your environment' close
```

Display a message on the message line and *stdout* for each field in a form (a pseudo-"field duration" message).

```
fieldmsg="message -o -f "Enter a filename.""
```

Display a blank transient message (effect is to "remove" a permanent or frame duration message).

```
done='message "" nop
```

**ATTRIBUTES**

See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

*sleep(1)*, *attributes(5)*

**NOTES**

If *message* is coded more than once on a single line, it may appear that only the right-most instance is interpreted and displayed. Use *sleep(1)* between uses of *message* in this case, to display multiple messages.

*message -f* should not be used in a stand-alone backquoted expression or with the *init* descriptor because the frame is not yet current when these are evaluated.

In cases where `'message -f "string"'` is part of a stand-alone backquoted expression, the context for evaluation of the expression is the previously current frame. The previously current frame can be the frame that issued the *open* command for the frame containing the backquoted expression, or it can be a frame given as an argument when *fml* was invoked. That is, the previously current frame is the one whose frame message will be modified.

Permanent duration messages are displayed when the user navigates to the command line.

|                              |                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>                  | mixerctl – audio mixer control command line application                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>              | <code>/usr/sbin/mixerctl [-a   -d dev ][-iv] [-e   -o ]</code>                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>           | Some audio devices support the audio mixer functionality. See <code>mixer(7I)</code> for a complete description of the audio mixer. The <code>mixerctl</code> command is used to control the mode of the audio mixer and to get information about the audio mixer and the audio device. See <code>audio(7I)</code> for details. |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>               | The following options are supported. If none are specified, option <code>-i</code> is assumed:                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                              | <code>-a</code>                                                                                                                                                                                                                                                                                                                 | The command applies to all audio devices.                                                                                                                                                                                                                                                                                                                                                                                                           |
|                              | <code>-d dev</code>                                                                                                                                                                                                                                                                                                             | The <code>dev</code> argument specifies an alternate audio control device for the command to use.                                                                                                                                                                                                                                                                                                                                                   |
|                              | <code>-e</code>                                                                                                                                                                                                                                                                                                                 | Enables the audio mixer function if the audio device supports it. If supported, the audio mixer may be enabled at any time. The command silently ignores the enable option if the audio mixer is already enabled.                                                                                                                                                                                                                                   |
|                              | <code>-i</code>                                                                                                                                                                                                                                                                                                                 | Prints the audio device type information for the device and indicates whether the audio device uses the audio mixer. If the device does use the audio mixer, this option displays the audio mixer's mode.                                                                                                                                                                                                                                           |
|                              | <code>-o</code>                                                                                                                                                                                                                                                                                                                 | Turns off the audio mixer function if the audio device supports it. If supported, the audio mixer may be turned off if only one process has the device opened with the <code>O_RDWR</code> flag, or, if two different processes have the device opened, one with the <code>O_RDONLY</code> flag and the other with the <code>O_WRONLY</code> flag. The command silently ignores the disable option if the audio mixer function is already disabled. |
|                              | <code>-v</code>                                                                                                                                                                                                                                                                                                                 | Verbose mode. Prints the <code>audio_info_t</code> structure for the device, along with the device type information. This option implies the <code>-i</code> option.                                                                                                                                                                                                                                                                                |
| <b>ENVIRONMENT VARIABLES</b> | <code>AUDIODEV</code>                                                                                                                                                                                                                                                                                                           | If the <code>-d</code> and <code>-a</code> options are not specified, the <code>AUDIODEV</code> environment variable is consulted. If set, <code>AUDIODEV</code> will contain the full path name of the user's default audio device. The default audio device will be converted into a control device, and then used. If the <code>AUDIODEV</code> variable is not set, <code>/dev/audioctl</code> is used.                                         |
| <b>FILES</b>                 | <code>/dev/audioctl</code><br><code>/dev/sound/{0..n}ctl</code>                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>                  | mkdir - make directories                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>              | <b>mkdir</b> [-m <i>mode</i> ] [-p] <i>dir...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>           | <p>The <code>mkdir</code> command creates the named directories in mode 777 (possibly altered by the file mode creation mask <code>umask(1)</code>).</p> <p>Standard entries in a directory (for instance, the files “.”, for the directory itself, and “..”, for its parent) are made automatically. <code>mkdir</code> cannot create these entries by name. Creation of a directory requires write permission in the parent directory.</p> <p>The owner-ID and group-ID of the new directories are set to the process’s effective user-ID and group-ID, respectively. <code>mkdir</code> calls the <code>mkdir(2)</code> system call.</p> |
| <b>setgid and mkdir</b>      | <p>To change the <code>setgid</code> bit on a newly created directory, you must use <code>chmod g+s</code> or <code>chmod g-s</code> after executing <code>mkdir</code>.</p> <p>The <code>setgid</code> bit setting is inherited from the parent directory.</p>                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <p><code>-m mode</code>      This option allows users to specify the mode to be used for new directories. Choices for modes can be found in <code>chmod(1)</code>.</p> <p><code>-p</code>              With this option, <code>mkdir</code> creates <i>dir</i> by creating all the non-existing parent directories first. The mode given to intermediate directories will be the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).</p>                                         |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><i>dir</i>          A path name of a directory to be created.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>mkdir</code> when encountering files greater than or equal to 2 Gbyte (2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using <code>mkdir</code></p> <p>The following example:</p> <pre>example% mkdir -p ltr/jd/jan</pre> <p>creates the subdirectory structure <code>ltr/jd/jan</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mkdir</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>EXIT STATUS</b>           | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

- 0 All the specified directories were created successfully or the `-p` option was specified and all the specified directories now exist.
- >0 An error occurred.

| <b>NAME</b>        | mkmsgs – create message files for use by gettext                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>mkmsgs</b> [-o] [-i <i>locale</i> ] <i>inputstrings</i> <i>msgfile</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>mkmsgs</code> utility is used to create a file of text strings that can be accessed using the text retrieval tools (see <code>gettext(1)</code>, <code>srchtxt(1)</code>, <code>exstr(1)</code>, and <code>gettext(3C)</code>). It will take as input a file of text strings for a particular geographic locale (see <code>setlocale(3C)</code>) and create a file of text strings in a format that can be retrieved by both <code>gettext(1)</code> and <code>gettext(3C)</code>. By using the <code>-i</code> option, you can install the created file under the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory (<code>locale</code> corresponds to the language in which the text strings are written).</p> <p><i>inputstrings</i> is the name of the file that contains the original text strings. <i>msgfile</i> is the name of the output file where <code>mkmsgs</code> writes the strings in a format that is readable by <code>gettext(1)</code> and <code>gettext(3C)</code>. The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either <code>\0</code> (null) or the ASCII code for <code>/</code> (slash) or <code>:</code> (colon).</p> <p>The input file contains a set of text strings for the particular geographic locale. Text strings are separated by a newline character. Nongraphic characters must be represented as alphabetic escape sequences. Messages are transformed and copied sequentially from <i>inputstrings</i> to <i>msgfile</i>. To generate an empty message in <i>msgfile</i>, leave an empty line at the correct place in <i>inputstrings</i>.</p> <p>Strings can be changed simply by editing the file <i>inputstrings</i>. New strings must be added only at the end of the file; then a new <i>msgfile</i> file must be created and installed in the correct place. If this procedure is not followed, the retrieval function will retrieve the wrong string and software compatibility will be broken.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-o</code> Overwrite <i>msgfile</i>, if it exists.</li> <li><code>-i locale</code> Install <i>msgfile</i> in the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory. Only someone who is super user or a member of group <code>bin</code> can create or overwrite files in this directory. Directories under <code>/usr/lib/locale</code> will be created if they do not exist.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using the <code>mkmsgs</code> command.</p> <p>The following example shows an input message source file <code>C.str</code>:</p> <pre>File %s:\t cannot be opened\n %s: Bad directory\n . . . write error\n .</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**EXAMPLE 2** Using Input Strings From `C.str` to Create Text Strings in a File

The following command uses the input strings from `C.str` to create text strings in the appropriate format in the file `UX` in the current directory:

```
example% mkmsgs C.str UX
```

**EXAMPLE 3** Using Input Strings From `FR.str` to Create Text Strings in a File

The following command uses the input strings from `FR.str` to create text strings in the appropriate format in the file `UX` in the directory

```
/usr/lib/locale/fr/LC_MESSAGES:
```

```
example% mkmsgs -i fr FR.str UX
```

These text strings would be accessed if you had set the environment variable `LC_MESSAGES=fr` and then invoked one of the text retrieval tools listed at the beginning of the `DESCRIPTION` section.

**FILES**

```
/usr/lib/locale/locale/LC_MESSAGES/*
message files created by mkmsgs
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

| <b>NAME</b>        | mkstr – create an error message file by massaging C source files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/mkstr [-] messagefile prefix filename...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>mkstr</code> utility creates files of error messages. You can use <code>mkstr</code> to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out.</p> <p><code>mkstr</code> processes each of the specified <i>filenames</i>, placing a massaged version of the input file in a file with a name consisting of the specified <i>prefix</i> and the original source file name. A typical example of using <code>mkstr</code> would be:</p> <pre>mkstr pistrings processed *.c</pre> <p>This command would cause all the error messages from the C source files in the current directory to be placed in the file <code>pistrings</code> and processed copies of the source for these files to be placed in files whose names are prefixed with <i>processed</i>.</p> <p>To process the error messages in the source to the message file, <code>mkstr</code> keys on the string <code>'error( '</code> in the input stream. Each time it occurs, the C string starting at the <code>' '</code> is placed in the message file followed by a null character and a NEWLINE character; the null character terminates the message so it can be easily used when retrieved, the NEWLINE character makes it possible to sensibly <code>cat</code> the error message file to see its contents. The massaged copy of the input file then contains a <code>lseek</code> pointer into the file which can be used to retrieve the message, that is:</p> <pre>char efilename[] = "/usr/lib/pi_strings"; int efil = -1;  error(a1, a2, a3, a4) {     char     buf[256];     if (efil &lt; 0) {          efil = open(efilename, 0);         if (efil &lt; 0) { oops:             perror (efilename);             exit (1);         }     }     if (lseek(efil, (long) a1, 0)    read(efil, buf, 256) &lt;= 0)         goto oops;     printf(buf, a2, a3, a4); }</pre> |

**OPTIONS** – Place error messages at the end of the specified message file for recompiling part of a large `mkstred` program.

| <b>NAME</b>                | more, page – browse or page through a text file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>            | <pre> /usr/bin/more [-cdfllrsuw] [-lines] [+ <i>linenumber</i>] [+/<i> pattern</i>] [<i>file...</i>] /usr/bin/page [-cdfllrsuw] [-lines] [+ <i>linenumber</i>] [+/<i> pattern</i>] [<i>file...</i>] /usr/xpg4/bin/more [-cdeisu] [-n <i>number</i>] [-p <i>command</i>] [-t <i>tagstring</i>] [<i>file...</i>] /usr/xpg4/bin/more [-cdeisu] [-n <i>number</i>] [+ <i>command</i>] [-t <i>tagstring</i>] [<i>file...</i>] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>         | <p>The <code>more</code> utility is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. <code>/usr/bin/more</code> then prints <code>--More--</code> and <code>/usr/xpg4/bin/more</code> then prints <code>file</code> at the bottom of the screen. If <code>more</code> is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.</p> <p>The <code>more</code> utility scrolls up to display one more line in response to a RETURN character; it displays another screenful in response to a SPACE character. Other commands are listed below.</p> <p>The <code>page</code> utility clears the screen before displaying the next screenful of text; it only provides a one-line overlap between screens.</p> <p>The <code>more</code> utility sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the <code>/</code> and <code>!</code> commands.</p> <p>The <code>/usr/bin/more</code> utility exits after displaying the last specified file; <code>/usr/xpg4/bin/more</code> prompts for a command at the last line of the last specified file.</p> <p>If the standard output is not a terminal, <code>more</code> acts just like <code>cat(1)</code>, except that a header is printed before each file in a series.</p> |
| <b>OPTIONS</b>             | <p>The following options are supported for both <code>/usr/bin/more</code> and <code>/usr/xpg4/bin/more</code>:</p> <ul style="list-style-type: none"> <li><code>-c</code> Clear before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line.</li> <li><code>-d</code> Display error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.</li> <li><code>-s</code> Squeeze. Replace multiple blank lines with a single blank line. This is helpful when viewing <code>nroff(1)</code> output on the screen.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>/usr/bin/more</code> | <p>The following options are supported for <code>/usr/bin/more</code> only:</p> <ul style="list-style-type: none"> <li><code>-f</code> Do not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when <code>nroff(1)</code> output is piped through <code>ul(1)</code>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- l Do not treat FORMFEED characters (CTRL-L) as page breaks. If -l is not used, more pauses to accept commands after any line containing a ^L character (CTRL-L). Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.
  - r Normally, more ignores control characters that it does not interpret in some way. The -r option causes these to be displayed as ^ C where C stands for any such control character.
  - u Suppress generation of underlining escape sequences. Normally, more handles underlining, such as that produced by nroff(1), in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, more supplies appropriate escape sequences as called for in the text file.
  - w Normally, more exits when it comes to the end of its input. With -w, however, more prompts and waits for any key to be struck before exiting.
  - lines Display the indicated number of lines in each screenful, rather than the default (the number of lines in the terminal screen less two).
  - +  
linenumber Start up at linenumber.
  - +/  
pattern Start up two lines above the line containing the regular expression pattern. Note: Unlike editors, this construct should not end with a '/' . If it does, then the trailing slash is taken as a character in the search pattern.
- /usr/xpg4/bin/more** The following options are supported for /usr/xpg4/bin/more only:
- e Exit immediately after writing the last line of the last file in the argument list.
  - i Perform pattern matching in searches without regard to case.
  - n  
number Specify the number of lines per screenful. The number argument is a positive decimal integer. The -n option overrides any values obtained from the environment.
  - P  
command

**+**  
*command* For each file examined, initially execute the `more` command in the *command* argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands:

```
more -p 1000j file
more -p 1000G file
```

are equivalent and start the display with the current position at line 1000, bypassing the lines that `j` would write and scroll off the screen if it had been issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.

**-t**  
*tagstring* Write the screenful of the file containing the tag named by the *tagstring* argument. See the `ctags(1)` utility.

**-u** Treat a backspace character as a printable control character, displayed as a `^H` (CTRL-H), suppressing backspacing and the special handling that produces underlined or standout-mode text on some terminal types. Also, do not ignore a carriage-return character at the end of a line.

If both the `-t tagstring` and `-p command` (or the obsolescent `+command`) options are given, the `-t tagstring` is processed first.

## USAGE

### Environment

`more` uses the terminal's `terminfo(4)` entry to determine its display characteristics.

`more` looks in the environment variable `MORE` for any preset options. For instance, to page through files using the `-c` mode by default, set the value of this variable to `-c`. (Normally, the command sequence to set up this environment variable is placed in the `.login` or `.profile` file).

### Commands

The commands take effect immediately. It is not necessary to type a carriage return unless the command requires a *file*, *command*, *tagstring*, or *pattern*. Up to the time when the command character itself is given, the user may type the line kill character to cancel the numerical argument being formed. In addition, the user may type the erase character to redisplay the `'--More--( XX %)'` or *file* message.

In the following commands, *i* is a numerical argument (1 by default).

|                                 |                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>i</i><br>SPACE               | Display another screenful, or <i>i</i> more lines if <i>i</i> is specified.                                                                                                                                                                                                                                                                         |
| <i>i</i><br>RETURN              | Display another line, or <i>i</i> more lines, if specified.                                                                                                                                                                                                                                                                                         |
| <i>i</i><br>b<br><i>i</i><br>^B | (CTRL-B) Skip back <i>i</i> screenfuls and then print a screenful.                                                                                                                                                                                                                                                                                  |
| <i>i</i><br>d<br><i>i</i><br>^D | (CTRL-D) Scroll forward one half screenful or <i>i</i> more lines. If <i>i</i> is specified, the count becomes the default for subsequent <i>d</i> and <i>u</i> commands.                                                                                                                                                                           |
| <i>i</i><br>f                   | Skip <i>i</i> screens full and then print a screenful.                                                                                                                                                                                                                                                                                              |
| h                               | Help. | Q                               | Exit from <code>more</code> .                                                                                                                                                                                                                                                                                                                       |
| <i>i</i><br>s                   | Skip <i>i</i> lines and then print a screenful.                                                                                                                                                                                                                                                                                                     |
| v                               | Drop into the <code>vi</code> editor at the current line of the current file.                                                                                                                                                                                                                                                                       |
| <i>i</i><br>z                   | Same as SPACE, except that <i>i</i> , if present, becomes the new default number of lines per screenful.                                                                                                                                                                                                                                            |
| =                               | Display the current line number.                                                                                                                                                                                                                                                                                                                    |
| <i>i</i><br>/<br><i>pattern</i> | Search forward for the <i>i</i> th occurrence of the regular expression <i>pattern</i> . Display the screenful starting two lines before the line that contains the <i>i</i> th match for the regular expression <i>pattern</i> , or the end of a pipe, whichever comes first. If <code>more</code> is displaying a file and there is no match, its |

|                    |                     |                                                                                                                                                                                                                                                                                                          |
|--------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    |                     | position in the file remains unchanged. Regular expressions can be edited using erase and kill characters. Erasing back past the first column cancels the search command.                                                                                                                                |
|                    | !<br><i>command</i> | Invoke a shell to execute <i>command</i> . The characters % and !, when used within <i>command</i> are replaced with the current filename and the previous shell command, respectively. If there is no current filename, % is not expanded. Prepend a backslash to these characters to escape expansion. |
|                    | :f                  | Display the current filename and line number.                                                                                                                                                                                                                                                            |
|                    | <i>i</i><br>:n      | Skip to the <i>i</i> th next filename given in the command line, or to the last filename in the list if <i>i</i> is out of range.                                                                                                                                                                        |
|                    | <i>i</i><br>:p      | Skip to the <i>i</i> th previous filename given in the command line, or to the first filename if <i>i</i> is out of range. If given while <i>more</i> is positioned within a file, go to the beginning of the file. If <i>more</i> is reading from a pipe, <i>more</i> simply rings the terminal bell.   |
|                    | :q<br>:Q            | Exit from <i>more</i> (same as q or Q).                                                                                                                                                                                                                                                                  |
| /usr/bin/more      |                     | The following commands are available only in /usr/bin/more:                                                                                                                                                                                                                                              |
|                    | '                   | Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file.                                                                                                                                                  |
|                    | .                   | Dot. Repeat the previous command.                                                                                                                                                                                                                                                                        |
|                    | ^\                  | Halt a partial display of text. <i>more</i> stops sending output, and displays the usual --More-- prompt. Some output is lost as a result.                                                                                                                                                               |
| /usr/xpg4/bin/more |                     | The following commands are available only in /usr/xpg4/bin/more:                                                                                                                                                                                                                                         |
|                    | <i>i</i>            | (CTRL-F) Skip <i>i</i> screens full and print a screenful. (Same as <i>i</i> f.)                                                                                                                                                                                                                         |
|                    | ^F                  |                                                                                                                                                                                                                                                                                                          |
|                    | ^G                  | (CTRL-G) Display the current line number (same as =).                                                                                                                                                                                                                                                    |
|                    | <i>i</i><br>g       | Go to line number <i>i</i> with the default of the first line in the file.                                                                                                                                                                                                                               |
|                    | <i>i</i><br>G       | Go to line number <i>i</i> with the default of the Last line in the file.                                                                                                                                                                                                                                |
|                    | <i>i</i><br>j       | Display another line, or <i>i</i> more lines, if specified. (Same as <i>i</i> RETURN.)                                                                                                                                                                                                                   |

|                                                     |                                                                                                                                                                                                    |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>i</i>                                            | Scroll backwards one or <i>i</i> lines, if specified.                                                                                                                                              |
| <i>k</i>                                            |                                                                                                                                                                                                    |
| <i>m</i><br><i>letter</i>                           | Mark the current position with the name <i>letter</i> .                                                                                                                                            |
| <i>N</i>                                            | Reverse direction of search.                                                                                                                                                                       |
| <i>r</i>                                            | Refresh the screen.                                                                                                                                                                                |
| <i>R</i>                                            | Refresh the screen, discarding any buffered input.                                                                                                                                                 |
| <i>i</i><br><i>u</i><br><i>i</i><br><i>^U</i>       | (CTRL-U) Scroll backwards one half a screen of <i>i</i> lines, if specified. If <i>i</i> is specified, the count becomes the new default for subsequent <i>d</i> and <i>u</i> commands.            |
| <i>ZZ</i>                                           | Exit from <code>more</code> (same as <i>q</i> ).                                                                                                                                                   |
| <i>:e</i><br><i>file</i>                            | Examine (display) a new file. If no <i>file</i> is specified, the current file is redisplayed.                                                                                                     |
| <i>:t</i><br><i>tagstring</i>                       | Go to the tag named by the <i>tagstring</i> argument and scroll/rewrite the screen with the tagged line in the current position. See the <code>ctags</code> utility.                               |
| <i>'</i><br><i>letter</i>                           | Return to the position that was previously marked with the name <i>letter</i> .                                                                                                                    |
| <i>''</i>                                           | Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.                                                                          |
| <i>i</i><br><i>?</i><br><i>!</i><br><i>]pattern</i> | Search backward in the file for the <i>i</i> th line containing the <i>pattern</i> . The <i>!</i> specifies to search backward for the <i>i</i> th line that does not contain the <i>pattern</i> . |
| <i>i</i><br><i>/</i><br><i>!</i><br><i>pattern</i>  | Search forward in the file for the <i>i</i> th line that does not contain the pattern.                                                                                                             |

**Large File Behavior**

See largefile(5) for the description of the behavior of more and page when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**ENVIRONMENT VARIABLES**

See environ(5) for descriptions of the following environment variables that affect the execution of more : LC\_COLLATE (/usr/xpg4/bin/more only), LC\_CTYPE , LC\_MESSAGES , NLSPATH , and TERM .

/usr/xpg4/bin/more

The following environment variables also affect the execution of /usr/xpg4/bin/more :

COLUMNS Override the system selected horizontal screen size.

EDITOR Used by the v command to select an editor.

LINES Override the system selected vertical screen size. The -n option has precedence over LINES in determining the number of lines in a screen.

MORE A string specifying options as described in the OPTIONS section, above. As in a command line, The options must be separated by blank characters and each option specification must start with a -. Any command line options are processed after those specified in MORE as though the command line were: more \$MORE options operands

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES**

/usr/lib/more.help help file for /usr/bin/more and /usr/bin/page only.

**ATTRIBUTES**

/usr/bin/more  
/usr/bin/page

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Not enabled     |

/usr/xpg4/bin/more

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |
| CSI            | Enabled         |

**SEE ALSO**

cat(1), csh(1), ctags(1), man(1), nroff(1), script(1), sh(1), ul(1),  
 environ(4), terminfo(4), attributes(5), environ(5), largefile(5)

/usr/bin/page

/usr/xpg4/bin/more

regex(5), XPG4(5)

**NOTES**

/usr/bin/more

Skipping backwards is too slow on large files.

/usr/xpg4/bin/more

This utility will not behave correctly if the terminal is not set up properly.

| <b>NAME</b>        | mp - PostScript pretty printer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>mp</b> [-A4] [-C] [-F] [-L <i>localename</i> ] [-PS] [-US] [-a] [-c <i>chars</i> ] [-d] [-e] [-ff] [-fp] [-l] [-m] [-o] [-p <i>prologue</i> ] [-s <i>subject</i> ] [-tm] [-ts] [-v] [-w <i>words</i> ] [-?] [ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>mp</code> program reads each <i>filename</i> in sequence and generates a prettified version of the contents in PostScript™ format, sent to standard output. If no filename argument is provided, <code>mp</code> reads the standard input. If the standard input is a terminal, input is terminated by an EOF signal, usually Control-d.</p> <p>The <code>mp</code> program accepts international text files of various Solaris locales and produces output which is proper for the specified locale. The output will also contain proper text layout, for instance, bidirectional text rendering, and shaping as the complex text layout (CTL) is supported in <code>mp</code>.</p> <p>Depending on each locale's system font configuration for <code>mp</code>, the PostScript output file can contain glyph images from Solaris system-resident scalable or bitmap fonts.</p> <p>Mail items, news articles, ordinary ASCII files, complete mail folders, and digests are all acceptable input formats for <code>mp</code>. The output format includes grayscale lozenges containing banner information at the top and bottom of every page.</p> <p>The program is conveniently used in conjunction with the print button of the <code>mailtool(1)</code> program, or the <code>pipe</code> command provided by <code>mail(1)</code>. Add the following two lines to your <code>.mailrc</code> file:</p> <pre>set printmail='mp   lp' set cmd="mp   lp &amp;"</pre> <p>Then source the <code>.mailrc</code> file and you are ready to use <code>mp</code>. For printing ordinary ASCII files, the following alias (to be placed in your <code>.cshrc</code> file) may also prove useful:</p> <pre>alias print 'mp -o -s "\!*" &lt;\!*   lp'</pre> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a            Formats the file as a news article. The top banner contains the text: "Article from <i>newsgroup</i>", where <i>newsgroup</i> is the first news group found on the 'Newsgroups:' line.</li> <li>-A4           Uses A4 paper size (8.26 x 11.69 inches).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c <i>chars</i>      | The maximum number of characters to extract from the <code>gecos</code> field of the users <code>/etc/passwd</code> entry. The default is 18.                                                                                                                                                                                                                                                                                                                                                                             |
| -C                   | Instead of using "\nFrom" to denote the start of new mail messages, <code>mp</code> will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and <code>mp</code> falls back to looking for the next "\nFrom" in the mail folder.                                                                                                                                                                                              |
| -d                   | Formats the file as a digest.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -e                   | Assumes the ELM mail frontend intermediate file format. Used when printing messages from within ELM (using the "p" command), especially for printing tagged messages. This option must be specified in your ELM option setup.                                                                                                                                                                                                                                                                                             |
| -ff                  | Formats the file for use with a Filofax personal organizer.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -fp                  | Formats the file for use with a Franklin Planner personal organizer.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -F                   | Instead of printing who the mail article is for, the top header will contain who the mail article is from. A useful option for people with their own personal printer.                                                                                                                                                                                                                                                                                                                                                    |
| -l                   | Formats output in landscape mode. Two pages of text will be printed per sheet of paper.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -L <i>localename</i> | Provides the locale of the file to be printed. If this command line option is not present, then <code>mp</code> looks for the <code>MP_LANG</code> environment variable. If that is not present, then the <code>LANG</code> environment variable is used. If none of these options are present, then <code>mp</code> tries to determine the locale it is running in, and if it cannot, then it assumes it is running in the C locale. Otherwise, a prologue file specific to the given locale is prepended to the output. |
| -m                   | Formats the file as a mail folder, printing multiple messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -o                   | Formats the file as an ordinary ASCII file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -p <i>prologue</i>   | Employs the file <i>prologue</i> as the PostScript prologue file, overriding any previously defined file names. The locale prologue file, <code>prolog.ps</code> , cannot be overridden with this option. This is specifically for the files in the SUPPLIED PROLOGUE FILES section below.                                                                                                                                                                                                                                |
| -PS                  | If the mail or digest message just has PostScript as the text of the message, then this is normally just passed straight                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                |                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | through. Specifying this option causes PostScript to be printed as text.                                                                                                                                     |
| <code>-s <i>subject</i></code> | Uses <i>subject</i> as the new subject for the printout. If you are printing ordinary ASCII files that have been specified on the command line, the subject will default to the name of each of these files. |
| <code>-tm</code>               | Formats the file for use with the Time Manager personal organizer.                                                                                                                                           |
| <code>-ts</code>               | Formats the file for use with the Time/System International personal organizer.                                                                                                                              |
| <code>-US</code>               | Uses US paper size (8.5 x 11 inches). This is the default paper size.                                                                                                                                        |
| <code>-v</code>                | Prints the version number of this release of mp.                                                                                                                                                             |
| <code>-w <i>words</i></code>   | The maximum number of words to extract from the <code>gecos</code> field of the users <code>/etc/passwd</code> entry. The default is 3.                                                                      |
| <code>-?</code>                | Prints the usage line for mp (notice that the <code>?</code> character must be escaped if using <code>cs(1)</code> ).                                                                                        |

**OPERANDS**

The following operand is supported:

*filename*      The name of the file to be read.

**ENVIRONMENT VARIABLES**

The location of the mp prologue file that is used for laying out the print page is determined by looking for the environment variable `MP_PROLOGUE`, which specifies the directory where mp prologue files are to be found. This does not mean that the `prolog.ps` file will be loaded from the `MP_PROLOGUE` directory; only the files listed in the SUPPLIED PROLOGUE FILES section will be loaded from this directory. If `MP_PROLOGUE` is not found, then the default directory is assumed (`/usr/lib/lp/locale/C/mp`).

mp also checks for the `MP_LANG` and `LANG` environment variables. If present, a prologue file called `/usr/lib/lp/locale/localename/mp/prolog.ps`, where *localename* is the value of the `MP_LANG` or `LANG` environment variables, is prepended to the output to be printed. If this file is not present, a configuration file of the locale called `/usr/lib/lp/locale/localename/mp/mp.conf` is used as the source of the configuration information that substitutes the prologue information for printing. Presence of `prolog.ps` disables `mp.conf` for backward compatibility.

**EXIT STATUS**

The following exit values are returned:

0              Successful completion.  
1              An error occurred.

**SUPPLIED  
PROLOGUE FILES**

The following prologue files are provided:

|                            |                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>mp.common.ps</code>  | Common prologue file for all other files in this directory.                                                                      |
| <code>mp.pro.ps</code>     | Used by default.                                                                                                                 |
| <code>mp.pro.ff.ps</code>  | Used if the <code>-ff</code> option is in effect.                                                                                |
| <code>mp.pro.fp.ps</code>  | Used if the <code>-fp</code> option is in effect.                                                                                |
| <code>mp.pro.tm.ps</code>  | Used if the <code>-tm</code> option is in effect.                                                                                |
| <code>mp.pro.ts.ps</code>  | Used if the <code>-ts</code> option is in effect.                                                                                |
| <code>mp.pro.alt.ps</code> | An alternative modification of the default prologue file which outputs the page number in the right corner of the bottom banner. |

**FILES**

|                                                    |                                                                                                          |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>.cshrc</code>                                | Initialization file for <code>cs(1)</code> .                                                             |
| <code>.mailrc</code>                               | Initialization file for <code>mail(1)</code> .                                                           |
| <code>/usr/bin/mp</code>                           | Executable.                                                                                              |
| <code>/usr/lib/lp/locale/C/mp/mp.conf</code>       | Default configuration file.                                                                              |
| <code>/usr/lib/lp/locale/C/mp/mp.common.ps</code>  | Common prolog file for all other files in this directory.                                                |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.ps</code>     | Default PostScript prologue for mail printing.                                                           |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.l.ps</code>   | Default PostScript prologue for landscape format.                                                        |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.alt.ps</code> | Alternative "default" PostScript prologue. Inserts page numbers in the bottom right corner of each page. |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.ff.ps</code>  | Default PostScript prologue for Filofax format.                                                          |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.fp.ps</code>  | Default PostScript prologue for Franklin Planner format.                                                 |
| <code>/usr/lib/lp/locale/C/mp/mp.pro.tm.ps</code>  | Default PostScript prologue for Time Manager format.                                                     |

`/usr/lib/lp/locale/C/mp/mp.pro.ts.ps`

Default PostScript prologue for Time/System International format.

`/usr/lib/lp/locale/localename/mp/prolog.ps`

Default locale-specific prologued file as an alternative to the `mp.conf` file.  
See ENVIRONMENT VARIABLES for more detail on the relationship.

For all the above prologue files, there can be localized versions under `/usr/lib/lp/locale/localename/mp/`. If such localized versions are available, and the locale specified is the *localename*, `mp` will use prologue files under the *localename* directory.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmp          |

| <b>NAME</b>                  | msgfmt – create a message object from a message file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>              | <b>msgfmt</b> [-v] [-o <i>output-file</i> ] <i>filename.po...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b>           | <p>msgfmt creates message object files from portable object files (<i>filename.po</i>), without changing the portable object files.</p> <p>The <i>.po</i> file contains messages displayed to users by system commands or by application programs. <i>.po</i> files can be edited, and the messages in them can be rewritten in any language supported by the system.</p> <p>The <code>xgettext(1)</code> command can be used to create <i>.po</i> files from script or programs.</p> <p>msgfmt interprets data as characters according to the current setting of the <code>LC_CTYPE</code> locale category.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Portable Object Files</b> | <p>Formats for all <i>.po</i> files are the same. Each <i>.po</i> file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a hash mark (#) and end with the newline character. All comments are ignored. The format of a statement is:</p> <p><i>directive value</i></p> <p>Each directive starts at the beginning of the line and is separated from <i>value</i> by white space (such as one or more space or tab characters). <i>value</i> consists of one or more quoted strings separated by white space. Use any of the following types of directives:</p> <pre> domain domainname msgid <i>message_identifier</i> msgstr <i>message_string</i> </pre> <p>The behavior of the <code>domain</code> directive is affected by the options used. See <b>OPTIONS</b> for the behavior when the <code>-o</code> option is specified. If the <code>-o</code> option is not specified, the behavior of the <code>domain</code> directive is as follows:</p> <ul style="list-style-type: none"> <li>■ All <i>msgid</i>s from the beginning of each <i>.po</i> file to the first <code>domain</code> directive are put into a default message object file, <code>messages.mo</code>.</li> <li>■ When msgfmt encounters a <code>domain domainname</code> directive in the <i>.po</i> file, all following <i>msgid</i>s until the next <code>domain</code> directive are put into the message object file <code>domainname.mo</code>.</li> <li>■ Duplicate <i>msgid</i>s are defined in the scope of each domain. That is, a <i>msgid</i> is considered a duplicate only if the identical <i>msgid</i> exists in the same domain.</li> <li>■ All duplicate <i>msgid</i>s are ignored.</li> </ul> <p>The <code>msgid</code> directive specifies the value of a message identifier associated with the directive that follows it. The <i>message_identifier</i> string identifies a target string</p> |

to be used at retrieval time. Each statement containing a `msgid` directive must be followed by a statement containing a `msgstr` directive.

The `msgstr` directive specifies the target string associated with the `message_identifier` string declared in the immediately preceding `msgid` directive.

Message strings can contain the escape sequences `\n` for newline, `\t` for tab, `\v` for vertical tab, `\b` for backspace, `\r` for carriage return, `\f` for formfeed, `\\` for backslash, `\"` for double quote, `\ddd` for octal bit pattern, and `\xDD` for hexadecimal bit pattern.

## OPTIONS

- `-v` Verbose. List duplicate message identifiers. Message strings are not redefined.
- `-o output-file` Specify output file name as *output-file*. All domain directives and duplicate *msgids* in the `.po` file are ignored.

## EXAMPLES

**EXAMPLE 1** Examples of creating message objects from message files.

In this example `module1.po` and `module2.po` are portable message objects files.

```
example% cat module1.po
default domain "messages.mo"
msgid "msg 1"
msgstr "msg 1 translation"
#
domain "help_domain"
msgid "help 2"
msgstr "help 2 translation"
#
domain "error_domain"
msgid "error 3"
msgstr "error 3 translation"
example% cat module2.po
default domain "messages.mo"
msgid "mesg 4"
msgstr "mesg 4 translation"
#
domain "error_domain"
msgid "error 5"
msgstr "error 5 translation"
#
domain "window_domain"
msgid "window 6"
msgstr "window 6 translation"
```

The following command will produce the output files, `messages.mo`, `help_domain.mo`, and `error_domain.mo`.

```
example% msgfmt module1.po
```

The following command will produce the output files, `messages.mo`, `help_domain.mo`, `error_domain.mo`, and `window_domain.mo`.

```
example% msgfmt module1.po module2.po
```

The following example will produce the output file `hello.mo`.

```
example% msgfmt -o hello.mo module1.po module2.po
```

Install message object files in `/usr/lib/locale/locale/LC_MESSAGES/domain.mo` where `locale` is the message locale as set by `setlocale(3C)`, and `domain` is text domain as set by `textdomain()`. The `/usr/lib/locale` portion can optionally be changed by calling `bindtextdomain()`. See `gettext(3C)`.

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environmental variables that affect the execution of `msgfmt`: `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |
| CSI            | Enabled         |

## SEE ALSO

`xgettext(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

## NOTES

Neither `msgfmt` nor any `gettext()` routine imposes a limit on the total length of a message. However, each line in the `*.po` file is limited to `MAX_INPUT` (512) bytes.

Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

| <b>NAME</b>        | mt – magnetic tape control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>mt</b> [-f <i>tapename</i> ] <i>command</i> ... [ <i>count</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | mt sends commands to a magnetic tape drive. If -f <i>tapename</i> is not specified, the environment variable TAPE is used. If TAPE does not exist, mt uses the device /dev/rmt/0n.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | -f <i>tapename</i> Specify the raw tape device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPERANDS</b>    | <p><i>count</i>            The number of times that the requested operation is to be performed. By default, mt performs <i>command</i> once; multiple operations of <i>command</i> may be performed by specifying <i>count</i>.</p> <p><i>command</i>          Available commands that can be sent to a magnetic tape drive. Only as many characters as are required to uniquely identify a <i>command</i> need be specified.</p> <p>eof, weof          Write <i>count</i> EOF marks at the current position on the tape.</p> <p>fsf                Forward space over <i>count</i> EOF marks. The tape is positioned on the first block of the file.</p> <p>fsr                Forward space <i>count</i> records.</p> <p>bsf                Back space over <i>count</i> EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.</p> <p>bsr                Back space <i>count</i> records.</p> <p>nbsf              Back space <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count+1</i> bsf's followed by one fsf.</p> <p>asf                Absolute space to <i>count</i> file number. This is equivalent to a rewind followed by a fsf <i>count</i>.</p> <p>If <i>count</i> is specified with any of the following commands, the <i>count</i> is ignored and the command is performed only once.</p> <p>eom                Space to the end of recorded media on the tape. This is</p> |

|  |                  |                                                                                                                                                             |
|--|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  |                  | useful for appending files onto previously written tapes.                                                                                                   |
|  | rewind           | Rewind the tape.                                                                                                                                            |
|  | offline, rewoffl | Rewind the tape and, if appropriate, take the drive unit off-line by unloading the tape. It cycles through all four tapes.                                  |
|  | status           | Print status information about the tape unit.                                                                                                               |
|  | retension        | Rewind the cartridge tape completely, then wind it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.                 |
|  | reserve          | Allow the tape drive to remain reserved after closing the device. The drive must then be explicitly released.                                               |
|  | release          | Re-establish the default behavior of releasing at close.                                                                                                    |
|  | forcereserve     | Break the reservation of the tape drive held by another host and then reserve the tape drive. This command can be executed only with super-user privileges. |
|  | erase            | Erase the entire tape. Erasing a tape may take a long time depending on the device and/or tape. Refer to the device specific manual for time details.       |

**BUGS**

Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.

`mt` is architecture sensitive. Heterogeneous operation (that is, Sun3 to Sun4 or the reverse) is not supported.

| <b>NAME</b>        | mv – move files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre> /usr/bin/mv [-fi] source target_file /usr/bin/mv [-fi] source... target_dir /usr/xpg4/bin/mv [-fi] source target_file /usr/xpg4/bin/mv [-fi] source... target_dir </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>In the first synopsis form, the <code>mv</code> utility moves the file named by the <i>source</i> operand to the destination specified by the <i>target_file</i>. <i>source</i> and <i>target_file</i> may not have the same name. If <i>target_file</i> does not exist, <code>mv</code> creates a file named <i>target_file</i>. If <i>target_file</i> exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.</p> <p>In the second synopsis form, <code>mv</code> moves each file named by a <i>source</i> operand to a destination file in the existing directory named by the <i>target_dir</i> operand. The destination path for each <i>source</i> is the concatenation of the target directory, a single slash character (/), and the last path name component of the <i>source</i>. This second form is assumed when the final operand names an existing directory.</p> <p>If <code>mv</code> determines that the mode of <i>target_file</i> forbids writing, it will print the mode (see <code>chmod(2)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the <code>mv</code> occurs, if permissible; otherwise, the command exits. Note that the mode displayed may not fully represent the access permission if <i>target</i> is associated with an ACL. When the parent directory of <i>source</i> is writable and has the sticky bit set, one or more of the following conditions must be true:</p> <ul style="list-style-type: none"> <li>■ the user must own the file</li> <li>■ the user must own the directory</li> <li>■ the file must be writable by the user</li> <li>■ the user must be a privileged user</li> </ul> <p>If <i>source</i> is a file and <i>target_file</i> is a link to another file with links, the other links remain and <i>target_file</i> becomes a new file.</p> <p>If <i>source</i> and <i>target_file</i>/<i>target_dir</i> are on different file systems, <code>mv</code> copies the source and deletes the original; any hard links to other files are lost. <code>mv</code> will attempt to duplicate the source file characteristics to the target, that is, the owner and group id, permission modes, modification and access times, and ACLs, if applicable. For symbolic links, <code>mv</code> will preserve only the owner and group of the link itself.</p> <p>If unable to preserve owner and group id, <code>mv</code> will clear <code>S_ISUID</code> and <code>S_ISGID</code> bits in the target. <code>mv</code> will print a diagnostic message to <code>stderr</code> if unable to clear</p> |

these bits, though the exit code will not be affected. Only `/usr/xpg4/bin/mv` will print a diagnostic message to `stderr` for all other failed attempts to duplicate file characteristics; the exit code will not be affected.

In order to preserve the source file characteristics, users must have the appropriate file access permissions; this includes being super-user or having the same owner id as the destination file.

**OPTIONS**

The following options are supported:

- `-f` `mv` will move the file(s) without prompting even if it is writing over an existing *target*. Note that this is the default if the standard input is not a terminal.
- `-i` `mv` will prompt for confirmation whenever the move would overwrite an existing *target*. An affirmative answer means that the move should proceed. Any other answer prevents `mv` from overwriting the *target*.

**/usr/bin/mv**

Specifying both the `-f` and the `-i` options is not considered an error. The `-f` option will override the `-i` option.

**/usr/xpg4/bin/mv**

Specifying both the `-f` and the `-i` options is not considered an error. The last option specified will determine the behavior of `mv`.

**OPERANDS**

The following operands are supported:

- source* A path name of a file or directory to be moved.
- target\_file* A new path name for the file or directory being moved.
- target\_dir* A path name of an existing directory into which to move the input files.

**USAGE**

See `largefile(5)` for the description of the behavior of `mv` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `mv`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 All input files were moved successfully.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/mv**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

**/usr/xpg4/bin/mv**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |
| CSI            | Enabled         |

**SEE ALSO**

cp(1), cpio(1), ln(1), rm(1), setfacl(1), chmod(2), attributes(5), environ(5), largefile(5), XPG4(5)

**NOTES**

A '-' permits the user to mark explicitly the end of any command line options, allowing mv to recognize filename arguments that begin with a '-'. As an aid to BSD migration, mv will accept '-' as a synonym for '-'. This migration aid may disappear in a future release. If a '-' and a '-' both appear on the same command line, the second will be interpreted as a filename.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>DESCRIPTION</b> | <p>The <code>/usr/bin/nawk</code> and <code>/usr/xpg4/bin/awk</code> utilities execute <i>programs</i> written in the <code>nawk</code> programming language, which is specialized for textual data manipulation. A <code>nawk program</code> is a sequence of patterns and corresponding actions. The string specifying <i>program</i> must be enclosed in single quotes (') to protect it from interpretation by the shell. The sequence of pattern - action statements can be specified in the command line as <i>program</i> or in one, or more, file(s) specified by the <code>-f progfile</code> option. When input is read that matches a pattern, the action associated with the pattern is performed.</p> <p>Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the <code>RS</code> built-in variable. Each record of input is matched to each pattern in the <i>program</i>. For each pattern matched, the associated action is executed.</p> <p>The <code>nawk</code> utility interprets each input record as a sequence of fields where, by default, a field is a string of non-blank characters. This default white-space field delimiter (blanks and/or tabs) can be changed by using the <code>FS</code> built-in variable or the <code>-F ERE</code> option. The <code>nawk</code> utility denotes the first field in a record <code>\$1</code>, the second <code>\$2</code>, and so forth. The symbol <code>\$0</code> refers to the entire record; setting any other field causes the reevaluation of <code>\$0</code>. Assigning to <code>\$0</code> resets the values of all fields and the <code>NF</code> built-in variable.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-F ERE</code> Define the input field separator to be the extended regular expression <i>ERE</i>, before any input is read (can be a character).</li> <li><code>-f progfile</code> Specifies the pathname of the file <i>progfile</i> containing a <code>nawk</code> program. If multiple instances of this option are specified, the concatenation of the files specified as <i>progfile</i> in the order specified is the <code>nawk</code> program. The <code>nawk</code> program can alternatively be specified in the command line as a single argument.</li> <li><code>-v assignment</code> The <i>assignment</i> argument must be in the same form as an <i>assignment</i> operand. The assignment is of the form <i>var=value</i>, where <i>var</i> is the name of one of the variables described below. The specified assignment occurs before executing the <code>nawk</code> program, including the actions associated with <code>BEGIN</code> patterns (if any). Multiple occurrences of this option can be specified.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**OPERANDS**

The following operands are supported:

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>program</i>    | If no <i>-f</i> option is specified, the first operand to <i>nawk</i> is the text of the <i>nawk</i> program. The application supplies the <i>program</i> operand as a single argument to <i>nawk</i> . If the text does not end in a newline character, <i>nawk</i> interprets the text as if it did.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>argument</i>   | Either of the following two types of <i>argument</i> can be intermixed:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>file</i>       | A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no <i>file</i> operands are specified, or if a <i>file</i> operand is <i>-</i> , the standard input is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>assignment</i> | An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabets from the portable character set, followed by the = character specifies a variable assignment rather than a pathname. The characters before the = represent the name of a <i>nawk</i> variable; if that name is a <i>nawk</i> reserved word the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the <i>nawk</i> program preceded and followed by a double-quote (") character, as a <i>STRING</i> token, except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence "\". The variable is assigned the value of that <i>STRING</i> token. If the value is considered a <i>numericstring</i> , the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following <i>file</i> , if any. Thus, an assignment before the first <i>file</i> argument is executed after the <i>BEGIN</i> actions (if any), while an assignment after |

the last *file* argument is executed before the `END` actions (if any). If there are no *file* arguments, assignments are executed before processing the standard input.

**INPUT FILES**

Input files to the `nawk` program from any of the following sources:

- any *file* operands or their equivalents, achieved by modifying the `nawk` variables `ARGV` and `ARGC`
- standard input in the absence of any *file* operands
- arguments to the `getline` function

must be text files. Whether the variable `RS` is set to a value other than a newline character or not, for these files, implementations support records terminated with the specified separator up to `{LINE_MAX}` bytes and may support longer records.

If `-f progfile` is specified, the files named by each of the *progfile* option-arguments must be text files containing an `nawk` program.

The standard input are used only if no *file* operands are specified, or if a *file* operand is `-`.

**EXTENDED DESCRIPTION**

A `nawk` program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the `nawk` program starts by first executing the actions associated with all `BEGIN` patterns in the order they occur in the program. Then each *file* operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of `FS`, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all `END` patterns is executed in the order they occur in the program.

**Expressions in nawk**

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators are evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while *lvalue* represents any entity that can be assigned to (that is, on the left side of an assignment operator).

| Syntax                     | Name                     | Type of Result      | Associativity |
|----------------------------|--------------------------|---------------------|---------------|
| ( <i>expr</i> )            | Grouping                 | type of <i>expr</i> | n/a           |
| <i>Sexpr</i>               | Field reference          | string              | n/a           |
| ++ <i>lvalue</i>           | Pre-increment            | numeric             | n/a           |
| -- <i>lvalue</i>           | Pre-decrement            | numeric             | n/a           |
| <i>lvalue</i> ++           | Post-increment           | numeric             | n/a           |
| <i>lvalue</i> --           | Post-decrement           | numeric             | n/a           |
| <i>expr</i> ^ <i>expr</i>  | Exponentiation           | numeric             | right         |
| ! <i>expr</i>              | Logical not              | numeric             | n/a           |
| + <i>expr</i>              | Unary plus               | numeric             | n/a           |
| - <i>expr</i>              | Unary minus              | numeric             | n/a           |
| <i>expr</i> * <i>expr</i>  | Multiplication           | numeric             | left          |
| <i>expr</i> / <i>expr</i>  | Division                 | numeric             | left          |
| <i>expr</i> % <i>expr</i>  | Modulus                  | numeric             | left          |
| <i>expr</i> + <i>expr</i>  | Addition                 | numeric             | left          |
| <i>expr</i> - <i>expr</i>  | Subtraction              | numeric             | left          |
| <i>expr</i> <i>expr</i>    | String concatenation     | string              | left          |
| <i>expr</i> < <i>expr</i>  | Less than                | numeric             | none          |
| <i>expr</i> <= <i>expr</i> | Less than or equal to    | numeric             | none          |
| <i>expr</i> != <i>expr</i> | Not equal to             | numeric             | none          |
| <i>expr</i> == <i>expr</i> | Equal to                 | numeric             | none          |
| <i>expr</i> > <i>expr</i>  | Greater than             | numeric             | none          |
| <i>expr</i> >= <i>expr</i> | Greater than or equal to | numeric             | none          |

| Syntax                                        | Name                                   | Type of Result                                       | Associativity |

| <i>lvalue</i> = <i>expr</i>                   | Assignment                             | type of <i>expr</i>                                  | right         |

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the `sprintf` function with the string `%d` as the `fmt` argument and the numeric value being converted as the first and only `expr` argument. Any other numeric value is converted to a string by the equivalent of a call to the `sprintf` function with the value of the variable `CONVFMT` as the `fmt` argument and the numeric value being converted as the first and only `expr` argument.

A string value is considered to be a *numeric string* in the following case:

1. Any leading and trailing blank characters is ignored.
2. If the first unignored character is a `+` or `-`, it is ignored.
3. If the remaining unignored characters would be lexically recognized as a `NUMBER` token, the string is considered a *numeric string*.

If a `-` character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized `NUMBER` token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized `NUMBER` token. Whether or not a string is a *numeric string* is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the second expression of a `for` statement.
- the expression of an `if` statement.
- the expression of the `while` clause in either a `while` or `do . . . while` statement.
- an expression used as a pattern (as in Overall Program Structure).

The `nawk` language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes changes dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.
- the `NAME` token following any use of the keyword `in`.

A valid array *index* consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because `nawk` arrays are really one-dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the `SUBSEP` variable.

Thus, the following two index operations are equivalent:

```
var[expr1, expr2, ... exprn]
var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

A multi-dimensioned *index* used with the `in` operator must be put in parentheses. The `in` operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

## Variables and Special Variables

Variables can be used in an `nawk` program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string.

Field variables are designated by a `$` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after `$NF`) produce the null string. However, assigning to a non-existent field (for example, `$(NF+2) = 5`) increases the value of `NF`, create any intervening fields with the null string as their values and cause the value of `$0` to be recomputed, with the fields being separated by the value of `OFS`. Each field variable has a string value when created. If the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a *numeric string* (see `Expressions in nawk` above), the field variable also has the numeric value of the *numeric string*.

`nawk` sets the following special variables:

- `ARGC` The number of elements in the `ARGV` array.
- `ARGV` An array of command line arguments, excluding options and the *program* argument, numbered from zero to `ARGC-1`.

/usr/xpg4/bin/awk

The arguments in ARGV can be modified or added to; ARGC can be altered. As each input file ends, `nawk` treats the next non-null element of ARGV, up to the current value of ARGC-1, inclusive, as the name of the next input file. Setting an element of ARGV to null means that it is not treated as an input file. The name - indicates the standard input. If an argument matches the format of an *assignment* operand, this argument is treated as an assignment rather than a *file* argument.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONVFMT  | The <code>printf</code> format for converting numbers to strings (except for output statements, where OFMT is used); <code>% . 6g</code> by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENVIRON  | The variable ENVIRON is an array representing the value of the environment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If the value of an environment variable is considered a <i>numeric string</i> , the array element also has its numeric value.<br><br>In all cases where <code>nawk</code> behavior is affected by environment variables (including the environment of any commands that <code>nawk</code> executes via the <code>system</code> function or via pipeline redirections with the <code>print</code> statement, the <code>printf</code> statement, or the <code>getline</code> function), the environment used is the environment at the time <code>nawk</code> began executing. |
| FILENAME | A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value is the name of the last input file processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FNR      | The ordinal number of the current record in the current file. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed in the last file processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FS       | Input field separator regular expression; a space character by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| NF       | The number of fields in the current record. Inside a BEGIN action, the use of NF is undefined unless a <code>getline</code> function without a <i>var</i> argument is executed previously. Inside an END action, NF retains the value it had for the last record read, unless a subsequent, redirected, <code>getline</code> function without a <i>var</i> argument is performed prior to entering the END action.                                                                                                                                                                                                                                                                                                                                                                                                                            |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NR     | The ordinal number of the current record from the start of input. Inside a <code>BEGIN</code> action the value is zero. Inside an <code>END</code> action the value is the number of the last record processed.                                                                                                                                                                                                                                                                                     |
| OFMT   | The <code>printf</code> format for converting numbers to strings in output statements <code>"%.6g"</code> by default. The result of the conversion is unspecified if the value of <code>OFMT</code> is not a floating-point format specification.                                                                                                                                                                                                                                                   |
| OFS    | The <code>print</code> statement output field separator; a space character by default.                                                                                                                                                                                                                                                                                                                                                                                                              |
| ORS    | The <code>print</code> output record separator; a newline character by default.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LENGTH | The length of the string matched by the <code>match</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RS     | The first character of the string value of <code>RS</code> is the input record separator; a newline character by default. If <code>RS</code> contains more than one character, the results are unspecified. If <code>RS</code> is null, then records are separated by sequences of one or more blank lines: leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of <code>FS</code> . |
| RSTART | The starting position of the string matched by the <code>match</code> function, numbering from 1. This is always equivalent to the return value of the <code>match</code> function.                                                                                                                                                                                                                                                                                                                 |
| SUBSEP | The subscript separator string for multi-dimensional arrays; the default value is <code>1</code>                                                                                                                                                                                                                                                                                                                                                                                                    |

**Regular Expressions**

The `nawk` utility makes use of the extended regular expression notation (see `regex(5)`) except that it allows the use of C-language conventions to escape special characters within the EREs, namely `\\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, and those specified in the following table. These escape sequences are recognized both inside and outside bracket expressions. Note that records need not be separated by newline characters and string constants can contain newline characters, so even the `\n` sequence is valid in `nawk` EREs. Using a slash character within the regular expression requires escaping as shown in the table below:

| Escape Sequence | Description              | Meaning                  |
|-----------------|--------------------------|--------------------------|
| <code>\"</code> | Backslash quotation-mark | Quotation-mark character |

|                   |                                                                                                                                                                                                                                                     |                                                                                                                                                                                                  |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\/</code>   | Backslash slash                                                                                                                                                                                                                                     | Slash character                                                                                                                                                                                  |
| <code>\ddd</code> | A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NULL character), the behavior is undefined.                             | The character encoded by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences, including the leading <code>\</code> for each byte. |
| <code>\c</code>   | A backslash character followed by any character not described in this table or special characters ( <code>\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ). | Undefined                                                                                                                                                                                        |

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `~` and `!~`. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `~` expression evaluates to the value 1, and the `!~` expression evaluates to the value 0. If the regular expression does not match the string, the `~` expression evaluates to the value 0, and the `!~` expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token `ERE`, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions also are applied in the determining the value of a string literal (the lexical token `STRING`), and is applied a second time when a string literal is used in this context.

When an `ERE` token appears as an expression in any context other than as the right-hand of the `~` or `!~` operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

```
$0 ~ /ere/
```

The `ere` argument to the `gsub`, `match`, `sub` functions, and the `fs` argument to the `split` function (see `String Functions`) is interpreted as extended regular expressions. These can be either `ERE` tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the `~` or `!~` operator.

An extended regular expression can be used to separate fields by using the `-F ERE` option or by assigning a string containing the expression to the built-in variable `FS`. The default value of the `FS` variable is a single space character. The following describes `FS` behavior:

1. If `FS` is a single character:

- If `FS` is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
  - Otherwise, if `FS` is any other character `c`, fields are delimited by each single occurrence of `c`.
2. Otherwise, the string value of `FS` is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.

Except in the `gsub`, `match`, `split`, and `sub` built-in functions, regular expression matching is based on input records; that is, record separator characters (the first character of the value of the variable `RS`, a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern will match any character. However, in all `nawk` regular expression matching, the use of one or more NUL characters in the pattern, input record or text string produces undefined results.

#### Patterns

A *pattern* is any valid *expression*, a range specified by two expressions separated by comma, or one of the two special patterns `BEGIN` or `END`.

#### Special Patterns

The `nawk` utility recognizes two special patterns, `BEGIN` and `END`. Each `BEGIN` pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the `getline` function in a prior `BEGIN` action) and before command line assignment is done. Each `END` pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions.

`BEGIN` and `END` do not combine with other patterns. Multiple `BEGIN` and `END` patterns are allowed. The actions associated with the `BEGIN` patterns are executed in the order specified in the program, as are the `END` actions. An `END` pattern can precede a `BEGIN` pattern in a program.

If an `nawk` program consists of only actions with the pattern `BEGIN`, and the `BEGIN` action contains no `getline` function, `nawk` exits without reading its input when the last statement in the last `BEGIN` action is executed. If an `nawk` program consists of only actions with the pattern `END` or only actions with the patterns `BEGIN` and `END`, the input is read before the statements in the `END` actions are executed.

**Expression Patterns**

An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.

**Pattern Ranges**

A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.

**Actions**

An action is a sequence of statements. A statement may be one of the following:

```

if (expression) statement [else statement]
while (expression) statement
do statement while (expression)
for (expression ; expression ; expression) statement
for (var in array) statement
delete array[subscript] #delete an array element
break
continue
{ [statement] ... }
expression # commonly variable = expression
print [expression-list] [>expression]
printf format [,expression-list] [>expression]
next # skip remaining patterns on this input line
exit [expr] # skip the rest of the input; exit status is expr
return [expr]

```

Any single statement can be replaced by a statement list enclosed in braces. The statements are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.

The `next` statement causes all further processing of the current input record to be abandoned. The behavior is undefined if a `next` statement appears or is invoked in a `BEGIN` or `END` action.

The `exit` statement invokes all `END` actions in the order in which they occur in the program source and then terminate the program without reading further input. An `exit` statement inside an `END` action terminates the program without further execution of `END` actions. If an expression is specified in an `exit` statement, its numeric value is the exit status of `nawk`, unless subsequent errors are encountered or a subsequent `exit` statement with an expression is executed.

**Output Statements**

Both `print` and `printf` statements write to standard output by default. The output is written to the location specified by `output_redirection` if one is supplied, as follows:

```
> expression
>> expression
| expression
```

In all cases, the *expression* is evaluated to produce a string that is used as a full pathname to write into (for > or >>) or as a command to be executed (for |). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value simply appends output to the file. The file remains open until the `close` function, which is called with an expression that evaluates to the same string value.

The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of *expression* as its command name. The stream created is equivalent to one created by a call to the `popen(3C)` function with the value of *expression* as the *command* argument and a value of `w` as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value writes output to the existing stream. The stream will remain open until the `close` function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the `pclose` function.

These output statements take a comma-separated list of *expression*s referred in the grammar by the non-terminal symbols `expr_list`, `print_expr_list` or `print_expr_list_opt`. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The `print` statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable `OFS` above), and terminated by the output record separator (see variable `ORS` above). All expression arguments is taken as strings, being converted if necessary; with the exception that the `printf` format in `OFMT` is used instead of the value in `CONVFMT`. An empty expression list stands for the whole input record (`$0`).

The `printf` statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document Output is produced as specified with the first expression argument as the string *format* and subsequent expression arguments as the strings *arg1* to *argn*, inclusive, with the following exceptions:

1. The *format* is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The

space character in the *format* string, in any context other than a *flag* of a conversion specification, is treated as an ordinary character that is copied to the output.

2. If the character set contains a Delta character and that character appears in the *format* string, it is treated as an ordinary character that is copied to the output.
3. The *escape sequences* beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by `nawk` when they appear in literal strings, but they is not treated specially by the `printf` statement.
4. A *field width* or *precision* can be specified as the `*` character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.
5. The implementation does not precede or follow output from the `d` or `u` conversion specifications with blank characters not specified by the *format* string.
6. The implementation does not precede output from the `o` conversion specification with leading zeros not specified by the *format* string.
7. For the `c` conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value will be output; if the string does not contain any characters the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument will be evaluated. With the exception of the `c` conversion, the value will be converted to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.
10. If any character sequence in the *format* string begins with a `%` character, but does not form a valid conversion specification, the behavior is unspecified.

Both `print` and `printf` can output at least `{LINE_MAX}` bytes.

### Functions

The `nawk` language has a variety of built-in functions: arithmetic, string, input/output and general.

### Arithmetic Functions

The arithmetic functions, except for `int`, are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless

the argument or parentheses are indicated as optional in the following list (by displaying them within the [ ] brackets), such use is undefined.

|                            |                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>atan2(y,x)</code>    | Return arctangent of $y/x$ .                                                                                                                        |
| <code>cos(x)</code>        | Return cosine of $x$ , where $x$ is in radians.                                                                                                     |
| <code>sin(x)</code>        | Return sine of $x$ , where $x$ is in radians.                                                                                                       |
| <code>exp(x)</code>        | Return the exponential function of $x$ .                                                                                                            |
| <code>log(x)</code>        | Return the natural logarithm of $x$ .                                                                                                               |
| <code>sqrt(x)</code>       | Return the square root of $x$ .                                                                                                                     |
| <code>int(x)</code>        | Truncate its argument to an integer. It will be truncated toward 0 when $x > 0$ .                                                                   |
| <code>rand( )</code>       | Return a random number $n$ , such that $0 \leq n < 1$ .                                                                                             |
| <code>srand([expr])</code> | Set the seed value for <code>rand</code> to <i>expr</i> or use the time of day if <i>expr</i> is omitted. The previous seed value will be returned. |

### String Functions

The string functions in the following list shall be supported. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the [ ] brackets), such use is undefined.

|                                    |                                                                                                                                                                                                                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gsub(ere, repl[, in])</code> | Behave like <code>sub</code> (see below), except that it will replace all occurrences of the regular expression (like the <code>ed</code> utility global substitute) in $\$0$ or in the <i>in</i> argument, when specified.                                                                    |
| <code>index(s,t)</code>            | Return the position, in characters, numbering from 1, in string <i>s</i> where string <i>t</i> first occurs, or zero if it does not occur at all.                                                                                                                                              |
| <code>length[([s])]</code>         | Return the length, in characters, of its argument taken as a string, or of the whole record, $\$0$ , if there is no argument.                                                                                                                                                                  |
| <code>match(s,ere)</code>          | Return the position, in characters, numbering from 1, in string <i>s</i> where the extended regular expression <i>ere</i> occurs, or zero if it does not occur at all. <code>RSTART</code> will be set to the starting position (which is the same as the returned value), zero if no match is |

`split(s,a, fs)`

found; `RLENGTH` will be set to the length of the matched string, `-1` if no match is found.

Split the string `s` into array elements `a[1]`, `a[2]`, . . . , `a[n]`, and return `n`. The separation will be done with the extended regular expression `fs` or with the field separator `FS` if `fs` is not given. Each array element will have a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a *numeric string*; the array element will also have the numeric value of the *numeric string*. The effect of a null string as the value of `fs` is unspecified.

`sprintf(fmt,expr,expr, . . .)`

Format the expressions according to the `printf` format given by `fmt` and return the resulting string.

`sub(ere,repl[, in])`

Substitute the string `repl` in place of the first instance of the extended regular expression `ERE` in string `in` and return the number of substitutions. An ampersand ( `&` ) appearing in the string `repl` will be replaced by the string from `in` that matches the regular expression. For each occurrence of backslash ( `\` ) encountered when scanning the string `repl` from beginning to end, the next character is taken literally and loses its special meaning (for example, `\&` will be interpreted as a literal ampersand character). Except for `&` and `\`, it is unspecified what the special meaning of any such character is. If `in` is specified and it is not an *Ivalue* the behavior is

|                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| substr( <i>s,m[, n]</i> )                                                                                                                                        | undefined. If <i>in</i> is omitted, <code>nawk</code> will substitute in the current record ( <code>\$0</code> ).                                                                                                                                                                                                                                                                     |
| tolower( <i>s</i> )                                                                                                                                              | Return the at most <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> , numbering from 1. If <i>n</i> is missing, the length of the substring will be limited by the length of the string <i>s</i> .                                                                                                                                                          |
| toupper( <i>s</i> )                                                                                                                                              | Return a string based on the string <i>s</i> . Each character in <i>s</i> that is an upper-case letter specified to have a <code>tolower</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the lower-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string. |
| All of the preceding functions that take <i>ERE</i> as a parameter expect a pattern or a string valued expression that is a regular expression as defined below. |                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Input/Output and General Functions</b>                                                                                                                        | The input/output and general functions are:                                                                                                                                                                                                                                                                                                                                           |
| <code>close(<i>expression</i>)</code>                                                                                                                            | Close the file or pipe opened by a <code>print</code> or <code>printf</code> statement or a call to <code>getline</code> with the same string-valued <i>expression</i> . If the <code>close</code> was successful, the function will return 0; otherwise, it will return non-zero.                                                                                                    |
| <code><i>expression</i>   getline [<i>var</i>]</code>                                                                                                            | Read a record of input from a stream piped from the output of a command. The stream will be created if no stream is currently open with the value of <i>expression</i> as its command                                                                                                                                                                                                 |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The <i>expression</i> will be</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

evaluated to produce a string that is used as a full pathname. If the file of that name is not currently open, it will be opened. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value will read subsequent records from the file. The file will remain open until the `close` function is called with an expression that evaluates to the same string value. If *var* is missing, `$0` and `NF` will be set; otherwise, *var* will be set.

The `getline` operator can form ambiguous constructs when there are binary operators that are not in parentheses (including concatenate) to the right of the `<` (up to the end of the expression containing the `getline`). The result of evaluating such a construct is unspecified, and all such uses of portable applications must be put in parentheses properly.

`system(expression)`

Execute the command given by *expression* in a manner equivalent to the `system(3C)` function and return the exit status of the command.

All forms of `getline` will return 1 for successful input, 0 for end of file, and -1 for an error.

Where strings are used as the name of a file or pipeline, the strings must be textually identical. The terminology “same string value” implies that “equivalent strings”, even those that differ only by space characters, represent different files.

#### User-defined Functions

The `nawk` language also provides user-defined functions. Such functions can be defined as:

```
function name(args, ...) { statements }
```

A function can be referred to anywhere in an `nawk` program; in particular, its use can precede its definition. The scope of a function will be global.

Function arguments can be either scalars or arrays; the behavior is undefined if an array name is passed as an argument that the function uses as a scalar, or if a scalar expression is passed as an argument that the function uses as an array. Function arguments will be passed by value if scalar and by reference if array name. Argument names will be local to the function; all other variable names will be global. The same name will not be used as both an argument name and as the name of a function or a special `nawk` variable. The same name must not be used both as a variable name with global scope and as the name of a function. The same name must not be used within the same scope both as a scalar variable and as an array.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars will be initialized with a string value of the null string and a numeric value of zero, and the extra parameters that are used in the function body as arrays will be initialized as empty arrays. If more arguments are supplied in a function call than are in the function definition, the behavior is undefined.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function's parameters will be unchanged, except for array parameters passed by reference. The `return` statement can be used to return a value. If a `return` statement appears outside of a function definition, the behavior is undefined.

In the function definition, newline characters are optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a *pattern-action* pair is allowed.

#### USAGE

The `index`, `length`, `match`, and `substr` functions should not be confused with similar functions in the ISO C standard; the `nawk` versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

See `largefile(5)` for the description of the behavior of `nawk` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

#### EXAMPLES

The `nawk` program specified in the command line is most easily specified within single-quotes (for example, `'program'`) for applications using `sh`, because `nawk` programs commonly contain characters that are special to the shell, including double-quotes. In the cases where a `nawk` program contains single-quote

characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/\''/ { print "quote:", $0 }
```

prints all lines from the standard input containing a single-quote character, prefixed with `quote:`.

The following are examples of simple `nawk` programs:

**EXAMPLE 1** Write to the standard output all input lines for which field 3 is greater than 5:

```
$3 > 5
```

**EXAMPLE 2** Write every tenth line:

```
(NR % 10) == 0
```

**EXAMPLE 3** Write any line with a substring matching the regular expression:

```
/(G|D)(2[0-9][[:alpha:]]*)/
```

**EXAMPLE 4** Print any line with a substring containing a G or D, followed by a sequence of digits and characters:

This example uses character classes `digit` and `alpha` to match language-independent digit and alphabetic characters, respectively.

```
/(G|D)([[:digit:]][[:alpha:]]*)/
```

**EXAMPLE 5** Write any line in which the second field matches the regular expression and the fourth field does not:

```
$2 ~ /xyz/ && $4 !~ /xyz/
```

**EXAMPLE 6** Write any line in which the second field contains a backslash:

```
$2 ~ /\
```

**EXAMPLE 7** Write any line in which the second field contains a backslash (alternate method):

Note that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression.

```
$2 ~ "\\\"
```

**EXAMPLE 8** Write the second to the last and the last field in each line, separating the fields by a colon:

```
{OFS=":";print $(NF-1), $NF}
```

**EXAMPLE 9** Write the line number and number of fields in each line:

The three strings representing the line number, the colon and the number of fields are concatenated and that string is written to standard output.

```
{print NR ":" NF}
```

**EXAMPLE 10** Write lines longer than 72 characters:

```
{length($0) > 72}
```

**EXAMPLE 11** Write first two fields in opposite order separated by the OFS:

```
{ print $2, $1 }
```

**EXAMPLE 12** Same, with input fields separated by comma or space and tab characters, or both:

```
BEGIN { FS = ",[\t]*|[\t]+" }
{ print $2, $1 }
```

**EXAMPLE 13** Add up first column, print sum and average:

```
{s += $1 }
END {print "sum is ", s, " average is", s/NR}
```

**EXAMPLE 14** Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

**EXAMPLE 15** Write all lines between occurrences of the strings "start" and "stop":

```
/start/, /stop/
```

**EXAMPLE 16** Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

**EXAMPLE 17** Simulate the echo command:

```
BEGIN {
 for (i = 1; i < ARGV; ++i)
 printf "%s%s", ARGV[i], i==ARGV-1?"\n":""
}
```

**EXAMPLE 18** Write the path prefixes contained in the PATH environment variable, one per line:

```
BEGIN {
 n = split (ENVIRON["PATH"], path, ":")
 for (i = 1; i <= n; ++i)
 print path[i]
}
```

}

**EXAMPLE 19** Print the file “input”, filling in page numbers starting at 5:

If there is a file named `input` containing page headers of the form

```
Page#
```

and a file named `program` that contains

```
/Page/{ $2 = n++; }
{ print }
```

then the command line

```
nawk -f program n=5 input
```

will print the file `input`, filling in page numbers starting at 5.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect execution: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`LC_NUMERIC` Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing `awk` programs (including assignments in command-line arguments).

**EXIT STATUS**

The following exit values are returned:

0 All input files were processed successfully.

>0 An error occurred.

The exit status can be altered within the program by using an `exit` expression.

**ATTRIBUTES**  
`/usr/bin/nawk`

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

`/usr/xpg4/bin/awk`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

**SEE ALSO**

`awk(1)`, `ed(1)`, `egrep(1)`, `grep(1)`, `lex(1)`, `sed(1)`, `popen(3C)`, `printf(3C)`, `system(3C)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `regex(5)`, `XPG4(5)`

Aho, A. V., B. W. Kernighan, and P. J. Weinberger, *The AWK Programming Language*, Addison-Wesley, 1988.

**DIAGNOSTICS**

If any *file* operand is specified and the named file cannot be accessed, `nawk` will write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *profilename* operand is not a valid `nawk` program (as specified in EXTENDED DESCRIPTION), the behavior is undefined.

**NOTES**

`nawk` is a new version of `awk` that provides capabilities unavailable in previous versions. This version will become the default version of `awk` in the next major release.

Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string (" ") to it.

**NAME** nca, snca – the Solaris Network Cache and Accelerator (NCA)

**DESCRIPTION** The Solaris Network Cache and Accelerator ("NCA ") is a kernel module designed to provide improved web server performance. The kernel module, ncakmod , services HTTP requests. To improve the performance of servicing HTTP requests, the NCA kernel module maintains an in-kernel cache of web pages. If the NCA kernel module cannot service the request itself, it passes the request to the http daemon (httpd ) by means of a private interface. The logging facility, ncalogd , logs all requests. This private interface uses the Solaris Doors RPC mechanism. See, for example, door\_create(3DOOR) , door\_call(3DOOR) , and door\_bind(3DOOR) .

The NCA cache consistency is maintained by honoring HTTP headers dealing with a given content type and expiration date, much the same way as a proxy cache.

For configuration information, see *System Administration Guide, Volume 3*

NCA is intended to be run on a dedicated webserver. Running other large processes while running NCA may cause undesirable behavior.

| <b>SYNOPSIS</b>    | <code>/usr/bin/ncab2clf [-Dhv] [-i <i>input-file</i>] [-o <i>output-file</i>] [-b <i>size</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | The <code>ncab2clf</code> command is used to convert the log file generated by the Solaris Network Cache and Accelerator (“NCA”) from binary format, to Common Log File (“CLF”) format. If no <i>input-file</i> is specified, <code>ncab2clf</code> uses <code>stdin</code> . If no <i>output-file</i> is specified, the output goes to <code>stdout</code> .                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <p><code>-b</code> Specifies the binary-log-file blocking in kilobytes; the default is 64 Kbyte.</p> <p><code>-D</code> Specifies that direct I/O be disabled.</p> <p><code>-h</code> Prints usage message.</p> <p><code>-i <i>input-file</i></code> Specifies the input file.</p> <p><code>-o <i>output-file</i></code> Specifies the output file.</p> <p><code>-v</code> Provides verbose output.</p>                                                                                                                                                                                                                                 |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Converting a Binary File to a Common Log File Format</p> <p>The following example converts the binary file <code>/var/nca/logs/nca.blf</code> to a file <code>/var/nca/logs/nca.clf</code>, which is in Common Log File format.</p> <pre>example% ncab2clf -D -i /var/nca/logs/nca.blf -o /var/nca/logs/nca.clf</pre> <p><b>EXAMPLE 2</b> Converting Multiple Log Files</p> <p>The following script may be used to convert multiple log files. The directory designated by “*” must only contain log files.</p> <pre>#!/bin/ksh for filename in * do     ncab2clf -D &lt; \$filename &gt; \$filename.clf done</pre> |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 The file converted successfully</p> <p>&gt;0 An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**NOTES**

The binary log files generated by NCA can become very large. When converting these large binary files, use the `-b` option to the `ncab2clf` command to help performance.

Direct I/O is a benefit to the user if the data being written does not come in as large chunks. However, if the user wishes to convert the log file in large chunks using the `-b` option, then direct I/O should be disabled by using the `-D` option.

| <b>NAME</b>         | ncakmod – start or stop the NCA kernel module                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                            |                |                 |              |          |                     |          |

| <b>SYNOPSIS</b>     | <code>/etc/init.d/ncakmod start   stop</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                            |                |                 |              |          |                     |          |
| <b>DESCRIPTION</b>  | <p>ncakmod is used to start or stop the Solaris Network Cache and Accelerator (“NCA”) kernel module.</p> <p>When the <code>start</code> option is specified at the command-line, the NCA kernel module will be activated for all physical interfaces listed in the <code>nca.if</code> file. When the <code>ncakmod</code> command is invoked with the <code>stop</code> option, the NCA kernel module will print the following message:</p> <pre>To stop NCA, please set the status configuration parameter to disable in ncakmod.conf and then reboot your system. See the ncakmod.conf(4) manual page for more information.</pre> <p>Note that in order to properly stop NCA on your system, you must first edit the <code>ncakmod.conf(4)</code> file and set the status field to “disable,” then reboot your system.</p> |                                                            |                |                 |              |          |                     |          |
| <b>OPTIONS</b>      | <code>start</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Starts the NCA kernel module.                              |                |                 |              |          |                     |          |
|                     | <code>stop</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Describes the current method for stopping the NCA feature. |                |                 |              |          |                     |          |
| <b>EXAMPLES</b>     | <p><b>EXAMPLE 1</b> Starting and Stopping the NCA Feature</p> <p>The following command is used to start the NCA feature:</p> <pre>example% /etc/init.d/ncakmod start</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                            |                |                 |              |          |                     |          |

| <b>DESCRIPTION</b>          | Netscape Communicator for Solaris is comprised of a comprehensive set of components that integrates browsing, email, web-based word processing, chat, and group scheduling to allow users to easily communicate, share, and access information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                               |           |                                          |              |                             |                     |                                            |                             |                                                                                           |                           |                                                            |       |                |                            |                                          |       |                                              |         |                                    |                      |                                                                                                                     |                        |                                                                    |          |                            |                          |                                                                                                 |
| <b>OPTIONS</b>              | <p>Any argument that is not a switch is interpreted as either a file or URL. The following options are supported:</p> <table border="0"> <tr> <td style="vertical-align: top;">-component-bar</td> <td>Shows only the Component Bar.</td> </tr> <tr> <td style="vertical-align: top;">-composer</td> <td>Opens all command line URLs in Composer.</td> </tr> <tr> <td style="vertical-align: top;">-discussions</td> <td>Shows Collabra Discussions.</td> </tr> <tr> <td style="vertical-align: top;">-display <i>dpy</i></td> <td>Specifies the X server to use for display.</td> </tr> <tr> <td style="vertical-align: top;">-dont-force-window-stacking</td> <td>Ignores the alwaysraised, alwayslowered, and z-lock JavaScript window.open( ) attributes.</td> </tr> <tr> <td style="vertical-align: top;">-dont-save-geometry-prefs</td> <td>Does not save window geometry preferences for the session.</td> </tr> <tr> <td style="vertical-align: top;">-edit</td> <td>See -composer.</td> </tr> <tr> <td style="vertical-align: top;">-geometry =<i>WxH+X+Y</i></td> <td>Positions and sizes the Netscape window.</td> </tr> <tr> <td style="vertical-align: top;">-help</td> <td>Shows the command line options for Netscape.</td> </tr> <tr> <td style="vertical-align: top;">-iconic</td> <td>Minimizes Netscape after start up.</td> </tr> <tr> <td style="vertical-align: top;">-id <i>window-id</i></td> <td>Identifies an X window to receive -remote commands. If you do not specify a window, the first window found is used.</td> </tr> <tr> <td style="vertical-align: top;">-ignore-geometry-prefs</td> <td>Ignores saved window geometry preferences for the current session.</td> </tr> <tr> <td style="vertical-align: top;">-install</td> <td>Installs private colormap.</td> </tr> <tr> <td style="vertical-align: top;">-irix-session-management</td> <td>Enables IRIX session management. On SGI systems, IRIX session management is enabled by default.</td> </tr> </table> | -component-bar | Shows only the Component Bar. | -composer | Opens all command line URLs in Composer. | -discussions | Shows Collabra Discussions. | -display <i>dpy</i> | Specifies the X server to use for display. | -dont-force-window-stacking | Ignores the alwaysraised, alwayslowered, and z-lock JavaScript window.open( ) attributes. | -dont-save-geometry-prefs | Does not save window geometry preferences for the session. | -edit | See -composer. | -geometry = <i>WxH+X+Y</i> | Positions and sizes the Netscape window. | -help | Shows the command line options for Netscape. | -iconic | Minimizes Netscape after start up. | -id <i>window-id</i> | Identifies an X window to receive -remote commands. If you do not specify a window, the first window found is used. | -ignore-geometry-prefs | Ignores saved window geometry preferences for the current session. | -install | Installs private colormap. | -irix-session-management | Enables IRIX session management. On SGI systems, IRIX session management is enabled by default. |
| -component-bar              | Shows only the Component Bar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                               |           |                                          |              |                             |                     |                                            |                             |                                                                                           |                           |                                                            |       |                |                            |                                          |       |                                              |         |                                    |                      |                                                                                                                     |                        |                                                                    |          |                            |                          |                                                                                                 |

On SGI systems, IRIX session management is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                               |           |                                          |              |                             |                     |                                            |                             |                                                                                           |                           |                                                            |       |                |                            |                                          |       |                                              |         |                                    |                      |                                                                                                                     |                        |                                                                    |          |                            |                          |                                                                                                 |

|                                            |                                                                                                                                                                                                           |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            | IRIX session management is available on other platforms and may work with session managers other than the IRIX desktop. See <code>-no-irix-session-management</code> .                                    |
| <code>-mail</code>                         | Same as <code>-messenger</code> .                                                                                                                                                                         |
| <code>-messenger</code>                    | Shows the Messenger Mailbox (Inbox).                                                                                                                                                                      |
| <code>-mono</code>                         | Forces a one-bit deep image display.                                                                                                                                                                      |
| <code>-ncols <i>N</i></code>               | Sets the maximum number of colors to allocate for images when not using <code>-install</code> .                                                                                                           |
| <code>-nethelp</code>                      | Starts NetHelp, Netscape's online help system.                                                                                                                                                            |
| <code>-news</code>                         | Same as <code>-discussions</code> .                                                                                                                                                                       |
| <code>-no-about-splash</code>              | Bypasses the startup license page.                                                                                                                                                                        |
| <code>-no-install</code>                   | Uses the default colormap.                                                                                                                                                                                |
| <code>-no-irix-session-management</code>   | Disables IRIX session management. See <code>-irix-session-management</code> .                                                                                                                             |
| <code>-no-session-management</code>        | Disables session management. Session management is enabled by default. See <code>-session-management</code> .                                                                                             |
| <code>-noraise</code>                      | Does not display the remote window on top when using <code>-remote</code> commands. See <code>-raise</code> and <code>-remote</code> .                                                                    |
| <code>-raise</code>                        | Displays the remote window on top when using <code>-remote</code> commands. See <code>-noraise</code> and <code>-remote</code> .                                                                          |
| <code>-remote <i>remote-command</i></code> | Connects to and controls an existing process. You can issue multiple <code>-remote</code> options on the same command line. The commands are executed sequentially unless a command fails. If there is no |

Netscape process currently running, this command fails.

The following options exist for finer-grained control of the `-remote` commands:

`-id X_window_ID`

If there is more than one Netscape Navigator window open, this option selects the window to control. If you do not use this option, the first window found is controlled. See EXAMPLES.

`-raise`

`-noraise`

Controls whether the `-remote` command causes the Netscape window to raise/not raise itself to the top. The default is raise.

You can use `-raise` and `-noraise` options with the `addBookmark` and `openURL` arguments. See EXAMPLES.

`-session-management`

Enables session management. Session management is enabled by default. See `-no-session-management`.

`-version`

Displays the version number and build date.

`-visual id-or-number`

Uses the specified server visual.

`-xrm resource-spec`

Sets the specified X resource.

## ARGUMENTS

Invoking an action with no arguments has the same effect as selecting the corresponding menu item. However, with some actions you can pass the following arguments:

`addBookmark()`

Adds the current document to the Bookmark list.

`addBookmark(URL)`

Adds the specified document to the Bookmark list. See EXAMPLES.

`addBookmark(URL, title)`

Adds the specified document and title to the Bookmark list.

`mailto()`

Opens the mail dialog box with an empty `TO:` field.

|                                               |                                                                           |
|-----------------------------------------------|---------------------------------------------------------------------------|
| <code>mailto(<i>a, b, c</i>)</code>           | Inserts the specified address(es) in the default <code>To:</code> field.  |
| <code>openFile()</code>                       | Opens a dialog box that prompts for a file.                               |
| <code>openFile(<i>filename</i>)</code>        | Opens the specified file.                                                 |
| <code>openURL()</code>                        | Opens a dialog box that prompts for a URL.                                |
| <code>openURL(<i>URL</i>)</code>              | Opens the specified document. See <b>EXAMPLES</b> .                       |
| <code>openURL(<i>URL, new window</i>)</code>  | Opens a new window displaying the specified document.                     |
| <code>saveAs()</code>                         | Opens a dialog box that prompts for a URL.                                |
| <code>saveAs(<i>output_file</i>)</code>       | Writes HTML to the specified file.                                        |
| <code>saveAs(<i>output_file, type</i>)</code> | Writes the <i>type</i> to the specified file (HTML, text, or PostScript). |

**EXIT STATUS**

If a command fails, an error message is reported to `stderr` and the command exits with a nonzero status.

**EXAMPLES**

**EXAMPLE 1** Selecting among open Netscape windows

```
example% netscape -id 0x3c00124 -remote 'openURL(http://www.sun.com)'
```

**EXAMPLE 2** Adding a bookmark without raising a window

To add a bookmark without raising a window, then open a URL and raise the window:

```
example% netscape -noraise -remote 'addBookmark(http://www.sun.com)' \
 -raise -remote 'openURL(http://home.netscape.com)'
```

For more information and examples, see <http://home.netscape.com/newsref/std/x-remote.html>

**EXAMPLE 3** Adding a specified document to the Bookmark list

```
example% netscape -remote 'addBookmark(http://www.sun.com)'
```

**EXAMPLE 4** Opening a specified document

```
example% netscape -remote 'openURL(http://www.sun.com)'
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | NSCPcom         |

| <b>NAME</b>        | newform - change the format of a text file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>newform</b> [-s] [-i <i>tabspec</i> ] [-o <i>tabspec</i> ] [-bn] [-en] [-pn] [-an] [-f] [-cchar]<br>[-ln] [ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p><code>newform</code> reads lines from the named <i>filenames</i>, or the standard input if no input file is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with command line options in effect.</p> <p>Except for <code>-s</code>, command line options may appear in any order, may be repeated, and may be intermingled with the optional <i>filenames</i>. Command line options are processed in the order specified. This means that option sequences like “<code>-e15 -l60</code>” will yield results different from “<code>-l60 -e15</code>”. Options are applied to all <i>filenames</i> on the command line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-s</code>           Shears off leading characters on each line up to the first tab and places up to 8 of the sheared characters at the end of the line. If more than 8 characters (not counting the first tab) are sheared, the eighth character is replaced by a * and any characters to the right of it are discarded. The first tab is always discarded.</p> <p>                  An error message and program exit will occur if this option is used on a file without a tab on each line. The characters sheared off are saved internally until all other options specified are applied to that line. The characters are then added at the end of the processed line.</p> <p>                  For example, to convert a file with leading digits, one or more tabs, and text on each line, to a file beginning with the text, all tabs after the first expanded to spaces, padded with spaces out to column 72 (or truncated to column 72), and the leading digits placed starting at column 73, the command would be:</p> <pre>newform -s -i -l -a -e filename</pre> <p><code>-i <i>tabspec</i></code>   Input tab specification: expands tabs to spaces, according to the tab specifications given. <i>Tabspec</i> recognizes all tab specification forms described in <code>tabs(1)</code>. In addition, <i>tabspec</i> may be <code>-</code>, in which <code>newform</code> assumes that the tab specification is to be found in the first line read from the standard input (see <code>fspec(4)</code>). If no <i>tabspec</i> is given, <i>tabspec</i> defaults to <code>-8</code>. A <i>tabspec</i> of <code>-0</code> expects no tabs; if any are found, they are treated as <code>-1</code>.</p> |

- `-o tabspec` Output tab specification: replaces spaces by tabs, according to the tab specifications given. The tab specifications are the same as for `-i tabspec`. If no *tabspec* is given, *tabspec* defaults to `-8`. A *tabspec* of `-0` means that no spaces will be converted to tabs on output.
- `-bn` Truncate *n* characters from the beginning of the line when the line length is greater than the effective line length (see `-ln`). Default is to truncate the number of characters necessary to obtain the effective line length. The default value is used when `-b` with no *n* is used. This option can be used to delete the sequence numbers from a COBOL program as follows:
- ```
newform -ll -b7 filename
```
- `-en` Same as `-bn` except that characters are truncated from the end of the line.
- `-pn` Prefix *n* characters (see `-cchar`) to the beginning of a line when the line length is less than the effective line length. Default is to prefix the number of characters necessary to obtain the effective line length.
- `-an` Same as `-pn` except characters are appended to the end of a line.
- `-f` Write the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the last `-o` option. If no `-o` option is specified, the line which is printed will contain the default specification of `-8`.
- `-cchar` Change the prefix/append character to *char*. Default character for *char* is a space.
- `-ln` Set the effective line length to *n* characters. If *n* is not entered, `-l` defaults to `72`. The default line length without the `-l` option is `80` characters. Note: Tabs and backspaces are considered to be one character (use `-i` to expand tabs to spaces).
- The `-ll` must be used to set the effective line length shorter than any existing line in the file so that the `-b` option is activated.

OPERANDS

The following operand is supported:

filename Input file

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO

`csplit(1)`, `tabs(1)`, `fspec(4)`, `attributes(5)`

DIAGNOSTICS

All diagnostics are fatal.

usage: . . .

newform was called with a bad option.

"not -s format"

There was no tab on one line.

"can't open file"

Self-explanatory.

"internal line too long"

A line exceeds 512 characters after being expanded in the internal work buffer.

"tabspec in error"

A tab specification is incorrectly formatted, or specified tab stops are not ascending.

"tabspec indirection illegal"

A *tabspec* read from a file (or standard input) may not contain a *tabspec* referencing another file (or standard input).

NOTES

`newform` normally only keeps track of physical characters; however, for the `-i` and `-o` options, `newform` will keep track of backspaces in order to line up tabs in the appropriate logical columns.

`newform` will not prompt the user if a *tabspec* is to be read from the standard input (by use of `-i-` or `-o-`).

If the `-f` option is used, and the last `-o` option specified was `-o-`, and was preceded by either a `-o-` or a `-i-`, the tab specification format line will be incorrect.

NAME	newgrp – log in to a new group
SYNOPSIS	
Command	<code>/usr/bin/newgrp [-l -1] [group]</code>
sh Built-in	<code>newgrp [argument]</code>
ksh Built-in	<code>*newgrp [argument]</code>
DESCRIPTION	
Command	<p>The <code>newgrp</code> command logs a user into a new group by changing a user's real and effective group ID. The user remains logged in and the current directory is unchanged. The execution of <code>newgrp</code> always replaces the current shell with a new shell, even if the command terminates with an error (unknown group).</p> <p>Any variable that is not exported is reset to null or its default value. Exported variables retain their values. System variables (such as <code>PS1</code>, <code>PS2</code>, <code>PATH</code>, <code>MAIL</code>, and <code>HOME</code>), are reset to default values unless they have been exported by the system or the user. For example, when a user has a primary prompt string (<code>PS1</code>) other than <code>\$</code> (default) and has not exported <code>PS1</code>, the user's <code>PS1</code> will be set to the default prompt string <code>\$</code>, even if <code>newgrp</code> terminates with an error. Note that the shell command <code>export</code> (see <code>sh(1)</code> and <code>set(1)</code>) is the method to export variables so that they retain their assigned value when invoking new shells.</p> <p>With no operands and options, <code>newgrp</code> changes the user's group IDs (real and effective) back to the group specified in the user's password file entry. This is a way to exit the effect of an earlier <code>newgrp</code> command.</p> <p>A password is demanded if the group has a password and the user is not listed in <code>/etc/group</code> as being a member of that group. The only way to create a password for a group is to use <code>passwd(1)</code>, then cut and paste the password from <code>/etc/shadow</code> to <code>/etc/group</code>. Group passwords are antiquated and not often used.</p>
sh Built-in	Equivalent to <code>exec newgrp argument</code> where <i>argument</i> represents the options and/or operand of the <code>newgrp</code> command.
ksh Built-in	Equivalent to <code>exec to/bin/newgrp argument</code> where <i>argument</i> represents the options and/or operand of the <code>newgrp</code> command.
	<p>On this man page, <code>ksh(1)</code> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none"> 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments. 3. Errors cause a script that contains them to abort.

4. Words, following a command preceded by ****** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

OPTIONS

The following option is supported:

- 1** | **-** Change the environment to what would be expected if the user actually logged in again as a member of the new group.

OPERANDS

The following operands are supported:

group A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs will be set. If *group* is a non-negative numeric string and exists in the group database as a group name (see `getgrnam(3C)`), the numeric group ID associated with that group name will be used as the group ID.

argument `sh` and `ksh` only. Options and/or operand of the `newgrp` command.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `newgrp`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

If `newgrp` succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status will be the exit status of the shell. Otherwise, the following exit value is returned:

- >0 An error occurred.

FILES

`/etc/group` system's group file

`/etc/passwd` system's password file

NAME	news – print news items						
SYNOPSIS	news [-a] [-n] [-s] [<i>items</i>]						
DESCRIPTION	<p><i>news</i> is used to keep the user informed of current events. By convention, these events are described by files in the directory <code>/var/news</code>.</p> <p>When invoked without arguments, <i>news</i> prints the contents of all current files in <code>/var/news</code>, most recent first, with each preceded by an appropriate header. <i>news</i> stores the “currency” time as the modification date of a file named <code>.news_time</code> in the user’s home directory (the identity of this directory is determined by the environment variable <code>\$HOME</code>); only files more recent than this currency time are considered “current.”</p>						
OPTIONS	<p>-a Print all items, regardless of currency. In this case, the stored time is not changed.</p> <p>-n Report the names of the current items without printing their contents, and without changing the stored time.</p> <p>-s report how many current items exist, without printing their names or contents, and without changing the stored time. It is useful to include such an invocation of <i>news</i> in one’s <code>.profile</code> file, or in the system’s <code>/etc/profile</code>.</p> <p>All other arguments are assumed to be specific news items that are to be printed.</p> <p>If a <i>delete</i> is typed during the printing of a news item, printing stops and the next item is started. Another <i>delete</i> within one second of the first causes the program to terminate.</p>						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for a description of the <code>LC_CTYPE</code> environment variable that affects the execution of <i>news</i> .						
FILES	<p><code>/etc/profile</code></p> <p><code>/var/news/*</code></p> <p><code>\$HOME/.news_time</code></p>

NAME	nice – invoke a command with an altered scheduling priority
SYNOPSIS	<code>/usr/bin/nice</code> [<i>-increment</i> <i>-n increment</i>] <i>command</i> [<i>argument...</i>] <code>/usr/xpg4/bin/nice</code> [<i>-increment</i> <i>-n increment</i>] <i>command</i> [<i>argument...</i>]
csH Builtin	nice [<i>-increment</i> <i>+increment</i>] [<i>command</i>]
DESCRIPTION	<p>The <code>nice</code> utility invokes <code>command</code>, requesting that it be run with a different system scheduling priority. The <code>pricntl(1)</code> command is a more general interface to scheduler functions.</p> <p>The invoking process (generally the user's shell) must be in a scheduling class that supports <code>nice</code>.</p> <p>If the C shell (see <code>csH(1)</code>) is used, the full path of the command must be specified; otherwise, the <code>csH</code> built-in version of <code>nice</code> will be invoked. See <code>csH Builtin</code> below.</p> <p><code>/usr/bin/nice</code> If <code>nice</code> executes commands with arguments, it uses the default shell <code>/usr/bin/sh</code> (see <code>sh(1)</code>).</p> <p><code>/usr/xpg4/bin/nice</code> If <code>nice</code> executes commands with arguments, it uses <code>/usr/xpg4/bin/sh</code>, which is equivalent to <code>/usr/bin/ksh</code> (see <code>ksh(1)</code>).</p> <p>csH Builtin <code>nice</code> is also a <code>csH</code> built-in command with behavior different from the utility versions. See <code>csH(1)</code> for description.</p>
OPTIONS	<p>The following options are supported:</p> <p><i>-increment</i> <i>-n increment</i> <i>increment</i> must be in the range 1-19; if not specified, an increment of 10 is assumed. An <i>increment</i> greater than 19 is equivalent to 19.</p> <p>The super-user may run commands with priority higher than normal by using a negative increment such as <i>-10</i>. A negative <i>increment</i> assigned by an unprivileged user is ignored.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>command</i> The name of a command that is to be invoked. If <code>command</code> names any of the special built-in utilities (see <code>shell_builtins(1)</code>), the results are undefined.</p> <p><i>argument</i> Any string to be supplied as an argument when invoking <code>command</code>.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>nice</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , <code>PATH</code> , and <code>NLSPATH</code> .
EXIT STATUS	If <code>command</code> is invoked, the exit status of <code>nice</code> will be the exit status of <code>command</code> ; otherwise, <code>nice</code> will exit with one of the following values:

1-125 An error occurred.

126 *command* was found but could not be invoked.

127 *command* could not be found.

NAME	nis+, NIS+, nis – a new version of the network information name service
DESCRIPTION	<p>NIS+ is a new version of the network information nameservice. This version differs in several significant ways from version 2, which is referred to as NIS or YP in earlier releases. Specific areas of enhancement include the ability to scale to larger networks, security, and the administration of the service.</p> <p>The man pages for NIS+ are broken up into three basic categories. Those in section 1 are the user commands that are most often executed from a shell script or directly from the command line. Section 1M man pages describe utility commands that can be used by the network administrator to administer the service itself. The NIS+ programming API is described by man pages in section 3N.</p> <p>All commands and functions that use NIS version 2 are prefixed by the letters <i>yp</i> as in <i>ypmatch(1)</i>, <i>ypcat(1)</i>, <i>yp_match(3NSL)</i>, and <i>yp_first(3NSL)</i>. Commands and functions that use the new replacement software NIS+ are prefixed by the letters <i>nis</i> as in <i>nismatch(1)</i>, <i>nischown(1)</i>, <i>nis_list(3NSL)</i>, and <i>nis_add_entry(3NSL)</i>. A complete list of NIS+ commands is in the LIST OF COMMANDS section.</p> <p>This man page introduces the NIS+ terminology. It also describes the NIS+ namespace, authentication, and authorization policies.</p>
NIS+ NAMESPACE	<p>The naming model of NIS+ is based upon a tree structure. Each node in the tree corresponds to an NIS+ object. There are six types of NIS+ objects: <i>directory</i>, <i>table</i>, <i>group</i>, <i>link</i>, <i>entry</i>, and <i>private</i>.</p>
NIS+ Directory Object	<p>Each NIS+ namespace will have at least one NIS+ directory object. An NIS+ directory is like a UNIX file system directory which contains other NIS+ objects including NIS+ directories. The NIS+ directory that forms the root of the NIS+ namespace is called the root directory. There are two special NIS+ directories: <i>org_dir</i> and <i>groups_dir</i>. The <i>org_dir</i> directory consists of all the system-wide administration tables, such as <i>passwd</i>, <i>hosts</i>, and <i>mail_aliases</i>. The <i>groups_dir</i> directory consists of NIS+ group objects which are used for access control. The collection of <i>org_dir</i>, <i>groups_dir</i> and their parent directory is referred to as an NIS+ domain. NIS+ directories can be arranged in a tree-like structure so that the NIS+ namespace can match the organizational or administrative hierarchy.</p>
NIS+ Table Object	<p>NIS+ tables (not files), contained within NIS+ directories, store the actual information about some particular type. For example, the <i>hosts</i> system table stores information about the IP address of the hosts in that domain. NIS+ tables are multicolumn and the tables can be searched through any of the searchable columns. Each table object defines the schema for its table. The NIS+ tables consist of NIS+ entry objects. For each entry in the NIS+ table, there is an NIS+</p>

	entry object. NIS+ entry objects conform to the schema defined by the NIS+ table object.
NIS+ Group Object	NIS+ group objects are used for access control at group granularity. NIS+ group objects, contained within the <code>groups_dir</code> directory of a domain, contain a list of all the NIS+ principals within a certain NIS+ group. An NIS+ principal is a user or a machine making NIS+ requests.
NIS+ Link Object	NIS+ link objects are like UNIX symbolic file-system links—they are typically used for shortcuts in the NIS+ namespace. Refer to <code>nis_objects(3NSL)</code> for more information about the NIS+ objects.
NIS+ NAMES	The NIS+ service defines two forms of names, <i>simple</i> names and <i>indexed</i> names. Simple names are used by the service to identify NIS+ objects contained within the NIS+ namespace. Indexed names are used to identify NIS+ entries contained within NIS+ tables. Furthermore, entries within NIS+ tables are returned to the caller as NIS+ objects of type <i>entry</i> . NIS+ objects are implemented as a union structure which is described in the file <code><rpcsvc/nis_object.x></code> . The differences between the various types and the meanings of the components of these objects are described in <code>nis_objects(3NSL)</code> .
Simple Names	Simple names consist of a series of labels that are separated by the '.' (dot) character. Each label is composed of printable characters from the ISO Latin 1 set. Each label can be of any nonzero length, provided that the fully qualified name is fewer than <code>NIS_MAXNAMELEN</code> octets including the separating dots. (See <code><rpcsvc/nis.h></code> for the actual value of <code>NIS_MAXNAMELEN</code> in the current release.) Labels that contain special characters (see <code>Grammar</code>) must be quoted. The NIS+ namespace is organized as a singly rooted tree. Simple names identify nodes within this tree. These names are constructed such that the leftmost label in a name identifies the leaf node and all of the labels to the right of the leaf identify that object's parent node. The parent node is referred to as the leaf's <i>directory</i> . This is a naming directory and should not be confused with a file system directory. For example, the name <code>example.simple.name</code> is a simple name with three labels, where <code>example</code> is the leaf node in this name, the directory of this leaf is <code>simple.name</code> , which by itself is a simple name. The leaf of which is <code>simple</code> and its directory is simply <code>name</code> . The function <code>nis_leaf_of(3NSL)</code> returns the first label of a simple name. The function <code>nis_domain_of(3NSL)</code> returns the name of the directory that contains the leaf. Iterative use of these two functions can break a simple name into each of its label components. The name '.' (dot) is reserved to name the <i>global root</i> of the namespace. For systems that are connected to the Internet, this global root will be served by a

Domain Name Service. When an NIS+ server is serving a root directory whose name is not '.' (dot) this directory is referred to as a *local root*.

NIS+ names are said to be *fully qualified* when the name includes all of the labels identifying all of the directories, up to the global root. Names without the trailing dot are called *partially qualified*.

Indexed Names

Indexed names are compound names that are composed of a search criterion and a simple name. The search criterion component is used to select entries from a table; the simple name component is used to identify the NIS+ table that is to be searched. The search criterion is a series of column names and their desired values enclosed in bracket '['] ' characters. These criteria take the following form:

```
[ column_name = value , column_name = value , ... ]
```

A search criterion is combined with a simple name to form an indexed name by concatenating the two parts, separated by a ',' (comma) character as follows.

```
[ search-criterion ] , table.directory
```

When multiple column name/value pairs are present in the search criterion, only those entries in the table that have the appropriate value in all columns specified are returned. When no column name/value pairs are specified in the search criterion, [] , *all* entries in the table are returned.

Grammar

The following text represents a context-free grammar that defines the set of legal NIS+ names. The terminals in this grammar are the characters '.' (dot), '[' (open bracket), ']' (close bracket), ',' (comma), '=' (equals) and whitespace. Angle brackets ('<' and '>'), which delineate non-terminals, are not part of the grammar. The character '|' (vertical bar) is used to separate alternate productions and should be read as "this production OR this production".

```

name           ::=  . | <simple name > | <indexed name >
simple name     ::=  <string >. | <string >.<simple name >
indexed name   ::=  <search criterion >,<simple name >
search criterion ::=  [ <attribute list > ]
attribute list ::=  <attribute > | <attribute >,<attribute list >
attribute      ::=  <string > = <string >
string         ::=  ISO Latin 1 character set except the character '/' (slash).
                   The initial character may not be a terminal character or
                   the characters '@' (at), '+' (plus), or '-' (hyphen).
```

Name Expansion

Terminals that appear in strings must be quoted with "" (double quote). The "" character may be quoted by quoting it with itself "" "".

The NIS+ service only accepts fully qualified names. However, since such names may be unwieldy, the NIS+ commands in section 1 employ a set of standard expansion rules that will attempt to fully qualify a partially qualified name. This expansion is actually done by the NIS+ library function `nis_getnames(3NSL)` which generates a list of names using the default NIS+ directory search path or the `NIS_PATH` environment variable. The default NIS+ directory search path includes all the names in its path. `nis_getnames()` is invoked by the functions `nis_lookup(3NSL)` and `nis_list(3NSL)` when the `EXPAND_NAME` flag is used.

The `NIS_PATH` environment variable contains an ordered list of simple names. The names are separated by the ':' (colon) character. If any name in the list contains colons, the colon should be quoted as described in the `Grammar` section. When the list is exhausted, the resolution function returns the error `NIS_NOTFOUND`. This may mask the fact that the name existed but a server for it was unreachable. If the name presented to the list or lookup interface is fully qualified, the `EXPAND_NAME` flag is ignored.

In the list of names from the `NIS_PATH` environment variable, the '\$' (dollar sign) character is treated specially. Simple names that end with the label '\$' have this character replaced by the default directory (see `nis_local_directory(3NSL)`). Using "\$" as a name in this list results in this name being replaced by the list of directories between the default directory and the global root that contain at least two labels.

Below is an example of this expansion. Given the default directory of *some.long.domain.name.*, and the `NIS_PATH` variable set to `fred.bar.:org_dir.$:$`. This path is initially broken up into the list:

```
1      fred.bar.
2      org_dir.$
3      $
```

The dollar sign in the second component is replaced by the default directory. The dollar sign in the third component is replaced with the names of the directories between the default directory and the global root that have at least two labels in them. The effective path value becomes:

```
1      fred.bar.
2a     org_dir.some.long.domain.name.
3a     some.long.domain.name.
3b     long.domain.name.
3c     domain.name.
```

Each of these simple names is appended to the partially qualified name that was passed to the `nis_lookup(3NSL)` or `nis_list(3NSL)` interface. Each is tried in turn until `NIS_SUCCESS` is returned or the list is exhausted.

If the `NIS_PATH` variable is not set, the path "\$" is used.

The library function `nis_getnames(3NSL)` can be called from user programs to generate the list of names that would be attempted. The program `nisdefaults(1)` with the `-s` option can also be used to show the fully expanded path.

Concatenation Path

Normally, all the entries for a certain type of information are stored within the table itself. However, there are times when it is desirable for the table to point to other tables where entries can be found. For example, you may want to store all the IP addresses in the host table for their own domain, and yet want to be able to resolve hosts in some other domain without explicitly specifying the new domain name. NIS+ provides a mechanism for concatenating different but related tables with a "NIS+ Concatenation Path". With a concatenation path, you can create a sort of flat namespace from a hierarchical structure. You can also create a table with no entries and just point the hosts or any other table to its parent domain. Note that with such a setup, you are moving the administrative burden of managing the tables to the parent domain. The concatenation path will slow down the request response time because more tables and more servers are searched. It will also decrease the availability if all the servers are incapacitated for a particular directory in the table path.

The NIS+ Concatenation Path is also referred to as the "table path". This path is set up at table creation time through `nistbladm(1)`. You can specify more than one table to be concatenated and they will be searched in the given order. Note that the NIS+ client libraries, by default, will not follow the concatenation path set in site-specific tables. Refer to `nis_list(3NSL)` for more details.

Namespaces

The NIS+ service defines two additional *disjoint* namespaces for its own use. These namespaces are the NIS+ *Principal* namespace, and the NIS+ *Group* namespace. The names associated with the group and principal namespaces are syntactically identical to simple names. However, the information they represent *cannot* be obtained by directly presenting these names to the NIS+ interfaces. Instead, special interfaces are defined to map these names into NIS+ names so that they may then be resolved.

Principal Names

NIS+ principal names are used to uniquely identify users and machines that are making NIS+ requests. These names have the form:

principal .domain

Here *domain* is the fully qualified name of an NIS+ directory where the named principal's credentials can be found. See `Directories` and `Domains` for more information on domains. Note that in this name, *principal*, is not a leaf in the NIS+ namespace.

Credentials are used to map the identity of a host or user from one context such as a process UID into the NIS+ context. They are stored as records in an NIS+ table named *cred*, which always appears in the *org_dir* subdirectory of the directory named in the principal name.

This mapping can be expressed as a replacement function:

```
principal.domain ->[cname=principal.domain ],cred.org_dir.domain
```

This latter name is an NIS+ name that can be presented to the `nis_list(3NSL)` interface for resolution. NIS+ principal names are administered using the `nisaddcred(1M)` command.

The *cred* table contains five columns named *cname*, *auth_name*, *auth_type*, *public_data*, and *private_data*. There is one record in this table for each identity mapping for an NIS+ principal. The current service supports three types of mappings:

LOCAL	This mapping is used to map from the UID of a given process to the NIS+ principal name associated with that UID. If no mapping exists, the name <i>nobody</i> is returned. When the effective UID of the process is 0 (for example, the superuser), the NIS+ name associated with the host is returned. Note that UIDs are sensitive to the context of the machine on which the process is executing.
DES	This mapping is used to map to and from a Secure RPC "netname" into an NIS+ principal name. See <code>secure_rpc(3NSL)</code> for more information on netnames. Note that since netnames contain the notion of a domain, they span NIS+ directories.
DHnnn-m	Example: DH640-0, DH1024-0. Analogous to DES mappings, these are used to map netnames and NIS+ principal names for extended Diffie-Hellman keys. See <code>nisauthconf(1M)</code> for further information.

The NIS+ client library function `nis_local_principal(3NSL)` uses the *cred.org_dir* table to map the UNIX notion of an identity, a process' UID, into an NIS+ principal name. Shell programs can use the program `nisdefaults(1)` with the `-p` switch to return this information.

Mapping from UIDs to an NIS+ principal name is accomplished by constructing a query of the form:

```
[auth_type=LOCAL, auth_name= uid ],cred.org_dir. default-domain .
```

This query will return a record containing the NIS+ principal name associated with this UID, in the machine's default domain.

The NIS+ service uses the DES mapping to map the names associated with Secure RPC requests into NIS+ principal names. RPC requests that use Secure RPC include the *netname* of the client making the request in the RPC header. This netname has the form:

```
unix. UID @ domain
```

The service constructs a query using this name of the form:

```
[auth_type=DES, auth_name= netname ],cred.org_dir. domain .
```

where the domain part is extracted from the netname rather than using the default domain. This query is used to look up the mapping of this netname into an NIS+ principal name in the domain where it was created.

This mechanism of mapping UID and netnames into an NIS+ principal name guarantees that a client of the NIS+ service has only one principal name. This principal name is used as the basis for authorization which is described below. All objects in the NIS+ namespace and all entries in NIS+ tables must have an owner specified for them. This owner field always contains an NIS+ principal name.

Group Names

Like NIS+ principal names, NIS+ group names take the form:

```
group_name.domain
```

All objects in the NIS+ namespace and all entries in NIS+ tables may optionally have a *group owner* specified for them. This group owner field, when filled in, always contains the fully qualified NIS+ group name.

The NIS+ client library defines several interfaces (`nis_groups(3NSL)`) for dealing with NIS+ groups. These interfaces internally map NIS+ group names into an NIS+ simple name which identifies the NIS+ group object associated with that group name. This mapping can be shown as follows:

```
group.domain -> group .groups_dir .domain
```

This mapping eliminates collisions between NIS+ group names and NIS+ directory names. For example, without this mapping, a directory with the name *engineering.foo.com.*, would make it impossible to have a group named *engineering.foo.com.*. This is due to the restriction that within the NIS+ namespace, a name unambiguously identifies a single object. With this mapping, the NIS+ *group* name *engineering.foo.com.* maps to the NIS+ *object* name *engineering.groups_dir.foo.com.*

The contents of a group object is a list of NIS+ principal names, and the names of other NIS+ groups. See *nis_groups(3NSL)* for a more complete description of their use.

NIS+ SECURITY

NIS+ defines a security model to control access to information managed by the service. The service defines access rights that are selectively granted to individual clients or groups of clients. Principal names and group names are used to define clients and groups of clients that may be granted or denied access to NIS+ information. These principals and groups are associated with NIS+ domains as defined below.

The security model also uses the notion of a class of principals called *nobody*, which contains all clients, whether or not they have authenticated themselves to the service. The class *world* includes any client who has been authenticated.

Directories and Domains

Some directories within the NIS+ namespace are referred to as NIS+ *Domains*. Domains are those NIS+ directories that contain the subdirectories *groups_dir* and *org_dir*. Further, the subdirectory *org_dir* should contain the table named *cred*. NIS+ Group names and NIS+ Principal names always include the NIS+ domain name after their first label.

Authentication

The NIS+ name service uses Secure RPC for the integrity of the NIS+ service. This requires that users of the service and their machines must have a Secure RPC key pair associated with them. This key is initially generated with either the *nisaddcred(1M)* or *nisclient(1M)* commands and modified with the *chkey(1)* or *nispaswd(1)* commands.

The use of Secure RPC allows private information to be stored in the name service that will not be available to untrusted machines or users on the network.

In addition to the Secure RPC key, users need a mapping of their UID into an NIS+ principal name. This mapping is created by the system administrator using either the *nisclient(1M)* or the *nisaddcred(1M)* command.

Users that will be using machines in several NIS+ domains must insure that they have a *local* credential entry in each of those domains. This credential should be created with the NIS+ principal name of the user in the user's "home" domain. For the purposes of NIS+ and Secure RPC, the home domain is defined to be the one where the user's Secure RPC key pair is located.

Authorization

Although extended Diffie-Hellman keys use an alternative to Secure RPC, administration is done through the same commands. See `nisauthconf(1M)`.

The NIS+ service defines four access rights that can be granted or denied to clients of the service. These rights are `read`, `modify`, `create`, and `destroy`. These rights are specified in the object structure at creation time and may be modified later with the `nischmod(1)` command. In general, the rights granted for an object apply only to that object. However, for purposes of authorization, rights granted to clients reading `directory` and `table` objects are granted to those clients for all of the objects “contained” by the parent object. This notion of containment is abstract. The objects do not actually contain other objects within them. Note that `group` objects do contain the list of principals within their definition.

Access rights are interpreted as follows:

- `read` This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.
- `modify` This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.
- `create` This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.
- `destroy` This right gives a client permission to destroy or remove an existing object or entry. When a client attempts to destroy an entry or object by removing it, the service first checks to see if the table or directory containing that object grants the client destroy access. If it does, the operation proceeds, if the containing object does not grant this right then the object itself is checked to see if it grants this right to the client. If the object grants the right, then the operation proceeds; otherwise the request is rejected.

Each of these rights may be granted to any one of four different categories.

- `owner` A right may be granted to the *owner* of an object. The owner is the NIS+ principal identified in the owner field. The owner can be changed with the `nischown(1)` command.

	Note that if the owner does not have modification access rights to the object, the owner cannot change any access rights to the object, unless the owner has modification access rights to its parent object.
<i>group owner</i>	A right may be granted to the <i>group owner</i> of an object. This grants the right to any principal that is identified as a member of the group associated with the object. The group owner may be changed with the <code>nischgrp(1)</code> command. The object owner need not be a member of this group.
<i>world</i>	A right may be granted to everyone in the <i>world</i> . This grants the right to all clients who have authenticated themselves with the service.
<i>nobody</i>	A right may be granted to the <i>nobody</i> principal. This has the effect of granting the right to any client that makes a request of the service, regardless of whether they are authenticated or not.

Note that for bootstrapping reasons, directory objects that are NIS+ domains, the *org_dir* subdirectory and the *cred* table within that subdirectory must have `read` access to the *nobody* principal. This makes navigation of the namespace possible when a client is in the process of locating its credentials. Granting this access does not allow the contents of other tables within *org_dir* to be read (such as the entries in the password table) unless the table itself gives "real" access rights to the *nobody* principal.

Directory Authorization

Additional capabilities are provided for granting access rights to clients for directories. These rights are contained within the *object access rights* (OAR) structure of the directory. This structure allows the NIS+ service to grant rights that are not granted by the directory object to be granted for objects contained by the directory of a specific type.

An example of this capability is a directory object which does not grant create access to all clients, but does grant create access in the OAR structure for *group* type objects to clients who are members of the NIS+ group associated with the directory. In this example the only objects that could be created as children of the directory would have to be of the type *group*.

Another example is a directory object that grants create access only to the owner of the directory, and then additionally grants create access through the OAR structure for objects of type *table*, *link*, *group*, and *private* to any member of the directory's group. This has the effect of giving nearly complete create access to the group with the exception of creating subdirectories. This restricts the creation of new NIS+ domains because creating a domain requires creating both a *groups_dir* and *org_dir* subdirectory.

Note that there is currently no command line interface to set or change the OAR of the directory object.

Table Authorization

As with directories, additional capabilities are provided for granting access to entries within tables. Rights granted to a client by the access rights field in a table object apply to the table object and all of the entry objects “contained” by that table. If an access right is not granted by the table object, it may be granted by an entry within the table. This holds for all rights except *create*.

For example, a table may not grant read access to a client performing a `nis_list(3NSL)` operation on the table. However, the access rights field of entries within that table may grant read access to the client. Note that access rights in an entry are granted to the owner and group owner of the *entry* and not the owner or group of the table. When the list operation is performed, all entries that the client has read access to are returned. Those entries that do not grant read access are not returned. If none of the entries that match the search criterion grant read access to the client making the request, no entries are returned and the result status contains the `NIS_NOTFOUND` error code.

Access rights that are granted by the rights field in an entry are granted for the entire entry. However, in the table object an additional set of access rights is maintained for each column in the table. These rights apply to the equivalent column in the entry. The rights are used to grant access when neither the table nor the entry itself grant access. The access rights in a column specification apply to the owner and group owner of the entry rather than the owner and group owner of the table object.

When a read operation is performed, if read access is not granted by the table and is not granted by the entry but *is* granted by the access rights in a column, that entry is returned with the correct values in all columns that are readable and the string `*NP*` (No Permission) in columns where read access is not granted.

As an example, consider a client that has performed a list operation on a table that does not grant read access to that client. Each entry object that satisfied the search criterion specified by the client is examined to see if it grants read access to the client. If it does, it is included in the returned result. If it does not, then each column is checked to see if it grants read access to the client. If any columns grant read access to the client, data in those columns is returned. Columns that do not grant read access have their contents replaced by the string `*NP*`. If none of the columns grant read access, then the entry is not returned.

Protocol Operation Authorization

Most NIS+ operations have implied access control through the permissions on the objects that they manipulate. For example, in order to read an entry in a table, you must have read permission on that entry. However, some NIS+ operations by default perform no access checking at all and so are allowed for anyone.

<i>Operation</i>	<i>Example of commands that use the operation</i>
NIS_CHECKPOINT	nisping -C
NIS_CPTIME	nisping , rpc.nisd
NIS_MKDIR	nismkdir
NIS_PING	nisping , rpc.nisd
NIS_RMDIR	nisrmdir
NIS_SERVSTATE	nisbackup , nisrestore
NIS_STATUS	nisstat , rpc.nispasswd

See `nisopaccess(1)` for a description of how to enforce access control to these NIS+ operations.

The following lists all commands and programming functions related to NIS+ :

**LIST OF
COMMANDS
NIS+ User
Commands**

<code>nisaddent(1M)</code>	add <code>/etc</code> files and NIS maps into their corresponding NIS+ tables
<code>niscat(1)</code>	display NIS+ tables and objects
<code>nischgrp(1)</code>	change the group owner of a NIS+ object
<code>nischmod(1)</code>	change access rights on a NIS+ object
<code>nischown(1)</code>	change the owner of a NIS+ object
<code>nischttl(1)</code>	change the time to live value of a NIS+ object
<code>nisdefaults(1)</code>	display NIS+ default values
<code>niserror(1)</code>	display NIS+ error messages
<code>nisgrep(1)</code>	utilities for searching NIS+ tables
<code>nisgrpadm(1)</code>	NIS+ group administration command

	nislnd(1)	symbolically link NIS+ objects
	nislsl(1)	list the contents of a NIS+ directory
	nismatch(1)	utilities for searching NIS+ tables
	nismkdir(1)	create NIS+ directories
	nisopaccess(1)	access control for protocol operations
	nispaswd(1)	change NIS+ password information
	nisrm(1)	remove NIS+ objects from the namespace
	nisrmdir(1)	remove NIS+ directories
	nisshowcache(1M)	NIS+ utility to print out the contents of the shared cache file
	nistbladm(1)	NIS+ table administration command
	nistest(1)	return the state of the NIS+ namespace using a conditional expression
NIS+ Administrative Commands	aliasadm(1M)	manipulate the NIS+ aliases map
	nis_cachemgr(1M)	NIS+ utility to cache location information about NIS+ servers
	nisaddcred(1M)	create NIS+ credentials
	nisaddent(1M)	create NIS+ tables from corresponding /etc files or NIS+ maps
	nisauthconf(1M)	configure extended Diffie-Hellman keys
	nisbackup(1M)	backup NIS+ directories

<code>nisclient(1M)</code>	initialize NIS+ credentials for NIS+ principals
<code>nisd(1M)</code>	NIS+ service daemon
<code>nisd_resolv(1M)</code>	NIS+ service daemon
<code>nisinit(1M)</code>	NIS+ client and server initialization utility
<code>nislog(1M)</code>	display the contents of the NIS+ transaction log
<code>nisping(1M)</code>	send ping to NIS+ servers
<code>nispopulate(1M)</code>	populate the NIS+ tables in a NIS+ domain
<code>nisprefadm(1M)</code>	NIS+ utility to set server preferences for NIS+ clients
<code>nisrestore(1M)</code>	restore NIS+ directory backup
<code>nissserver(1M)</code>	set up NIS+ servers
<code>nissetup(1M)</code>	initialize a NIS+ domain
<code>nisshowcache(1M)</code>	NIS+ utility to print out the contents of the shared cache file
<code>nisstat(1M)</code>	report NIS+ server statistics
<code>nisupdkeys(1M)</code>	update the public keys in a NIS+ directory object
<code>rpc.nisd(1M)</code>	NIS+ service daemon
<code>rpc.nisd_resolv(1M)</code>	NIS+ service daemon
<code>sysidns(1M)</code>	system configuration
<code>nis_add(3NSL)</code>	NIS+ namespace functions

<code>nis_add_entry(3NSL)</code>	NIS+ table functions
<code>nis_addmember(3NSL)</code>	NIS+ group manipulation functions
<code>nis_checkpoint(3NSL)</code>	miscellaneous NIS+ log administration functions
<code>nis_clone_object(3NSL)</code>	NIS+ subroutines
<code>nis_creategroup(3NSL)</code>	NIS+ group manipulation functions
<code>nis_destroy_object(3NSL)</code>	NIS+ subroutines
<code>nis_destroygroup(3NSL)</code>	NIS+ group manipulation functions
<code>nis_dir_cmp(3NSL)</code>	NIS+ subroutines
<code>nis_domain_of(3NSL)</code>	NIS+ subroutines
<code>nis_error(3NSL)</code>	display NIS+ error messages
<code>nis_first_entry(3NSL)</code>	NIS+ table functions
<code>nis_freenames(3NSL)</code>	NIS+ subroutines
<code>nis_freeresult(3NSL)</code>	NIS+ namespace functions
<code>nis_freeservlist(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_freetags(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_getnames(3NSL)</code>	NIS+ subroutines
<code>nis_getservlist(3NSL)</code>	miscellaneous NIS+ functions

<code>nis_groups(3NSL)</code>	NIS+ group manipulation functions
<code>nis_ismember(3NSL)</code>	NIS+ group manipulation functions
<code>nis_leaf_of(3NSL)</code>	NIS+ subroutines
<code>nis_lerror(3NSL)</code>	display some NIS+ error messages
<code>nis_list(3NSL)</code>	NIS+ table functions
<code>nis_local_directory(3NSL)</code>	NIS+ local names
<code>nis_local_group(3NSL)</code>	NIS+ local names
<code>nis_local_host(3NSL)</code>	NIS+ local names
<code>nis_local_names(3NSL)</code>	NIS+ local names
<code>nis_local_principal(3NSL)</code>	NIS+ local names
<code>nis_lookup(3NSL)</code>	NIS+ namespace functions
<code>nis_mkdir(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_modify(3NSL)</code>	NIS+ namespace functions
<code>nis_modify_entry(3NSL)</code>	NIS+ table functions
<code>nis_name_of(3NSL)</code>	NIS+ subroutines
<code>nis_names(3NSL)</code>	NIS+ namespace functions
<code>nis_next_entry(3NSL)</code>	NIS+ table functions

<code>nis_objects(3NSL)</code>	NIS+ object formats
<code>nis_perror(3NSL)</code>	display NIS+ error messages
<code>nis_ping(3NSL)</code>	miscellaneous NIS+ log administration functions
<code>nis_print_group_entry(3NSL)</code>	NIS+ group manipulation functions
<code>nis_print_object(3NSL)</code>	NIS+ subroutines
<code>nis_remove(3NSL)</code>	NIS+ namespace functions
<code>nis_remove_entry(3NSL)</code>	NIS+ table functions
<code>nis_removemember(3NSL)</code>	NIS+ group manipulation functions
<code>nis_rmdir(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_server(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_servstate(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_sperrno(3NSL)</code>	display NIS+ error messages
<code>nis_sperror(3NSL)</code>	display NIS+ error messages
<code>nis_sperror_r(3NSL)</code>	display NIS+ error messages
<code>nis_stats(3NSL)</code>	miscellaneous NIS+ functions
<code>nis_subr(3NSL)</code>	NIS+ subroutines
<code>nis_tables(3NSL)</code>	NIS+ table functions

NIS+ Files and Directories**FILES**

<code>nis_verifygroup(3NSL)</code>	NIS+ group manipulation functions
<code>nisfiles(4)</code>	NIS+ database files and directory structure
<code><rpcsvc/nis_object.x></code>	protocol description of an NIS+ object
<code><rpcsvc/nis.x></code>	defines the NIS+ protocol using the RPC language as described in the <i>ONC+ Developer's Guide</i>
<code><rpcsvc/nis.h></code>	should be included by all clients of the NIS+ service

NAME	niscat – display NIS+ tables and objects
SYNOPSIS	niscat [-AhLMv] [-s <i>sep</i>] <i>tablename</i> ... niscat [-ALMP] -o <i>name</i> ...
DESCRIPTION	In the first synopsis, <code>niscat</code> displays the contents of the NIS+ tables named by <i>tablename</i> . In the second synopsis, it displays the internal representation of the NIS+ objects named by <i>name</i> .
OPTIONS	The following options are supported: -A Display the data within the table and all of the data in tables in the initial table's concatenation path. -h Display the header line prior to displaying the table. The header consists of the '#' (hash) character followed by the name of each column. The column names are separated by the table separator character. -L Follow links. When this option is specified, if <i>tablename</i> or <i>name</i> names a LINK type object, the link is followed and the object or table named by the link is displayed. -M Master server only. This option specifies that the request should be sent to the master server of the named data. This guarantees that the most up-to-date information is seen at the possible expense of increasing the load on the master server and increasing the possibility of the NIS+ server being unavailable or busy for updates. -P Follow concatenation path. This option specifies that the request should follow the concatenation path of a table if the initial search is unsuccessful. This option is only useful when using an indexed name for <i>name</i> and the -o option. -v Display binary data directly. This option displays columns containing binary data on the standard output. Without this option binary data is displayed as the string *BINARY*. -o <i>name</i> Display the internal representation of the named NIS+ object(s). If <i>name</i> is an indexed name (see <code>nismatch(1)</code>), then each of the matching entry objects is displayed. This option is used to display access rights and other attributes of individual columns. -s <i>sep</i> This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.

EXAMPLES**EXAMPLE 1** Examples of the `niscat` command

This example displays the contents of the `hosts` table.

```
example% niscat -h hosts.org_dir
# cname name addr comment
client1 client1 129.144.201.100 Joe Smith
crunchy crunchy 129.144.201.44 Jane Smith
crunchy softy 129.144.201.44
```

The string `*NP*` is returned in those fields where the user has insufficient access rights.

Display the `passwd.org_dir` on the standard output.

```
example% niscat passwd.org_dir
```

Display the contents of table `frodo` and the contents of all tables in its concatenation path.

```
example% niscat -A frodo
```

Display the entries in the table `groups.org_dir` as NIS+ objects. Note that the brackets are protected from the shell by single quotes.

```
example% niscat -o '[ ]groups.org_dir'
```

Display the table object of the `passwd.org_dir` table.

```
example% niscat -o passwd.org_dir
```

The previous example displays the `passwd` table object and not the `passwd` table. The table object include information such as the number of columns, column type, searchable or not searchable separator, access rights, and other defaults.

Display the directory object for `org_dir`, which includes information such as the access rights and replica information.

```
example% niscat -o org_dir
```

ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see `nisdefaults(1)`).

EXIT STATUS

`niscat` returns the following values:

0 Successful completion

1 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nis+(1)`, `nisdefaults(1)`, `nismatch(1)`, `nistbladm(1)`, `nis_objects(3NSL)`, `nis_tables(3NSL)`, `attributes(5)`

NOTES

Columns without values in the table are displayed by two adjacent separator characters.

NAME nischgrp – change the group owner of a NIS+ object

SYNOPSIS **nischgrp** [-AfLP] *group name*...

DESCRIPTION **nischgrp** changes the group owner of the NIS+ objects or entries specified by *name* to the specified NIS+ *group*. Entries are specified using indexed names (see **nismatch(1)**). If *group* is not a fully qualified NIS+ group name, it will be resolved using the directory search path (see **nisdefaults(1)**).

The only restriction on changing an object's group owner is that you must have modify permissions for the object.

This command will fail if the master NIS+ server is not running.

OPTIONS The following options are supported:

- A Modify all entries in all tables in the concatenation path that match the search criterion specified in *name*. This option implies the -P switch.
- f Force the operation and fail silently if it does not succeed.
- L Follow links and change the group owner of the linked object or entries rather than the group owner of the link itself.
- P Follow the concatenation path within a named table. This option only makes sense when either *name* is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.

EXAMPLES **EXAMPLE 1** Examples of the **nischgrp** command.

The following two examples show how to change the group owner of an object to a group in a different domain, and how to change it to a group in the local domain, respectively.

```
example% nischgrp newgroup.remote.domain. object
example% nischgrp my-buds object
```

This example shows how to change the group owner for a password entry.

```
example% nischgrp admins '[uid=99],passwd.org_dir'
```

In the previous example, **admins** is a NIS+ group in the same domain.

The next two examples change the group owner of the object or entries pointed to by a link, and the group owner of all entries in the **hobbies** table.

```
example% nischgrp -L my-buds linkname
example% nischgrp my-buds '[],hobbies'
```

**ENVIRONMENT
VARIABLES**

NIS_PATH

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see [nisdefaults\(1\)](#)).

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

[nis+\(1\)](#), [nischmod\(1\)](#), [nischown\(1\)](#), [nisdefaults\(1\)](#), [nisgrpadm\(1\)](#), [nismatch\(1\)](#), [nis_objects\(3NSL\)](#), [attributes\(5\)](#)

NOTES

The NIS+ server will check the validity of the group name prior to effecting the modification.

NAME	nischmod – change access rights on a NIS+ object
SYNOPSIS	nischmod [-AFLP] <i>mode name</i> ...
DESCRIPTION	<p>nischmod changes the access rights (mode) of the NIS+ objects or entries specified by <i>name</i> to <i>mode</i>. Entries are specified using indexed names (see nismatch(1)). Only principals with modify access to an object may change its mode.</p> <p><i>mode</i> has the following form:</p> <p><i>rights</i> [, <i>rights</i>]...</p> <p><i>rights</i> has the form:</p> <p>[<i>who</i>] <i>op permission</i> [<i>op permission</i>]...</p> <p><i>who</i> is a combination of:</p> <ul style="list-style-type: none"> n Nobody's permissions. o Owner's permissions. g Group's permissions. w World's permissions. a All, or owg. <p>If <i>who</i> is omitted, the default is a.</p> <p><i>op</i> is one of:</p> <ul style="list-style-type: none"> + To grant the <i>permission</i>. - To revoke the <i>permission</i>. = To set the permissions explicitly. <p><i>permission</i> is any combination of:</p> <ul style="list-style-type: none"> r Read. m Modify. c Create. d Destroy.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A Modify all entries in all tables in the concatenation path that match the search criteria specified in <i>name</i>. This option implies the -P switch. -f Force the operation and fail silently if it does not succeed.

- L Follow links and change the permission of the linked object or entries rather than the permission of the link itself.
- P Follow the concatenation path within a named table. This option is only applicable when either *name* is an indexed name or the -L switch is also specified and the named object is a link pointing to an entry.

EXAMPLES

EXAMPLE 1 Examples of the `nischmod` command.

This example gives everyone read access to an object. (that is, access for owner, group, and all).

```
example% nischmod a+r object
```

This example denies create and modify privileges to `group` and unauthenticated clients (`nobody`).

```
example% nischmod gn-cm object
```

In this example, a complex set of permissions are set for an object.

```
example% nischmod o=rmdc,g=rm,w=rc,n=r object
```

This example sets the permissions of an entry in the password table so that the group owner can modify them.

```
example% nischmod g+m '[uid=55],passwd.org_dir'
```

The next example changes the permissions of a linked object.

```
example% nischmod -L w+mr linkname
```

ENVIRONMENT VARIABLES

`NIS_PATH`

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

chmod(1), nis+(1), nischgrp(1), nischown(1), nisdefaults(1),
nismatch(1), nis_objects(3NSL), attributes(5)

NOTES

Unlike the system chmod(1) command, this command does not accept an octal notation.

NAME nischown - change the owner of a NIS+ object

SYNOPSIS nischown [-AfLP] owner name...

DESCRIPTION nischown changes the owner of the NIS+ objects or entries specified by *name* to *owner*. Entries are specified using indexed names (see nismatch(1)). If *owner* is not a fully qualified NIS+ principal name (see nisaddcred(1M)), the default domain (see nisdefaults(1)) will be appended to it.

The only restriction on changing an object's owner is that you must have modify permissions for the object. Note: If you are the current owner of an object and you change ownership, you may not be able to regain ownership unless you have modify access to the new object.

The command will fail if the master NIS+ server is not running.

OPTIONS The following options are supported:

- A Modify all entries in all tables in the concatenation path that match the search criteria specified in *name*. It implies the -P option.
- f Force the operation and fail silently if it does not succeed.
- L Follow links and change the owner of the linked object or entries rather than the owner of the link itself.
- P Follow the concatenation path within a named table. This option is only meaningful when either *name* is an indexed name or the -L option is also specified and the named object is a link pointing to entries.

EXAMPLES **EXAMPLE 1** Examples of the nischown command.

The following two examples show how to change the owner of an object to a principal in a different domain, and to change it to a principal in the local domain, respectively.

```
example% nischown bob.remote.domain. object
example% nischown skippy object
```

The next example shows how to change the owner of an entry in the passwd table.

```
example% nischown bob.remote.domain. '[uid=99],passwd.org_dir'
```

This example shows how to change the object or entries pointed to by a link.

```
example% nischown -L skippy linkname
```

ENVIRONMENT VARIABLES

NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each

directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NOTES

The NIS+ server will check the validity of the name before making the modification.

NAME	nischttl – change the time to live value of a NIS+ object
SYNOPSIS	nischttl [-AfLP] <i>time name</i> ...
DESCRIPTION	<p>nischttl changes the time to live value (ttl) of the NIS+ objects or entries specified by <i>name</i> to <i>time</i>. Entries are specified using indexed names (see nismatch(1)).</p> <p>The time to live value is used by object caches to expire objects within their cache. When an object is read into the cache, this value is added to the current time in seconds yielding the time when the cached object would expire. The object may be returned from the cache until the current time is earlier than the calculated expiration time. When the expiration time has been reached, the object will be flushed from the cache.</p> <p>The time to live <i>time</i> may be specified in seconds or in days, hours, minutes, seconds format. The latter format uses a suffix letter of d, h, m, or s to identify the units of time. See the examples below for usage.</p> <p>The command will fail if the master NIS+ server is not running.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A Modify all tables in the concatenation path that match the search criterion specified in <i>name</i>. This option implies the -P switch. -f Force the operation and fail silently if it does not succeed. -L Follow links and change the time to live of the linked object or entries rather than the time to live of the link itself. -P Follow the concatenation path within a named table. This option only makes sense when either <i>name</i> is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.
EXAMPLES	<p>EXAMPLE 1 Changing the ttl of an object</p> <p>The following example shows how to change the ttl of an object using the seconds format and the days, hours, minutes, seconds format. The ttl of the second object is set to 1 day and 12 hours.</p> <pre>example% nischttl 184000 object example% nischttl 1d12h object</pre> <p>EXAMPLE 2 Changing the ttl for a password entry</p> <p>This example shows how to change the ttl for a password entry.</p> <pre>example% nischttl 1h30m '[uid=99],passwd.org_dir'</pre>

EXAMPLE 3 Changing the ttl of entries pointed to by a link

The next two examples change the `ttl` of the object or entries pointed to by a link, and the `ttl` of all entries in the `hobbies` table.

```
example% nischttl -L 12h linkname
```

```
example% nischttl 3600 '[,hobbies'
```

ENVIRONMENT VARIABLES

NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nis+(1)`, `nischgrp(1)`, `nischmod(1)`, `nischown(1)`, `nisdefaults(1)`, `nismatch(1)`, `nis_objects(3NSL)`, `attributes(5)`

NOTES

Setting a high `ttl` value allows objects to stay persistent in caches for a longer period of time and can improve performance. However, when an object changes, in the worst case, the number of seconds in this attribute must pass before that change is visible to all clients. Setting a `ttl` value of 0 means that the object should not be cached at all.

A high `ttl` value is a week, a low value is less than a minute. Password entries should have `ttl` values of about 12 hours (easily allows one password change per day), entries in the RPC table can have `ttl` values of several weeks (this information is effectively unchanging).

Only directory and group objects are cached in this implementation.

NAME	nisdefaults - display NIS+ default values
SYNOPSIS	nisdefaults [-adghprstv]
DESCRIPTION	The <code>nisdefaults</code> utility prints the default values that are returned by calls to the NIS+ local name functions (see <code>nis_local_names(3NSL)</code>). With no options specified, all defaults will be printed in a verbose format. With options, only that option is displayed in a terse form suitable for shell scripts. See the example below.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Print all defaults in a terse format. -d Print the default domain name. -g Print the default group name. -h Print the default host name. -p Print the default principal name. -r Print the default access rights with which new objects will be created. -s Print the default directory search path. -t Print the default time to live value. -v Print the defaults in a verbose format. This prepends an identifying string to the output.
EXAMPLES	<p>EXAMPLE 1 Printing NIS+ defaults</p> <p>The following prints the NIS+ defaults for a root process on machine <code>example</code> in the <code>foo.bar.</code> domain:</p> <pre>example# nisdefaults Principal Name : example.foo.bar. Domain Name : foo.bar. Host Name : example.foo.bar. Group Name : Access Rights : ----rmcdr---r--- Time to live : 12:00:00 Search Path : foo.bar.</pre> <p>EXAMPLE 2 Setting a variable in the shell script</p> <p>This example sets a variable in a shell script to the default domain:</p> <pre>DOMAIN=`nisdefaults -d`</pre> <p>EXAMPLE 3 Printing the default time to live in verbose format</p> <p>This example prints out the default time to live in a verbose format:</p>

```
example% nisdefaults -tv
Time to live      :      12:00:00
```

EXAMPLE 4 Printing the time to live in terse format

This example prints out the time to live in the terse format:

```
example% nisdefaults -t
43200
```

**ENVIRONMENT
VARIABLES**

Several environment variables affect the defaults associated with a process.

NIS_DEFAULTS This variable contains a defaults string that will override the NIS+ standard defaults. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

t_{tl}=time

This token sets the default time to live for objects that are created. The value *time* is specified in the format as defined by the `nischttl(1)` command. The default value is 12 hours.

owner=ownername

This token specifies that the NIS+ principal *ownername* should own created objects. The default for this value is the principal who is executing the command.

group=groupname

This token specifies that the group *groupname* should be the group owner for created objects. The default is NULL.

access=rights

This token specifies the set of access rights that are to be granted for created objects. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is: `---rmdr---r---`.

`NIS_GROUP` This variable contains the name of the local NIS+ group. If the name is not fully qualified, the default domain will be appended to it.

`NIS_PATH` This variable overrides the default NIS+ directory search path. It contains an ordered list of directories separated by ':' (colon) characters. The '\$' (dollar sign) character is treated specially. Directory names that end in '\$' have the default domain appended to them, and a '\$' by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is '\$'.

Refer to the `Name Expansion` subsection in `nis+(1)` for more details.

ATTRIBUTES

NAME niserror – display NIS+ error messages

SYNOPSIS **niserror** *error-num*

DESCRIPTION niserror prints the NIS+ error associated with status value *error-num* on the standard output. It is used by shell scripts to translate NIS+ error numbers that are returned into text messages.

EXAMPLES **EXAMPLE 1** An example of niserror.

The following example prints the error associated with the error number 20:

```
example% niserror 20
Not Found, no such name
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NAME	nisgrpadm - NIS+ group administration command
SYNOPSIS	<p>nisgrpadm -a -r -t [-s] <i>group principal...</i></p> <p>nisgrpadm -d -l [-M] [-s] <i>group</i></p> <p>nisgrpadm -c [-D <i>defaults</i>] [-M] [-s] <i>group</i></p>
DESCRIPTION	<p>The <code>nisgrpadm</code> utility is used to administer NIS+ groups. This command administers both groups and the groups' membership lists. <code>nisgrpadm</code> can create, destroy, or list NIS+ groups. <code>nisgrpadm</code> can be used to administer a group's membership list. It can add or delete principals to the group, or test principals for membership in the group.</p> <p>The names of NIS+ groups are syntactically similar to names of NIS+ objects but they occupy a separate namespace. A group named <code>a.b.c.d.</code> is represented by a NIS+ group object named <code>a.groups_dir.b.c.d.</code>; the functions described here all expect the name of the group, not the name of the corresponding group object.</p> <p>There are three types of group members:</p> <ul style="list-style-type: none"> ■ An <i>explicit</i> member is just a NIS+ principal-name. For example: <code>wickedwitch.west.oz.</code> ■ An <i>implicit</i> ("domain") member, written <code>*.west.oz.</code>, means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed; <code>wickedwitch.*.oz.</code> is invalid, as is <code>wickedwitch.west.*..</code> Note that principals in subdomains of the given domain are <i>not</i> included. ■ A <i>recursive</i> ("group") member, written <code>@cowards.oz.</code>, refers to another group; all principals that belong to that group are considered to belong here. <p>Any member may be made <i>negative</i> by prefixing it with a minus sign ('-'). A group may thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative recursive members.</p> <p>A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.</p>
OPTIONS	<p>The following options are supported:</p> <p>-a Adds the list of NIS+ principals specified to <i>group</i>. The principal name should be fully qualified.</p> <p>-c Creates <i>group</i> in the NIS+ namespace. The NIS+ group name should be fully qualified.</p> <p>-d Destroys (removes) <i>group</i> from the namespace.</p>

-D *defaults*

When creating objects, this option specifies a different set of defaults to be used during this operation. The *defaults* string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

ttl=time

This token sets the default time to live for objects that are created by this command. The value *time* is specified in the format as defined by the `nischttl(1)` command. The default value is 12 hours.

owner=ownername

This token specifies that the NIS+ principal *ownername* should own the created object. Normally this value is the same as the principal who is executing the command.

group=groupname

This token specifies that the group *groupname* should be the group owner for the object that is created. The default value is NULL.

access=rights

This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is `---rmdr---r---`.

-l

Lists the membership list of the specified *group*. (See **-M** option.)

-M

Master server only. Sends the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. Note that the **-M** flag is applicable only with the **-l** flag.

- r Removes the list of principals specified from *group*. The principal name should be fully qualified.
- s Work silently. Results are returned using the exit status of the command. This status can be translated into a text string using the `niserror(1)` command.
- t Displays whether the principals specified are members in *group*.

EXAMPLES**Administering Groups****EXAMPLE 1** Creating a group

This example shows how to create a group in the `foo.com.` domain:
`example% nisgrpadm -c my_buds.foo.com.`

EXAMPLE 2 How to remove a group

This example shows how to remove the group from the current domain.
`example% nisgrpadm -d freds_group`

Administering Members**EXAMPLE 3** Adding to the group

This example shows how one would add two principals, bob and betty, to the group `my_buds.foo.com.:`
`example% nisgrpadm -a my_buds.foo.com. bob.bar.com. betty.foo.com.`

EXAMPLE 4 How to remove a principal from the group

This example shows how to remove betty from `freds_group`:
`example% nisgrpadm -r freds_group betty.foo.com.`

ENVIRONMENT VARIABLES**NIS_DEFAULTS**

This variable contains a defaults string that will override the NIS+ standard defaults.

NIS_PATH

If this variable is set, and the NIS+ group name is not fully qualified, each directory specified will be searched until the group is found (see `nisdefaults(1)`).

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

nis+(1), nischgrp(1), nischmod(1), nischttl(1), nisdefaults(1), niserror(1), nis_groups(3NSL), attributes(5)

DIAGNOSTICS

NIS_SUCCESS	On success, this command returns an exit status of 0.
NIS_PERMISSION	When you do not have the needed access right to change the group, the command returns this error.
NIS_NOTFOUND	This is returned when the group does not exist.
NIS_TRYAGAIN	This error is returned when the server for the group's domain is currently checkpointing or otherwise in a read-only state. The command should be retried at a later date.
NIS_MODERROR	This error is returned when the group was modified by someone else during the execution of the command. Reissue the command and optionally recheck the group's membership list.

NOTES

Principal names *must* be fully qualified, whereas groups can be abbreviated on all operations *except* create.

NAME nisl - symbolically link NIS+ objects

SYNOPSIS nisl [-L] [-D *defaults*] *name linkname*

DESCRIPTION The nisl command links a NIS+ object named *name* to a NIS+ name *linkname*. If *name* is an indexed name (see nismatch(1)), the link points to entries within a NIS+ table. Clients wishing to look up information in the name service can use the FOLLOW_LINKS flag to force the client library to follow links to the name they point to. Further, all of the NIS+ administration commands accept the -L switch indicating they should follow links (see nis_names(3NSL) for a description of the FOLLOW_LINKS flag).

OPTIONS The following options are supported:

-L When present, this option specifies that this command should follow links. If *name* is itself a link, then this command will follow it to the linked object that it points to. The new link will point to that linked object rather than to *name*.

-D *defaults* Specify a different set of defaults to be used for the creation of the link object. The *defaults* string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

t_{tl}=*time* This token sets the default time to live for objects that are created by this command. The value *time* is specified in the format as defined by the nischttl(1) command. The default is 12 hours.

owner=*ownername* This token specifies that the NIS+ principal *ownername* should own the created object. The default for this value is the the principal who is executing the command.

group=*groupname* This token specifies that the group *groupname* should be the group owner for the object that is created. The default is NULL.

`access=rights`

This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is `---rmcdr---r---`.

EXAMPLES

EXAMPLE 1 Creating a link

In this example we create a link in the domain `foo.com.` named `hosts` that points to the object `hosts.bar.com.:`

```
example% nisl hosts.bar.com. hosts.foo.com.
```

In this example we make a link `example.sun.com.` that points to an entry in the `hosts` table in `eng.sun.com:`

EXAMPLE 2 Making a link that points to an entry in the `hosts` table

```
example% nisl '[name=example],hosts.eng.sun.com.' example.sun.com.
```

ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nisdefaults(1)`, `nismatch(1)`, `nism(1)`, `nistbladm(1)`, `nis_names(3NSL)`, `nis_tables(3NSL)`, `attributes(5)`

NOTES

When creating the link, `nisl` verifies that the linked object exists. Once created, the linked object may be deleted or replaced and the link will not be affected. At that time the link will become invalid and attempts to follow it will return `NIS_LINKNAMEERROR` to the client. When the path attribute in tables specifies a link rather than another table, the link will be followed if the flag `FOLLOW_LINKS`

was present in the call to `nisl_list()` (see `nisl_tables(3NSL)`) and ignored if the flag is not present. If the flag is present and the link is no longer valid, a warning is sent to the system logger and the link is ignored.

NAME	nisl – list the contents of a NIS+ directory
SYNOPSIS	nisl [-dglLmMR] [<i>name</i> ...]
DESCRIPTION	For each <i>name</i> that is a NIS+ directory, nisl lists the contents of the directory. For each <i>name</i> that is a NIS+ object other than a directory, nisl simply echos the name. If no <i>name</i> is specified, the first directory in the search path (see nisdefaults(1)) is listed.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d Treat NIS+ directories like other NIS+ objects, rather than listing their contents. -g Display group owner instead of owner when listing in long format. -l List in long format. This option displays additional information about the objects such as their type, creation time, owner, and access rights. The access rights are listed in the following order in long mode: nobody, owner, group owner, and world. -L This option specifies that links are to be followed. If <i>name</i> actually points to a link, it is followed to the linked object. -m Display modification time instead of creation time when listing in long format. -M Master only. This specifies that information is to be returned from the master server of the named object. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. -R List directories recursively. This option will reiterate the list for each subdirectory found in the process of listing each <i>name</i>.
ENVIRONMENT VARIABLES	<p>NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nisdefaults(1)).</p>
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful operation. 1 Operation failed.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

NAME	nismatch, nisgrep - utilities for searching NIS+ tables
SYNOPSIS	<p>nismatch [-AchMoPv] [-s <i>sep</i>] <i>key tablename</i></p> <p>nismatch [-AchMoPv] [-s <i>sep</i>] <i>colname = key... tablename</i></p> <p>nismatch [-AchMoPv] [-s <i>sep</i>] <i>indexedname</i></p> <p>nisgrep [-AchiMov] [-s <i>sep</i>] <i>keypat tablename</i></p> <p>nisgrep [-AchiMov] [-s <i>sep</i>] <i>colname = keypat... tablename</i></p>
DESCRIPTION	<p>The utilities <code>nismatch</code> and <code>nisgrep</code> can be used to search NIS+ tables. The command <code>nisgrep</code> differs from the <code>nismatch</code> command in its ability to accept regular expressions <i>keypat</i> for the search criteria rather than simple text matches.</p> <p>Because <code>nisgrep</code> uses a callback function, it is not constrained to searching only those columns that are specifically made searchable at the time of table creation. This makes it more flexible, but slower, than <code>nismatch</code>.</p> <p>In <code>nismatch</code>, the server does the searching, whereas in <code>nisgrep</code> the server returns all the readable entries and then the client does the pattern-matching.</p> <p>In both commands, the parameter <i>tablename</i> is the NIS+ name of the table to be searched. If only one key or key pattern is specified without the column name, then it is applied searching the first column. Specific named columns can be searched by using the <i>colname=key</i> syntax. When multiple columns are searched, only entries that match in all columns are returned. This is the equivalent of a logical join operation.</p> <p><code>nismatch</code> accepts an additional form of search criteria, <i>indexedname</i>, which is a NIS+ indexed name of the form:</p> <p>[<i>colname = value , ...</i>], <i>tablename</i></p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A All data. Return the data within the table and all of the data in tables in the initial table's concatenation path. -c Print only a count of the number of entries that matched the search criteria. -h Display a header line before the matching entries that contains the names of the table's columns -i Ignore upper/lower case distinction during comparisons. -M Master server only. Send the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.

- o Display the internal representation of the matching NIS+ object(s).
- P Follow concatenation path. Specify that the lookup should follow the concatenation path of a table if the initial search is unsuccessful.
- s This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.
sep
- v Verbose. Do not suppress the output of binary data when displaying matching entries. Without this option binary data is displayed as the string *BINARY* .

EXAMPLES

EXAMPLE 1 Searching a table for a username

This example searches a table named `passwd` in the `org_dir` subdirectory of the `zotz.com.` domain. It returns the entry that has the username of `skippy`. In this example, all the work is done on the server:

```
example% nismatch name=skippy passwd.org_dir.zotz.com.
```

EXAMPLE 2 Finding users using specific shells

This example is similar to the one above, except that it uses `nisgrep` to find all users in the table named `passwd` that are using either `ksh(1)` or `csh(1)` :

```
example% nisgrep 'shell=[ck]sh' passwd.org_dir.zotz.com.
```

ENVIRONMENT VARIABLES

NIS_PATH If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see `nisdefaults(1)`).

EXIT STATUS

- The following exit values are returned:
- 0 Successfully matches some entries.
 - 1 Successfully searches the table and no matches are found.
 - 2 An error condition occurs. An error message is also printed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

niscat(1), nisdefaults(1), nisls(1), nistbladm(1), nis_objects(3NSL), attributes(5)

DIAGNOSTICS

No memory

An attempt to allocate some memory for the search failed.

tablename
is not a table

The object with the name *tablename* was not a table object.

Can't compile regular expression

The regular expression in *keypat* was malformed.

column not found:
colname

The column named *colname* does not exist in the table named *tablename*.

NAME	nismkdir – create NIS+ directories								
SYNOPSIS	nismkdir [-D <i>defaults</i>] [-m <i>hostname</i>] [-s <i>hostname</i>] <i>dirname</i>								
DESCRIPTION	<p>The <code>nismkdir</code> command creates new NIS+ subdirectories within an existing domain. It can also be used to create replicated directories. Without options, this command will create a subdirectory with the same master and the replicas as its parent directory.</p> <p>It is advisable to use <code>nisserver(1M)</code> to create an NIS+ domain which consists of the specified directory along with the <code>org_dir</code> and <code>groups_dir</code> subdirectories.</p> <p>The two primary aspects that are controlled when making a directory are its access rights, and its degree of replication.</p>								
OPTIONS	<p>The following options are supported:</p> <p><code>-D <i>defaults</i></code> Specify a different set of defaults to be used when creating new directories. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.</p> <table border="0" style="margin-left: 40px;"> <tr> <td style="padding-right: 20px;"><code>t11=<i>time</i></code></td> <td>This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischtt1 (1)</code> command. The default value is 12h (12 hours).</td> </tr> <tr> <td style="padding-right: 20px;"><code>owner=<i>ownername</i></code></td> <td>This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.</td> </tr> <tr> <td style="padding-right: 20px;"><code>group=<i>groupname</i></code></td> <td>This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.</td> </tr> <tr> <td style="padding-right: 20px;"><code>access=<i>rights</i></code></td> <td>This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is</td> </tr> </table>	<code>t11=<i>time</i></code>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischtt1 (1)</code> command. The default value is 12h (12 hours).	<code>owner=<i>ownername</i></code>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.	<code>group=<i>groupname</i></code>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.	<code>access=<i>rights</i></code>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is
<code>t11=<i>time</i></code>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischtt1 (1)</code> command. The default value is 12h (12 hours).								
<code>owner=<i>ownername</i></code>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.								
<code>group=<i>groupname</i></code>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.								
<code>access=<i>rights</i></code>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is								

specified in the format as defined by the `nischmod(1)` command. The default value is `---rmcdr---r---`.

`-m hostname` If the directory named by *dirname* does not exist, then a new directory that is *not* replicated is created with host *hostname* as its master server.

If the directory name by *dirname* does exist, then the host named by *hostname* is made its master server.

`-s hostname` Specify that the host *hostname* will be a replica for an existing directory named *dirname*.

OPERANDS

The following operand is supported:

dirname The fully qualified NIS+ name of the directory that has to be created.

EXAMPLES

EXAMPLE 1 Using the `nismkdir` Command

To create a new directory `bar` under the `foo.com.` domain that shares the same master and replicas as the `foo.com.` directory one would use the command:

```
example% nismkdir bar.foo.com.
```

To create a new directory `bar.foo.com.` that is not replicated under the `foo.com.` domain one would use the command:

```
example% nismkdir -m myhost.foo.com. bar.foo.com.
```

To add a replica server of the `bar.foo.com.` directory, one would use the command:

```
example% nismkdir -s replica.foo.com. bar.foo.com.
```

ENVIRONMENT VARIABLES

`NIS_DEFAULTS`

This variable contains a defaults string that will override the NIS+ standard defaults. If the `-D` switch is used those values will then override both the `NIS_DEFAULTS` variable and the standard defaults.

`NIS_PATH`

If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

0 Successful operation.

1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nis+(1)`, `nischmod(1)`, `nischttl(1)`, `nisdefaults(1)`, `nislsls(1)`, `nisopaccess(1)`, `nismkdir(1)`, `nissserver(1M)`, `attributes(5)`

NOTES

A host that serves a NIS+ directory must be a NIS+ client in a directory above the one it is serving. The exceptions to this rule are the root NIS+ servers, which are both clients and servers of the same NIS+ directory.

When the host's default domain is different from the default domain on the client where the command is executed, the hostname supplied as an argument to the `-s` or `-m` options must be fully qualified.

Special per-server and per-directory access restrictions may apply when this command updates the serving lists of the affected NIS+ servers. See `nisopaccess(1)`.

NAME	nisopaccess – NIS+ operation access control administration command																
SYNOPSIS	nisopaccess [-v] <i>directory operation rights</i> nisopaccess [-v] [-r] <i>directory operation</i> nisopaccess [-v] [-l] <i>directory [operation]</i>																
DESCRIPTION	<p>Most NIS+ operations have implied access control through the permissions on the objects that they manipulate. For example, in order to read an entry in a table, you must have read permission on that entry. However, some NIS+ operations by default perform no access checking at all and are allowed to all:</p> <table border="0"> <thead> <tr> <th style="text-align: left;"><i>Operation</i></th> <th style="text-align: left;"><i>Example of commands that use the operation</i></th> </tr> </thead> <tbody> <tr> <td>NIS_CHECKPOINT</td> <td>nisping -C</td> </tr> <tr> <td>NIS_CPTIME</td> <td>nisping, rpc.nisd</td> </tr> <tr> <td>NIS_MKDIR</td> <td>nismkdir</td> </tr> <tr> <td>NIS_PING</td> <td>nisping, rpc.nisd</td> </tr> <tr> <td>NIS_RMDIR</td> <td>nisrmdir</td> </tr> <tr> <td>NIS_SERVSTATE</td> <td>nisbackup, nisrestore</td> </tr> <tr> <td>NIS_STATUS</td> <td>nisstat, rpc.nispasswd</td> </tr> </tbody> </table> <p>The nisopaccess command can be used to enforce access control on these operations on a per NIS+ directory basis.</p> <p>The <i>directory</i> argument should be the fully qualified name, including the trailing dot, of the NIS+ directory to which nisopaccess will be applied. As a short-hand, if the directory name does not end in a trailing dot, for example “org_dir”, then the domain name is appended. The domain name is also appended to partial paths such as “org_dir.xyz”.</p> <p>You can use upper or lower case for the <i>operation</i> argument; however, you cannot mix cases. The “NIS_” prefix may be omitted. For example, NIS_PING can be specified as NIS_PING, nis_ping, PING, or ping.</p> <p>The <i>rights</i> argument is specified in the format defined by the nischmod(1) command. Since only the read (“r”) rights are used to determine who has the right to perform the operation, the modify and delete rights may be used to control who can change access to the operation.</p> <p>The access checking performed for each operation is as follows. When an operation requires access be checked on all directories served by its rpc.nisd(1M), access is denied if even one of the directories prohibits the operation.</p>	<i>Operation</i>	<i>Example of commands that use the operation</i>	NIS_CHECKPOINT	nisping -C	NIS_CPTIME	nisping, rpc.nisd	NIS_MKDIR	nismkdir	NIS_PING	nisping, rpc.nisd	NIS_RMDIR	nisrmdir	NIS_SERVSTATE	nisbackup, nisrestore	NIS_STATUS	nisstat, rpc.nispasswd
<i>Operation</i>	<i>Example of commands that use the operation</i>																
NIS_CHECKPOINT	nisping -C																
NIS_CPTIME	nisping, rpc.nisd																
NIS_MKDIR	nismkdir																
NIS_PING	nisping, rpc.nisd																
NIS_RMDIR	nisrmdir																
NIS_SERVSTATE	nisbackup, nisrestore																
NIS_STATUS	nisstat, rpc.nispasswd																

NIS_CHECKPOINT	Check specified directory, or all directories if there is no directory argument (as is the case when NIS_CHECKPOINT is issued by the "nisping -Ca" command).. Return NIS_PERMISSION when access is denied.
NIS_CPTIME	Check specified directory. It returns 0 when access is denied.
NIS_MKDIR	Check parent of specified directory. Returns NIS_PERMISSION when access is denied. If the parent directory is not available locally, that is, it is not served by this <code>rpc.nisd(1M)</code> , NIS_MKDIR access is allowed, though the operation will be executed only if this <code>rpc.nisd</code> is a known replica of the directory. You should note that the NIS_MKDIR operation does not create a NIS+ directory; it adds a directory to the serving list for this <code>rpc.nisd</code> , if appropriate.
NIS_PING	Check specified directory. No return value.
NIS_RMDIR	Check specified directory. NIS_PERMISSION is returned when access denied. The NIS_RMDIR operation does not remove a NIS+ directory; it deletes the directory from the serving list for this <code>rpc.nisd</code> , if appropriate.
NIS_SERVSTATE	Check access on all directories served by this <code>rpc.nisd</code> . If access is denied for a tag, "<permission denied>" is returned instead of the tag value.
NIS_STATUS	Same as for NIS_SERVSTATE.

Note that older clients may not supply authentication information for some of the operations listed above. These clients are treated as "nobody" when access checking is performed.

OPTIONS

The following options are supported:

- l List the access control for a single operation, or for all operations that have access control enabled.

`-r` Remove access control for a certain operation on the specified directory.

`-v` Verbose mode.

EXAMPLES**EXAMPLE 1** Enabling Access Control for the NIS_PING Operation

To enable access control for the NIS_PING operation on "org_dir. 'domainname' ." such that only the owner of the directory can perform a NIS_PING, or change the NIS_PING rights:

```
example% nisopaccess org_dir NIS_PING o=racd,g=,w=,n=
```

EXAMPLE 2 Listing the Access to NIS_PING

To list the access to the NIS_PING operation for org_dir:

```
example% nisopaccess -l org_dir NIS_PING
```

```
NIS_PING  ----racd-----  owner.dom.ain.  group.dom.ain.
```

EXAMPLE 3 Removing Access Control for NIS_PING

To remove access control for NIS_PING on org_dir:

```
example% nisopaccess -r org_dir NIS_PING
```

EXIT STATUS

The following exit values are returned:

0 Successful operation.

other Operation failed. The status is usually the return status from a NIS+ command such as nistbladm.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

nis+(1), nischmod(1), nistbladm(1), rpc.nisd(1M), attributes(5)

NOTES

The access control is implemented by creating a NIS+ table called "proto_op_access" in each NIS+ directory to which access control should be applied. The table can be manipulated using normal NIS+ commands. However, nisopaccess is the only supported interface for NIS+ operation access control.

NAME	nispasswd – change NIS+ password information
SYNOPSIS	nispasswd [-ghs] [-D <i>domainname</i>] [<i>username</i>] nispasswd -a nispasswd [-D <i>domainname</i>] [-d [<i>username</i>] nispasswd [-l] [-f] [-n <i>min</i>] [-x <i>max</i>] [-w <i>warn</i>] [-D <i>domainname</i>] <i>username</i>
DESCRIPTION	<p>The <code>nispasswd</code> utility changes a password, <code>gecos</code> (<code>finger</code>) field (<code>-g</code> option), home directory (<code>-h</code> option), or login shell (<code>-s</code> option) associated with the <i>username</i> (invoker by default) in the NIS+ <code>passwd</code> table.</p> <p>Additionally, the command can be used to view or modify aging information associated with the user specified if the invoker has the right NIS+ privileges.</p> <p><code>nispasswd</code> uses secure RPC to communicate with the NIS+ server, and therefore, never sends unencrypted passwords over the communication medium.</p> <p><code>nispasswd</code> does not read or modify the local password information stored in the <code>/etc/passwd</code> and <code>/etc/shadow</code> files.</p> <p>When used to change a password, <code>nispasswd</code> prompts non-privileged users for their old password. It then prompts for the new password twice to forestall typing mistakes. When the old password is entered, <code>nispasswd</code> checks to see if it has “aged” sufficiently. If “aging” is insufficient, <code>nispasswd</code> terminates; see <code>getspnam(3C)</code>.</p> <p>The old password is used to decrypt the <i>username</i>’s secret key. If the password does not decrypt the secret key, <code>nispasswd</code> prompts for the old secure-RPC password. It uses this password to decrypt the secret key. If this fails, it gives the user one more chance. The old password is also used to ensure that the new password differs from the old by at least three characters. Assuming aging is sufficient, a check is made to ensure that the new password meets construction requirements described below. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated twice. The new password is used to re-encrypt the user’s secret key. Hence, it also becomes their secure-RPC password. Therefore, the secure-RPC password is no longer a different password from the user’s password.</p> <p>Passwords must be constructed to meet the following requirements:</p> <ul style="list-style-type: none"> ■ Each password must have at least six characters. Only the first eight characters are significant. ■ Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, “alphabetic” refers to all upper or lower case letters.

- Each password must differ from the user's login *username* and any reverse or circular shift of that login *username*. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.
- New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

Network administrators, who own the NIS+ password table, may change any password attributes if they establish their credentials (see `keylogin(1)`) before invoking `nispasswd`. Hence, `nispasswd` does not prompt these privileged-users for the old password and they are not forced to comply with password aging and password construction requirements.

Any user may use the `-d` option to display password attributes for his or her own login name. The format of the display will be:

```
username status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
username status
```

where

username The login ID of the user.

status The password status of *username*: "PS" stands for password exists or locked, "LK" stands for locked, and "NP" stands for no password.

mm/dd/yy The date password was last changed for *username*. (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and, therefore, may differ by as much as a day in other time zones.)

min The minimum number of days required between password changes for *username*.

max The maximum number of days the password is valid for *username*.

warn The number of days relative to *max* before the password expires that the *username* will be warned.

OPTIONS

The following options are supported:

`-g` Changes the `gecos` (finger) information.

`-h` Changes the home directory.

-s	Changes the login shell. By default, only the NIS+ administrator can change the login shell. User will be prompted for the new login shell.
-a	Shows the password attributes for all entries. This will show only the entries in the NIS+ passwd table in the local domain that the invoker is authorized to "read".
-d [<i>username</i>]	Displays password attributes for the caller or the user specified if the invoker has the right privileges.
-l	Locks the password entry for <i>username</i> . Subsequently, <code>login(1)</code> would disallow logins with this NIS+ password entry.
-f	Forces the user to change password at the next login by expiring the password for <i>username</i> .
-n <i>min</i>	Sets minimum field for <i>username</i> . The <i>min</i> field contains the minimum number of days between password changes for <i>username</i> . If <i>min</i> is greater than <i>max</i> , the user may not change the password. Always use this option with the <code>-x</code> option, unless <i>max</i> is set to -1 (aging turned off). In that case, <i>min</i> need not be set.
-x <i>max</i>	Set maximum field for <i>username</i> . The <i>max</i> field contains the number of days that the password is valid for <i>username</i> . The aging for <i>username</i> will be turned off immediately if <i>max</i> is set to -1. If it is set to 0, then the user is forced to change the password at the next login session and aging is turned off.
-w <i>warn</i>	Sets <i>warn</i> field for <i>username</i> . The <i>warn</i> field contains the number of days before the password expires that the user will be warned whenever he or she attempts to login.
-D <i>domainname</i>	Consults the <code>passwd.org_dir</code> table in <i>domainname</i> . If this option is not specified, the default <i>domainname</i> returned by <code>nis_local_directory()</code> will be used. This <i>domainname</i> is the same as that returned by <code>domainname(1M)</code> .

EXIT STATUS

The following exit values are returned:

0	Success.
1	Permission denied.
2	Invalid combination of options.
3	Unexpected failure. NIS+ passwd table unchanged.

- 4 NIS+ passwd table missing.
- 5 NIS+ is busy. Try again later.
- 6 Invalid argument to option.
- 7 Aging is disabled.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`keylogin(1)`, `login(1)`, `nis+(1)`, `nistbladm(1)`, `passwd(1)`, `rlogin(1)`, `domainname(1M)`, `nisserver(1M)`, `getpwnam(3C)`, `getspnam(3C)`, `nis_local_directory(3NSL)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

NOTES

The use of `nispasswd` is **STRONGLY** discouraged. Even though it is a hardlink to `passwd(1)`, its operation is subtly different and not desirable in a modern NIS+ domain.

In particular, `nispasswd` will not attempt to contact the `rpc.nispasswd` daemon running on the NIS+ master. It will instead attempt to do the updates by itself via the NIS+ API. For this to work, the permissions on the password data need to be modified from the default as set up by the `nisserver` setup script (see `nisserver(1M)`).

Using `passwd(1)` with the `-r nisplus` option will achieve the same result and will be consistent across all the different name services available. This is the recommended way to change the password in NIS+.

The login program, file access display programs (for example, `'ls -l'`), and network programs that require user passwords (for example, `rlogin(1)`, `ftp(1)`, and so on) use the standard `getpwnam(3C)` and `getspnam(3C)` interfaces to get password information. These programs will get the NIS+ password information, that is modified by `nispasswd`, only if the `passwd:` entry in the `/etc/nsswitch.conf` file includes `nisplus`. See `nsswitch.conf(4)` for more details.

NAME nisrm - remove NIS+ objects from the namespace

SYNOPSIS **nisrm** [-if] *name*...

DESCRIPTION The `nisrm` command removes NIS+ objects named *name* from the NIS+ namespace.

This command will fail if the NIS+ master server is not running.

OPTIONS The following options are supported:

- i Interactive mode. Like the system `rm(1)` command the `nisrm` command will ask for confirmation prior to removing an object. If the name specified by *name* is a non-fully qualified name this option is forced on. This prevents the removal of unexpected objects.
- f Force. The removal is attempted, and if it fails for permission reasons, a `nischmod(1)` is attempted and the removal retried. If the command fails, it fails silently.

OPERANDS The following operand is supported:

name A NIS+ named object.

EXAMPLES

EXAMPLE 1 An exmple of the `nisrm` command.

Remove the objects *foo*, *bar*, and *baz* from the namespace:

```
example% nisrm foo bar baz
```

ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

EXIT STATUS The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `nis+(1)`, `nischmod(1)`, `nisdefaults(1)`, `nisrmdir(1)`, `nistbladm(1)`, `rm(1)`, `attributes(5)`

NOTES

This command will not remove directories (see `nismdir(1)`) nor will it remove non-empty tables (see `nistbladm(1)`).

NAME	nisrmdir – remove NIS+ directories
SYNOPSIS	nisrmdir [-if] [-s <i>hostname</i>] <i>dirname</i>
DESCRIPTION	<p>nisrmdir deletes existing NIS+ subdirectories. It can remove a directory outright, or simply remove replicas from serving a directory.</p> <p>This command modifies the object that describes the directory <i>dirname</i>, and then notifies each replica to remove the directory named <i>dirname</i>. If the notification of any of the affected replicas fails, the directory object is returned to its original state unless the -f option is present.</p> <p>This command will fail if the NIS+ master server is not running.</p>
OPTIONS	<p>The following options are supported:</p> <p>-i Interactive mode. Like the system rm(1) command the nisrmdir command will ask for confirmation prior to removing a directory. If the name specified by <i>dirname</i> is a non-fully qualified name this option is forced on. This prevents the removal of unexpected directories.</p> <p>-f Force the command to succeed even though it may not be able to contact the affected replicas. This option should be used when a replica is known to be down and will not be able to respond to the removal notification. When the replica is finally rebooted it will read the updated directory object, note that it is no longer a replica for that directory, and stop responding to lookups on that directory. Cleanup of the files that held the now removed directory can be accomplished manually by removing the appropriate files in the <code>/var/nis</code> directory (see nisfiles(4) for more information).</p> <p>-s <i>hostname</i> Specify that the host <i>hostname</i> should be removed as a replica for the directory named <i>dirname</i>. If this option is not present <i>all</i> replicas and the master server for a directory are removed and the directory is removed from the namespace.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>dirname</i> An existing NIS+ directory.</p>
EXAMPLES	<p>EXAMPLE 1 Using the nisrmdir Command</p> <p>To remove a directory <code>bar</code> under the <code>foo.com.</code> domain, one would use the command:</p> <pre>example% nisrmdir bar.foo.com.</pre> <p>To remove a replica that is serving directory <code>bar.foo.com.</code> one would use the command:</p> <pre>example% nisrmdir -s replica.foo.com. bar.foo.com.</pre>

To force the removal of directory `bar.foo.com.` from the namespace, one would use the command:

```
example% nismkdir -f bar.foo.com.
```

ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

0 Successful operation.
1 Operation failed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nis+(1)`, `nisdefaults(1)`, `nisopaccess(1)`, `nism(1)`, `nisfiles(4)`, `attributes(5)`

NOTES

Special per-server and per-directory access restrictions may apply when this command updates the serving lists of the affected NIS+ servers. For more information, see `nisopaccess(1)`.

NAME	nistbladm - NIS+ table administration command
SYNOPSIS	<p>nistbladm -a -A [-D <i>defaults</i>] <i>colname</i> = <i>value...</i> <i>tablename</i></p> <p>nistbladm -a -A [-D <i>defaults</i>] <i>indexedname</i></p> <p>nistbladm -c [-D <i>defaults</i>] [-p <i>path</i>] [-s <i>sep</i>] <i>type</i> <i>colname</i> = [<i>flags</i>] [, <i>access ...</i>] <i>tablename</i></p> <p>nistbladm -d <i>tablename</i></p> <p>nistbladm -e -E <i>colname</i> = <i>value...</i> <i>indexedname</i></p> <p>nistbladm -m <i>colname</i> = <i>value...</i> <i>indexedname</i></p> <p>nistbladm -r -R [<i>colname</i> = <i>value...</i>] <i>tablename</i></p> <p>nistbladm -r -R <i>indexedname</i></p> <p>nistbladm -u [-p <i>path</i>] [-s <i>sep</i>] [-t <i>type</i>] [<i>colname</i> = <i>access...</i>] <i>tablename</i></p>
DESCRIPTION	<p>The <code>nistbladm</code> command is used to administer NIS+ tables. There are five primary operations that it performs: creating and deleting tables, adding entries to, modifying entries within, and removing entries from tables.</p> <p>Though NIS+ does not place restrictions on the size of tables or entries, the size of data has an impact on the performance and the disk space requirements of the NIS+ server. NIS+ is not designed to store huge pieces of data, such as files; instead, pointers to files should be stored in NIS+.</p> <p>NIS+ design is optimized to support 10,000 objects with a total size of 10M bytes. If the requirements exceed the above, it is suggested that the domain hierarchy be created, or the data stored in the tables be pointers to the actual data, instead of the data itself.</p> <p>When creating tables, a table type, <code>type</code>, and a list of column definitions must be provided.</p> <p><code>type</code> is a string that is stored in the table and later used by the service to verify that entries being added to it are of the correct type.</p> <p>Syntax for column definitions is:</p> <p><code>colname=[flags][,access]</code></p> <p><code>flags</code> is a combination of:</p> <ul style="list-style-type: none"> S Searchable. Specifies that searches can be done on the column's values (see <code>nismatch(1)</code>). I Case-insensitive (only makes sense in combination with <code>s</code>). Specifies that searches should ignore case. C Crypt. Specifies that the column's values should be encrypted.

- B** Binary data (does not make sense in combination with **S**). If not set, the column's values are expected to be null terminated ASCII strings.
- X** XDR encoded data (only makes sense in combination with **B**).

access is specified in the format as defined by the `nischmod(1)` command.

When manipulating entries, this command takes two forms of entry name. The first uses a series of space separated *colname=value* pairs that specify column values in the entry. The second is a NIS+ indexed name, *indexedname*, of the form:

[*colname=value, . . .*], *tablename*

OPTIONS

The following options are supported:

- a | A** Add entries to a NIS+ table. The difference between the lowercase 'a' and the uppercase 'A' is in the treatment of preexisting entries. The entry's contents are specified by the *column=value* pairs on the command line. Note: Values for *all* columns must be specified when adding entries to a table.
- Normally, NIS+ reports an error if an attempt is made to add an entry to a table that would overwrite an entry that already exists. This prevents multiple parties from adding duplicate entries and having one of them get overwritten. If you wish to force the add, the uppercase 'A' specifies that the entry is to be added, even if it already exists. This is analogous to a modify operation on the entry.
- c** Create a table named *tablename* in the namespace. The table that is created must have at least one column and at least one column must be searchable.
- d *tablename*** Destroy the table named *tablename*. The table that is being destroyed must be empty. The table's contents can be deleted with the **-R** option below.
- e | E** Edit the entry in the table that is specified by *indexedname*. *indexedname* must uniquely identify a single entry. It is possible to edit the value in a column that would change the indexed name of an entry.
- The change (*colname=value*) may affect other entries in the table if the change results in an entry whose indexed name is different from *indexedname* and which matches that of another existing entry. In this case, the **-e** option will fail and an error will be reported. The **-E** option will force the replacement of the existing entry by the new entry (effectively removing two old entries and adding a new one).

-m	A synonym for -E. This option has been superseded by the -E option.
-r R	Remove entries from a table. The entry is specified by either a series of <i>column=value</i> pairs on the command line, or an indexed name that is specified as <i>entryname</i> . The difference between the interpretation of the lowercase 'r' versus the uppercase 'R' is in the treatment of non-unique entry specifications. Normally the NIS+ server will disallow an attempt to remove an entry when the search criterion specified for that entry resolves to more than one entry in the table. However, it is sometimes desirable to remove more than one entry, as when you are attempting to remove all of the entries from a table. In this case, using the uppercase 'R' will force the NIS+ server to remove all entries matching the passed search criterion. If that criterion is null and no column values specified, then all entries in the table will be removed.
-u	Update attributes of a table. This allows the concatenation path (-p), separation character (specified with the (-s)), column access rights, and table type string (-t) of a table to be changed. Neither the number of columns, nor the columns that are searchable may be changed.
-D <i>defaults</i>	When creating objects, this option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.
tvl=time	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12 hours.
owner= <i>ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.

	<code>group=groupname</code>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.
	<code>access=rights</code>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default value is <code>---r-mcdr---r---</code> .
<code>-p path</code>		When creating or updating a table, this option specifies the table's search path. When a <code>nis_list()</code> function is invoked, the user can specify the flag <code>FOLLOW_PATH</code> to tell the client library to continue searching tables in the table's path if the search criteria used does not yield any entries. The path consists of an ordered list of table names, separated by colons. The names in the path must be fully qualified.
<code>-s sep</code>		When creating or updating a table, this option specifies the table's separator character. The separator character is used by <code>niscat(1)</code> when displaying tables on the standard output. Its purpose is to separate column data when the table is in ASCII form. The default value is a space.
<code>-t type</code>		When updating a table, this option specifies the table's type string.

EXAMPLES**EXAMPLE 1** Creating an unmodifiable table

This example creates a table named `hobbies` in the directory `foo.com.` of the type `hobby_tbl` with two searchable columns, `name` and `hobby`.

```
example% nistbladm -c hobby_tbl name=S,\
a+r,o+m hobby=S,a+r hobbies.foo.com.
```

The column `name` has read access for all (that is, `owner`, `group`, and `world`) and modify access for only the owner. The column `hobby` is readable by all, but not modifiable by anyone.

In this example, if the access rights had not been specified, the table's access rights would have come from either the standard defaults or the `NIS_DEFAULTS` variable (see below).

EXAMPLE 2 Adding entries to the table

To add entries to this table:

```
example% nistbladm -a name=bob hobby=skiing hobbies.foo.com.
example% nistbladm -a name=sue hobby=skiing hobbies.foo.com.
example% nistbladm -a name=tod hobby=swimming hobbies.foo.com.
```

EXAMPLE 3 Adding the concatenation path

To add the concatenation path:

```
example% nistbladm -u -p hobbies.bar.com.:hobbies.baz.com. hobbies
```

EXAMPLE 4 Deleting skiers from the list

To delete the skiers from our list:

```
example% nistbladm -R hobby=skiing hobbies.foo.com.
```

Note: The use of the `-r` option would fail because there are two entries with the value of `skiing`.

EXAMPLE 5 Naming a column with no flags set

To create a table with a column that is named with no flags set, you supply only the name and the equals (=) sign as follows:

```
example% nistbladm -c notes_tbl name=S,a+r,o+m note= notes.foo.com.
```

This example created a table, named `notes.foo.com.`, of type `notes_tbl` with two columns `name` and `note`. The `note` column is not searchable.

EXAMPLE 6 Protecting terminal characters

When entering data for columns in the form of a *value* string, it is essential that terminal characters be protected by single or double quotes. These are the characters equals (=), comma (,), left bracket ([), right bracket (]), and space (). These characters are parsed by NIS+ within an indexed name. These characters are protected by enclosing the entire value in double quote (") characters as follows:

```
example% nistbladm -a fullname="Joe User" nickname=Joe nicknames
```

If there is any doubt about how the string will be parsed, it is better to enclose it in quotes.

**ENVIRONMENT
VARIABLES****NIS_DEFAULTS**

This variable contains a defaults string that will be override the NIS+ standard defaults. If the `-D` switch is used those values will then override both the `NIS_DEFAULTS` variable and the standard defaults.

NIS_PATH If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see `nisdefaults(1)`).

EXIT STATUS The following exit values are returned:

0 Successful operation.
1 Operation failed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`nis+(1)`, `niscat(1)`, `nischmod(1)`, `nischown(1)`, `nischttl(1)`, `nisdefaults(1)`, `nismatch(1)`, `nissetup(1M)`, `attributes(5)`

WARNINGS

To modify one of the entries, say, for example, from “bob” to “robert”:

```
example% nistbladm -m name=robert [name=bob],hobbies
```

Note that “[name=bob],hobbies” is an indexed name, and that the characters ‘[’ (open bracket) and ‘]’ (close bracket) are interpreted by the shell. When typing entry names in the form of NIS+ indexed names, the name must be protected by using single quotes.

It is possible to specify a set of defaults such that you cannot read or modify the table object later.

NAME	nistest – return the state of the NIS+ namespace using a conditional expression
SYNOPSIS	<p>nistest [-ALMP] [-a <i>rights</i> -t <i>type</i>] <i>object</i></p> <p>nistest [-ALMP] [-a <i>rights</i>] <i>indexedname</i></p> <p>nistest -c <i>dir1 op dir2</i></p>
DESCRIPTION	nistest provides a way for shell scripts and other programs to test for the existence, type, and access rights of objects and entries. Entries are named using indexed names. See nismatch(1). With the -c option, directory names can be compared to test where they lie in relation to each other in the namespace.
OPTIONS	<p>The following options are supported:</p> <p>-a <i>rights</i> This option is used to verify that the current process has the desired or required access rights on the named object or entries. The access rights are specified in the same way as the nischmod(1) command.</p> <p>-A All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned. This option is only valid when using indexed names or following links.</p> <p>-L Follow links. If the object named by <i>object</i> or the tablename component of <i>indexedname</i> names a LINK type object, the link is followed when this switch is present.</p> <p>-M Master server only. This option specifies that the lookup should be sent to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.</p> <p>-P Follow concatenation path. This option specifies that the lookup should follow the concatenation path of a table if the initial search is unsuccessful. This option is only valid when using indexed names or following links.</p> <p>-t <i>type</i> This option tests the type of <i>object</i>. The value of <i>type</i> can be one of the following:</p> <p style="margin-left: 40px;">D Return true if the object is a directory object.</p> <p style="margin-left: 40px;">G Return true if the object is a group object.</p> <p style="margin-left: 40px;">L Return true if the object is a link object.</p> <p style="margin-left: 40px;">P Return true if the object is a private object.</p> <p style="margin-left: 40px;">T Return true if the object is a table object.</p>

`-c` Test whether or not two directory names have a certain relationship to each other, for example, higher than (`ht`) or lower than (`lt`). The complete list of values for `op` can be displayed by using the `-c` option with no arguments.

EXAMPLES

EXAMPLE 1 Examples of the `nistest` command.

When testing for access rights, `nistest` returns success (0) if the specified rights are granted to the current user. Thus, testing for access rights:

```
example% nistest -a w=mr skippy.domain
```

Tests that all authenticated NIS+ clients have read and modify access to the object named `skippy.domain`.

Testing for access on a particular entry in a table can be accomplished using the indexed name syntax. The following example tests to see if an entry in the password table can be modified:

```
example% nistest -a o=m '[uid=99],passwd.org_dir'
```

To test if a directory lies higher in the namespace than another directory, use the `-c` option with an `op` of `ht` (higher than) as in the following example (which would return true):

```
example% nistest -c dom.com. ht lower.dom.com.
```

ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See `nisdefaults(1)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Failure due to object not present, not of specified type, and/or no such access.
- 2 Failure due to illegal usage.

NAME nl – line numbering filter

SYNOPSIS `/usr/bin/nl [-p] [-b [type]] [-d [delim]] [-f [type]] [-h [type]] [-i [incr]] [-l [num]] [-n [format]] [-s [sep]] [-w [width]] [-v [startnum]] [file]`
`/usr/xpg4/bin/nl [-p] [-b type] [-d delim] [-f type] [-h type] [-i incr] [-l num] [-n format] [-s sep] [-w width] [-v startnum] [file]`

DESCRIPTION The `nl` command reads lines from the named `file`, or the standard input if no `file` is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.

`nl` views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer. For example, `-bt` (the default) numbers non-blank lines in the body section and does not number any lines in the header and footer sections.

The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):

Line contents	Start Of
<code>\:\:\:</code>	header
<code>\:\:</code>	body
<code>\:</code>	footer

Unless optioned otherwise, `nl` assumes the text being read is in a single logical page body.

OPTIONS Command options may appear in any order and may be intermingled with an optional file name. Only one file may be named. The specified default is used when the option is not entered on the command line. `/usr/xpg4/bin/nl` options require option arguments. A SPACE character *may* separate options from option arguments. `/usr/bin/nl` options *may* have option arguments. If option-arguments of `/usr/bin/nl` options are not specified, these options result in the default. The supported options are:

`-btype` Specifies which logical page body lines are to be numbered. Recognized types and their meanings are:

<code>a</code>	number all lines
<code>t</code>	number all non-empty lines.
<code>n</code>	no line numbering

	<i>pexp</i>	number only lines that contain the regular expression specified in <i>exp</i> ; see NOTES below.
		Default <i>type</i> for logical page body is <i>t</i> (text lines numbered).
-f <i>type</i>		Same as - <i>btype</i> except for footer. Default <i>type</i> for logical page footer is <i>n</i> (no lines numbered).
-d <i>delim</i>		The two delimiter characters specifying the start of a logical page section may be changed from the default characters (\ :) to two user-specified characters. If only one character is entered, the second character remains the default character (:). No space should appear between the - <i>d</i> and the delimiter characters. To enter a backslash, use two backslashes.
-h <i>type</i>		Same as - <i>btype</i> except for header. Default <i>type</i> for logical page header is <i>n</i> (no lines numbered).
-i <i>incr</i>		<i>incr</i> is the increment value used to number logical page lines. Default <i>incr</i> is 1.
-l <i>num</i>		<i>num</i> is the number of blank lines to be considered as one. For example, -12 results in only the second adjacent blank being numbered (if the appropriate - <i>ha</i> , - <i>ba</i> , and/or - <i>fa</i> option is set). Default <i>num</i> is 1.
-n <i>format</i>		<i>format</i> is the line numbering format. Recognized values are:
	ln	left justified, leading zeroes suppressed
	rn	right justified, leading zeroes suppressed
	rz	right justified, leading zeroes kept
		Default <i>format</i> is <i>rn</i> (right justified).
-p		Do not restart numbering at logical page delimiters.
-s <i>sep</i>		<i>sep</i> is the character(s) used in separating the line number and the corresponding text line. Default <i>sep</i> is a TAB.
-v <i>startnum</i>		<i>startnum</i> is the initial value used to number logical page lines. Default <i>startnum</i> is 1.
-w <i>width</i>		<i>width</i> is the number of characters to be used for the line number. Default <i>width</i> is 6.

OPERANDS

The following operand is supported:

file A path name of a text file to be line-numbered.

EXAMPLES

EXAMPLE 1 An example of the `nl` command.

The command:

```
example% nl -v10 -i10 -d!+ filename1
```

will cause the first line of the page body to be numbered 10, the second line of the page body to be numbered 20, the third 30, and so forth. The logical page delimiters are `!+`.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nl`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

FILES

`/usr/lib/locale/locale/LC_COLLATE/CollTable`
collation table generated by `localedef`

`/usr/lib/locale/locale/LC_COLLATE/coll.so`
shared object containing string transformation library routines

ATTRIBUTES

`/usr/bin/nl`

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

`/usr/xpg4/bin/nl`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

SEE ALSO

`pr(1)`, `attributes(5)`, `environ(5)`, `regex(5)`, `regexp(5)`

NOTES

Internationalized Regular Expressions are used in the POSIX and "C" locales. In other locales, Internationalized Regular Expressions are used if the following two conditions are met:

- `/usr/lib/locale/locale/LC_COLLATE/CollTable` is present
- `/usr/lib/locale/locale/LC_COLLATE/coll.so` is not present;

otherwise, Simple Regular Expressions are used.

Internationalized Regular Expressions are explained on `regex(5)`. Simple Regular Expressions are explained on `regexp(5)`.

NAME	nm – print name list of an object file										
SYNOPSIS	<pre>/usr/ccs/bin/nm [-ACDhlnPprRsTuVv] [-efox] [-g -u][-t <i>format</i>] <i>file</i>...</pre> <pre>/usr/xpg4/bin/nm [-ACDhlnPprRsTuVv] [-efox] [-g -u][-t <i>format</i>] <i>file</i>...</pre>										
DESCRIPTION	<p>The nm utility displays the symbol table of each ELF object file that is specified by <i>file</i>.</p> <p>If no symbolic information is available for a valid input file, the nm utility will report that fact, but not consider it an error condition.</p>										
OPTIONS	<p>The output of nm may be controlled using the following options:</p> <p>-A Write the full path name or library name of an object on each line.</p> <p>-C Demangle C++ symbol names before printing them out.</p> <p>-D Display the SHT_DYNSYM symbol information. This is the symbol table used by ld.so.1 and is present even in stripped dynamic executables. By default the SHT_SYMTAB symbol table is displayed.</p> <p>-e See NOTES below.</p> <p>-f See NOTES below.</p> <p>-g Write only external (global) symbol information.</p> <p>-h Do not display the output heading data.</p> <p>-l Distinguish between WEAK and GLOBAL symbols by appending a * to the key letter for WEAK symbols.</p> <p>-n Sort external symbols by name before they are printed.</p> <p>-o Print the value and size of a symbol in octal instead of decimal (equivalent to -t o).</p> <p>-P Produce easy to parse, terse output. Each symbol name is preceded by its value (blanks if undefined) and one of the letters:</p> <table style="margin-left: 40px;"> <tr> <td>A</td> <td>absolute symbol</td> </tr> <tr> <td>B</td> <td>bss (uninitialized data space) symbol</td> </tr> <tr> <td>D</td> <td>data object symbol</td> </tr> <tr> <td>F</td> <td>file symbol.</td> </tr> <tr> <td>N</td> <td>symbol has no type</td> </tr> </table>	A	absolute symbol	B	bss (uninitialized data space) symbol	D	data object symbol	F	file symbol.	N	symbol has no type
A	absolute symbol										
B	bss (uninitialized data space) symbol										
D	data object symbol										
F	file symbol.										
N	symbol has no type										

S section symbol
 T text symbol
 U undefined

If the symbol's binding attribute is:

LOCAL the key letter is lower case
 WEAK the key letter is upper case; if the `-l` modifier is specified, the upper case key letter is followed by a `*`
 GLOBAL the key letter is upper case.

`-P` Write information in a portable output format, as specified in Standard Output.
`-r` Prepend the name of the object file or archive to each output line.
`-R` Print the archive name (if present), followed by the object file and symbol name. If the `-r` option is also specified, this option is ignored.
`-s` Print section name instead of section index.
`-t format` Write each numeric value in the specified format. The format is dependent on the single character used as the *format* option-argument:
 d The offset is written in decimal (default).
 o The offset is written in octal.
 x The offset is written in hexadecimal.
`-T` See NOTES below.
`-u` Print undefined symbols only.
`-u` Print long listing for each undefined symbol. See OUTPUT below.
`-v` Sort external symbols by value before they are printed.
`-V` Print the version of the `nm` command executing on the standard error output.
`-x` Print the value and size of a symbol in hexadecimal instead of decimal (equivalent to `-t x`).

/usr/ccs/bin/nm

/usr/xpg4/bin/nm

Options may be used in any order, either singly or in combination, and may appear anywhere in the command line. When conflicting options are specified (such as `-v` and `-n`, or `-o` and `-x`) the first is taken and the second ignored with a warning message to the user. (See `-R` for exception.)

OPERANDS

The following operand is supported:

file A path name of an object file, executable file or object-file library.

OUTPUT

Standard Output

For each symbol, the following information will be printed:

Index	The index of the symbol. (The index appears in brackets.)													
Value	The value of the symbol is one of the following: <ul style="list-style-type: none"> ■ A section offset for defined symbols in a relocatable file. ■ Alignment constraints for symbols whose section index is SHN_COMMON. ■ A virtual address in executable and dynamic library files. 													
Size	The size in bytes of the associated object.													
Type	A symbol is of one of the following types: <table style="margin-left: 2em;"> <tr> <td>NOTYPE</td> <td>No type was specified.</td> </tr> <tr> <td>OBJECT</td> <td>A data object such as an array or variable.</td> </tr> <tr> <td>FUNC</td> <td>A function or other executable code.</td> </tr> <tr> <td>REGI</td> <td>A register symbol (SPARC only).</td> </tr> <tr> <td>SECTION</td> <td>A section symbol.</td> </tr> <tr> <td>FILE</td> <td>Name of the source file.</td> </tr> </table>		NOTYPE	No type was specified.	OBJECT	A data object such as an array or variable.	FUNC	A function or other executable code.	REGI	A register symbol (SPARC only).	SECTION	A section symbol.	FILE	Name of the source file.
NOTYPE	No type was specified.													
OBJECT	A data object such as an array or variable.													
FUNC	A function or other executable code.													
REGI	A register symbol (SPARC only).													
SECTION	A section symbol.													
FILE	Name of the source file.													
Bind	The symbol's binding attributes. <table style="margin-left: 2em;"> <tr> <td>LOCAL symbols</td> <td>Have a scope limited to the object file containing their definition.</td> </tr> <tr> <td>GLOBAL asymbols</td> <td>Are visible to all object files being combined.</td> </tr> <tr> <td>WEAK symbols</td> <td>Are essentially global symbols with a lower precedence than GLOBAL.</td> </tr> </table>		LOCAL symbols	Have a scope limited to the object file containing their definition.	GLOBAL asymbols	Are visible to all object files being combined.	WEAK symbols	Are essentially global symbols with a lower precedence than GLOBAL.						
LOCAL symbols	Have a scope limited to the object file containing their definition.													
GLOBAL asymbols	Are visible to all object files being combined.													
WEAK symbols	Are essentially global symbols with a lower precedence than GLOBAL.													
Other	A field reserved for future use, currently containing 0.													

Shndx	Except for three special values, this is the section header table index in relation to which the symbol is defined. The following special values exist:
ABS	Indicates the symbol's value will not change through relocation.
COMMON	Indicates an unallocated block and the value provides alignment constraints.
UNDEF	Indicates an undefined symbol.
Name	The name of the symbol.
Object Name	The name of the object or library if <code>-A</code> is specified.

If the `-P` option is specified, the previous information is displayed using the following portable format. The three versions differ depending on whether `-t d`, `-t o`, or `-t x` was specified, respectively:

```
"%s%s %s %d %d\n", <library/object name>, name, type, value, size "%s%s
%s %o %o\n", <library/object name>, name, type, value, size "%s%s %s %x
%x\n", <library/object name>, name, type, value, size
```

where `<library/object name>` is formatted as follows:

- If `-A` is not specified, `<library/object name>` is an empty string.
- If `-A` is specified and the corresponding `file` operand does not name a library:

```
"%s: ", file
```

- If `-A` is specified and the corresponding `file` operand names a library. In this case, `<object file>` names the object file in the library containing the symbol being described:

```
"%s[%s]: ", file, <object file>
```

If `-A` is not specified, then if more than one `file` operand is specified or if only one `file` operand is specified and it names a library, `nm` will write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding `file` operand does not name a library:

```
"%s:\n", file
```

- If the corresponding *file* operand names a library; in this case, *<object file>* is the name of the file in the library containing the following symbols:

```
"%s[%s]:\n", file, <object file>
```

If `-P` is specified, but `-t` is not, the format is as if `-t x` had been specified.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nm`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

`/usr/ccs/bin/nm`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

`/usr/xpg4/bin/nm`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

SEE ALSO

`ar(1)`, `as(1)`, `dump(1)`, `ld(1)`, `ld.so.1(1)`, `a.out(4)`, `ar(4)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

NOTES

The following options are obsolete because of changes to the object file format and will be deleted in a future release.

- `-e` Print only external and static symbols. The symbol table now contains only static and external symbols. Automatic symbols no longer appear in the symbol table. They do appear in the debugging information produced by `cc -g`, which may be examined using `dump(1)`.
- `-f` Produce full output. Redundant symbols (such as `.text`, `.data`, and so forth), which existed previously, do not exist and producing full output will be identical to the default output.
- `-T` By default, `nm` prints the entire name of the symbols listed. Since symbol names have been moved to the last column, the problem of overflow is removed and it is no longer necessary to truncate the symbol name.

NAME	nohup – run a command immune to hangups
SYNOPSIS	<code>/usr/bin/nohup</code> <i>command</i> [<i>argument...</i>] <code>/usr/xpg4/bin/nohup</code> <i>command</i> [<i>argument...</i>]
DESCRIPTION	<p>The <code>nohup</code> utility invokes the named <i>command</i> with the arguments supplied. When the <i>command</i> is invoked, <code>nohup</code> arranges for the <code>SIGHUP</code> signal to be ignored by the process.</p> <p>The <code>nohup</code> utility can be used when it is known that <i>command</i> will take a long time to run and the user wants to logout of the terminal; when a shell exits, the system sends its children <code>SIGHUP</code> signals, which by default cause them to be killed. All stopped, running, and background jobs will ignore <code>SIGHUP</code> and continue running, if their invocation is preceded by the <code>nohup</code> command or if the process programmatically has chosen to ignore <code>SIGHUP</code>.</p> <p><code>/usr/bin/nohup</code> Processes run by <code>/usr/bin/nohup</code> are immune to <code>SIGHUP</code> (hangup) and <code>SIGQUIT</code> (quit) signals.</p> <p><code>/usr/xpg4/bin/nohup</code> Processes run by <code>/usr/xpg4/bin/nohup</code> are immune to <code>SIGHUP</code>.</p> <p>The <code>nohup</code> utility does not arrange to make processes immune to a <code>SIGTERM</code> (terminate) signal, so unless they arrange to be immune to <code>SIGTERM</code> or the shell makes them immune to <code>SIGTERM</code>, they will receive it.</p> <p>If <code>nohup.out</code> is not writable in the current directory, output is redirected to <code>\$HOME/nohup.out</code>. If a file is created, the file will have read and write permission (600, see <code>chmod(1)</code>). If the standard error is a terminal, it is redirected to the standard output, otherwise it is not redirected. The priority of the process run by <code>nohup</code> is not altered.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>command</i> The name of a command that is to be invoked. If the <i>command</i> operand names any of the special <code>shell_builtins(1)</code> utilities, the results are undefined.</p> <p><i>argument</i> Any string to be supplied as an argument when invoking the <i>command</i> operand.</p>
EXAMPLES	<p>EXAMPLE 1 Applying <code>nohup</code> to pipelines or command lists</p> <p>It is frequently desirable to apply <code>nohup</code> to pipelines or lists of commands. This can be done only by placing pipelines and command lists in a single file, called a shell script. One can then issue:</p> <pre>example\$ nohup sh file</pre>

and the `nohup` applies to everything in *file*. If the shell script *file* is to be executed often, then the need to type `sh` can be eliminated by giving *file* execute permission.

Add an ampersand and the contents of *file* are run in the background with interrupts also ignored (see `sh(1)`):

```
example$ nohup file &
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nohup`: `LC_CTYPE`, `LC_MESSAGES`, `PATH`, and `NLSPATH`.

`HOME` Determine the path name of the user's home directory: if the output file `nohup.out` cannot be created in the current directory, the `nohup` command will use the directory named by `HOME` to create the file.

EXIT STATUS

The following exit values are returned:

126 *command* was found but could not be invoked.

127 An error occurred in `nohup`, or *command* could not be found

Otherwise, the exit values of `nohup` will be that of the *command* operand.

FILES

`nohup.out` the output file of the `nohup` execution if standard output is a terminal and if the current directory is writable.

`$HOME/nohup.out` the output file of the `nohup` execution if standard output is a terminal and if the current directory is not writable.

ATTRIBUTES

`/usr/bin/nohup`

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

`/usr/xpg4/bin/nohup`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled

SEE ALSO

`batch(1)`, `chmod(1)`, `csh(1)`, `ksh(1)`, `nice(1)`, `sh(1)`, `shell_builtins(1)`, `signal(3C)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

WARNINGS

If you are running the Korn shell (`ksh(1)`) as your login shell, and have `nohup`'ed jobs running when you attempt to logout, you will be warned with the message

```
You have jobs running.
```

You will then need to logout a second time to actually logout; however, your background jobs will continue to run.

NOTES

The C-shell (`csh(1)`) has a built-in command `nohup` that provides immunity from `SIGHUP`, but does not redirect output to `nohup.out`. Commands executed with `'&'` are automatically immune to `HUP` signals while in the background.

`nohup` does not recognize command sequences. In the case of the following command,

```
example$ nohup command1; command2
```

the `nohup` utility applies only to `command1`. The command,

```
example$ nohup (command1; command2)
```

is syntactically incorrect.

NAME	nroff – format documents for display or line-printer																								
SYNOPSIS	nroff [-ehiq] [-mname] [-nN] [-opagelist] [-raN] [-sN] [-Tname]																								
DESCRIPTION	nroff formats text in the named <i>files</i> for typewriter-like devices. See also troff(1). If no <i>file</i> argument is present, nroff reads the standard input. An argument consisting of a '-' is taken to be a file name corresponding to the standard input.																								
OPTIONS	The following options are supported. Options may appear in any order so long as they appear <i>before</i> the files. <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">-e</td> <td>Produce equally-spaced words in adjusted lines, using full terminal resolution.</td> </tr> <tr> <td style="vertical-align: top;">-h</td> <td>Use output TAB characters during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.</td> </tr> <tr> <td style="vertical-align: top;">-i</td> <td>Read the standard input after the input files are exhausted.</td> </tr> <tr> <td style="vertical-align: top;">-q</td> <td>Invoke the simultaneous input-output mode of the rd(9F) request.</td> </tr> <tr> <td style="vertical-align: top;">-mname</td> <td>Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files.</td> </tr> <tr> <td style="vertical-align: top;">-nN</td> <td>Number first generated page <i>N</i>.</td> </tr> <tr> <td style="vertical-align: top;">-opagelist</td> <td>Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; and a final <i>N-</i> means from <i>N</i> to the end.</td> </tr> <tr> <td style="vertical-align: top;">-raN</td> <td>Set register <i>a</i> (one-character) to <i>N</i>.</td> </tr> <tr> <td style="vertical-align: top;">-sN</td> <td>Stop every <i>N</i> pages. nroff will halt prior to every <i>N</i> pages (default <i>N</i>=1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE.</td> </tr> <tr> <td style="vertical-align: top;">-Tname</td> <td>Prepare output for a device of the specified <i>name</i>. Known <i>names</i> are: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">37</td> <td>Teletype Corporation Model 37 terminal — this is the default.</td> </tr> <tr> <td style="vertical-align: top;">lp tn300</td> <td>GE — any line printer or terminal without half-line capability.</td> </tr> </table> </td> </tr> </table>	-e	Produce equally-spaced words in adjusted lines, using full terminal resolution.	-h	Use output TAB characters during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.	-i	Read the standard input after the input files are exhausted.	-q	Invoke the simultaneous input-output mode of the rd(9F) request.	-mname	Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files.	-nN	Number first generated page <i>N</i> .	-opagelist	Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i> ; an initial - <i>N</i> means from the beginning to page <i>N</i> ; and a final <i>N-</i> means from <i>N</i> to the end.	-raN	Set register <i>a</i> (one-character) to <i>N</i> .	-sN	Stop every <i>N</i> pages. nroff will halt prior to every <i>N</i> pages (default <i>N</i> =1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE.	-Tname	Prepare output for a device of the specified <i>name</i> . Known <i>names</i> are: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">37</td> <td>Teletype Corporation Model 37 terminal — this is the default.</td> </tr> <tr> <td style="vertical-align: top;">lp tn300</td> <td>GE — any line printer or terminal without half-line capability.</td> </tr> </table>	37	Teletype Corporation Model 37 terminal — this is the default.	lp tn300	GE — any line printer or terminal without half-line capability.
-e	Produce equally-spaced words in adjusted lines, using full terminal resolution.																								
-h	Use output TAB characters during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.																								
-i	Read the standard input after the input files are exhausted.																								
-q	Invoke the simultaneous input-output mode of the rd(9F) request.																								
-mname	Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files.																								
-nN	Number first generated page <i>N</i> .																								
-opagelist	Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i> ; an initial - <i>N</i> means from the beginning to page <i>N</i> ; and a final <i>N-</i> means from <i>N</i> to the end.																								
-raN	Set register <i>a</i> (one-character) to <i>N</i> .																								
-sN	Stop every <i>N</i> pages. nroff will halt prior to every <i>N</i> pages (default <i>N</i> =1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE.																								
-Tname	Prepare output for a device of the specified <i>name</i> . Known <i>names</i> are: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">37</td> <td>Teletype Corporation Model 37 terminal — this is the default.</td> </tr> <tr> <td style="vertical-align: top;">lp tn300</td> <td>GE — any line printer or terminal without half-line capability.</td> </tr> </table>	37	Teletype Corporation Model 37 terminal — this is the default.	lp tn300	GE — any line printer or terminal without half-line capability.																				
37	Teletype Corporation Model 37 terminal — this is the default.																								
lp tn300	GE — any line printer or terminal without half-line capability.																								

- 300 DASI-300.
- 300-12 DASI-300 — 12-pitch.
- 300S DASI-300S.
- 300S-12 DASI-300S.
- 382 DASI-382 (fancy DTC 382).
- 450 DASI-450 (Diablo Hyterm).
- 450-12 DASI-450 (Diablo Hyterm) — 12-pitch.
- 832 AJ 832.

EXAMPLES

EXAMPLE 1 Formatting with a macro package

The following command formats `users.guide` using the `-me` macro package, and stopping every 4 pages:

```
example% nroff -s4 -me users.guide
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nroff`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

FILES

- `/usr/tmp/trtmp*` temporary file (see `NOTES`)
- `/usr/share/lib/tmac/tmac.*` standard macro files
- `/usr/share/lib/nterm/*` terminal driving tables for `nroff`
- `/usr/share/lib/nterm/README` index to terminal description files

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc
CSI	Enabled

SEE ALSO

`checknr(1)`, `col(1)`, `eqn(1)`, `man(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `environ(5)`, `me(5)`, `ms(5)`, `term(5)`, `rd(9F)`

NOTES

`/usr/tmp` is currently a symbolic link to `/var/tmp`.

Previous documentation incorrectly described the numeric register `yr` as being the "Last two digits of current year". `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in

a document and subsequently used to display a two-digit year. Note that any other available one- or two-character register name may be substituted for `yy`.

```
.\" definition of new string register yy--last two digits of year
.\" use yr (# of years since 1900) if it is < 100
.ie \n(yr<100 .ds yy \n(yr
.el \{          .\" else, subtract 100 from yr, store in ny
.nr ny \n(yr-100
.ie \n(ny>9 \{   .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny

NAME	od - octal dump
SYNOPSIS	<pre> /usr/bin/od [-bcCDdFfOoSsvXx] [-] [file] [offset_string] /usr/bin/od [-bcCDdFfOoSsvXx] [-A address_base] [-j skip] [-N count] [-t type_string...] [-] [file...] /usr/xpg4/bin/od [-bcCDdFfOoSsvXx] [-] [file] [offset_string] /usr/xpg4/bin/od [-bcCDdFfOoSsvXx] [-A address_base] [-j skip] [-N count] [-t type_string...] [-] [file...] </pre>
DESCRIPTION	<p>The <code>od</code> command copies sequentially each input file to standard output and transforms the input data according to the output types specified by the <code>-t</code> or <code>-bcCDdFfOoSsvXx</code> options. If no output type is specified, the default output is as if <code>-t o2</code> had been specified. Multiple types can be specified by using multiple <code>-bcCDdFfOoSstvXx</code> options. Output lines are written for each type specified in the order in which the types are specified. If no <code>file</code> is specified, the standard input is used. The <code>[offset_string]</code> operand is mutually exclusive from the <code>-A</code>, <code>-j</code>, <code>-N</code>, and <code>-t</code> options. For the purposes of this description, the following terms are used:</p> <p>word Refers to a 16-bit unit, independent of the word size of the machine.</p> <p>long word Refers to a 32-bit unit.</p> <p>double long word Refers to a 64-bit unit.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-A address_base</code> Specify the input offset base. The <code>address_base</code> option-argument must be a character. The characters <code>d</code>, <code>o</code> and <code>x</code> specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character <code>n</code> specifies that the offset will not be written. Unless <code>-A n</code> is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the <code>-A address_base</code> option and the <code>[offset_string]</code> operand, the input offset base is displayed in octal.</p> <p><code>-b</code> Interpret bytes in octal. This is equivalent to <code>-t o1</code>.</p> <p><code>-c</code> Display single-byte characters. Certain non-graphic characters appear as C-language escapes:</p> <pre> null \0 backspace \b form-feed \f </pre>

```
new-line  \n
return    \r
tab       \t
```

Others appear as 3-digit octal numbers. For example:

```
echo "hello world" | od -c
0000000  h e l l o      w o r l d \n
0000014
```

/usr/xpg4/bin/od

-c

Interpret bytes as single-byte or multibyte characters according to the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; the two character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Non-graphic characters appear the same as they would using the -C option.

-C

Interpret bytes as single-byte or multibyte characters according to the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; two character sequence ** are written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes:

```
null      \0
backspace \b
form-feed \f
new-line  \n
return    \r
tab       \t
```

Other non-printable characters appear as one three-digit octal number for each byte in the character.

-d

Interpret words in unsigned decimal. This is equivalent to -t u2.

-D

Interpret long words in unsigned decimal. This is equivalent to -t u4.

-f

Interpret long words in floating point. This is equivalent to -t f4.

-F

Interpret double long words in extended precision. This is equivalent to -t f8.

-j *skip*

Jump over *skip* bytes from the beginning of the input. The od command will read or seek past the first *skip* bytes in the

concatenated input files. If the combined input is not at least *skip* bytes long, the `od` command will write a diagnostic message to standard error and exit with a non-zero exit status.

By default, the *skip* option-argument is interpreted as a decimal number. With a leading `0x` or `0X`, the offset is interpreted as a hexadecimal number; otherwise, with a leading `0`, the offset will be interpreted as an octal number. Appending the character `b`, `k`, or `m` to *offset* will cause it to be interpreted as a multiple of 512, 1024 or 1 048 576 bytes, respectively. If the *skip* number is hexadecimal, any appended `b` is considered to be the final hexadecimal digit. The address is displayed starting at 0000000, and its base is not implied by the base of the *skip* option-argument.

- `-N count` Format no more than *count* bytes of input. By default, *count* is interpreted as a decimal number. With a leading `0x` or `0X`, *count* is interpreted as a hexadecimal number; otherwise, with a leading `0`, it is interpreted as an octal number. If *count* bytes of input (after successfully skipping, if `-jskip` is specified) are not available, it will not be considered an error; the `od` command will format the input that is available. The base of the address displayed is not implied by the base of the *count* option-argument.
- `-o` Interpret words in octal. This is equivalent to `-t o2`.
- `-O` Interpret long words in unsigned octal. This is equivalent to `-t o4`.
- `-s` Interpret words in signed decimal. This is equivalent to `-t d2`.
- `-S` Interpret long words in signed decimal. This is equivalent to `-t d4`.
- `-t type_string` Specify one or more output types. The *type_string* option-argument must be a string specifying the types to be used when writing the input data. The string must consist of the type specification characters:
 - `a` *Named character*. Interpret bytes as named characters. Only the least significant seven bits of each byte will be used for this type specification. Bytes with the values listed in the following table will be written using the corresponding names for those characters.

Named Characters in od

Value Name	Value Name	Value Name	Value Name
\000 nul	\001 soh	\002 stx	\003 etx
\004 eot	\005 enq	\006 ack	\007 bel
\010 bs	\011 ht	\012 lf	\013 vt
\014 ff	\015 cr	\016 so	\017 si
\020 dle	\021 dc1	\022 dc2	\023 dc3
\024 dc4	\025 nak	\026 syn	\027 etb
\030 can	\031 em	\032 sub	\033 esc
\034 fs	\035 gs	\036 rs	\037 us
\040 sp	\177 del		

- c** *Character.* Interpret bytes as single-byte or multibyte characters specified by the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; the two character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes: \0, \a, \b, \f, \n, \r, \t, \v. Other non-printable characters appear as one three-digit octal number for each byte in the character.

The type specification characters d, f, o, u, and x can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type.

- f** *Floating point.* Can be followed by an optional F, D, or L indicating that the conversion should be applied to an item of type float, double, or long double, respectively.

d, o, u, and x *Signed decimal, octal, unsigned decimal, and hexadecimal, respectively. Can be followed by an optional C, S, I, or L indicating that the conversion should be applied to an item of type char, short, int, or long, respectively.*

Multiple types can be concatenated within the same *type_string* and multiple *-t* options can be specified. Output lines are written for each type specified in the order in which the type specification characters are specified.

- v Show all input data (verbose). Without the *-v* option, all groups of output lines that would be identical to the immediately preceding output line (except for byte offsets), will be replaced with a line containing only an asterisk (*).
- x Interpret words in hex. This is equivalent to *-t x2*.
- X Interpret long words in hex. This is equivalent to *-t x4*.

OPERANDS

The following operands are supported for both */usr/bin/od* and */usr/xpg4/bin/od*:

- Use the standard input in addition to any files specified. When this operand is not given, the standard input is used only if no *file* operands are specified.

/usr/bin/od

The following operands are supported for */usr/bin/od* only:

file A path name of a file to be read. If no *file* operands are specified, the standard input will be used. If there are no more than two operands, none of the *-A*, *-j*, *-N*, or *-t* options is specified, and *any* of the following are true:

1. the first character of the last operand is a plus sign (+)
2. the first character of the second operand is numeric
3. the first character of the second operand is *x* and the second character of the second operand is a lower-case hexadecimal character or digit
4. the second operand is named "*x*"
5. the second operand is named "."

then the corresponding operand is assumed to be an offset operand rather than a file operand.

Without the `-N` count option, the display continues until an end-of-file is reached.

```
[+][0] offset [.] [b|B]
[+][0] [offset] [.]
[+][0x|x] [offset]
[+][0x|x] offset [B]
```

The *offset_string* operand specifies the byte offset in the file where dumping is to commence. The offset is interpreted in octal bytes by default. If *offset* begins with "0", it is interpreted in octal. If *offset* begins with "x" or "0x", it is interpreted in hexadecimal and any appended "b" is considered to be the final hexadecimal digit. If "." is appended, the offset is interpreted in decimal. If "b" or "B" is appended, the offset is interpreted in units of 512 bytes. If the *file* argument is omitted, the *offset* argument must be preceded by a plus sign (+). The address is displayed starting at the given offset. The radix of the address will be the same as the radix of the offset, if specified, otherwise it will be octal. Decimal overrides octal, and it is an error to specify both hexadecimal and decimal conversions in the same offset operand.

`/usr/xpg4/bin/od`

The following operands are supported for `/usr/xpg4/bin/od` only:

file

Same as `/usr/bin/od`, except only one of the first two conditions must be true.

```
[+] [0] offset
[.] [b|B]
+ [offset] [.]
[+][0x|x] [offset]
[+][0x|x] offset [B]
+x [offset]
+xoffset [B]
```

Description of *offset_string* is the same as for `/usr/bin/od`.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `od`: `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

NAME on – execute a command on a remote system, but with the local environment

SYNOPSIS **on** [-i] [-d] [-n] *host command [argument] ...*

DESCRIPTION The **on** program is used to execute commands on another system, in an environment similar to that invoking the program. All environment variables are passed, and the current working directory is preserved. To preserve the working directory, the working file system must be either already mounted on the host or be exported to it. Relative path names will only work if they are within the current file system; absolute path names may cause problems.

The standard input is connected to the standard input of the remote command, and the standard output and the standard error from the remote command are sent to the corresponding files for the **on** command.

OPTIONS

- i Interactive mode. Use remote echoing and special character processing. This option is needed for programs that expect to be talking to a terminal. All terminal modes and window size changes are propagated.
- d Debug mode. Print out some messages as work is being done.
- n No Input. This option causes the remote program to get EOF when it reads from the standard input, instead of passing the standard input from the standard input of the **on** program. For example, **-n** is necessary when running commands in the background with job control.

ATTRIBUTES See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO [chkey\(1\)](#), [rlogin\(1\)](#), [rsh\(1\)](#), [telnet\(1\)](#), [attributes\(5\)](#)

DIAGNOSTICS

unknown host	Host name not found.
cannot connect to server	Host down or not running the server.
can't find	Problem finding the working directory.
can't locate mount point	Problem finding current file system.
RPC: Authentication error	The server requires DES authentication and you do not have a secret key registered with keyserv . Perhaps you logged in without a

password. Try to keylogin. If that fails try to set your publickey with chkey.

Other diagnostic messages may be passed back from the server.

BUGS

When the working directory is remote mounted over NFS, a CTRL-Z hangs the window.

Root cannot use on.

NAME optisa – determine which variant instruction set is optimal to use

SYNOPSIS **optisa** *instruction_set*...

DESCRIPTION **optisa** prints which *instruction_set* out of the ones specified in the command will perform best on this machine. In this case, “best” is defined by the order in which instruction set names are returned by `isalist(1)`. Possible values for *instruction_set* are given in `isalist(5)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

EXIT STATUS The following exit values are returned:

0 One of the *instruction_set* values you specified is printed by this command.

1 There is no output; that is, this machine cannot use any *instruction_set* that you specified with the `optisa` command.

SEE ALSO `isalist(1)`, `uname(1)`, `attributes(5)`, `isalist(5)`

NOTES `optisa` is preferable to `uname -p` or `uname -m` (see `uname(1)`) in determining which of several binary versions of a given program should be used on the given machine.

NAME	pack, pcat, unpack – compress and expand files
SYNOPSIS	pack [-f] [-] file... pcat file... unpack file...
DESCRIPTION	
pack	<p>The <code>pack</code> command attempts to store the specified files in a compressed form. Wherever possible (and useful), each input file <code>file</code> is replaced by a packed file <code>file.z</code> with the same access modes, access and modified dates, and owner as those of <code>file</code>. If <code>pack</code> is successful, <code>file</code> will be removed.</p> <p>The amount of compression obtained depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each <code>.z</code> file, it is usually not worthwhile to pack files smaller than three blocks, unless the character frequency distribution is very skewed, which may occur with printer plots or pictures.</p> <p>Typically, text files are reduced to 60-75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.</p> <p><code>pack</code> returns a value that is the number of files that it failed to compress.</p> <p>No packing will occur if:</p> <ul style="list-style-type: none"> ■ the file appears to be already packed ■ the file name has more than 14 - 2 bytes ■ the file has links ■ the file is a directory ■ the file cannot be opened ■ the file is empty ■ no disk storage blocks will be saved by packing ■ a file called <code>file.z</code> already exists ■ the <code>.z</code> file cannot be created ■ an I/O error occurred during processing. <p>The last segment of the file name must contain no more than 14 - 2 bytes to allow space for the appended <code>.z</code> extension. Directories cannot be compressed.</p>
pcat	The <code>pcat</code> command does for packed files what <code>cat(1)</code> does for ordinary files, except that <code>pcat</code> cannot be used as a filter. The specified files are unpacked and written to the standard output.

`pcat` returns the number of files it was unable to unpack. Failure may occur if:

- the file cannot be opened;
- the file does not appear to be the output of `pack`.

unpack

The `unpack` command expands files created by `pack`. For each `file` specified in the command, a search is made for a file called `file.z` (or just `file`, if `file` ends in `.z`). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the `.z` suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.

`unpack` returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in `pcat`, as well as for the following:

- a file with the “unpacked” name already exists;
- the unpacked file cannot be created.
- the filename (excluding the `.z` extension) has more than 14 bytes.

OPTIONS

The following options are supported by `pack`:

- `-f` Forces packing of `file`. This is useful for causing an entire directory to be packed even if some of the files will not benefit. Packed files can be restored to their original form using `unpack` or `pcat`.

OPERANDS

The following operands are supported:

- `file` A path name of a file to be packed, unpacked, or `pcat`ed; `file` can include or omit the `.z` suffix.
- `-` `pack` uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the `-` argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of `-` in place of `file` will cause the internal flag to be set and reset.

USAGE

See `largefile(5)` for the description of the behavior of `pack`, `pcat`, and `unpack` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 Viewing a Packed File

To view a packed file named `file.z` use:

```
example% pcat file.z
```

or just:

```
example% pcat file
```

EXAMPLE 2 Making and Unpacked Copy:

To make an unpacked copy, say `nnn`, of a packed file named `file.z` (without destroying `file.z`) use the command:

```
example% pcat file >nnn
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pack`, `pcat`, and `unpack`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred. The number of files the command failed to pack/unpack is returned.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME pagesize – display the size of a page of memory

SYNOPSIS `/usr/bin/pagesize`

DESCRIPTION `pagesize` prints the size of a page of memory in bytes, as returned by `getpagesize(3C)`. This program is useful in constructing portable shell scripts.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `getpagesize(3C)`, `attributes(5)`

NAME	passwd – change login password and password attributes
SYNOPSIS	<pre> passwd [-r files -r ldap -r nis -r nisplus][name] passwd [-r files] [-egh] [name] passwd [-r files] -s [-a] passwd [-r files] -s [name] passwd [-r files] [-d -l][-f] [-n min] [-w warn] [-x max] name passwd -r ldap [-egh] [name] passwd -r nis [-egh] [name] passwd -r nisplus [-egh] [-D domainname] [name] passwd -r nisplus -s [-a] passwd -r nisplus [-D domainname] -s [name] passwd -r nisplus [-l] [-f] [-n min] [-w warn] [-x max] [-D domainname] name </pre>
DESCRIPTION	<p>The <code>passwd</code> command changes the password or lists password attributes associated with the user's login <i>name</i>. Additionally, privileged users may use <code>passwd</code> to install or change passwords and attributes associated with any login <i>name</i>.</p> <p>When used to change a password, <code>passwd</code> prompts everyone for their old password, if any. It then prompts for the new password twice. When the old password is entered, <code>passwd</code> checks to see if it has "aged" sufficiently. If "aging" is insufficient, <code>passwd</code> terminates; see <code>pwconv(1M)</code>, <code>nistbladm(1)</code>, and <code>shadow(4)</code> for additional information.</p> <p>When LDAP, NIS, or NIS+ is in effect on a system, <code>passwd</code> changes the NIS or NIS+ database. The NIS or NIS+ password may be different from the password on the local machine. If NIS or NIS+ is running, use <code>passwd -r</code> to change password information on the local machine.</p> <p>The <code>pwconv</code> command creates and updates <code>/etc/shadow</code> with information from <code>/etc/passwd</code>. <code>pwconv</code> relies on a special value of 'x' in the password field of <code>/etc/passwd</code>. This value of 'x' indicates that the password for the user is already in <code>/etc/shadow</code> and should not be modified.</p> <p>If aging is sufficient, a check is made to ensure that the new password meets construction requirements. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated for, at most, two more times.</p> <p>Passwords must be constructed to meet the following requirements:</p>

- Each password must have `PASSLENGTH` characters, where `PASSLENGTH` is defined in `/etc/default/passwd` and is set to 6. Only the first eight characters are significant.
- Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, "alphabetic" refers to all upper or lower case letters.
- Each password must differ from the user's login *name* and any reverse or circular shift of that login *name*. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.
- New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

If all requirements are met, by default, the `passwd` command will consult `/etc/nsswitch.conf` to determine in which repositories to perform password update. It searches the `passwd` and `passwd_compat` entries. The sources (repositories) associated with these entries will be updated. However, the password update configurations supported are limited to the following cases. Failure to comply with the configurations will prevent users from logging onto the system. The password update configurations are:

- `passwd: files`
- `passwd: files ldap`
- `passwd: files nis`
- `passwd: files nisplus`
- `passwd: compat (==> files nis)`
- `passwd: compat (==> files ldap)`
`passwd_compat: ldap`
- `passwd: compat (==> files nisplus)`
`passwd_compat: nisplus`

Network administrators, who own the NIS+ password table, may change any password attributes.

In the `files` case, superusers (for instance, real and effective uid equal to 0, see `id(1M)` and `su(1M)`) may change any password; hence, `passwd` does not prompt privileged users for the old password. Privileged users are not forced to comply with password aging and password construction requirements. A privileged user can create a null password by entering a carriage return in response to the prompt for a new password. (This differs from `passwd -d` because the "password" prompt will still be displayed.) If NIS is in effect, superuser on the root master can change any password without being prompted for the old NIS `passwd`, and is not forced to comply with password construction requirements.

Normally, `passwd` entered with no arguments will change the password of the current user. When a user logs in and then invokes `su(1M)` to become super-user or another user, `passwd` will change the original user's password, not the password of the super-user or the new user.

Any user may use the `-s` option to show password attributes for his or her own login *name*, provided they are using the `-r nisplus` argument. Otherwise, the `-s` argument is restricted to the superuser.

The format of the display will be:

```
name status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
name status
```

where

name The login ID of the user.

status The password status of *name*: `PS` stands for passworded or locked, `LK` stands for locked, and `NP` stands for no password.

mm/dd/yy The date password was last changed for *name*. (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and therefore may differ by as much as a day in other time zones.)

min The minimum number of days required between password changes for *name*. `MINWEEKS` is found in `/etc/default/passwd` and is set to `NULL`.

max The maximum number of days the password is valid for *name*. `MAXWEEKS` is found in `/etc/default/passwd` and is set to `NULL`.

warn The number of days relative to *max* before the password expires and the *name* will be warned.

Security

`passwd` uses `pam(3PAM)` for password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the password modules to be used for `passwd`. Here is a partial `pam.conf` file with entries for the `passwd` command using the UNIX password module:

```
passwd required password /usr/lib/security/pam_unix.so.1
```

If there are no entries for the `passwd` service, then the entries for the "other" service will be used. If multiple password modules are listed, then the user may be prompted for multiple passwords.

OPTIONS

The following options are supported:

- `-r` Specifies the repository to which an operation is applied. The supported repositories are `files`, `ldap`, `nis`, or `nisplus`.
- `-e` Changes the login shell. For the `files` repository, this only works for the super-user. Normal users may change the `ldap`, `nis`, or `nisplus` repositories. The choice of shell is limited by the requirements of `getusershell(3C)`. If the user currently has a shell that is not allowed by `getusershell`, only root may change it.
- `-g` Changes the `gecos` (finger) information. For the `files` repository, this only works for the superuser. Normal users may change the `ldap`, `nis`, or `nisplus` repositories.
- `-h` Changes the home directory.
- `-D domainname` Consults the `passwd.org_dir` table in `domainname`. If this option is not specified, the default `domainname` returned by `nis_local_directory(3NSL)` will be used. This domain name is the same as that returned by `domainname(1M)`.
- `-s name` Shows password attributes for the login `name`. For the `nisplus` repository, this works for everyone. However for the `files` repository, this only works for the superuser. It does not work at all for the `nis` repository which does not support password aging.
- `-a` Shows password attributes for all entries. Use only with the `-s` option; `name` must not be provided. For the `nisplus` repository, this will show only the entries in the NIS+ password table in the local domain that the invoker is authorized to "read". For the `files` repository, this is restricted to the superuser.

Privileged User Options

Only a privileged user can use the following options:

- `-f` Forces the user to change password at the next login by expiring the password for `name`.
- `-l` Locks password entry for `name`.
- `-n min` Sets minimum field for `name`. The `min` field contains the minimum number of days between password changes for `name`. If `min` is greater than `max`, the user may not change

the password. Always use this option with the `-x` option, unless `max` is set to `-1` (aging turned off). In that case, `min` need not be set.

`-w warn` Set warn field for `name`. The `warn` field contains the number of days before the password expires and the user is warned. This option is not valid if password aging is disabled.

`-x max` Sets maximum field for `name`. The `max` field contains the number of days that the password is valid for `name`. The aging for `name` will be turned off immediately if `max` is set to `-1`. If it is set to `0`, then the user is forced to change the password at the next login session and aging is turned off.

`-d` Deletes password for `name`. The login `name` will not be prompted for password. It is only applicable to the files repository.

OPERANDS

`name` User login name.

ENVIRONMENT VARIABLES

If any of the `LC_*` variables, that is, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY` (see `environ(5)`), are not set in the environment, the operational behavior of `passwd` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `passwd` behaves.

`LC_CTYPE` Determines how `passwd` handles characters. When `LC_CTYPE` is set to a valid value, `passwd` can display and handle text and filenames containing valid characters for that locale. `passwd` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `passwd` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_MESSAGES` Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

EXIT STATUS

The `passwd` command exits with one of the following values:

0 Success.

- 1 Permission denied.
- 2 Invalid combination of options.
- 3 Unexpected failure. Password file unchanged.
- 4 Unexpected failure. Password file(s) missing.
- 5 Password file(s) busy. Try again later.
- 6 Invalid argument to option.
- 7 Aging option is disabled.

FILES

/etc/oshadow

/etc/shells

/etc/passwd Password file.

/etc/shadow Shadow password file.

/etc/default/passwd Default values can be set for the following flags in /etc/default/passwd. For example:
MAXWEEKS=26

MAXWEEKS	Maximum time period that password is valid.
MINWEEKS	Minimum time period before the password can be changed.
PASSLENGTH	Minimum length of password, in characters.
WARNWEEKS	Time period until warning of date of password's ensuing expiration.

NOTES

The `passwd` command replaces the `nispaswd` and `yppaswd` commands and should be used in their place.

NAME	paste – merge corresponding or subsequent lines of files
SYNOPSIS	paste [-s] [-d <i>list</i>] <i>file</i> ...
DESCRIPTION	<p>The <code>paste</code> utility will concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.</p> <p>The default operation of <code>paste</code> will concatenate the corresponding lines of the input files. The NEWLINE character of every line except the line from the last input file will be replaced with a TAB character.</p> <p>If an EOF (end-of-file) condition is detected on one or more input files, but not all input files, <code>paste</code> will behave as though empty lines were read from the files on which EOF was detected, unless the <code>-s</code> option is specified.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-d list</code> Unless a backslash character (<code>\</code>) appears in <i>list</i>, each character in <i>list</i> is an element specifying a delimiter character. If a backslash character appears in <i>list</i>, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default TAB character, to replace the NEWLINE character of the input lines. The elements in <i>list</i> are used circularly; that is, when the list is exhausted the first element from the list is reused.</p> <p>When the <code>-s</code> option is specified:</p> <ul style="list-style-type: none"> ■ The last newline character in a file will not be modified. ■ The delimiter will be reset to the first element of list after each <code>file</code> operand is processed. <p>When the option is not specified:</p> <ul style="list-style-type: none"> ■ The NEWLINE characters in the file specified by the last <code>file</code> will not be modified. ■ The delimiter will be reset to the first element of list each time a line is processed from each file. <p>If a backslash character appears in <i>list</i>, it and the character following it will be used to represent the following delimiter characters:</p> <p><code>\n</code> Newline character.</p> <p><code>\t</code> Tab character.</p>

\\ Backslash character.

\0 Empty string (not a null character). If \0 is immediately followed by the character x, the character X, or any character defined by the LC_CTYPE digit keyword, the results are unspecified.

If any other characters follow the backslash, the results are unspecified.

-s Concatenate all of the lines of each separate input file in command line order. The NEWLINE character of every line except the last line in each input file will be replaced with the TAB character, unless otherwise specified by the -d option.

OPERANDS

The following operand is supported:

file A path name of an input file. If - is specified for one or more of the files, the standard input will be used; the standard input will be read one line at a time, circularly, for each instance of -. Implementations support pasting of at least 12 file operands.

USAGE

See largefile(5) for the description of the behavior of paste when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 List a directory in one column.

```
ls | paste -d" " -
```

EXAMPLE 2 List a directory in four columns.

```
ls | paste - - - -
```

EXAMPLE 3 Combine pairs of lines from a file into single lines.

```
paste -s -d"\t\n" file
```

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of paste: LC_CTYPE and LC_MESSAGES.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled

SEE ALSO

cut(1), grep(1), pr(1), attributes(5), environ(5), largefile(5)

DIAGNOSTICS

"line too long" Output lines are restricted to 511 characters.
"too many files" Except for `-s` option, no more than 12 input
files may be specified.
"no delimiters" The `-d` option was specified with an empty list.
"cannot open file" The specified file cannot be opened.

NAME	patch - apply changes to files
SYNOPSIS	patch [-b NR] [-c -e -n][-d <i>dir</i>] [-D <i>define</i>] [-i <i>patchfile</i>] [-o <i>outfile</i>] [-p <i>num</i>] [-r <i>rejectfile</i>] [<i>file</i>]
DESCRIPTION	<p>The <code>patch</code> command reads a source (patch) file containing any of the three forms of difference (diff) listings produced by the <code>diff(1)</code> command (normal, context or in the style of <code>ed(1)</code>) and apply those differences to a file. By default, <code>patch</code> reads from the standard input.</p> <p><code>patch</code> attempts to determine the type of the <code>diff</code> listing, unless overruled by a <code>-c</code>, <code>-e</code> or <code>-n</code> option.</p> <p>If the patch file contains more than one patch, <code>patch</code> will attempt to apply each of them as if they came from separate patch files. (In this case the name of the patch file must be determinable for each <code>diff</code> listing.)</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-b</code> Save a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix <code>.orig</code> appended to it. If the file already exists, it will be overwritten; if multiple patches are applied to the same file, the <code>.orig</code> file will be written only for the first patch. When the <code>-ooutfile</code> option is also specified, <code>file.orig</code> will not be created but, if <code>outfile</code> already exists, <code>outfile.orig</code> will be created.</p> <p><code>-c</code> Interpret the patch file as a context difference (the output of the command <code>diff</code> when the <code>-c</code> or <code>-C</code> options are specified).</p> <p><code>-ddir</code> Change the current directory to <i>dir</i> before processing as described in EXTENDED DESCRIPTION.</p> <p><code>-Ddefine</code> Mark changes with the C preprocessor construct:</p> <pre style="margin-left: 40px;">#ifdef define . . . #endif</pre> <p>The option-argument <i>define</i> will be used as the differentiating symbol.</p> <p><code>-e</code> Interpret the patch file as an <code>ed</code> script, rather than a <code>diff</code> script.</p> <p><code>-ipatchfile</code> Read the patch information from the file named by the path name <i>patchfile</i>, rather than the standard input.</p>

- l (The letter ell.) Cause any sequence of blank characters in the difference script to match any sequence of blank characters in the input file. Other characters will be matched exactly.
- n Interpret the script as a normal difference.
- N Ignore patches where the differences have already been applied to the file; by default, already-applied patches are rejected.
- o*outfile* Instead of modifying the files (specified by the *file* operand or the difference listings) directly, write a copy of the file referenced by each patch, with the appropriate differences applied, to *outfile*. Multiple patches for a single file will be applied to the intermediate versions of the file created by any previous patches, and will result in multiple, concatenated versions of the file being written to *outfile*.
- p*num* For all path names in the patch file that indicate the names of files to be patched, delete *num* path name components from the beginning of each path name. If the path name in the patch file is absolute, any leading slashes are considered the first component (that is, -p 1 removes the leading slashes). Specifying -p 0 causes the full path name to be used. If -p is not specified, only the basename (the final path name component) is used.
- R Reverse the sense of the patch script; that is, assume that the difference script was created from the new version to the old version. The -R option cannot be used with *ed* scripts. *patch* attempts to reverse each portion of the script before applying it. Rejected differences will be saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, *patch* attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user will be prompted to determine if the -R option should be set.
- r*rejectfile* Override the default reject filename. In the default case, the reject file will have the same name as the output file, with the suffix *.rej* appended to it. See *Patch Application*.

OPERANDS

The following operand is supported:

file A path name of a file to patch.

USAGE

The `-R` option will not work with `ed` scripts because there is too little information to reconstruct the reverse operation.

The `-p` option makes it possible to customise a patchfile to local user directory structures without manually editing the patchfile. For example, if the filename in the patch file was:

```
/curds/whey/src/blurfl/blurfl.c
```

Setting `-p 0` gives the entire path name unmodified; `-p 1` gives:

```
curds/whey/src/blurfl/blurfl.c
```

without the leading slash, `-p 4` gives:

```
blurfl/blurfl.c
```

and not specifying `-p` at all gives:

```
blurfl.c.
```

When using `-b` in some file system implementations, the saving of a `.orig` file may produce unwanted results. In the case of 12, 13 or 14-character filenames, on file systems supporting 14-character maximum filenames, the `.orig` file will overwrite the new file.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `patch`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLS_PATH`.

OUTPUT FILES

The output of `patch` the save files (`.orig` suffixes) and the reject files (`.rej` suffixes) will be text files.

EXTENDED DESCRIPTION

A patchfile may contain patching instructions for more than one file; filenames are determined as specified in `Patch Determination`. When the `-b` option is specified, for each patched file, the original will be saved in a file of the same name with the suffix `.orig` appended to it.

For each patched file, a reject file may also be created as noted in `Patch Application`. In the absence of a `-r` option, the name of this file will be formed by appending the suffix `.rej` to the original filename.

Patchfile Format

The patch file must contain zero or more lines of header information followed by one or more patches. Each patch must contain zero or more lines of filename identification in the format produced by `diff -c`, and one or more sets of `diff` output, which are customarily called hunks.

`patch` recognizes the following expression in the header information:

`Index: pathname` The file to be patched is named *pathname*.

If all lines (including headers) within a patch begin with the same leading sequence of blank characters, `patch` will remove this sequence before proceeding. Within each patch, if the type of difference is context, `patch` recognizes the following expressions:

`*** filename timestamp`

The patches arose from *filename*.

`--- filename timestamp`

The patches should be applied to *filename*.

Each hunk within a patch must be the `diff` output to change a line range within the original file. The line numbers for successive hunks within a patch must occur in ascending order.

Filename Determination

If no `file` operand is specified, `patch` performs the following steps to obtain a path name:

1. If the patch contains the strings `***` and `---`, `patch` strips components from the beginning of each path name (depending on the presence or value of the `-p` option), then tests for the existence of both files in the current directory (or directory specified with the `-d` option).
2. If both files exist, `patch` assumes that no path name can be obtained from this step. If the header information contains a line with the string `Index:`, `patch` strips components from the beginning of the path name (depending on `-p`), then tests for the existence of this file in the current directory (or directory specified with the `-d` option).
3. If an `SCCS` directory exists in the current directory, `patch` will attempt to perform a `get -e SCCS/s.filename` command to retrieve an editable version of the file.
4. If no path name can be obtained by applying the previous steps, or if the path names obtained do not exist, `patch` will write a prompt to standard output and request a filename interactively from standard input.

Patch Application

If the `-c`, `-e` or `-n` option is present, `patch` will interpret information within each hunk as a context difference, an `ed` difference or a normal difference, respectively. In the absence of any of these options, `patch` determines the type of difference based on the format of information within the hunk.

For each hunk, `patch` begins to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found,

`patch` scans both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan will take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context will be ignored and another scan will be made. Implementations may search more extensively for installation locations.

If no location can be found, `patch` will append the hunk to the reject file. The rejected hunk will be written in context-difference format regardless of the format of the patch file. If the input was a normal or `ed -style` difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they will reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an `ed diff`, the implementation may accomplish the patching by invoking the `ed` command.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 One or more lines were written to a reject file.
- >1 An error occurred.

ATTRIBUTES

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`ed(1)`, `diff(1)`, `attributes(5)`, `environ(5)`

NAME	pathchk – check path names
SYNOPSIS	pathchk [-p] <i>path</i> ...
DESCRIPTION	<p>The <code>pathchk</code> command will check that one or more path names are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation will result). More extensive portability checks are provided by the <code>-p</code> option.</p> <p>By default, <code>pathchk</code> will check each component of each <i>path</i> operand based on the underlying file system. A diagnostic will be written for each <i>path</i> operand that:</p> <ul style="list-style-type: none"> ■ is longer than <code>PATH_MAX</code> bytes. ■ contains any component longer than <code>NAME_MAX</code> bytes in its containing directory ■ contains any component in a directory that is not searchable ■ contains any character in any component that is not valid in its containing directory. <p>The format of the diagnostic message is not specified, but will indicate the error detected and the corresponding <i>path</i> operand.</p> <p>It will not be considered an error if one or more components of a <i>path</i> operand do not exist as long as a file matching the path name specified by the missing components could be created that does not violate any of the checks specified above.</p>
OPTIONS	<p>The following option is supported:</p> <p><code>-p</code> Instead of performing checks based on the underlying file system, write a diagnostic for each <i>path</i> operand that:</p> <ul style="list-style-type: none"> ■ is longer than <code>_POSIX_PATH_MAX</code> bytes ■ contains any component longer than <code>_POSIX_NAME_MAX</code> bytes ■ contains any character in any component that is not in the portable filename character set.
OPERANDS	<p>The following operand is supported:</p> <p><i>path</i> A path to be checked.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>pathchk</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Examples of the <code>pathchk</code> command.</p> <p>To verify that all paths in an imported data interchange archive are legitimate and unambiguous on the current system:</p>

```

pax -f archive | sed -e '/ == ./s///' | xargs pathchk
if [ $? -eq 0 ]
then
    pax -r -f archive
else
    echo Investigate problems before importing files.
    exit 1
fi

```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the X/Open specification that also supports the `pax(1)` command:

```

find . -print | xargs pathchk -p
if [ $? -eq 0 ]
then
    pax -w -f archive .
else
    echo Portable archive cannot be created.
    exit 1
fi

```

To verify that a user-supplied path names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```

case $- in
*C*)   reset="";;
*)     reset="set +C"
    set -C;;
esac
test -r "$path" && pathchk "$path.out" &&
rm "$path.out" > "$path.out"
if [ $? -ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset # reset the noclobber option in case a trap
    # on EXIT depends on it
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"

```

The following assumptions are made in this example:

1. `PROCESSING` represents the code that will be used by the application to use `$path` once it is verified that `$path.out` will work as intended.
2. The state of the `noclobber` option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The `reset` variable is used in this example to restore the initial state.)

3. Note the usage of:

```
rm "$path.out" > "$path.out"
```

- a. The `pathchk` command has already verified, at this point, that `$path.out` will not be truncated.
- b. With the `noclobber` option set, the shell will verify that `$path.out` does not already exist before invoking `rm`.
- c. If the shell succeeded in creating `$path.out`, `rm` will remove it so that the application can create the file again in the `PROCESSING` step.
- d. If the `PROCESSING` step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:

```
> "$path.out"
```

which will verify that the file did not already exist, but leave `$path.out` in place for use by `PROCESSING`.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pathchk`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 All *path* operands passed all of the checks.
- >0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

NAME	pathconv – search FMLI criteria for filename
SYNOPSIS	pathconv [-f] [-v <i>alias</i>] pathconv [-t] [-l] [-n <i>num</i>] [-v <i>string</i>]
DESCRIPTION	The <code>pathconv</code> function converts an alias to its pathname. By default, it takes the alias as a string from the standard input.
OPTIONS	<p>-f If -f is specified, the full path will be returned (this is the default).</p> <p>-t If -t is specified, <code>pathconv</code> will truncate a pathname specified in <i>string</i> in a format suitable for display as a frame title. This format is a shortened version of the full pathname, created by deleting components of the path from the middle of the string until it is under <code>DISPLAYW — 6</code> characters in length, and then inserting ellipses (. . .) between the remaining pieces. Ellipses are also used to show truncation at the ends of the strings if necessary, unless the -l option is given.</p> <p>-l If -l is specified, < and > will be used instead of ellipses (. . .) to indicate truncation at the ends of the string generated by the -t option. Using -l allows display of the longest possible string while still notifying users it has been truncated.</p> <p>-n<i>num</i> If -n is specified, <i>num</i> is the maximum length of the string (in characters) generated by the -t option. The argument <i>num</i> can be any integer from 1 to 255.</p> <p>-v<i>alias</i> <i>string</i> If the -v option is used, then <i>alias</i> or <i>string</i> can be specified when <code>pathconv</code> is called. The argument <i>alias</i> must be an alias defined in the <i>alias_file</i> named when <code>fml</code> was invoked. The argument <i>string</i> can only be used with the -t option and must be a pathname.</p>
EXAMPLES	<p>EXAMPLE 1 A sample that uses <code>pathconv</code> to construct the menu title. It searches for <code>MYPATH</code> in the <i>alias_file</i> named when <code>fml</code> command.</p> <p>Here is a menu descriptor that uses <code>pathconv</code> to construct the menu title. It searches for <code>MYPATH</code> in the <i>alias_file</i> named when <code>fml</code> was invoked:</p> <pre>menu='pathconv -v MYPATH/ls' . . .</pre> <p>where there is a line in <i>alias_file</i> that defines <code>MYPATH</code> . For example, <code>MYPATH=\$HOME/bin:/usr/bin</code> .</p> <p>Here is a menu descriptor that takes <i>alias</i> from the standard input.</p>

```
menu='echo MYPATH/ls | pathconv`  
.  
.  
.
```

NAME	pax - portable archive interchange
SYNOPSIS	<p>pax [-cdnv] [-f <i>archive</i>] [-s <i>replstr</i>] ... [<i>pattern</i>...]</p> <p>pax -r [-cdiknuv] [-f <i>archive</i>] [-o <i>options</i>...] [-p <i>string</i>] ... [-s <i>replstr</i>] ... [<i>pattern</i>...]</p> <p>pax -w [-dituvX] [-b <i>blocksize</i>] [-a] [-f <i>archive</i>] [-o <i>options</i>] ... [-s <i>replstr</i>] ... [-x <i>format</i>] [<i>file</i>...]</p> <p>pax -r -w [-diklntuvX] [-p <i>string</i>] ... [-s <i>replstr</i>] ... [<i>file</i>...] <i>directory</i></p>
DESCRIPTION	The <code>pax</code> command reads, writes and writes lists of the members of archive files and copy directory hierarchies. A variety of archive formats are supported; see the <code>-xformat</code> option.
Modes of Operations	<p>The action to be taken depends on the presence of the <code>-r</code> and <code>-w</code> options. The four combinations of <code>-r</code> and <code>-w</code> are referred to as the four modes of operation: list, read, write, and copy modes, corresponding respectively to the four forms shown in the SYNOPSIS.</p> <p>list In list mode (when neither <code>-r</code> nor <code>-w</code> are specified), <code>pax</code> writes the names of the members of the archive file read from the standard input, with path names matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file will be written out as well.</p> <p>read In read mode (when <code>-r</code> is specified, but <code>-w</code> is not), <code>pax</code> extracts the members of the archive file read from the standard input, with path names matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file will be extracted as well. The extracted files is created relative to the current file hierarchy.</p> <p style="padding-left: 2em;">The ownership, access and modification times, and file mode of the restored files are discussed under the <code>-p</code> option.</p> <p>write In write mode (when <code>-w</code> is specified, but <code>-r</code> is not), <code>pax</code> writes the contents of the file operands to the standard output in an archive format. If no <code>file</code> operands are specified, a list of files to copy, one per line, will be read from the standard input. A file of type directory will include all of the files in the file hierarchy rooted at the file.</p> <p>copy In copy mode (when both <code>-r</code> and <code>-w</code> are specified), <code>pax</code> copies the file operands to the destination directory.</p> <p style="padding-left: 2em;">If no <code>file</code> operands are specified, a list of files to copy, one per line, will be read from the standard input. A file of type directory will include all of the files in the file hierarchy rooted at the file.</p>

The effect of the copy is as if the copied files were written to an archive file and then subsequently extracted, except that there may be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. It is an error if *directory* doesn't exist, is not writable by the user, or is not a directory.

In read or copy modes, if intermediate directories are necessary to extract an archive member, `pax` will perform actions equivalent to the `mkdir(2)` function, called with the following arguments:

- the intermediate directory used as the *path* argument
- the octal value of 777 or *rxw* (read, write, and execute permissions) as the *mode* argument (see `chmod(1)`).

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, `pax` will write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The supported archive formats are automatically detected on input. The default output archive format is `tar(1)`.

If the selected archive format supports the specification of linked files, it is an error if these files cannot be linked when the archive is extracted. Any of the various names in the archive that represent a file can be used to select the file for extraction.

OPTIONS

The following options are supported:

- `-r` Read an archive file from standard input.
- `-w` Write files to the standard output in the specified archive format.
- `-a` Append files to the end of the archive. This option will not work for some archive devices, such as 1/4-inch streaming tapes and 8mm tapes.
- `-bblocksize` Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking is automatically determined on input. Portable applications must not specify a *blocksize* value larger than 32256. Default blocking when creating archives depends on the archive format. (See the `-x` option below.)
- `-c` Match all file or archive members except those specified by the *pattern* or *file* operands.

-d	Cause files of type directory being copied or archived or archive members of type directory being extracted to match only the file or archive member itself and not the file hierarchy rooted at the file.
-f <i>archive</i>	Specify the path name of the input or output archive, overriding the default standard input (in list or read modes) or standard output (write mode).
-i	Interactively rename files or archive members. For each archive member matching a <i>pattern</i> operand or file matching a <i>file</i> operand, a prompt will be written to the file <code>/dev/tty</code> . The prompt will contain the name of the file or archive member. A line will then be read from <code>/dev/tty</code> . If this line is blank, the file or archive member will be skipped. If this line consists of a single period, the file or archive member will be processed with no modification to its name. Otherwise, its name will be replaced with the contents of the line. The <code>pax</code> command will immediately exit with a non-zero exit status if end-of-file is encountered when reading a response or if <code>/dev/tty</code> cannot be opened for reading and writing.
-k	Prevent the overwriting of existing files.
-l	Link files. In copy mode, hard links will be made between the source and destination file hierarchies whenever possible.
-n	Select the first archive member that matches each <i>pattern</i> operand. No more than one archive member will be matched for each pattern (although members of type directory will still match the file hierarchy rooted at that file).
-o <i>options</i>	Reserved for special format-specific options.
-p <i>string</i>	Specify one or more file characteristic options (privileges). The <i>string</i> option-argument must be a string specifying file characteristics to be retained or discarded on extraction. The string consists of the specification characters <code>a</code> , <code>e</code> , <code>m</code> , <code>o</code> and <code>p</code> . Multiple characteristics can be concatenated within the same string and multiple <code>-p</code> options can be specified. The meaning of the specification characters are as follows:
a	Do not preserve file access times.
e	Preserve the user ID, group ID, file mode bits, access time, and modification time.

- m Do not preserve file modification times.
- o Preserve the user ID and group ID.
- p Preserve the file mode bits. Other, implementation-dependent file-mode attributes may be preserved.

In the preceding list, “preserve” indicates that an attribute stored in the archive will be given to the extracted file, subject to the permissions of the invoking process; otherwise, the attribute will be determined as part of the normal file creation action.

If neither the `e` nor the `o` specification character is specified, or the user ID and group ID are not preserved for any reason, `pax` will not set the `setuid` and `setgid` bits of the file mode.

If the preservation of any of these items fails for any reason, `pax` will write a diagnostic message to standard error. Failure to preserve these items will affect the final exit status, but will not cause the extracted file to be deleted.

If file-characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last will take precedence. For example, if `-peme` is specified, file modification times will be preserved.

`-sreplstr`

Modify file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, which is based on the `ed(1) s` (substitution) command, using the regular expression syntax on the `regex(5)` manual page. The concepts of “address” and “line” are meaningless in the context of the `pax` command, and must not be supplied. The format is:

```
-s / old/new/ [ gp ]
```

where, as in `ed`, *old* is a basic regular expression and *new* can contain an ampersand (&) or a `\n` backreference, where *n* is a digit. The *old* string also is permitted to contain newline characters.

Any non-null character can be used as a delimiter (/ shown here). Multiple `-s` expressions can be specified; the expressions will be applied in the order specified,

	terminating with the first successful substitution. The optional trailing <code>g</code> is as defined in the <code>ed</code> command. The optional trailing <code>p</code> causes successful substitutions to be written to standard error. File or archive member names that substitute to the empty string are ignored when reading and writing archives.						
<code>-t</code>	Cause the access times of the archived files to be the same as they were before being read by <code>pax</code> .						
<code>-u</code>	Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name.						
	<table border="0"> <tr> <td>read mode</td> <td>an archive member with the same name as a file in the file system will be extracted if the archive member is newer than the file.</td> </tr> <tr> <td>write mode</td> <td>an archive file member with the same name as a file in the file system will be superseded if the file is newer than the archive member.</td> </tr> <tr> <td>copy mode</td> <td>the file in the destination hierarchy will be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.</td> </tr> </table>	read mode	an archive member with the same name as a file in the file system will be extracted if the archive member is newer than the file.	write mode	an archive file member with the same name as a file in the file system will be superseded if the file is newer than the archive member.	copy mode	the file in the destination hierarchy will be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.
read mode	an archive member with the same name as a file in the file system will be extracted if the archive member is newer than the file.						
write mode	an archive file member with the same name as a file in the file system will be superseded if the file is newer than the archive member.						
copy mode	the file in the destination hierarchy will be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.						
<code>-v</code>	In list mode, produce a verbose table of contents (see Standard Output). Otherwise, write archive member path names to standard error (see Standard Error).						
<code>-xformat</code>	Specify the output archive format. The <code>pax</code> command recognizes the following formats: <table border="0"> <tr> <td><code>cpio</code></td> <td>The extended <code>cpio</code> interchange format; see the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 5120. Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512. This archive format allows files with UIDs and GIDs up to 262143 to be stored in the archive. Files with UIDs and GIDs greater</td> </tr> </table>	<code>cpio</code>	The extended <code>cpio</code> interchange format; see the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 5120. Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512. This archive format allows files with UIDs and GIDs up to 262143 to be stored in the archive. Files with UIDs and GIDs greater				
<code>cpio</code>	The extended <code>cpio</code> interchange format; see the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 5120. Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512. This archive format allows files with UIDs and GIDs up to 262143 to be stored in the archive. Files with UIDs and GIDs greater						

than this value will be archived with the UID and GID of 60001.

ustar

The extended *tar* interchange format; see the IEEE 1003.1(1990) specifications. The default *blocksize* for this format for character special archive files is 10240. Implementations support all *blocksize* values less than or equal to 32256 that are multiples of 512.

Any attempt to append to an archive file in a format different from the existing archive format will cause *pax* to exit immediately with a non-zero exit status.

This archive format allows files with UIDs and GIDs up to 2097151 to be stored in the archive. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.

-X When traversing the file hierarchy specified by a path name, *pax* will not descend into directories that have a different device ID (*st_dev*, see *stat(2)*).

The options that operate on the names of files or archive members (*-c*, *-i*, *-n*, *-s*, *-u* and *-v*) interact as follows. In read mode, the archive members are selected based on the user-specified *pattern* operands as modified by the *-c*, *-n* and *-u* options. Then, any *-s* and *-i* options will modify, in that order, the names of the selected files. The *-v* option will write names resulting from these modifications.

In write mode, the files are selected based on the user-specified path names as modified by the *-n* and *-u* options. Then, any *-s* and *-i* options will, in that order, modify the names of these selected files. The *-v* option will write names resulting from these modifications.

If both the *-u* and *-n* options are specified, *pax* does not consider a file selected unless it is newer than the file to which it is compared.

OPERANDS

The following operands are supported:

directory The destination directory path name for copy mode.

file A path name of a file to be copied or archived.

pattern A pattern matching one or more path names of archive members. A pattern must conform to the pattern matching notation found on the *fnmatch(5)* manual page. The

OUTPUT
Standard Output

default, if no *pattern* is specified, is to select all members in the archive.

In write mode, if *-f* is not specified, the standard output will be the archive formatted according to *cpio* or *ustar*. (See *-x* format.)

In list mode, the table of contents of the selected archive members will be written to standard output using the following format:

```
"%s\n" <pathname>
```

If the *-v* option is specified in list mode, the table of contents of the selected archive members will be written to standard output using the following formats:

For path names representing hard links to previous members of the archive:

```
"%s==%s\n" <ls -l listing>, linkname
```

For all other path names:

```
<pathname> "%s\n" <ls -l listing>
```

where *<ls -l listing>* is the format specified by the *ls* command with the *-l* option. When writing path names in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of blank-character-separated fields will be written.

In list mode, standard output will not be buffered more than a line at a time.

Standard Error

If *-v* is specified in read, write or copy modes, *pax* will write the path names it processes to the standard error output using the following format:

```
"%s\n" <pathname>
```

These path names will be written as soon as processing is begun on the file or archive member, and will be flushed to standard error. The trailing newline character, which will not be buffered, will be written when the file has been read or written.

If the *-s* option is specified, and the replacement string has a trailing *p*, substitutions will be written to standard error in the following format:

```
"%s>>%s\n" <original pathname>, <new pathname>
```

In all operating modes of `pax`, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in path names or linknames are written.

ERRORS

If `pax` cannot create a file or a link when reading an archive or cannot find a file when writing an archive, or cannot preserve the user ID, group ID or file mode when the `-p` option is specified, a diagnostic message will be written to standard error and a non-zero exit status will be returned, but processing will continue. In the case where `pax` cannot create a link to a file, `pax` will not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, `pax` may have only partially extracted the file or (if the `-n` option was not specified) may have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories may have additional bits from the read, write, execute mask set as well as incorrect modification and access times.

USAGE

The `-p` (privileges) option was invented to reconcile differences between historical `tar(1)` and `cpio(1)` implementations. In particular, the two utilities use `-m` in diametrically opposed ways. The `-p` option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it may seem complex, there are really two modes that will be most commonly used:

- `-p e` “Preserve everything”. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The `e` flag is the sum of `o` and `p`, and other implementation-dependent attributes.
- `-p p` “Preserve” the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.

See `largefile(5)` for the description of the behavior of `pax` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 Examples of the `pax` command.

The following command:

```
example pax -w -f /dev/rmt/lm .
```

copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures. The historical BSD device name would be /dev/rmt9).

The following commands:

```
example% mkdir newdir
example% pax -rw olddir newdir
```

copy the olddir directory hierarchy to newdir.

```
example pax -r -s ',^//*usr//*,,' -f a.pax
```

reads the archive a.pax, with all files rooted in /usr in the archive extracted relative to the current directory.

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of pax: LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPATH.
LC_COLLATE Determine the locale for the behaviour of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the *pattern* operand, the basic regular expression for the -s option, and the extended regular expression defined for the *yesexpr* locale keyword in the LC_MESSAGES category.

EXIT STATUS

The following exit values are returned:
0 All files were processed successfully.
>0 An error occurred.

NAME perl – Practical Extraction and Report Language

SYNOPSIS **perl** [-sTuU] [-hv] [-v[:*configvar*]] [-cw] [-d[:*debugger*]] [-D[*number/list*]] [-pna] [-F*pattern*] [-l[*octal*]] [-O[*octal*]] [-I*dir*] [-m[-]*module*] [-M[-]'*module...*'] [-P] [-S] [-x[*dir*]] [-i[*extension*]] [-e '*command*'] [-] [*programfile*] [*argument*] ...

DESCRIPTION The Perl manual pages are provided with the programming modules. To view the manual pages for the Perl modules with the man command, add /usr/perl5/man to the MANPATH environment variable. See man(1) for more information. Running catman(1M) on the Perl manual pages is not supported.

For ease of access, the Perl manual has been split up into a number of sections:

perl	Perl overview (this section)
perldelta	Perl changes since previous version
perl5004delta	Perl changes in version 5.004
perlfaq	Perl frequently asked questions
perltoc	Perl documentation table of contents
perldata	Perl data structures
perlsyn	Perl syntax
perlop	Perl operators and precedence
perlre	Perl regular expressions
perlrun	Perl execution and options
perlfunc	Perl builtin functions
perlopentut	Perl open() tutorial
perlvar	Perl predefined variables
perlsub	Perl subroutines
perlmod	Perl modules: how they work
perlmodlib	Perl modules: how to write and use
perlmodinstall	Perl modules: how to install from CPAN
perlform	Perl formats
perllocale	Perl locale support
perlref	Perl references
perlreftut	Perl references short introduction
perldsc	Perl data structures intro
perllol	Perl data structures: lists of lists
perltoot	Perl OO tutorial
perlobj	Perl objects
perltie	Perl objects hidden behind simple variables
perlbot	Perl OO tricks and examples
perlipc	Perl interprocess communication
perlthrtut	Perl threads tutorial
perldebug	Perl debugging
perldiag	Perl diagnostic messages
perlsec	Perl security
perltrap	Perl traps for the unwary
perlport	Perl portability guide
perlstyle	Perl style guide
perlpod	Perl plain old documentation

perlbook	Perl book information
perlembed	Perl ways to embed perl in your C or C++ application
perlapi	Perl internal IO abstraction interface
perlxs	Perl XS application programming interface
perlxsut	Perl XS tutorial
perlguts	Perl internal functions for those doing extensions
perlcall	Perl calling conventions from C
perlhist	Perl history records

(If you're intending to read these straight through for the first time, the suggested order will tend to reduce the number of forward references.)

By default, all of the above manpages are installed in the `/usr/local/man/` directory.

Extensive additional documentation for Perl modules is available. The default configuration for perl will place this additional documentation in the `/usr/local/lib/perl5/man` directory (or else in the man subdirectory of the Perl library directory). Some of this additional documentation is distributed standard with Perl, but you'll also find documentation for third-party modules there.

You should be able to view Perl's documentation with your `man(1)` program by including the proper directories in the appropriate start-up files, or in the `MANPATH` environment variable. To find out where the configuration has installed the manpages, type:

```
perl -V:man.dir
```

If the directories have a common stem, such as `/usr/local/man/man1` and `/usr/local/man/man3`, you need only to add that stem (`/usr/local/man`) to your `man(1)` configuration files or your `MANPATH` environment variable. If they do not share a stem, you'll have to add both stems.

If that doesn't work for some reason, you can still use the supplied `perldoc` script to view module information. You might also look into getting a replacement man program.

If something strange has gone wrong with your program and you're not sure where you should look for help, try the `-w` switch first. It will often point out exactly where the trouble is.

Perl is a language optimized for scanning arbitrary text files, extracting information from those text files, and printing reports based on that information. It's also a good language for many system management tasks. The language is

intended to be practical (easy to use, efficient, complete) rather than beautiful (tiny, elegant, minimal).

Perl combines (in the author's opinion, anyway) some of the best features of C, `sed`, `awk`, and `sh`, so people familiar with those languages should have little difficulty with it. (Language historians will also note some vestiges of `csh`, Pascal, and even BASIC-PLUS.) Expression syntax corresponds quite closely to C expression syntax. Unlike most Unix utilities, Perl does not arbitrarily limit the size of your data—if you've got the memory, Perl can slurp in your whole file as a single string. Recursion is of unlimited depth. And the tables used by hashes (sometimes called "associative arrays") grow as necessary to prevent degraded performance. Perl can use sophisticated pattern matching techniques to scan large amounts of data very quickly. Although optimized for scanning text, Perl can also deal with binary data, and can make `dbm` files look like hashes. Setuid Perl scripts are safer than C programs through a dataflow tracing mechanism which prevents many stupid security holes.

If you have a problem that would ordinarily use `sed` or `awk` or `sh`, but it exceeds their capabilities or must run a little faster, and you don't want to write the silly thing in C, then Perl may be for you. There are also translators to turn your `sed` and `awk` scripts into Perl scripts.

But wait, there's more...

Perl version 5 is nearly a complete rewrite, and provides the following additional benefits:

- Many usability enhancements
It is now possible to write much more readable Perl code (even within regular expressions). Formerly cryptic variable names can be replaced by mnemonic identifiers. Error messages are more informative, and the optional warnings will catch many of the mistakes a novice might make. This cannot be stressed enough. Whenever you get mysterious behavior, try the `-w` switch!!! Whenever you don't get mysterious behavior, try using `-w` anyway.
- Simplified grammar
The new `yacc` grammar is one half the size of the old one. Many of the arbitrary grammar rules have been regularized. The number of reserved words has been cut by 2/3. Despite this, nearly all old Perl scripts will continue to work unchanged.
- Lexical scoping
Perl variables may now be declared within a lexical scope, like "auto" variables in C. Not only is this more efficient, but it contributes to better privacy for "programming in the large". Anonymous subroutines exhibit deep binding of lexical variables (closures).
- Arbitrarily nested data structures

Any scalar value, including any array element, may now contain a reference to any other variable or subroutine. You can easily create anonymous variables and subroutines. Perl manages your reference counts for you.

- **Modularity and reusability**
The Perl library is now defined in terms of modules which can be easily shared among various packages. A package may choose to import all or a portion of a module's published interface. Pragmas (that is, compiler directives) are defined and used by the same mechanism.
- **Object-oriented programming**
A package can function as a class. Dynamic multiple inheritance and virtual methods are supported in a straightforward manner and with very little new syntax. Filehandles may now be treated as objects.
- **Embeddable and Extensible**
Perl may now be embedded easily in your C or C++ application, and can either call or be called by your routines through a documented interface. The XS preprocessor is provided to make it easy to glue your C or C++ routines into Perl. Dynamic loading of modules is supported, and Perl itself can be made into a dynamic library.
- **POSIX compliant**
A major new module is the POSIX module, which provides access to all available POSIX routines and definitions, via object classes where appropriate.
- **Package constructors and destructors**
The new BEGIN and END blocks provide means to capture control as a package is being compiled, and after the program exits. As a degenerate case they work just like AWK's BEGIN and END when you use the -p or -n switches.
- **Multiple simultaneous DBM implementations**
A Perl program may now access DBM, NDBM, SDBM, GDBM, and Berkeley DB files from the same script simultaneously. In fact, the old dbmopen interface has been generalized to allow any variable to be tied to an object class which defines its access methods.
- **Subroutine definitions may now be autoloading**
In fact, the AUTOLOAD mechanism also allows you to define any arbitrary semantics for undefined subroutine calls. It's not for just autoloading.
- **Regular expression enhancements**
You can now specify nongreedy quantifiers. You can now do grouping without creating a backreference. You can now write regular expressions with embedded whitespace and comments for readability. A consistent

extensibility mechanism has been added that is upwardly compatible with all old regular expressions.

- Innumerable Unbundled Modules

The Comprehensive Perl Archive Network described in the `perlmodlib` manpage contains hundreds of plug-and-play modules full of reusable code. See <http://www.perl.com/CPAN> for a site near you.

- Compilability

While not yet in full production mode, a working perl-to-C compiler does exist. It can generate portable byte code, simple C, or optimized C code.

Okay, that's *definitely* enough hype.

AVAILABILITY

Perl is available for the vast majority of operating system platforms, including most Unix-like platforms. The following situation is as of February 1999 and Perl 5.005_03.

The following platforms are able to build Perl from the standard source code distribution available at <http://www.perl.com/CPAN/src/index.html>:

AIX	Linux	SCO ODT/OSR
A/UX	MachTen	Solaris
BeOS	MPE/iX	SunOS
BSD/OS	NetBSD	SVR4
DG/UX	NextSTEP	Tru64 UNIX ¹
DomainOS	OpenBSD	Ultrix
DOS DJGPP ²	OpenSTEP	UNICOS
DYNIX/ptx	OS/2	VMS
FreeBSD	OS390 ³	VOS
HP-UX	PowerMAX	Windows 3.1 ²
Hurd	QNX	Windows 95 ^{2 4}
IRIX		Windows 98 ^{2 4}
		Windows NT ^{2 4}

1. formerly known as Digital UNIX and before that DEC OSF/1

2. in DOS mode either the DOS or OS/2 ports can be used

3. formerly known as MVS

4. compilers; Borland, Cygwin32, Mingw32 EGCS/GCC, VC++

The following platforms have been known to build Perl from the source but for the Perl release 5.005_03 we haven't been able to verify them, either because the hardware/software platforms are rather rare or because we don't have an active champion on these platforms, or both.

3bl	FPS	Plan 9
AmigaOS	GENIX	PowerUX
ConvexOS	Greenhills	RISC/os
CX/UX	ISC	Stellar
DC/OSx	MachTen 68k	SVR2
DDE SMES	MiNT	TII500
DOS EMX	MPC	TitanOS
DYNIX	NEWS-OS	UNICOS/mk
EP/IX	Opus	Unisys Dynix
Esix		Unixware

The following platforms are planned to be supported in the standard source code distribution of the Perl release 5.006 but are not supported in the Perl release 5.005_03:

BS2000
Netware
Rhapsody
VM/ESA

The following platforms have their own source code distributions and binaries available via <http://www.perl.com/CPAN/ports/index.html>:

	Perl release
AS/400	5.003
MacOS	5.004
Netware	5.003_07
Tandem Guardian	5.004

The following platforms have only binaries available via <http://www.perl.com/CPAN/ports/index.html>:

Perl release

Acorn RISCOS	5.005_02
AOS	5.002
LynxOS	5.004_02

ENVIRONMENT

See the `perlrun` manpage.

AUTHOR

Larry Wall <larry@wall.org>, with the help of oodles of other folks.

DIAGNOSTICS

The `-w` switch produces some lovely diagnostics.

See the `perldiag` manpage for explanations of all Perl's diagnostics. The use `diagnostics` pragma automatically turns Perl's normally terse warnings and errors into these longer forms.

Compilation errors will tell you the line number of the error, with an indication of the next token or token type that was to be examined. (In the case of a script passed to Perl via `-e` switches, each `-e` is counted as one line.)

Setuid scripts have additional constraints that can produce error messages such as "Insecure dependency". See the `perlsec` manpage.

Did we mention that you should definitely consider using the `-w` switch?

NOTES

The Perl motto is "There's more than one way to do it." Divining how many more is left as an exercise to the reader.

BUGS

The three principal virtues of a programmer are Laziness, Impatience, and Hubris. See the Camel Book for why.

The `-w` switch is not mandatory.

Perl is at the mercy of your machine's definitions of various operations such as type casting, `atof()`, and floating-point output with `sprintf()`.

If your `stdio` requires a seek or eof between reads and writes on a particular stream, so does Perl. (This doesn't apply to `sysread()` and `syswrite()`.)

While none of the built-in data types have any arbitrary size limits (apart from memory size), there are still a few arbitrary limits: a given variable name may not be longer than 251 characters. Line numbers displayed by diagnostics are internally stored as short integers, so they are limited to a maximum of 65535 (higher numbers usually being affected by wraparound).

You may mail your bug reports (be sure to include full configuration information as output by the `myconfig` program in the perl source tree, or by `perl -v`) to `<perlbug@perl.com>`. If you've succeeded in compiling perl, the `perlbug` script in the `utils/` subdirectory can be used to help mail in a bug report.

Perl actually stands for Pathologically Eclectic Rubbish Lister, but don't tell anyone I said that.

NAME pfexec, pfs, pfcsh, pfksh – execute a command in a profile

SYNOPSIS

```
/usr/bin/pfexec command
/usr/bin/pfs [ options ] [ argument ... ]
/usr/bin/pfcsh [ options ] [ argument ... ]
/usr/bin/pfksh [ options ] [ argument ... ]
```

DESCRIPTION

The `pfexec` program is used to execute commands with the attributes specified by the user's profiles in the `exec_attr(4)` database. It is invoked by the profile shells, `pfs`, `pfcsh`, and `pfksh` which are linked to the Bourne shell, C shell, and Korn shell, respectively.

Profiles are searched in the order specified in the user's entry in the `user_attr(4)` database. If the same command appears in more than one profile, the profile shell uses the first matching entry.

USAGE

`pfexec` is used to execute commands with predefined process attributes, such as specific user or group IDs.

Refer to the `sh(1)`, `csh(1)`, and `ksh(1)` man pages for complete usage descriptions of the profile shells.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

1 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME	pg – files perusal filter for CRTs
SYNOPSIS	pg [<i>-number</i>] [<i>-p string</i>] [<i>-cefnr</i> s] [<i>+ linenumber</i>] [<i>+ / pattern /</i>] [<i>filename...</i>]
DESCRIPTION	<p>The <code>pg</code> command is a filter that allows the examination of <i>filenames</i> one screenful at a time on a CRT. If the user types a RETURN, another page is displayed; other possibilities are listed below.</p> <p>This command is different from previous paginators in that it allows you to back up and review something that has already passed. The method for doing this is explained below.</p> <p>To determine terminal attributes, <code>pg</code> scans the <code>terminfo(4)</code> data base for the terminal type specified by the environment variable <code>TERM</code>. If <code>TERM</code> is not defined, the terminal type <code>dumb</code> is assumed.</p>
OPTIONS	<p><i>-number</i> An integer specifying the size (in lines) of the window that <code>pg</code> is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23).</p> <p><i>-p string</i> <code>pg</code> uses <i>string</i> as the prompt. If the prompt string contains a <code>%d</code>, the first occurrence of <code>%d</code> in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is “:”.</p> <p><i>-c</i> Home the cursor and clear the screen before displaying each page. This option is ignored if <code>clear_screen</code> is not defined for this terminal type in the <code>terminfo(4)</code> data base.</p> <p><i>-e</i> <code>pg</code> does <i>not</i> pause at the end of each file.</p> <p><i>-f</i> Normally, <code>pg</code> splits lines longer than the screen width, but some sequences of characters in the text being displayed (for instance, escape sequences for underlining) generate undesirable results. The <i>-f</i> option inhibits <code>pg</code> from splitting lines.</p> <p><i>-n</i> Normally, commands must be terminated by a <code><newline></code> character. This option causes an automatic end of command as soon as a command letter is entered.</p> <p><i>-r</i> Restricted mode. The shell escape is disallowed. <code>pg</code> prints an error message but does not exit.</p> <p><i>-s</i> <code>pg</code> prints all messages and prompts in the standard output mode (usually inverse video).</p> <p><i>+linenumber</i> Start up at <i>linenumber</i>.</p>

`+ /pattern/` Start up at the first line containing the regular expression pattern.

OPERANDS

The following operands are supported:

filename A path name of a text file to be displayed. If no *filename* is given, or if it is `-`, the standard input is read.

USAGE**Commands**

The responses that may be typed when `pg` pauses can be divided into three categories: those causing further perusal, those that search, and those that modify the perusal environment.

Commands that cause further perusal normally take a preceding *address*, an optionally signed number indicating the point from which further text should be displayed. This *address* is interpreted in either pages or lines depending on the command. A signed *address* specifies a point relative to the current page or line, and an unsigned *address* specifies an address relative to the beginning of the file. Each command has a default address that is used if none is provided.

The perusal commands and their defaults are as follows:

`(+1)<newline>` or `<blank>` This causes one page to be displayed. The address is specified in pages.

`(+1) l` With a relative address this causes `pg` to simulate scrolling the screen, forward or backward, the number of lines specified. With an absolute address this command prints a screenful beginning at the specified line.

`(+1) d` or `^D` Simulates scrolling half a screen forward or backward.

`iF` Skip *i* screens of text.

`iz` Same as `<newline>` except that *i*, if present, becomes the new default number of lines per screenful.

The following perusal commands take no *address*.

`.` or `^L` Typing a single period causes the current page of text to be redisplayed.

`$` Displays the last windowful in the file. Use with caution when the input is a pipe.

The following commands are available for searching for text patterns in the text. The regular expressions are described on the `regex(5)` manual page. They must always be terminated by a `<newline>`, even if the `-n` option is specified.

<i>i/pattern/</i>	Search forward for the <i>i</i> th (default <i>i</i> =1) occurrence of <i>pattern</i> . Searching begins immediately after the current page and continues to the end of the current file, without wrap-around.
<i>i^pattern^</i> <i>i?pattern?</i>	Search backwards for the <i>i</i> th (default <i>i</i> =1) occurrence of <i>pattern</i> . Searching begins immediately before the current page and continues to the beginning of the current file, without wrap-around. The ^ notation is useful for Adds 100 terminals which will not properly handle the ?.

After searching, `pg` will normally display the line found at the top of the screen. This can be modified by appending `m` or `b` to the search command to leave the line found in the middle or at the bottom of the window from now on. The suffix `t` can be used to restore the original situation.

The user of `pg` can modify the environment of perusal with the following commands:

<i>in</i>	Begin perusing the <i>i</i> th next file in the command line. The <i>i</i> is an unsigned number, default value is 1.
<i>ip</i>	Begin perusing the <i>i</i> th previous file in the command line. <i>i</i> is an unsigned number, default is 1.
<i>iw</i>	Display another window of text. If <i>i</i> is present, set the window size to <i>i</i> .
<i>s filename</i>	Save the input in the named file. Only the current file being perused is saved. The white space between the <i>s</i> and <i>filename</i> is optional. This command must always be terminated by a <i><newline></i> , even if the <code>-n</code> option is specified.
<i>h</i>	Help by displaying an abbreviated summary of available commands.
<i>q</i> or <i>Q</i>	Quit <code>pg</code> .
<i>!command</i>	<i>Command</i> is passed to the shell, whose name is taken from the <code>SHELL</code> environment variable. If this is not available, the default shell is used. This command must always be terminated by a <i><newline></i> , even if the <code>-n</code> option is specified.

At any time when output is being sent to the terminal, the user can hit the quit key (normally CTRL-\) or the interrupt (break) key. This causes `pg` to stop sending output, and display the prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost

when this is done, because any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

If the standard output is not a terminal, then `pg` acts just like `cat(1)`, except that a header is printed before each file (if there is more than one).

Large File Behavior

See `largefile(5)` for the description of the behavior of `pg` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 An example of the `pg` command.

The following command line uses `pg` to read the system news:

```
example% news | pg -p "(Page %d):"
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pg`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The following environment variables affect the execution of `pg`:

<code>COLUMNS</code>	Determine the horizontal screen size. If unset or <code>NULL</code> , use the value of <code>TERM</code> , the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
<code>LINES</code>	Determine the number of lines to be displayed on the screen. If unset or <code>NULL</code> , use the value of <code>TERM</code> , the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
<code>SHELL</code>	Determine the name of the command interpreter executed for a <code>!command</code> .
<code>TERM</code>	Determine terminal attributes. Optionally attempt to search a system-dependent database, keyed on the value of the <code>TERM</code> environment variable. If no information is available, a terminal incapable of cursor-addressable movement is assumed.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

FILES

<code>/tmp/pg*</code>	temporary file when input is from a pipe
<code>/usr/share/lib/terminfo/?/*</code>	terminal information database

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

cat(1), grep(1), more(1), terminfo(4), attributes(5), environ(5), largefile(5), regex(5)

NOTES

While waiting for terminal input, `pg` responds to BREAK, CTRL-C, and CTRL-\ by terminating execution. Between prompts, however, these signals interrupt `pg`'s current task and place the user in prompt mode. These should be used with caution when input is being read from a pipe, since an interrupt is likely to terminate the other commands in the pipeline.

The terminal `/`, `^`, or `?` may be omitted from the searching commands.

If terminal tabs are not set every eight positions, undesirable results may occur.

When using `pg` as a filter with another command that changes the terminal I/O options, terminal settings may not be restored correctly.

NAME	pgrep, pkill - find or signal processes by name and other attributes
SYNOPSIS	<p>pgrep [-f lnvx] [-d <i>delim</i>] [-P <i>ppidlist</i>] [-g <i>pgrplist</i>] [-s <i>sidlist</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [-G <i>gidlist</i>] [-t <i>termlist</i>] [<i>pattern</i>]</p> <p>pkill [-signal] [-fnvx] [-P <i>ppidlist</i>] [-g <i>pgrplist</i>] [-s <i>sidlist</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [-G <i>gidlist</i>] [-t <i>termlist</i>] [<i>pattern</i>]</p>
DESCRIPTION	<p>The <code>pgrep</code> utility examines the active processes on the system and reports the process IDs of the processes whose attributes match the criteria specified on the command line. Each process ID is printed as a decimal value and is separated from the next ID by a delimiter string, which defaults to a newline. For each attribute option, the user can specify a set of possible values separated by commas on the command line. For example,</p> <pre>pgrep -G other,daemon</pre> <p>matches processes whose real group ID is <code>other</code> OR <code>daemon</code>. If multiple criteria options are specified, <code>pgrep</code> matches processes whose attributes match the logical AND of the criteria options. For example,</p> <pre>pgrep -G other,daemon -U root,daemon</pre> <p>matches processes whose attributes are:</p> <pre>(real group ID is other OR daemon) AND (real user ID is root OR daemon)</pre> <p><code>pkill</code> functions identically to <code>pgrep</code>, except that each matching process is signaled as if by <code>kill(1)</code> instead of having its process ID printed. A signal name or number may be specified as the first command line option to <code>pkill</code>.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-d</code> <i>delim</i> Specifies the output delimiter string to be printed between each matching process ID. If no <code>-d</code> option is specified, the default is a newline character. The <code>-d</code> option is only valid when specified as an option to <code>pgrep</code>.</p> <p><code>-f</code> The regular expression <i>pattern</i> should be matched against the full process argument string (obtained from the <code>pr_psargs</code> field of the <code>/proc/nnnn/psinfo</code> file). If no <code>-f</code> option is specified, the expression is matched only against the name of the executable file (obtained from the <code>pr_fname</code> field of the <code>/proc/nnnn/psinfo</code> file).</p>

-g <i>pgrplist</i>	Matches only processes whose process group ID is in the given list. If group 0 is included in the list, this is interpreted as the process group ID of the <code>pgrep</code> or <code>pkill</code> process.
-G <i>gidlist</i>	Matches only processes whose real group ID is in the given list. Each group ID may be specified as either a group name or a numerical group ID .
-l	Long output format. Prints the process name along with the process ID of each matching process. The process name is obtained from the <code>pr_psargs</code> or <code>pr_fname</code> field, depending on whether the <code>-f</code> option was specified (see above). The <code>-l</code> option is only valid when specified as an option to <code>pgrep</code> .
-n	Matches only the newest (most recently created) process which meets all other specified matching criteria.
-P <i>ppidlist</i>	Matches only processes whose parent process ID is in the given list.
-s <i>sidlist</i>	Matches only processes whose process session ID is in the given list. If ID 0 is included in the list, this is interpreted as the session ID of the <code>pgrep</code> or <code>pkill</code> process.
-t <i>termlist</i>	Matches only processes which are associated with a terminal in the given list. Each terminal is specified as the suffix following <code>"/dev/"</code> of the terminal's device path name in <code>/dev</code> . For example, <code>term/a</code> or <code>pts/0</code> .
-u <i>uidlist</i>	Matches only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID .
-U <i>uidlist</i>	Matches only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID .
-v	Reverses the sense of the matching. Matches all processes <i>except</i> those which meet the specified matching criteria.
-x	Considers only processes whose argument string or executable file name <i>exactly</i> matches the specified <i>pattern</i> to be matching processes. The pattern match is considered to be exact when all characters in the process argument string or executable file name match the pattern.
-signal	Specifies the signal to send to each matched process. If no signal is specified, <code>SIGTERM</code> is sent by default.

The value of *signal* can be one of the symbolic names defined in `signal(3HEAD)` without the `SIG` prefix, or the corresponding signal number as a decimal value. The `-signal` option is only valid when specified as the first option to `pgrep`.

OPERANDS

The following operand is supported:

pattern Specifies an Extended Regular Expression (ERE) pattern to match against either the executable file name or full process argument string. See `regex(5)` for a complete description of the ERE syntax.

EXAMPLES

EXAMPLE 1 Obtaining a process ID

Obtain the process ID of `sendmail`:

```
example% pgrep -x -u root sendmail
283
```

EXAMPLE 2 Terminating a process

Terminate the most recently created `xterm`:

```
example% pkill -n xterm
```

EXIT STATUS

The following exit values are returned:

- 0 One or more processes were matched.
- 1 No processes were matched.
- 2 Invalid command line options were specified.
- 3 A fatal error occurred.

FILES

`/proc/nnnnn/psinfo` process information files

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`kill(1)`, `proc(1)`, `ps(1)`, `truss(1)`, `kill(2)`, `signal(3HEAD)`, `proc(4)`, `attributes(5)`, `regex(5)`

NOTES

Both utilities match the ERE *pattern* argument against either the `pr_fname` or `pr_psargs` fields of the `/proc/nnnnn/psinfo` files. The lengths of these strings are limited according to definitions in `<sys/procfs.h>`. Patterns which can match strings longer than the current limits may fail to match the intended set of processes.

If the *pattern* argument contains ERE meta-characters which are also shell meta-characters, it may be necessary to enclose the pattern with appropriate shell quotes.

Defunct processes are never matched by either `pgrep` or `pkill`.

The current `pgrep` or `pkill` process will never consider itself a potential match.

NAME	pkginfo - display software package information
SYNOPSIS	<p>pkginfo [-q -x -l][-p -i][-r] [-a <i>arch</i>] [-v <i>version</i>] [-c <i>category...</i>] [<i>pkginst...</i>]</p> <p>pkginfo [-d <i>device</i>] [-R <i>root_path</i>] [-q -x -l][-a <i>arch</i>] [-v <i>version</i>] [-c <i>category...</i>] [<i>pkginst...</i>]</p>
DESCRIPTION	<p>pkginfo displays information about software packages that are installed on the system (with the first synopsis) or that reside on a particular device or directory (with the second synopsis).</p> <p>Without options, pkginfo lists the primary category, package instance, and the names of all completely installed and partially installed packages. It displays one line for each package selected.</p>
OPTIONS	<p>The -p and -i options are meaningless if used in conjunction with the -d option.</p> <p>The options -q, -x, and -l are mutually exclusive.</p> <p>-a <i>arch</i> Specify the architecture of the package as <i>arch</i>.</p> <p>-c <i>category</i> Display packages that match <i>category</i>. Categories are defined with the CATEGORY parameter in the pkginfo(4) file. If more than one category is supplied, the package needs to match only one category in the list. The match is not case specific.</p> <p>-d <i>device</i> Defines a device, <i>device</i>, on which the software resides. <i>device</i> can be an absolute directory pathname or the identifiers for tape, floppy disk, removable disk, and so forth. The special token <i>spool</i> may be used to indicate the default installation spool directory (<i>/var/spool/pkg</i>).</p> <p>-i Display information for fully installed packages only.</p> <p>-l Specify long format, which includes all available information about the designated package(s).</p> <p>-p Display information for partially installed packages only.</p> <p>-q Do not list any information. Used from a program to check whether or not a package has been installed.</p> <p>-r List the installation base for relocatable packages.</p> <p>-R <i>root_path</i> Defines the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p>

-v *version* Specify the version of the package as *version*. The version is defined with the `VERSION` parameter in the `pkginfo(4)` file. All compatible versions can be requested by preceding the version name with a tilde (`~`). Multiple white spaces are replaced with a single white space during version comparison.

-x Designate an extracted listing of package information. The listing contains the package abbreviation, package name, package architecture (if available) and package version (if available).

OPERANDS

pkginst A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, `inst.1` or `inst.2`). All instances of a package can be requested by `inst.*`. The asterisk character (`*`) is a special character to some shells and may need to be escaped. In the C-Shell, `"*"` must be surrounded by single quotes (`'`) or preceded by a backslash (`\`).

EXIT STATUS

0 Successful completion.
 >0 An error occurred.

FILES

`/var/spool/pkg` default installation spool directory

Application Packaging Developer's Guide

NAME	pkgmk – produce an installable package
SYNOPSIS	pkgmk [-o] [-a <i>arch</i>] [-b <i>base_src_dir</i>] [-d <i>device</i>] [-f <i>prototype</i>] [-l <i>limit</i>] [-p <i>pstamp</i>] [-r <i>root_path</i>] [-v <i>version</i>] [<i>variable=value...</i>] [<i>pkginst</i>]
DESCRIPTION	<p>pkgmk produces an installable package to be used as input to the pkgadd(1M) command. The package contents will be in directory structure format.</p> <p>The command uses the package <i>prototype</i>(4) file as input and creates a <i>pkgmap</i>(4) file. The contents for each entry in the <i>prototype</i> file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the <i>pkgmap</i> file, along with attribute information specified in the <i>prototype</i> file.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -o Overwrite the same instance; package instance will be overwritten if it already exists. -a <i>arch</i> Override the architecture information provided in the <i>pkginfo</i>(4) file with <i>arch</i>. -b <i>base_src_dir</i> Prepend the indicated <i>base_src_dir</i> to locate relocatable objects on the source machine. -d <i>device</i> Create the package on <i>device</i>. <i>device</i> can be an absolute directory pathname or the identifiers for a floppy disk or removable disk (for example, <i>/dev/diskette</i>). The default device is the installation spool directory (<i>/var/spool/pkg</i>). -f <i>prototype</i> Use the file <i>prototype</i> as input to the command. The default <i>prototype</i> filename is <i>[Pp]prototype</i>. -l <i>limit</i> Specify the maximum size in 512 byte blocks of the output device as <i>limit</i>. By default, if the output file is a directory or a mountable device, <i>pkgmk</i> will employ the <i>df</i>(1M) command to dynamically calculate the amount of available space on the output device. This option is useful in conjunction with <i>pkgtrans</i>(1) to create a package with a datastream format. -p <i>pstamp</i> Override the production stamp definition in the <i>pkginfo</i>(4) file with <i>pstamp</i>. -r <i>root_path</i> Ignore destination paths in the <i>prototype</i>(4) file. Instead, use the indicated <i>root_path</i> with the source pathname appended to locate objects on

the source machine, using a comma (,) as the separator for the path elements.

-v version Override the version information provided in the `pkginfo(4)` file with *version*.

variable=value Place the indicated variable in the packaging environment. (See `prototype(4)` for definitions of variable specifications.)

OPERANDS

The following operand is supported:

pkginst A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, `inst.1` or `inst.2`). All instances of a package can be requested by `inst.*`. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`pkgparam(1)`, `pkgproto(1)`, `pkgtrans(1)`, `uname(1)`, `df(1M)`, `pkgadd(1M)`, `pkginfo(4)`, `pkgmap(4)`, `prototype(4)`, `attributes(5)`

Application Packaging Developer's Guide

NOTES

Architecture information is provided on the command line with the `-a` option or in the `prototype(4)` file. If no architecture information is supplied, `pkgmk` uses the output of `uname -m` (see `uname(1)`).

Version information is provided on the command line with the `-v` option or in the `pkginfo(4)` file. If no version information is supplied, a default based on the current date will be provided.

Command line definitions for both architecture and version override the `prototype(4)` definitions.

NAME	pkgparam – display package parameter values
SYNOPSIS	pkgparam [-v] [-d <i>device</i>] [-R <i>root_path</i>] <i>pkginst</i> [<i>param...</i>] pkgparam -f <i>filename</i> [-v] [<i>param...</i>]
DESCRIPTION	<p>pkgparam displays the value associated with the parameter or parameters requested on the command line. The values are located in either the pkginfo(4) file for <i>pkginst</i> or from the specific file named with the -f option.</p> <p>One parameter value is shown per line. Only the value of a parameter is given unless the -v option is used. With this option, the output of the command is in this format:</p> <pre>parameter1= 'value1' parameter2= 'value2' parameter3= 'value3'</pre> <p>If no parameters are specified on the command line, values for all parameters associated with the package are shown.</p>
OPTIONS	<p>Options and arguments for this command are:</p> <p>-d <i>device</i> Specify the <i>device</i> on which a <i>pkginst</i> is stored. It can be a directory pathname or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The special token <i>spool</i> may be used to represent the default installation spool directory (/var/spool/pkg).</p> <p>-f <i>filename</i> Read <i>filename</i> for parameter values.</p> <p>-R <i>root_path</i> Defines the full path name of a subdirectory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p> <p>-v Verbose mode. Display name of parameter and its value.</p>
OPERANDS	<p><i>pkginst</i> Defines a specific package instance for which parameter values should be displayed.</p> <p><i>param</i> Defines a specific parameter whose value should be displayed.</p>
ERRORS	If parameter information is not available for the indicated package, the command exits with a non-zero status.
EXIT STATUS	0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`pkgmk(1)`, `pkgproto(1)`, `pkgtrans(1)`, `pkginfo(4)`, `attributes(5)`

Application Packaging Developer's Guide

NOTES

With the `-f` option, you can specify the file from which parameter values should be extracted. This file should be in the same format as a `pkginfo(4)` file. For example, such a file might be created during package development and used while testing software during this stage.

NAME	pkgproto - generate prototype file entries for input to pkgmk command
SYNOPSIS	pkgproto [-i] [-c <i>class</i>] [<i>path1</i>] pkgproto [-i] [-c <i>class</i>] [<i>path1=path2...</i>]
DESCRIPTION	<p>pkgproto scans the indicated paths and generates prototype(4) file entries that may be used as input to the pkgmk(1) command.</p> <p>If no paths are specified on the command line, standard input is assumed to be a list of paths. If the pathname listed on the command line is a directory, the contents of the directory is searched. However, if input is read from stdin, a directory specified as a pathname will not be searched.</p>
OPTIONS	<p>-i Ignores symbolic links and records the paths as <i>f</i>type=<i>f</i> (a file) versus <i>f</i>type=<i>s</i> (symbolic link).</p> <p>-c <i>class</i> Maps the class of all paths to <i>class</i>.</p>
OPERANDS	<p><i>path1</i> Pathname where objects are located.</p> <p><i>path2</i> Pathname which should be substituted on output for <i>path1</i>.</p>
EXAMPLES	<p>EXAMPLE 1 Examples of the use of pkgproto.1.</p> <p>The following two examples show uses of pkgproto and a partial listing of the output produced.</p> <p>Example 1:</p> <pre>example% pkgproto /bin=bin /usr/bin=usrbin /etc=etc f none bin/sed=/bin/sed 0775 bin bin f none bin/sh=/bin/sh 0755 bin daemon f none bin/sort=/bin/sort 0755 bin bin f none usrbin/sdb=/usr/bin/sdb 0775 bin bin f none usrbin/shl=/usr/bin/shl 4755 bin bin d none etc/master.d 0755 root daemon f none etc/master.d/kernel=/etc/master.d/kernel 0644 root daemon f none etc/rc=/etc/rc 0744 root daemon</pre> <p>Example 2:</p> <pre>example% find / -type d -print pkgproto d none / 755 root root d none /bin 755 bin bin d none /usr 755 root root d none /usr/bin 775 bin bin d none /etc 755 root root d none /tmp 777 root root</pre>
EXIT STATUS	<p>0 Successful completion.</p> <p>>0 An error occurred.</p>

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`pkgmk(1)`, `pkgparam(1)`, `pkgtrans(1)`, `prototype(4)`, `attributes(5)`

Application Packaging Developer's Guide

NOTES

By default, `pkgproto` creates symbolic link entries for any symbolic link encountered (`ftype=s`). When you use the `-i` option, `pkgproto` creates a file entry for symbolic links (`ftype=f`). The `prototype(4)` file would have to be edited to assign such file types as `v` (volatile), `e` (editable), or `x` (exclusive directory). `pkgproto` detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

By default, `pkgproto` prints prototype entries on the standard output. However, the output should be saved in a file (named `Prototype` or `prototype`, for convenience) to be used as input to the `pkgmk(1)` command.

NAME	pkgtrans – translate package format
SYNOPSIS	pkgtrans [-inos] <i>device1 device2</i> [<i>pkginst...</i>]
DESCRIPTION	<p>pkgtrans translates an installable package from one format to another. It translates:</p> <ul style="list-style-type: none"> ■ a file system format to a datastream ■ a datastream to a file system format ■ one file system format to another file system format
OPTIONS	<p>The options and arguments for this command are:</p> <ul style="list-style-type: none"> -i Copy only the <i>pkginfo</i>(4) and <i>pkgmap</i>(4) files. -n Create a new instance of the package on the destination device if any instance of this package already exists, up to the number specified by the <i>MAXINST</i> variable in the <i>pkginfo</i>(4) file. -o Overwrite the same instance on the destination device; package instance will be overwritten if it already exists. -s Indicates that the package should be written to <i>device2</i> as a datastream rather than as a file system. The default behavior is to write a file system format on devices that support both formats.
OPERANDS	<p><i>device1</i> Indicates the source device. The package or packages on this device will be translated and placed on <i>device2</i>.</p> <p><i>device2</i> Indicates the destination device. Translated packages will be placed on this device.</p> <p><i>pkginst</i> Specifies which package instance or instances on <i>device1</i> should be translated. The token <i>all</i> may be used to indicate all packages. <i>pkginst.*</i> can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate.</p> <p>The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).</p>
EXAMPLES	<p>EXAMPLE 1 Examples of the <i>pkgtrans</i> command.</p> <p>The following example translates all packages on the floppy drive <i>/dev/diskette</i> and places the translations on <i>/tmp</i>:</p> <pre>example% pkgtrans /dev/diskette /tmp all</pre>

The next example translates packages pkg1 and pkg2 on /tmp and places their translations (that is, a datastream) on the 9track1 output device:

```
example% pkgtrans /tmp 9track1 pkg1 pkg2
```

The next example translates pkg1 and pkg2 on /tmp and places them on the diskette in a datastream format:

```
example% pkgtrans -s /tmp /dev/diskette pkg1 pkg2
```

ENVIRONMENT VARIABLES

The MAXINST variable is set in the pkginfo(4) file and declares the maximum number of package instances.

EXIT STATUS

- 0 Successful completion.
- >0 An error occurred.

Application Packaging Developer's Guide

NOTES

Device specifications can be either the special node name (for example, /dev/diskette) or a device alias (for example, diskette1). The device spool indicates the default spool directory. Source and destination devices cannot be the same.

By default, pkgtrans will not translate any instance of a package if any instance of that package already exists on the destination device. Using the -n option creates a new instance if an instance of this package already exists. Using the -o option overwrites an instance of this package if it already exists. Neither of these options are useful if the destination device is a datastream.

NAME	plimit – get or set the resource limits of running processes
SYNOPSIS	plimit [-km] <i>pid</i> ... plimit {-cdfnstv} <i>soft,hard</i> ... <i>pid</i> ...
DESCRIPTION	<p>If one or more of the <i>cdfnstv</i> options is specified, <i>plimit</i> sets the soft (current) limit and/or the hard (maximum) limit of the indicated resource(s) in the processes identified by the process-ID list, <i>pid</i>. Otherwise <i>plimit</i> reports the resource limits of the processes identified by the process-ID list, <i>pid</i>.</p> <p>Only the owner of a process or the super-user is permitted either to get or to set the resource limits of a process. Only the super-user can increase the hard limit.</p>
OPTIONS	<p>The following options are supported:</p> <p>-k On output, show file sizes in kilobytes (1024 bytes) rather than in 512-byte blocks.</p> <p>-m On output, show file and memory sizes in megabytes (1024*1024 bytes).</p> <p>The remainder of the options are used to change specified resource limits. They each accept an argument of the form:</p> <p><i>soft,hard</i></p> <p>where <i>soft</i> specifies the soft (current) limit and <i>hard</i> specifies the hard (maximum) limit. If the hard limit is not specified, the comma may be omitted. If the soft limit is an empty string, only the hard limit is set. Each limit is either the literal string <i>unlimited</i>, or a number, with an optional scaling factor, as follows:</p> <p><i>nk</i> <i>n</i> kilobytes</p> <p><i>nm</i> <i>n</i> megabytes (minutes for CPU time)</p> <p><i>nh</i> <i>n</i> hours (for CPU time only)</p> <p><i>mm:ss</i> minutes and seconds (for CPU time only)</p> <p>The soft limit cannot exceed the hard limit.</p> <p>-c <i>soft,hard</i> Set core file size limits (default unit is 512-byte blocks).</p> <p>-d <i>soft,hard</i> Set data segment (heap) size limits (default unit is kilobytes).</p> <p>-f <i>soft,hard</i> Set file size limits (default unit is 512-byte blocks).</p> <p>-n <i>soft,hard</i> Set file descriptor limits (no default unit).</p> <p>-s <i>soft,hard</i> Set stack segment size limits (default unit is kilobytes).</p>

-t *soft,hard* Set CPU time limits (default unit is seconds).
 -v *soft,hard* Set virtual memory size limits (default unit is kilobytes).

OPERANDS

The following operands are supported.
 pid Process ID list.

EXIT STATUS

plimit returns the exit value zero on success, non-zero on failure (such as no such process, permission denied, or invalid option).

NAME	postdaisy – PostScript translator for Diablo 630 daisy-wheel files
SYNOPSIS	postdaisy [-c <i>num</i>] [-f <i>num</i>] [-h <i>num</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-r <i>num</i>] [-s <i>num</i>] [-v <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postdaisy
DESCRIPTION	The <code>postdaisy</code> filter translates Diablo 630 daisy-wheel <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p><code>-c <i>num</i></code> Print <i>num</i> copies of each page. By default only one copy is printed.</p> <p><code>-f <i>name</i></code> Print <i>files</i> using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant-width fonts. The default font is Courier.</p> <p><code>-h <i>num</i></code> Set the initial horizontal motion index to <i>num</i>. Determines the character advance and the default point size, unless the <code>-s</code> option is used. The default is 12.</p> <p><code>-m <i>num</i></code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.</p> <p><code>-n <i>num</i></code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o <i>list</i></code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p <i>mode</i></code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p><code>-r <i>num</i></code> Selects carriage return and line feed behavior. If <i>num</i> is 1, a line feed generates a carriage return. If <i>num</i> is 2, a carriage return generates a line feed. Setting <i>num</i> to 3 enables both modes.</p> <p><code>-s <i>num</i></code> Use point size <i>num</i> instead of the default value set by the initial horizontal motion index.</p>

- v *num* Set the initial vertical motion index to *num*. The default is 8.
- x *num* Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive *num* moves everything right. The default offset is 0.25 inches.
- y *num* Translate the origin *num* inches along the positive y axis. Positive *num* moves text up the page. The default offset is -0.25 inches.

EXIT STATUS

The following exit values are returned:
 0 Successful completion.
 non-zero An error occurred.

NAME	postdmd – PostScript translator for DMD bitmap files
SYNOPSIS	postdmd [-b <i>num</i>] [-c <i>num</i>] [-f] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postdmd
DESCRIPTION	<code>postdmd</code> translates DMD bitmap <i>files</i> , as produced by <code>dmdps</code> , or <i>files</i> written in the Ninth Edition <code>bitfile(9.5)</code> format into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p><code>-b num</code> Pack the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6.</p> <p><code>-c num</code> Print <i>num</i> copies of each page. By default only one copy is printed.</p> <p><code>-f</code> Flip the sense of the bits in <i>files</i> before printing the bitmaps.</p> <p><code>-m num</code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which by default is located at the center of each page. The default magnification is 1.0.</p> <p><code>-n num</code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default <i>num</i> is set to 1.</p> <p><code>-o list</code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p mode</code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p><code>-x num</code> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0 inches.</p> <p><code>-y num</code> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.</p>

Only one bitmap is printed on each logical page, and each of the input *files* must contain complete descriptions of at least one bitmap. Decreasing the pattern size using the `-b` option may help throughput on printers with fast processors (such as PS-810s), while increasing the pattern size will often be the right move on older models (such as PS-800s).

EXIT STATUS

The following exit values are returned:
0 Successful completion.
non-zero An error occurred.

NAME	postio – serial interface for PostScript printers
SYNOPSIS	postio <i>-l line</i> [-D] [-i] [-q] [-t] [-S] [-b <i>speed</i>] [-B <i>num</i>] [-L <i>file</i>] [-P <i>string</i>] [-R <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postio
DESCRIPTION	<code>postio</code> sends <i>files</i> to the PostScript printer attached to <i>line</i> . If no <i>files</i> are specified the standard input is sent.
OPTIONS	<p>The first group of <i>options</i> should be sufficient for most applications:</p> <ul style="list-style-type: none"> -D Enable debug mode. Guarantees that everything read on <i>line</i> will be added to the log file (standard error by default). -q Prevents status queries while <i>files</i> are being sent to the printer. When status queries are disabled a dummy message is appended to the log file before each block is transmitted. -b <i>speed</i> Transmit data over <i>line</i> at baud rate <i>speed</i>. Recognized baud rates are 1200, 2400, 4800, 9600, and 19200. The default <i>speed</i> is 9600 baud. -B <i>num</i> Set the internal buffer size for reading and writing <i>files</i> to <i>num</i> bytes. By default <i>num</i> is 2048 bytes. -l <i>line</i> Connect to the printer attached to <i>line</i>. In most cases there is no default and <code>postio</code> must be able to read and write <i>line</i>. If the <i>line</i> does not begin with a / it may be treated as a Datakit destination. -L <i>file</i> Data received on <i>line</i> gets put in <i>file</i>. The default log <i>file</i> is standard error. Printer or status messages that don't show a change in state are not normally written to <i>file</i> but can be forced out using the -D option. -P <i>string</i> Send <i>string</i> to the printer before any of the input files. The default <i>string</i> is simple PostScript code that disables timeouts. -R <i>num</i> Run <code>postio</code> as a single process if <i>num</i> is 1 or as separate read and write processes if <i>num</i> is 2. By default <code>postio</code> runs as a single process. <p>The next two <i>options</i> are provided for users who expect to run <code>postio</code> on their own. Neither is suitable for use in spooler interface programs:</p> <ul style="list-style-type: none"> -i Run the program in interactive mode. Any <i>files</i> are sent first and followed by the standard input. Forces separate read and write processes and overrides many other options. To exit interactive mode

use your interrupt or quit character. To get a friendly interactive connection with the printer type `executive` on a line by itself.

- t Data received on `line` and not recognized as printer or status information is written to the standard output. Forces separate read and write processes. Convenient if you have a PostScript program that will be returning useful data to the host.

The last option is not generally recommended and should only be used if all else fails to provide a reliable connection:

- S Slow the transmission of data to the printer. Severely limits throughput, runs as a single process, disables the `-q` option, limits the internal buffer size to 1024 bytes, can use an excessive amount of CPU time, and does nothing in interactive mode.

The best performance will usually be obtained by using a large internal buffer (the `-B` option) and by running the program as separate read and write processes (the `-R 2` option). Inability to fork the additional process causes `postio` to continue as a single read/write process. When one process is used, only data sent to the printer is flow controlled.

The *options* are not all mutually exclusive. The `-i` option always wins, selecting its own settings for whatever is needed to run interactive mode, independent of anything else found on the command line. Interactive mode runs as separate read and write processes and few of the other *options* accomplish anything in the presence of the `-i` option. The `-t` option needs a reliable two way connection to the printer and therefore tries to force separate read and write processes. The `-S` option relies on the status query mechanism, so `-q` is disabled and the program runs as a single process.

In most cases `postio` starts by making a connection to `line` and then attempts to force the printer into the IDLE state by sending an appropriate sequence of `^T` (status query), `^C` (interrupt), and `^D` (end of job) characters. When the printer goes IDLE, *files* are transmitted along with an occasional `^T` (unless the `-q` option was used). After all the *files* are sent the program waits until it's reasonably sure the job is complete. Printer generated error messages received at any time except while establishing the initial connection (or when running interactive mode) cause `postio` to exit with a non-zero status. In addition to being added to the log file, printer error messages are also echoed to standard error.

EXAMPLES

EXAMPLE 1 Examples of the `postio` command.

Run as a single process at 9600 baud and send *file1* and *file2* to the printer attached to `/dev/tty01`:

```
example% postio -l /dev/tty01 file1 file2
```

Same as above except two processes are used, the internal buffer is set to 4096 bytes, and data returned by the printer gets put in file *log*:

```
example% postio -R 2 -B 4096 -l/dev/tty01 -L log file1 file2
```

Establish an interactive connection with the printer at Datakit destination *my/printer*:

```
example% postio -i -l my/printer
```

Send file program to the printer connected to */dev/tty22*, recover any data in file *results*, and put log messages in file *log*:

```
example% postio -t -l /dev/tty22 -L log program >results
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsf

SEE ALSO

[download\(1\)](#), [dpost\(1\)](#), [postdaisy\(1\)](#), [postdmd\(1\)](#), [postmd\(1\)](#), [postprint\(1\)](#), [postreverse\(1\)](#), [posttek\(1\)](#), [attributes\(5\)](#)

NOTES

The input *files* are handled as a single PostScript job. Sending several different jobs, each with their own internal end of job mark (^D) is not guaranteed to work properly. `postio` may quit before all the jobs have completed and could be restarted before the last one finishes.

All the capabilities described above may not be available on every machine or even across the different versions of the UNIX system that are currently supported by the program.

There may be no default `line`, so using the `-l` option is strongly recommended. If omitted, `postio` may attempt to connect to the printer using the standard output. If Datakit is involved, the `-b` option may be ineffective and attempts by `postio` to impose flow control over data in both directions may not work. The `-q` option can help if the printer is connected to RADIANT. The `-s` option is not generally recommended and should be used only if all other attempts to establish a reliable connection fail.

NAME	postmd - matrix display program for PostScript printers
SYNOPSIS	postmd [-b <i>num</i>] [-c <i>num</i>] [-d <i>dimen</i>] [-g <i>list</i>] [-i <i>list</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-w <i>window</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>] /usr/lib/lp/postscript/postmd
DESCRIPTION	The <code>postmd</code> filter reads a series of floating point numbers from <i>files</i> , translates them into a PostScript gray scale image, and writes the results on the standard output. In a typical application the numbers might be the elements of a large matrix, written in row major order, while the printed image could help locate patterns in the matrix. If no <i>files</i> are specified, or if - is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p>-b <i>num</i> Pack the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6.</p> <p>-c <i>num</i> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p>-d <i>dimen</i> Sets the default matrix dimensions for all input <i>files</i> to <i>dimen</i>. The <i>dimen</i> string can be given as rows or rowsxcolumns. If <i>columns</i> is omitted it will be set to rows. By default, <code>postmd</code> assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in each input file.</p> <p>-g <i>list</i> <i>list</i> is a comma or space separated string of integers, each lying between 0 and 255 inclusive, that assigns PostScript gray scales to the regions of the real line selected by the -i option. 255 corresponds to white, and 0, to black. The <code>postmd</code> filter assigns a default gray scale that omits white (that is, 255) and gets darker as the regions move from left to right along the real line.</p> <p>-i <i>list</i> <i>list</i> is a comma, space or slash(/) separated string of <i>N</i> floating point numbers that partition the real line into $2N+1$ regions. The <i>list</i> must be given in increasing numerical order. The partitions are used to map floating point numbers read from the input <i>files</i> into gray scale integers that are either assigned automatically by <code>postmd</code> or arbitrarily selected using the -g option. The default interval <i>list</i> is -1, 0, 1, which partitions the real line into seven regions.</p> <p>-m <i>num</i> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin which, by default, is</p>

- located at the center of each page. The default magnification is 1.0.
- `-n num` Print *num* logical pages on each piece of paper, where *num* can be any positive integer. By default, *num* is set to 1.
- `-o list` Print pages whose numbers are given in the comma separated *list*. The list contains single numbers *N* and ranges *N1 - N2*. A missing *N1* means the lowest numbered page, a missing *N2* means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then *only* page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.
- `-p mode` Print *files* in either portrait or landscape *mode*. Only the first character of *mode* is significant. The default *mode* is portrait.
- `-w window` *Window* is a comma or space separated list of four positive integers that select the upper left and lower right corners of a submatrix from each of the input *files*. Row and column indices start at 1 in the upper left corner and the numbers in the input *files* are assumed to be written in row major order. By default, the entire matrix is displayed.
- `-x num` Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive *num* moves everything right. The default offset is 0 inches.
- `-y num` Translate the origin *num* inches along the positive y axis. Positive *num* moves everything up the page. The default offset is 0.

Only one matrix is displayed on each logical page, and each of the input *files* must contain complete descriptions of exactly one matrix. Matrix elements are floating point numbers arranged in row major order in each input file. White space, including newlines, is not used to determine matrix dimensions. By default, `postmd` assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in the input file. Supplying default dimensions on the command line with the `-d` option overrides this default behavior, and in that case the dimensions apply to all input *files*.

An optional header can be supplied with each input file and is used to set the matrix dimensions, the partition of the real line, the gray scale map, and a window into the matrix. The header consists of keyword/value pairs, each on a separate line. It begins on the first line of each input file and ends with the first unrecognized string, which should be the first matrix element. Values set in the header take precedence, but apply only to the current input file. Recognized header keywords are dimension, interval, grayscale, and window. The syntax of the value string that follows each keyword parallels what is accepted by the `-d`, `-i`, `-g`, and `-w` options.

EXAMPLES

EXAMPLE 1 For example, suppose file initially contains the 1000 numbers in a 20x50 matrix. Then you can produce exactly the same output by completing three steps. First, issue the following command line:

```
example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file
```

EXAMPLE 2 Second, prepend the following header to file:

```
example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file
```

EXAMPLE 3 Third, issue the following command line:

```
example% postmd file
```

EXAMPLE 4 The interval list partitions the real line into five regions and the gray scale list maps numbers less than -100 or greater than 100 into 0 (that is, black), numbers equal to -100 or 100 into 128 (that is, 50 percent black), and numbers between -100 and 100 into 254 (that is, almost white).

FILES

/usr/lib/lp/postscript/forms.ps
/usr/lib/lp/postscript/ps.requests

EXIT STATUS

The following exit values are returned:
0 Successful completion.
non-zero An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

Availability	SUNWpsf

SEE ALSO

`dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postprint(1)`, `postreverse(1)`, `posttek(1)`, `attributes(5)`

NOTES

The largest matrix that can be adequately displayed is a function of the interval and gray scale lists, the printer resolution, and the paper size. A 600 by 600

matrix is an optimistic upper bound for a two element interval list (that is, five regions) using 8.5 by 11 inch paper on a 300 dpi printer.

Using white (that is, 255) in a gray scale list is not recommended and won't show up in the legend and bar graph that `postmd` displays below each image.

NAME	postplot – PostScript translator for plot(4B) graphics files
SYNOPSIS	postplot [-c <i>num</i>] [-f <i>name</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-w <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>filename...</i>]
DESCRIPTION	/usr/lib/lp/postscript/postplot The <code>postplot</code> filter translates <code>plot(1B)</code> graphics <i>filenames</i> into PostScript and writes the results on the standard output. If no <i>filenames</i> are specified, or if <code>-</code> is one of the input <i>filenames</i> , the standard input is read.
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -c <i>num</i> Print <i>num</i> copies of each page. By default, only one copy is printed. -f <i>name</i> Print text using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier. -m <i>num</i> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0. -n <i>num</i> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1. -o <i>list</i> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. -p <i>mode</i> Print <i>filenames</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is landscape. -w <i>num</i> Set the line width used for graphics to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0 points, which forces lines to be one pixel wide. -x <i>num</i> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0.0 inches. -y <i>num</i> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.0.
OPERANDS	The following operand is supported: <i>filename</i> The graphics filename to be translated
EXIT STATUS	The following exit value is returned: 0 <i>filename(s)</i> were successfully processed.

NOTES

The default line width is too small for write-white print engines, such as the one used by the PS-2400.

NAME	postprint – PostScript translator for text files
SYNOPSIS	postprint [-c <i>num</i>] [-f <i>name</i>] [-l <i>num</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-r <i>num</i>] [-s <i>num</i>] [-t <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>]
DESCRIPTION	/usr/lib/lp/postscript/postprint The <code>postprint</code> filter translates text <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p><code>-c <i>num</i></code> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p><code>-f <i>name</i></code> Print <i>files</i> using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</p> <p><code>-l <i>num</i></code> Set the length of a page to <i>num</i> lines. By default, <i>num</i> is 66. Setting <i>num</i> to 0 is allowed, and will cause <code>postprint</code> to guess a value, based on the point size that's being used.</p> <p><code>-m <i>num</i></code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.</p> <p><code>-n <i>num</i></code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o <i>list</i></code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p <i>mode</i></code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p><code>-r <i>num</i></code> Selects carriage return behavior. Carriage returns are ignored if <i>num</i> is 0, cause a return to column 1 if <i>num</i> is 1, and generate a newline if <i>num</i> is 2. The default <i>num</i> is 0.</p> <p><code>-s <i>num</i></code> Print <i>files</i> using point size <i>num</i>. When printing in landscape mode <i>num</i> is scaled by a factor that depends on the imaging area of the device. The default size for portrait mode is 10. Note that increasing point</p>

size increases virtual image size, so you either need to load larger paper, or use the `-l0` option to scale the number of lines per page.

`-t num` Assume tabs are set every *num* columns, starting with the first column. By default, tabs are set every 8 columns.

`-x num` Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive *num* moves everything to the right. The default offset is 0.25 inches.

`-y num` Translate the origin *num* inches along the positive y axis. Positive *num* moves text up the page. The default offset is -0.25 inches.

A new logical page is started after 66 lines have been printed on the current page, or whenever an ASCII form feed character is read. The number of lines per page can be changed using the `-l` option. Unprintable ASCII characters are ignored, and lines that are too long are silently truncated by the printer.

EXAMPLES

EXAMPLE 1 Examples of `postprint`.

To print *file1* and *file2* in landscape mode, issue the following command:

```
example% postprint -pland file1 file2
```

To print three logical pages on each physical page in portrait mode:

```
example% postprint -n3 file
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

NAME	postreverse – reverse the page order in a PostScript file
SYNOPSIS	postreverse [-o <i>list</i>] [-r] [<i>file</i>] /usr/lib/lp/postscript/postreverse
DESCRIPTION	<p>The <code>postreverse</code> filter reverses the page order in files that conform to Adobe's Version 1.0 or Version 2.0 file structuring conventions, and writes the results on the standard output. Only one input <code>file</code> is allowed and if no <code>file</code> is specified, the standard input is read.</p> <p>The <code>postreverse</code> filter can handle a limited class of files that violate page independence, provided all global definitions are bracketed by <code>%%BeginGlobal</code> and <code>%%EndGlobal</code> comments. In addition, files that mark the end of each page with <code>%%EndPage: label ordinal</code> comments will also reverse properly, provided the prologue and trailer sections can be located. If <code>postreverse</code> fails to find an <code>%%EndProlog</code> or <code>%%EndSetup</code> comment, the entire <code>file</code> is copied, unmodified, to the standard output.</p> <p>Because global definitions are extracted from individual pages and put in the prologue, the output file can be minimally conforming, even if the input <code>file</code> was not.</p>
OPTIONS	<p><code>-o list</code> Select pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-r</code> Do not reverse the pages in <code>file</code>.</p>
EXAMPLES	<p>EXAMPLE 1 Examples of <code>postreverse</code>.</p> <p>o select pages 1 to 100 from <code>file</code> and reverse the pages:</p> <pre>example% postreverse -o1-100 file</pre> <p>To print four logical pages on each physical page and reverse all the pages:</p> <pre>example% postprint -n4 file postreverse</pre> <p>To produce a minimally conforming file from output generated by <code>dpost</code> without reversing the pages:</p>

```
example% dpost file | postreverse -r
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NOTES

No attempt has been made to deal with redefinitions of global variables or procedures. If standard input is used, the input `file` will be read three times before being reversed.

NAME	posttek – PostScript translator for Tektronix 4014 files
SYNOPSIS	posttek [-c <i>num</i>] [-f <i>name</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-p <i>mode</i>] [-w <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [<i>file...</i>]
DESCRIPTION	/usr/lib/lp/postscript/posttek The <code>posttek</code> filter translates Tektronix 4014 graphics <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.
OPTIONS	<p><code>-c num</code> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p><code>-f name</code> Print text using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</p> <p><code>-m num</code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.</p> <p><code>-n num</code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o list</code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p mode</code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is landscape.</p> <p><code>-w num</code> Set the line width used for graphics to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0 points, which forces lines to be one pixel wide.</p> <p><code>-x num</code> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0.0 inches.</p> <p><code>-y num</code> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.0.</p>

NAME	pr - print files				
SYNOPSIS	<pre> /usr/bin/pr [+ page] [-column] [-adFmrt] [-e [char] [gap]] [-h header] [-i [char] [gap]] [-l lines] [-n [char] [width]] [-o offset] [-s [char]] [-w width] [-fp] [file...] /usr/xpg4/bin/pr [+ page] [-column -c column][-adFmrt] [-e [char] [gap]] [-h header] [-i [char] [gap]] [-l lines] [-n [char] [width]] [-o offset] [-s [char]] [-w width] [-fp] [file...] </pre>				
DESCRIPTION	<p>The <code>pr</code> utility is a printing and pagination filter. If multiple input files are specified, each is read, formatted, and written to standard output. By default, the input is separated into 66-line pages, each with:</p> <ul style="list-style-type: none"> ■ a 5-line header that includes the page number, date, time and the path name of the file ■ a 5-line trailer consisting of blank lines <p>If standard output is associated with a terminal, diagnostic messages will be deferred until the <code>pr</code> utility has completed processing.</p> <p>When options specifying multi-column output are specified, output text columns will be of equal width; input lines that do not fit into a text column will be truncated. By default, text columns are separated with at least one blank character.</p>				
OPTIONS	<p>The following options are supported. In the following option descriptions, <i>column</i>, <i>lines</i>, <i>offset</i>, <i>page</i>, and <i>width</i> are positive decimal integers; <i>gap</i> is a non-negative decimal integer. Some of the option-arguments are optional, and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the <code>-s</code> option does not allow the option letter to be separated from its argument, and the options <code>-e</code>, <code>-i</code>, and <code>-n</code> require that both arguments, if present, not be separated from the option letter.</p> <p>The following options are supported for both <code>/usr/bin/pr</code> and <code>/usr/xpg4/bin/pr</code>:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>+page</code></td> <td>Begin output at page number <i>page</i> of the formatted input.</td> </tr> <tr> <td style="vertical-align: top;"><code>-column</code></td> <td>Produce multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code>. The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with</td> </tr> </table>	<code>+page</code>	Begin output at page number <i>page</i> of the formatted input.	<code>-column</code>	Produce multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code> . The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with
<code>+page</code>	Begin output at page number <i>page</i> of the formatted input.				
<code>-column</code>	Produce multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code> . The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with				

	identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the <code>-l</code> option). When used with <code>-t</code> , use the minimum number of lines to write the output.
<code>-a</code>	Modify the effect of the <code>-column</code> option so that the columns are filled across the page in a round-robin order (for example, when <code>column</code> is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so forth).
<code>-d</code>	Produce output that is double-spaced; append an extra NEWLINE character following every NEWLINE character found in the input.
<code>-e [char] [gap]</code>	Expand each input TAB character to the next greater column position specified by the formula $n * gap + 1$, where n is an integer > 0 . If <code>gap</code> is 0 or is omitted, it defaults to 8. All TAB characters in the input will be expanded into the appropriate number of SPACE characters. If any non-digit character, <code>char</code> , is specified, it will be used as the input tab character.
<code>-f</code>	Use a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters. Pause before beginning the first page if the standard output is associated with a terminal.
<code>-h header</code>	Use the string <code>header</code> to replace the contents of the <code>file</code> operand in the page header.
<code>-l lines</code>	Override the 66-line default and reset the page length to <code>lines</code> . If <code>lines</code> is not greater than the sum of both the header and trailer depths (in lines), <code>pr</code> will suppress both the header and trailer, as if the <code>-t</code> option were in effect.
<code>-m</code>	Merge files. Standard output will be formatted so <code>pr</code> writes one line from each file specified by <code>file</code> , side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations support merging of at least nine files.

- n [*char*][*width*] Provide *width*-digit line numbering (default for *width* is 5). The number will occupy the first *width* column positions of each text column of default output or each line of *-m* output. If *char* (any non-digit character) is given, it will be appended to the line number to separate it from whatever follows (default for *char* is a TAB character).
- o *offset* Each line of output will be preceded by *offset* <space>*s*. If the *-o* option is not specified, the default *offset* is 0. The space taken will be in addition to the output line width (see *-w* option below).
- p Pause before beginning each page if the standard output is directed to a terminal (*pr* will write an ALERT character to standard error and wait for a carriage-return character to be read on */dev/tty*).
- r Write no diagnostic reports on failure to open files.
- s [*char*] Separate text columns by the single character *char* instead of by the appropriate number of SPACE characters (default for *char* is the TAB character).
- t Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.
- w *width* Set the width of the line to *width* column positions for multiple text-column output only. If the *-w* option is not specified and the *-s* option is not specified, the default width is 72. If the *-w* option is not specified and the *-s* option is specified, the default width is 512.

For single column output, input lines will not be truncated.

/usr/bin/pr

The following options are supported for */usr/bin/pr* only:

- F Fold the lines of the input file. When used in multi-column mode (with the *-a* or *-m* options), lines will be folded to fit the current column's width; otherwise, they will be folded to fit the current line width (80 columns).

`-i [char][gap]` In output, replace SPACE characters with TAB characters wherever one or more adjacent SPACE characters reach column positions $gap+1$, $2*gap+1$, $3*gap+1$, and so forth. If gap is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, $char$, is specified, it will be used as the output TAB character.

/usr/xpg4/bin/pr

The following options are supported for `/usr/xpg4/bin/pr` only:

`-F` Use a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters.

`-i [char][gap]` In output, replace multiple SPACE characters with TAB characters wherever two or more adjacent SPACE characters reach column positions $gap+1$, $2*gap+1$, $3*gap+1$, and so forth. If gap is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, $char$, is specified, it will be used as the output TAB character.

OPERANDS

The following operand is supported:

`file` A path name of a file to be written. If no `file` operands are specified, or if a `file` operand is `-`, the standard input will be used.

EXAMPLES

EXAMPLE 1 Print a numbered list of all files in the current directory:

```
ls -a | pr -n -h "Files in $(pwd)."
```

EXAMPLE 2 Print `file1` and `file2` as a double-spaced, three-column listing headed by "file list":

```
pr -3d -h "file list" file1 file2
```

EXAMPLE 3 Write `file1` on `file2`, expanding tabs to columns 10, 19, 28, ... :

```
pr -e9 -t <file1 >file2
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pr`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

NAME	praliases – display system mail aliases					
SYNOPSIS	praliases [-c <i>configfile</i>] [-f <i>aliasfile</i>] [<i>key</i>]					
DESCRIPTION	The praliases utility displays system mail aliases. When no key is given, praliases displays the current system aliases, one per line, in no particular order. The form is <i>key:value</i> . If a key is given, only that key is looked up and the appropriate <i>key:value</i> is displayed if found.					
OPTIONS	The following options are supported: -c <i>configfile</i> Specifies a sendmail configuration file. -f <i>aliasfile</i> Reads the specified file <i>aliasfile</i> instead of the default sendmail system aliases file.					
OPERANDS	<i>key</i>	A specific alias key to look up.				
EXIT STATUS	The following exit values are returned: 0 Successful operation. >0 An error occurred.					
FILES	/etc/mail/sendmail.cf	The default sendmail configuration file.				
	/etc/mail/aliases	The default sendmail system aliases file.				
	/etc/mail/aliases.dir					
	/etc/mail/aliases.pag	The database versions of the /etc/mail/aliases file.

NAME	prex – control tracing and manipulate probe points in a process or the kernel
SYNOPSIS	<pre>prex [-o trace_file_name] [-l libraries] [-s kbytes_size] cmd [cmd-args...] prex [-o trace_file_name] [-l libraries] [-s kbytes_size] -p pid prex -k [-s kbytes_size]</pre>
DESCRIPTION	<p>The <code>prex</code> command is the part of the Solaris tracing architecture that controls probes in a process or the kernel. See <code>tracing(3TNF)</code> for an overview of this tracing architecture, including example source code using it.</p> <p><code>prex</code> is the application used for external control of probes. It automatically preloads the <code>libtnfprobe</code> library. <code>prex</code> locates all the probes in a target executable or the kernel and provides an interface for the user to manipulate them. It allows a probe to be turned on for tracing, debugging, or both. Tracing generates a TNF (Trace Normal Form) trace file that can be converted to ASCII by <code>tnfdump(1)</code> and used for performance analysis. Debugging generates a line to standard error whenever the probe is hit at run time.</p>
Invoking prex	<p><code>prex</code> does not work on static executables. It only works on dynamic executables. There are three ways to invoke <code>prex</code>:</p> <ol style="list-style-type: none"> 1. Use <code>prex</code> to start the target application <code>cmd</code>. In this case, the target application need not be built with a dependency on <code>libtnfprobe</code>. See <code>TNF_PROBE(3TNF)</code>. <code>prex</code> sets the environment variable <code>LD_PRELOAD</code> to load <code>libtnfprobe</code> into the target process. See <code>ld(1)</code>. <code>prex</code> then uses the environment variable <code>PATH</code> to find the target application. 2. Attach <code>prex</code> to a running application. In this case, the running target application should have <code>libtnfprobe</code> already linked in. Alternatively, the user may manually set <code>LD_PRELOAD</code> to include <code>libtnfprobe.so.1</code> prior to invoking the target. 3. Use <code>prex</code> with the <code>-k</code> option to set <code>prex</code> to kernel mode. <code>prex</code> can then be used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands that are valid in other modes are invalid. See <code>Kernel Mode</code> below.
Control File Format and Command Language	<p>In a future release of <code>prex</code>, the command language may be moved to a syntax that is supported by an existing scripting language like <code>ksh(1)</code>. In the mean time, the interface to <code>prex</code> is uncommitted.</p> <ul style="list-style-type: none"> ■ Commands should be in ASCII. ■ Each command is terminated with the NEWLINE character. ■ A command can be continued onto the next line by ending the previous line with the backslash (<code>\</code>) character.

- Tokens in a command must be separated by whitespace (one or more spaces or tabs).
- The "#" character implies that the rest of the line is a comment.

Basic prex Commands

Command	Result
% prex a.out	Attaches prex to your program and starts prex.
prex> enable \$all	Enables all the probes.
prex> quit resume	Quits prex and resumes execution of program.

Control File Search Path

There are two different methods of communicating with prex:

- By specifications in a control file. During start-up, prex searches for a file named .prexrc in the directories specified below. prex does not stop at the first one it finds. This way a user can override any defaults that are set up. The search order is:

```
$HOME/  
./
```

- By typing commands at the prex prompt.

The command language for both methods is the same and is specified in USAGE. The commands that return output will not make sense in a control file. The output will go to standard output.

When using prex on a target process, the target will be in one of two states, running or stopped. This can be detected by the presence or absence of the prex> prompt. If the prompt is absent, it means that the target process is running. Typing CTRL-C will stop the target process and return the user to the prompt. There is no guarantee that CTRL-C will return to a prex prompt immediately. For example, if the target process is stopped on a job control stop (SIGSTOP), then CTRL-C in prex will wait until the target has been continued (SIGCONT). See Signals to Target Program below for more information on signals and the target process.

OPTIONS

The following options are supported:

-k kernel mode: prex is used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands valid in other modes are invalid. See Kernel Mode below.

- l *libraries*** The *libraries* mentioned are linked in to the target application using LD_PRELOAD (see ld(1)). This option cannot be used when attaching to a running process. The argument to the -l option should be a space-separated string enclosed in double quotes. Each token in the string is a library name. It follows the LD_PRELOAD rules on how libraries should be specified and where they will be found.
- o *trace_file_name*** File to be used for the trace output. *trace_file_name* is assumed to be relative to the current working directory of prex (that is, the directory that the user was in when prex was started).
- If prex attaches to a process that is already tracing, the new *trace_file_name* (if provided) will not be used. If no *trace_file_name* is specified, the default is /\$TMPDIR/trace-*pid* where *pid* is the process id of the target program. If TMPDIR is not set, /tmp is used.
- s *kbytes_size*** Maximum size of the output trace file in Kbytes. The default size of the trace *kbytes_size* is 4096 (2¹⁰) bytes or 4 Mbytes for normal usage, and 384 or 384 kbytes in kernel mode. The minimum size that can be specified is 128 Kbytes. The trace file can be thought of as a least recently used circular buffer. Once the file has been filled, newer events will overwrite the older ones.

USAGE Grammar

Probes are specified by a list of space-separated selectors. Selectors are of the form:

attribute=value

(see TNF_PROBE(3TNF)). The “*attribute=*” is optional. If it is not specified, it defaults to “*keys=*”.

The *attribute* or *value* (generically called “*spec*”) can be any of the following:

IDENT Any sequence of letters, digits, _, \, ., % not beginning with a digit. IDENT implies an exact match.

QUOTED_STR Usually used to escape reserved words (any commands in the command language). **QUOTED_STR** implies an exact match and has to be enclosed in single quotes (' ').

REGEXP An **ed(1)** regular expression pattern match. **REGEXP** has to be enclosed in slashes (/ /), A / can be included in a **REGEXP** by escaping it with a backslash \ .

The following grammar explains the syntax.

```

selector_list ::= | /* empty */
                selector_list selector
selector ::= spec=spec | /* whitespace around '=' opt */
              spec
spec ::= IDENT |
        QUOTED_STR |
        REGEXP

```

The terminals in the above grammar are:

```

IDENT = [a-zA-Z_\.\%]{[a-zA-Z0-9_\.\%]}+
QUOTED_STR = '[^\n]*' /* any string in single quotes */
REGEXP = /[^\n]/ /* regexp's have to be in / / */

```

This is a list of the remaining grammar that is needed to understand the syntax of the command language (defined in next subsection):

```

filename ::= QUOTED_STR /* QUOTED_STR defined above */
spec_list ::= /* empty */ |
              spec_list spec /* spec defined above */
fcn_handle ::= &IDENT /* IDENT defined above */
set_name ::= $IDENT /* IDENT defined above */

```

Command Language

1. Set Creation and Set Listing

```

create $set_name selector_list
list sets # list the defined sets

```

create can be used to define a set which contains probes that match the *selector_list*. The set *\$all* is pre-defined as *./.** and it matches all the probes.

2. Function Listing

```

list fcns # list the available fcn_handle

```

The user can list the different functions that can be connected to probe points. Currently, only the debug function called *&debug* is available.

3. Commands to Connect and Disconnect Probe Functions

```
connect &fcn_handle $set_name
connect &fcn_handle selector_list
clear $set_name
clear selector_list
```

The `connect` command is used to connect probe functions (which must be prefixed by `&`) to probes. The probes are specified either as a single set (with a `'$'`), or by explicitly listing the probe selectors in the command. The probe function has to be one that is listed by the `list fcns` command. This command does not enable the probes.

The `clear` command is used to disconnect all connected probe functions from the specified probes.

4. Commands to Toggle the Tracing Mode

```
trace $set_name
trace selector_list
untrace $set_name
untrace selector_list
```

The `trace` and `untrace` commands are used to toggle the tracing action of a probe point (that is, whether a probe will emit a trace record or not if it is hit). This command does not enable the probes specified. Probes have tracing on by default. The most efficient way to turn off tracing is by using the `disable` command. `untrace` is useful if you want debug output but no tracing. If so, set the state of the probe to enabled, untraced, and the debug function connected.

5. Commands to Enable and Disable Probes

```
enable $set_name
enable selector_list
disable $set_name
disable selector_list
```

The `enable` and `disable` commands are used to control whether the probes perform the action that they have been set up for. To trace a probe, it has to be both enabled and traced (using the `trace` command). Probes are disabled by default. The `list history` command is used to list the probe control commands issued: `connect`, `clear`, `trace`, `untrace`, `enable`, and `disable`. These are the commands that are executed whenever a new shared object is brought in to the target program by `dlopen(3DL)`. See the subsection, `dlopen'ed Libraries`, below for more information.

The following table shows the actions that result from specific combinations of tracing, enabling, and connecting:

Enabled or Disabled	Tracing State (On/Off)	Debug State (Connected/Cleared)	Results In
Enabled	On	Connected	Tracing and Debugging
Enabled	On	Cleared	Tracing only
Enabled	Off	Connected	Debugging only
Enabled	Off	Cleared	Nothing
Disabled	On	Connected	Nothing
Disabled	On	Cleared	Nothing
Disabled	Off	Connected	Nothing
Disabled	Off	Cleared	Nothing

6. List History

```
list history          # lists probe control command history
```

The `list history` command displays a list of the probe control commands previously issued in the tracing session, for example, `connect`, `clear`, `trace`, `disable`. Commands in the history list are executed wherever a new shared object is brought into the target program by `dlopen(3DL)`.

7. Commands to List Probes or List Values

```
list spec_list probes $set_name          # that is, list probes $all
list spec_list probes selector_list     # that is, list name probes\
                                         # file=test.c
list values spec_list                   # that is, list values keys
```

The first two commands list the selected attributes and values of the specified probes. They can be used to check the state of a probe. The third command lists the various values associated with the selected attributes.

8. Help Command

```
help topic
```

To get a list of the help topics that are available, invoke the `help` command with no arguments. If a `topic` argument is specified, help is printed for that topic.

9. Source a File

```
source filename
```

The `source` command can be used to source a file of `prex` commands. `source` can be nested (that is, a file can source another file). *filename* is a quoted string.

10. Process Control

```
continue          # resumes the target process
quit kill         # quit prex, kill target
quit resume      # quit prex, continue target
quit suspend     # quit prex, leave target suspended
quit             # quit prex (continue or kill target)
```

The default `quit` will continue the target process if `prex` attached to it. Instead, if `prex` had started the target program, `quit` will kill the target process.

dlopen'ed Libraries

Probes in shared objects that are brought in by `dlopen(3DL)` are automatically set up according to the command history of `prex`. When a shared object is removed by a `dlclose(3DL)`, `prex` again needs to refresh its understanding of the probes in the target program. This implies that there is more work to do for `dlopen(3DL)` and `dlclose(3DL)`—so they will take slightly longer. If a user is not interested in this feature and doesn't want to interfere with `dlopen(3DL)` and `dlclose(3DL)`, detach `prex` from the target to inhibit this feature.

Signals to Target Program

`prex` does not interfere with signals that are delivered directly to the target program. However, `prex` receives all signals normally generated from the terminal, for example, CTRL-C (SIGINT), and CTRL-Z (SIGSTOP), and does not forward them to the target program. To signal the target program, use the `kill(1)` command from a shell.

Interactions with Other Applications

Process managing applications like `dbx`, `truss(1)`, and `prex` cannot operate on the same target program simultaneously. `prex` will not be able to attach to a target which is being controlled by another application. A user can trace and debug a program serially by the following method: first attach `prex` to target (or start target through `prex`), set up the probes using the command language, and then type `quit suspend`. The user can then attach `dbx` to the suspended process and debug it. A user can also suspend the target by sending it a SIGSTOP signal, and then by typing `quit resume` to `prex`. In this case, the user should also send a SIGCONT signal after invoking `dbx` on the stopped process (else `dbx` will be hung).

Failure of Event Writing Operations

There are a few failure points that are possible when writing out events to a trace file, for example, system call failures. These failures result in a failure code being set in the target process. The target process continues normally, but no trace records are written. Whenever a user types CTRL-C to `prex` to get to a `prex` prompt, `prex` will check the failure code in the target and inform the user if there was a tracing failure.

Target Executing a Fork or exec

If the target program does a `fork(2)`, any probes that the child encounters will cause events to be logged to the same trace file. Events are annotated with a process id, so it will be possible to determine which process a particular event came from. In multi-threaded programs, there is a race condition with a thread doing a fork while the other threads are still running. For the trace file not to get corrupted, the user should either use `fork1(2)`, or make sure that all other threads are quiescent when doing a `fork(2)`,

If the target program itself (not any children it may `fork(2)`) does an `exec(2)`, `prex` detaches from the target and exits. The user can reconnect `prex` with `prex -p pid`.

A `vfork(2)` is generally followed quickly by an `exec(2)` in the child, and in the interim, the child borrows the parent's process while the parent waits for the `exec(2)`. Any events logged by the child from the parent process will appear to have been logged by the parent.

Kernel Mode

Invoking `prex` with the `-k` flag causes `prex` to run in `kernel` mode. In kernel mode, `prex` controls probes in the Solaris kernel. See `tnf_kernel_probes(4)` for a list of available probes in the Solaris kernel. A few `prex` commands are unavailable in kernel mode; many other commands are valid in kernel mode only.

The `-l`, `-o`, and `-p` command-line options are not valid in kernel mode (that is, they may not be combined with the `-k` flag).

The rest of this section describes the differences in the `prex` command language when running `prex` in kernel mode.

1. `prex` will not stop the kernel

When `prex` attaches to a running user program, it stops the user program. Obviously, it cannot do this when attaching to the kernel. Instead, `prex` provides a "tracing master switch": no probes will have any effect unless the tracing master switch is on. This allows the user to iteratively select probes to enable, then enable them all at once by turning on the master switch.

The command

```
ktrace [ on | off ]
```

is used to inspect and set the value of the master switch. Without an argument, `prex` reports the current state of the master switch.

Since `prex` will not stop or kill the kernel, the

```
quit resume
```

and

```
quit kill
```

commands are not valid in kernel mode.

2. No functions may be attached to probes in the kernel. In particular, the debug function is unavailable in kernel mode.
3. Trace output is written to an in-core buffer. In kernel mode, a trace output file is not generated directly, in order to allow probes to be placed in time-critical code. Instead, trace output is written to an in-core buffer, and copied out by a separate program, `tnfextract(1)`.

The in-core buffer is not automatically created. The following `prex` command controls buffer allocation and deallocation:

```
buffer [ alloc [ size ] | dealloc ]
```

Without an argument, the `buffer` command reports the size of the currently allocated buffer, if any. With an argument of `alloc [size]`, `prex` allocates a buffer of the given size. `size` is in bytes, with an optional suffix of 'k' or 'm' specifying a multiplier of 1024 or 1048576, respectively. If no `size` is specified, the `size` specified on the command line with the `-s` option is used as a default. If the `-s` command line option was not used, the "default default" is 384 kilobytes.

With an argument of `dealloc`, `prex` deallocates the trace buffer in the kernel.

`prex` will reject attempts to turn the tracing master switch on when no buffer is allocated, and to deallocate the buffer when the tracing master switch is on. `prex` will refuse to allocate a buffer when one is already allocated; use `buffer dealloc` first.

`prex` will not allocate a buffer larger than one-half of a machine's physical memory.

4. `Prex` supports per-process probe enabling in the kernel. In kernel mode, it is possible to select a set of processes for which probes are enabled. No trace output will be written when other processes traverse these probe points. This is called "process filter mode." By default, process filter mode is off, and all processes cause the generation of trace records when they hit an enabled probe.

Some kernel events such as interrupts cannot be associated with a particular user process. By convention, these events are considered to be generated by process id 0.

`prex` provides commands to turn process filter mode on and off, to get the current status of the process filter mode switch, to add and delete processes (by process id) from the process filter set, and to list the current process filter set.

The process filter set is maintained even when process filter mode is off, but has no effect unless process filter mode is on.

When a process in the process filter set exits, its process id is automatically deleted from the process filter set.

The command:

```
pfilter [ on | off | addpidlist | deletepidlist ]
```

controls the process filter switch, and process filter set membership. With no arguments, `pfilter` prints the current process filter set and the state of the process filter mode switch.

`on` or `off` set the state of the process filter mode switch.

`add pidlist`

`delete pidlist` add or delete processes from the process filter set. *pidlist* is a comma-separated list of one or more process ids.

EXAMPLES

See `tracing(3TNF)` for complete examples showing, among other things, the use of `prex` to do simple probe control.

When either the process or kernel is started, all probes are disabled.

EXAMPLE 1 Set creation and set listing

```
create $out name=/out/      # $out = probes with "out" in
                           #   value of "name" attribute
create $foo /page/ name=biodone # $foo = union of
  # probes with "page" in value of keys attribute
  # probes with "biodone" as value of "name" attribute
list sets                  # list the defined sets
list fcns                  # list the defined probe fcns
```

EXAMPLE 2 Commands to trace and connect probe functions

```
trace foobar='on'         # exact match on foobar attribute
trace $all                # trace all probes (predefined set $all)
connect &debug $foo       # connect debug func to probes in $foo
```

EXAMPLE 3 Commands to enable and disable probes

```
enable $all               # enable all probes
enable /vm/ name=alloc    # enable the specified probes
disable $foo              # disable probes in set $foo
list history              # list probe control commands issued
```

EXAMPLE 4 Process control

```

continue          # resumes the target process
^C                # stop target; give control to prex
quit resume      # exit prex, leave process running and resume execution of program

```

EXAMPLE 5 Kernel mode

```

buffer alloc 2m   # allocate a 2 Megabyte buffer
enable $all       # enable all probes
trace $all        # trace all probes
ktrace on         # turn tracing on
ktrace off        # turn tracing back off
pfilter on        # turn process filter mode on
pfilter add 1379  # add pid 1379 to process filter
ktrace on         # turn tracing on
                  # (only pid 1379 will be traced)

```

FILES

```

.prexrc          local prex initialization file
~/ .prexrc       user's prex initialization file
/proc/nnnnn     process files

```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnfc (32-bit) SUNWtnfcx (64-bit)

SEE ALSO ed(1), kill(1), ksh(1), ld(1), tnfdump(1), tnfextract(1), truss(1), exec(2), fork(2), fork1(2), vfork(2), TNF_DECLARE_RECORD(3TNF), TNF_PROBE(3TNF), dlclose(3DL), dlopen(3DL), gethrtime(3C), libtnfctl(3TNF), tnf_process_disable(3TNF), tracing(3TNF), tnf_kernel_probes(4), attributes(5)

NOTES Currently, the only probe function that is available is the &debug function. When this function is executed, it prints out the arguments sent in to the probe as well as the value associated with the sunw%debug attribute in the detail field (if any) to stderr.

For example, for the following probe point:

```

TNF_PROBE_2(input_values, "testapp main",
            "sunw%debug 'have read input values successfully'",
            tnf_long, int_input, x,
            tnf_string, string_input, input);

```

If *x* was 100 and *input* was the string "success", then the output of the debug probe function would be:

```

probe input_values; sunw%debug "have read input values successfully";
int_input=100; string_input="success";

```

Some non-SPARC hardware lacks a true high-resolution timer, causing `gethrtime()` to return the same value multiple times in succession. This can lead to problems in how some tools interpret the trace file. This situation can be improved by interposing a version of `gethrtime()`, which causes these successive values to be artificially incremented by one nanosecond:

```

hrtime_t
gethrtime()
{
    static mutex_t lock;
    static hrtime_t (*real_gethrtime)(void) = NULL;
    static hrtime_t last_time = 0;

    hrtime_t this_time;

    if (real_gethrtime == NULL) {
        real_gethrtime =
            (hrtime_t (*)(void)) dlsym(RTLD_NEXT, "gethrtime");
    }
    this_time = real_gethrtime();

    mutex_lock(&lock);
    if (this_time <= last_time)
        this_time = ++last_time;
    else
        last_time = this_time;
    mutex_unlock(&lock);

    return (this_time);
}

```

Of course, this does not increase the resolution of the timer, so timestamps for individual events are still relatively inaccurate. But this technique maintains ordering, so that if event A causes event B, B never appears to happen before or at the same time as A.

`dbx` is available with the Sun Workshop Products.

BUGS

`prex` should issue a notification when a process id has been automatically deleted from the filter set.

There is a known bug in `prex` which can result in this message:

```

Tracing shut down in target program due to an internal
error - Please restart prex and target

```

When `prex` runs as root, and the target process is not root, and the tracefile is placed in a directory where it cannot be removed and re-created (a directory

with the sticky bit on, like `/tmp`),mm then the target process will not be able to open the tracefile when it needs to. This results in tracing being disabled.

Changing any of the circumstances listed above should fix the problem. Either don't run `prex` as root, or run the target process as root, or specify the tracefile in a directory other than `/tmp`.

NAME print – shell built-in function to output characters to the screen or window

SYNOPSIS

ksh **print** [-Rnprsu [*n*]] [*arg...*]

DESCRIPTION

ksh The shell output mechanism. With no flags or with flag `-` or `-`, the arguments are printed on standard output as described by `echo(1)`.

OPTIONS

The following options are supported:

- `-n` suppresses `new-line` from being added to the output.
- `-R`
- `-r` (raw mode) ignore the escape conventions of `echo`. The `-R` option will print all subsequent arguments and options other than `-n`.
- `-p` causes the arguments to be written onto the pipe of the process spawned with `|&` instead of standard output.
- `-s` causes the arguments to be written onto the history file instead of standard output.
- `-u [n]` flag can be used to specify a one digit file descriptor unit number *n* on which the output will be placed. The default is 1.

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- >0 Output file is not open for writing.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`echo(1)`, `ksh(1)`, `attributes(5)`

NAME printenv - display environment variables currently set

SYNOPSIS /usr/ucb/printenv [*variable*]

DESCRIPTION printenv prints out the values of the variables in the environment. If a *variable* is specified, only its value is printed.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO csh(1), echo(1), sh(1), stty(1), tset(1B), attributes (5), environ(5)

DIAGNOSTICS If a *variable* is specified and it is not defined in the environment, printenv returns an exit status of 1.

NAME	printf – write formatted output
SYNOPSIS	printf <i>format</i> [<i>argument...</i>]
DESCRIPTION	The <code>printf</code> command writes formatted operands to the standard output. The <i>argument</i> operands are formatted under control of the <i>format</i> operand.
OPERANDS	<p>The following operands are supported:</p> <p><i>format</i> A string describing the format to use to write the remaining operands. The <i>format</i> operand is used as the <i>format</i> string described on the <code>formats(5)</code> manual page, with the following exceptions:</p> <ul style="list-style-type: none"> ■ A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output. ■ A character in the format string is treated as a character, not as a SPACE character. ■ In addition to the escape sequences described on the <code>formats(5)</code> manual page (<code>\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>), <code>\ddd</code>, where <i>ddd</i> is a one-, two- or three-digit octal number, is written as a byte with the numeric value specified by the octal number. ■ The program does not precede or follow output from the <code>d</code> or <code>u</code> conversion specifications with blank characters not specified by the <i>format</i> operand. ■ The program does not precede output from the <code>o</code> conversion specification with zeros not specified by the <i>format</i> operand. ■ An additional conversion character, <code>b</code>, is supported as follows. The argument is taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences are supported: <ul style="list-style-type: none"> – the escape sequences listed on the <code>formats(5)</code> manual page (<code>\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>), which are converted to the characters they represent – <code>\0ddd</code>, where <i>ddd</i> is a zero-, one-, two- or three-digit octal number that is converted to a byte with the numeric value specified by the octal number – <code>\c</code>, which is written and causes <code>printf</code> to ignore any remaining characters in the string operand containing it, any remaining string operands and any additional characters in the <i>format</i> operand.

The interpretation of a backslash followed by any other sequence of characters is unspecified.

Bytes from the converted string are written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it is taken to be infinite, so all bytes up to the end of the converted string are written. For each specification that consumes an argument, the next argument operand is evaluated and converted to the appropriate type for the conversion as specified below. The `format` operand is reused as often as necessary to satisfy the argument operands. Any extra `c` or `s` conversion specifications are evaluated as if a null string argument were supplied; other extra conversion specifications are evaluated as if a zero argument were supplied. If the `format` operand contains no conversion specifications and `argument` operands are present, the results are unspecified. If a character sequence in the `format` operand begins with a `%` character, but does not form a valid conversion specification, the behavior is unspecified.

argument

The strings to be written to standard output, under the control of `format`. The *argument* operands are treated as strings if the corresponding conversion character is `b`, `c` or `s`; otherwise, it is evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign is allowed.
- If the leading character is a single- or double-quote, the value is the numeric value in the underlying codeset of the character following the single- or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does not exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

USAGE

Note that this `printf` utility, like the `printf(3C)` function on which it is based, makes no special provision for dealing with multi-byte characters when using the `%c` conversion specification or when a precision is specified in a `%b` or `%s`

conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

Field widths and precisions cannot be specified as `*`.

For compatibility with previous versions of SunOS 5.x, the `$` format specifier is supported for formats containing *only* `%s` specifiers.

The `%b` conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the `echo` utility. See also the `USAGE` section of the `echo(1)` manual page for ways to use `printf` as a replacement for all of the traditional versions of the `echo` utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the `printf` utility reports an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion are to be reported as errors.

It is not considered an error if an argument operand is not completely used for a `c` or `s` conversion or if a string operand's first or second character is used to get the numeric value of a character.

EXAMPLES

EXAMPLE 1 Printing a series of prompts

To alert the user and then print and read a series of prompts:

```
printf "\aPlease fill in the following: \nName: "
read name
printf "Phone number: "
read phone
```

EXAMPLE 2 Printing a table of calculations

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single tab character. The percentage is written to one decimal place of accuracy:

```
while read right wrong ; do
  percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
  printf "%2d right\t%2d wrong\t(%s%)\n" \
    $right $wrong $percent
done < database_file
```

EXAMPLE 3 Printing number strings

The command:

```
printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
 1 21
3214321
```

```
54321 0
```

Note that the `format` operand is used three times to print all of the given strings and that a `0` was supplied by `printf` to satisfy the last `%4d` conversion specification.

EXAMPLE 4 Tabulating conversion errors

The `printf` utility tells the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the `format` operand:

Arguments	Standard	Diagnostic
5a	5	printf: 5a not completely converted
999999999	2147483647	printf: 999999999: Results too large
-999999999	-2147483648	printf: -999999999: Results too large
ABC	0	printf: ABC expected numeric value

Note that the value shown on standard output is what would be expected as the return value from the function `strtol(3C)`. A similar correspondence exists between `%u` and `strtoul(3C)`, and `%e`, `%f` and `%g` and `strtod(3C)`.

EXAMPLE 5 Printing output for a specific locale

In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```
printf "%d\n" 3 +3 -3 \'3 \'+3 \'-3"
```

produces:

3	Numeric value of constant 3
3	Numeric value of constant 3
-3	Numeric value of constant -3
51	Numeric value of the character '3' in the ISO/IEC 646:1991 standard codeset
43	Numeric value of the character '+' in the ISO/IEC 646:1991 standard codeset
45	Numeric value of the character '-' in the ISO/IEC 646:1991 standard codeset

Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the `wchar_t` representation of the character.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `printf`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

NAME	prioctl – display or set scheduling parameters of specified process(es)
SYNOPSIS	<pre>prioctl -l prioctl -d [-i <i>idtype</i>] [<i>idlist</i>] prioctl -s [-c <i>class</i>] [<i>class-specific options</i>] [-i <i>idtype</i>] [<i>idlist</i>] prioctl -e [-c <i>class</i>] [<i>class-specific options</i>] <i>command</i> [<i>argument(s)</i>]</pre>
DESCRIPTION	<p>The <code>prioctl</code> command displays or sets scheduling parameters of the specified process(es). It can also be used to display the current configuration information for the system's process scheduler or execute a command with specified scheduling parameters.</p> <p>Processes fall into distinct classes with a separate scheduling policy applied to each class. The process classes currently supported are the real-time class, time-sharing class, and the interactive class. The characteristics of these classes and the class-specific options they accept are described below in the <code>USAGE</code> section under the headings <code>Real-Time Class</code>, <code>Time-Sharing Class</code>, and <code>Inter-Active Class</code>. With appropriate permissions, the <code>prioctl</code> command can change the class and other scheduling parameters associated with a running process.</p> <p>In the default configuration, a runnable real-time process runs before any other process. Therefore, inappropriate use of real-time processes can have a dramatic negative impact on system performance.</p> <p>If an <i>idlist</i> is present it must appear last on the command line and the elements of the list must be separated by white space. If no <i>idlist</i> is present an <i>idtype</i> argument of <code>pid</code>, <code>ppid</code>, <code>pgid</code>, <code>sid</code>, <code>class</code>, <code>uid</code>, or <code>gid</code> specifies the process ID, parent process ID, process group ID, session ID, class, user ID, or group ID, respectively, of the <code>prioctl</code> command itself.</p> <p>The command</p> <pre>prioctl -d [-i <i>idtype</i>] [<i>idlist</i>]</pre> <p>displays the class and class-specific scheduling parameters of the process(es) specified by <i>idtype</i> and <i>idlist</i>.</p> <p>The command</p> <pre>prioctl -s [-c <i>class</i>] [<i>class-specific options</i>] [-i <i>idtype</i>] [<i>idlist</i>]</pre> <p>sets the class and class-specific parameters of the specified processes to the values given on the command line. The <code>-c class</code> option specifies the class to be set. (The valid <i>class</i> arguments are <code>RT</code> for real-time <code>TS</code> for time-sharing or <code>IA</code> for inter-active.)</p>

The class-specific parameters to be set are specified by the class-specific options as explained under the appropriate heading below. If the `-c class` option is omitted, `idtype` and `idlist` must specify a set of processes which are all in the same class, otherwise an error results. If no class-specific options are specified the process's class-specific parameters are set to the default values for the class specified by `-c class` (or to the default parameter values for the process's current class if the `-c class` option is also omitted).

In order to change the scheduling parameters of a process using `prioctl` the real or effective user ID (respectively, groupID) of the user invoking `prioctl` must match the real or effective user ID (respectively, groupID) of the receiving process or the effective user ID of the user must be super-user. These are the minimum permission requirements enforced for all classes. An individual class may impose additional permissions requirements when setting processes to that class or when setting class-specific scheduling parameters.

When `idtype` and `idlist` specify a set of processes, `prioctl` acts on the processes in the set in an implementation-specific order. If `prioctl` encounters an error for one or more of the target processes, it may or may not continue through the set of processes, depending on the nature of the error.

If the error is related to permissions, `prioctl` prints an error message and then continue through the process set, resetting the parameters for all target processes for which the user has appropriate permissions. If `prioctl` encounters an error other than permissions, it does not continue through the process set but prints an error message and exits immediately.

A special `sys` scheduling class exists for the purpose of scheduling the execution of certain special system processes (such as the swapper process). It is not possible to change the class of any process to `sys`. In addition, any processes in the `sys` class that are included in the set of processes specified by `idtype` and `idlist` are disregarded by `prioctl`. For example, if `idtype` were `uid`, an `idlist` consisting of a zero would specify all processes with a UID of 0, except processes in the `sys` class and (if changing the parameters using the `-s` option) the `init` process.

The `init` process (process ID 1) is a special case. In order for the `prioctl` command to change the class or other scheduling parameters of the `init` process, `idtype` must be `pid` and `idlist` must be consist of only a 1. The `init` process may be assigned to any class configured on the system, but the time-sharing class is almost always the appropriate choice. (Other choices may be highly undesirable; see the *System Administration Guide, Volume 1* for more information.)

The command

```
prioctl -e [-c class] [class-specific options] command [argument...]
```

executes the specified command with the class and scheduling parameters specified on the command line (*arguments* are the arguments to the command). If the `-c class` option is omitted the command is run in the user's current class.

OPTIONS

The following options are supported:

- `-c class` Specifies the *class* to be set. (The valid *class* arguments are `RT` for real-time or `TS` for time-sharing or `IA` for inter-active.) If the specified class is not already configured, it will automatically be configured.
- `-d` Display the scheduling parameters associated with a set of processes.
- `-e` Execute a specified command with the class and scheduling parameters associated with a set of processes.
- `-i idtype` This option together with the *idlist* arguments (if any), specify one or more processes to which the `prioctl` command is to apply. The interpretation of *idlist* depends on the value of *idtype*. The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:
 - `-i pid` *idlist* is a list of process IDs. The `prioctl` command applies to the specified processes.
 - `-i ppid` *idlist* is a list of parent process IDs. The `prioctl` command applies to all processes whose parent process ID is in the list.
 - `-i pgid` *idlist* is a list of process group IDs. The `prioctl` command applies to all processes in the specified process groups.
 - `-i sid` *idlist* is a list of session IDs. The `prioctl` command applies to all processes in the specified sessions.
 - `-i class` *idlist* consists of a single class name (`RT` for real-time or `TS` for time-sharing or `IA` for inter-active). The `prioctl` command applies to all processes in the specified class.

- i *uid* *idlist* is a list of user IDs. The `prioctl` command applies to all processes with an effective user ID equal to an ID from the list.
- i *gid* *idlist* is a list of group IDs. The `prioctl` command applies to all processes with an effective group ID equal to an ID from the list.
- i *all* The `prioctl` command applies to all existing processes. No *idlist* should be specified (if one is it is ignored). The permission restrictions described below still apply.

If the `-i idtype` option is omitted when using the `-d` or `-s` options the default *idtype* of `pid` is assumed.

- l Display a list of the classes currently configured in the system along with class-specific information about each class. The format of the class-specific information displayed is described under `USAGE`.
- s Set the scheduling parameters associated with a set of processes.

The valid class-specific options for setting real-time parameters are:

- p *rtpri* Set the real-time priority of the specified process(es) to *rtpri*.
- t *tqntm* [*-r res*] Set the time quantum of the specified process(es) to *tqntm*. You may optionally specify a resolution as explained below.

The valid class-specific options for setting time-sharing parameters are:

- m *tsuprilim* Set the user priority limit of the specified process(es) to *tsuprilim*.
- p *tsupri* Set the user priority of the specified process(es) to *tsupri*.

The valid class-specific options for setting inter-active parameters are:

- m *iauprilim* Set the user priority limit of the specified process(es) to *iauprilim*.
- p *iaupri* Set the user priority of the specified process(es) to *iaupri*.

USAGE

Real-Time Class

The real-time class provides a fixed priority preemptive scheduling policy for those processes requiring fast and deterministic response and absolute user/application control of scheduling priorities. If the real-time class is configured in the system it should have exclusive control of the highest range of scheduling priorities on the system. This ensures that a runnable real-time process is given CPU service before any process belonging to any other class.

The real-time class has a range of real-time priority (*rtpri*) values that may be assigned to processes within the class. Real-time priorities range from 0 to *x*, where the value of *x* is configurable and can be displayed for a specific installation that has already configured a real-time scheduler, by using the command

```
prioctl -l
```

The real-time scheduling policy is a fixed priority policy. The scheduling priority of a real-time process never changes except as the result of an explicit request by the user/application to change the *rtpri* value of the process.

For processes in the real-time class, the *rtpri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *rtpri* value completely determines the scheduling priority of a real-time process relative to other processes within its class. Numerically higher *rtpri* values represent higher priorities. Since the real-time class controls the highest range of scheduling priorities in the system it is guaranteed that the runnable real-time process with the highest *rtpri* value is always selected to run before any other process in the system.

In addition to providing control over priority, `prioctl` provides for control over the length of the time quantum allotted to processes in the real-time class. The time quantum value specifies the maximum amount of time a process may run assuming that it does not complete or enter a resource or event wait state (`sleep`). Note that if another process becomes runnable at a higher priority, the currently running process may be preempted before receiving its full time quantum.

The command

```
prioctl -d [-i idtype] [idlist]
```

displays the real-time priority and time quantum (in millisecond resolution) for each real-time process in the set specified by *idtype* and *idlist*.

Any combination of the `-p` and `-t` options may be used with `prioctl -s` or `prioctl -e` for the real-time class. If an option is omitted and the process is currently real-time, the associated parameter is unaffected. If an option is

omitted when changing the class of a process to real-time from some other class, the associated parameter is set to a default value. The default value for *rtpri* is 0 and the default for time quantum is dependent on the value of *rtpri* and on the system configuration; see `rt_dptbl(4)`.

When using the `-t tqntm` option you may optionally specify a resolution using the `-r res` option. (If no resolution is specified, millisecond resolution is assumed.) If *res* is specified it must be a positive integer between 1 and 1,000,000,000 inclusive and the resolution used is the reciprocal of *res* in seconds. For example, specifying `-t 10 -r 100` would set the resolution to hundredths of a second and the resulting time quantum length would be 10/100 seconds (one tenth of a second). Although very fine (nanosecond) resolution may be specified, the time quantum length is rounded up by the system to the next integral multiple of the system clock's resolution. Requests for time quanta of zero or quanta greater than the (typically very large) implementation-specific maximum quantum result in an error.

In order to change the class of a process to real-time (from any other class) the user invoking `priocntl` must have super-user privilege. In order to change the *rtpri* value or time quantum of a real-time process the user invoking `priocntl` must either be super-user, or must currently be in the real-time class (shell running as a real-time process) with a real or effective user ID matching the real or effective user ID of the target process.

The real-time priority and time quantum are inherited across the `fork(2)` and `exec(2)` system calls.

Time-Sharing Class

The time-sharing scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics. The objectives of the time-sharing policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs while providing a degree of user/application control over scheduling.

The time-sharing class has a range of time-sharing user priority (*tsupri*) values that may be assigned to processes within the class. User priorities range from $-x$ to $+x$, where the value of x is configurable. The range for a specific installation can be displayed by using the command

```
priocntl -l
```

The purpose of the user priority is to provide some degree of user/application control over the scheduling of processes in the time-sharing class. Raising or lowering the *tsupri* value of a process in the time-sharing class raises or lowers the scheduling priority of the process. It is not guaranteed, however, that a time-sharing process with a higher *tsupri* value will run before one with a lower *tsupri* value. This is because the *tsupri* value is just one factor used to

determine the scheduling priority of a time-sharing process. The system may dynamically adjust the internal scheduling priority of a time-sharing process based on other factors such as recent CPU usage.

In addition to the system-wide limits on user priority (displayed with `prioctl -l`), there is a per process user priority limit (*tsuprilim*), which specifies the maximum *tsupri* value that may be set for a given process.

The command

```
prioctl -d [-i idtype] [idlist]
```

displays the user priority and user priority limit for each time-sharing process in the set specified by *idtype* and *idlist*.

Any time-sharing process may lower its own *tsuprilim* (or that of another process with the same user ID). Only a time-sharing process with super-user privilege may raise a *tsuprilim*. When changing the class of a process to time-sharing from some other class, super-user privilege is required in order to set the initial *tsuprilim* to a value greater than zero.

Any time-sharing process may set its own *tsupri* (or that of another process with the same user ID) to any value less than or equal to the process's *tsuprilim*. Attempts to set the *tsupri* above the *tsuprilim* (and/or set the *tsuprilim* below the *tsupri*) result in the *tsupri* being set equal to the *tsuprilim*.

Any combination of the `-m` and `-p` options may be used with `prioctl -s` or `prioctl -e` for the time-sharing class. If an option is omitted and the process is currently time-sharing the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and `-m` is used to set a *tsuprilim* below the current *tsupri*. In this case the *tsupri* is set equal to the *tsuprilim* which is being set. If an option is omitted when changing the class of a process to time-sharing from some other class, the associated parameter is set to a default value. The default value for *tsuprilim* is 0 and the default for *tsupri* is to set it equal to the *tsuprilim* value which is being set.

The time-sharing user priority and user priority limit are inherited across the `fork(2)` and `exec(2)` system calls.

Inter-Active Class

The inter-active scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics while providing good responsiveness for user interaction. The objectives of the inter-active policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs. The priorities of processes in the inter-active class can be changed in the same manner as those in the time-sharing class, though the modified priorities will continue to be adjusted to provide good responsiveness for user interaction.

EXAMPLES**EXAMPLE 1** Real-Time Class examples.

Real-Time Class examples follow:

```
example% priocntl -s -c RT -t 1 -r 10 -i idtype idlist
```

The above example sets the class of any non-real-time processes selected by *idtype* and *idlist* to real-time and sets their real-time priority to the default value of 0. The real-time priorities of any processes currently in the real-time class are unaffected. The time quantum of all of the specified processes are set to 1/10 seconds.

```
example% priocntl -e -c RT -p 15 -t 20 command
```

This example executes *command* in the real-time class with a real-time priority of 15 and a time quantum of 20 milliseconds.

Time-Sharing Class examples follow:

```
example% priocntl -s -c TS -i idtype idlist
```

The above example sets the class of any non-time-sharing processes selected by *idtype* and *idlist* to time-sharing and sets both their user priority limit and user priority to 0. Processes already in the time-sharing class are unaffected.

This example executes *command* with the arguments *arguments* in the time-sharing class with a user priority limit of 0 and a user priority of -15.

```
example% priocntl -e -c TS -m 0 -p -15 command [arguments]
```

EXIT STATUS

The following exit values are returned:

For options *-d*, *-l*, and *-s*,

0	Successful operation.
1	Error condition.

For option *-e*,

Exit status of executed command.	Successful operation.
1	Command could not be executed at the specified priority.

ATTRIBUTES

DIAGNOSTICS

priocntl prints the following error messages:

Process(es) not found

None of the specified processes exists.

Specified processes from different classes

The `-s` option is being used to set parameters, the `-c class` option is not present, and processes from more than one class are specified.

Invalid option or argument

An unrecognized or invalid option or option argument is used.

NAME	proc, pflags, pcred, pmap, pldd, psig, pstack, pfiles, pwdx, pstop, prun, pwait, ptree, ptime – proc tools
SYNOPSIS	<pre> /usr/bin/pflags [-r] [pid core]... /usr/bin/pcred [pid core]... /usr/bin/pmap [-rxlF] [pid core]... /usr/bin/pldd [-F] [pid core]... /usr/bin/psig pid... /usr/bin/pstack [-F] [pid core]... /usr/bin/pfiles [-F] pid... /usr/bin/pwdx [-F] pid... /usr/bin/pstop pid... /usr/bin/prun pid... /usr/bin/pwait [-v] pid... /usr/bin/ptree [-a] [[pid user]...] /usr/bin/ptime command [arg...] </pre>
DESCRIPTION	<p>The proc tools are utilities that exercise features of /proc (see proc(4)). Most of them take a list of process-ids (<i>pid</i>); those that do also accept /proc/<i>nnn</i> as a process-id, so the shell expansion /proc/* can be used to specify all processes in the system. Some of the proc tools can also be applied to core files (see core(4)); those that do accept a list of either process ID s or names of core files or both.</p> <p><i>pflags</i> Print the /proc tracing flags, the pending and held signals, and other /proc status information for each lwp in each process.</p> <p><i>pcred</i> Print the credentials (effective, real, saved UIDs and GID s) of each process.</p> <p><i>pmap</i> Print the address space map of each process.</p> <p><i>pldd</i> List the dynamic libraries linked into each process, including shared objects explicitly attached using <i>dlopen(3DL)</i> . See also <i>ldd(1)</i> .</p> <p><i>psig</i> List the signal actions of each process. See <i>signal(3HEAD)</i> .</p> <p><i>pstack</i> Print a hex+symbolic stack trace for each lwp in each process.</p> <p><i>pfiles</i> Report <i>fstat(2)</i> and <i>fcntl(2)</i> information for all open files in each process.</p> <p><i>pwdx</i> Print the current working directory of each process.</p>

<code>pstop</code>	Stop each process (<code>PR_REQUESTED stop</code>).
<code>prun</code>	Set each process running (inverse of <code>pstop</code>).
<code>pwait</code>	Wait for all of the specified processes to terminate.
<code>ptree</code>	Print the process trees containing the specified <i>pid</i> s or <i>user</i> s, with child processes indented from their respective parent processes. An argument of all digits is taken to be a process-id, otherwise it is assumed to be a user login name. Default is all processes.
<code>ptime</code>	Time the <i>command</i> , like <code>time(1)</code> , but using microstate accounting for reproducible precision. Unlike <code>time(1)</code> , children of the command are not timed.

OPTIONS

The following options are supported:

- `-r` (`pflags` only) If the process is stopped, display its machine registers.
- `-r` (`pmap` only) Print the process's reserved addresses.
- `-x` (`pmap` only) Print resident/shared/private mapping details.
- `-l` (`pmap` only) Print unresolved dynamic linker map names.
- `-a` (`ptree` only) All; include children of process 0.
- `-v` (`pwait` only) Verbose; report terminations to standard output.
- `-F` Force; grab the target process even if another process has control.

USAGE

These `proc` tools stop their target processes while inspecting them and reporting the results: `pfiles`, `pldd`, `pmap`, and `pstack`. A process can do nothing while it is stopped. Thus, for example, if the X server is inspected by one of these `proc` tools running in a window under the X server's control, the whole window system can become deadlocked because the `proc` tool would be attempting to print its results to a window that cannot be refreshed. Logging in from another system using `rlogin(1)` and killing the offending `proc` tool would clear up the deadlock in this case.

Caution should be exercised when using the `-F` flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the `proc` tool in question.

Some of the `proc` tools can also be applied to core files, as shown by the synopsis above. A core file is a snapshot of a process's state and is produced by the kernel prior to terminating a process with a signal or by the `gcore(1)` utility. Some of the `proc` tools may need to derive the name of the executable corresponding

to the process which dumped core or the names of shared libraries associated with the process. These files are needed, for example, to provide symbol table information for `pstack(1)`. If the `proc` tool in question is unable to locate the needed executable or shared library, some symbol information will be unavailable for display. Similarly, if a core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) may not be able to initialize. In this case, symbol information for shared libraries will not be available.

EXIT STATUS

The following exit values are returned:

0 Successful operation.

non-zero An error has occurred.

FILES

`/proc/*` process files

`/usr/proc/lib/*` `proc` tools supporting files

NAME	prof - display profile data
SYNOPSIS	prof [-ChsVz] [-a c n t][-o x][-g l][-m <i>mdata</i>] [<i>prog</i>]
DESCRIPTION	The <code>prof</code> command interprets a profile file produced by the <code>monitor</code> function. The symbol table in the object file <i>prog</i> (<code>a.out</code> by default) is read and correlated with a profile file (<code>mon.out</code> by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.
OPTIONS	<p>The mutually exclusive options <code>-a</code>, <code>-c</code>, <code>-n</code>, and <code>-t</code> determine the type of sorting of the output lines:</p> <ul style="list-style-type: none"> <code>-a</code> Sort by increasing symbol address. <code>-c</code> Sort by decreasing number of calls. <code>-n</code> Sort lexically by symbol name. <code>-t</code> Sort by decreasing percentage of total time (default). <p>The mutually exclusive options <code>-o</code> and <code>-x</code> specify the printing of the address of each symbol monitored:</p> <ul style="list-style-type: none"> <code>-o</code> Print each symbol address (in octal) along with the symbol name. <code>-x</code> Print each symbol address (in hexadecimal) along with the symbol name. <p>The mutually exclusive options <code>-g</code> and <code>-l</code> control the type of symbols to be reported. The <code>-l</code> option must be used with care; it applies the time spent in a static function to the preceding (in memory) global function, instead of giving the static function a separate entry in the report. If all static functions are properly located, this feature can be very useful. If not, the resulting report may be misleading.</p> <p>Assume that <code>A</code> and <code>B</code> are global functions and only <code>A</code> calls static function <code>S</code>. If <code>S</code> is located immediately after <code>A</code> in the source code (that is, if <code>S</code> is properly located), then, with the <code>-l</code> option, the amount of time spent in <code>A</code> can easily be determined, including the time spent in <code>S</code>. If, however, both <code>A</code> and <code>B</code> call <code>S</code>, then, if the <code>-l</code> option is used, the report will be misleading; the time spent during <code>B</code>'s call to <code>S</code> will be attributed to <code>A</code>, making it appear as if more time had been spent in <code>A</code> than really had. In this case, function <code>S</code> cannot be properly located.</p> <ul style="list-style-type: none"> <code>-g</code> List the time spent in static (non-global) functions separately. The <code>-g</code> option function is the opposite of the <code>-l</code> function. <code>-l</code> Suppress printing statically declared functions. If this option is given, time spent executing in a static function is allocated to the closest global function loaded before the static function in the executable. This

option is the default. It is the opposite of the `-g` function and should be used with care.

The following options may be used in any combination:

- `-C` Demangle C++ symbol names before printing them out.
- `-h` Suppress the heading normally printed on the report. This is useful if the report is to be processed further.
- `-m mdata` Use file *mdata* instead of `mon.out` as the input profile file.
- `-s` Print a summary of several of the monitoring parameters and statistics on the standard error output.
- `-V` Print `prof` version information on the standard error output.
- `-z` Include all symbols in the profile range, even if associated with zero number of calls and zero time.

A program creates a profile file if it has been link edited with the `-p` option of `cc(1B)`. This option to the `cc(1B)` command arranges for calls to `monitor` at the beginning and end of execution. It is the call to `monitor` at the end of execution that causes the system to write a profile file. The number of calls to a function is tallied if the `-p` option was used when the file containing the function was compiled.

A single function may be split into subfunctions for profiling by means of the `MARK` macro. See `prof(5)`.

ENVIRONMENT VARIABLES

`PROFDIR` The name of the file created by a profiled program is controlled by the environment variable `PROFDIR`. If `PROFDIR` is not set, `mon.out` is produced in the directory current when the program terminates. If `PROFDIR=string`, `string/pid.progname` is produced, where *progname* consists of `argv[0]` with any path prefix removed, and *pid* is the process ID of the program. If `PROFDIR` is set, but null, no profiling output is produced.

FILES

`mon.out` default profile file
`a.out` default namelist (object) file

NOTES

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

Only programs that call `exit` or return from `main` are guaranteed to produce a profile file, unless a final call to `monitor` is explicitly coded.

The times for static functions are attributed to the preceding external text symbol if the `-g` option is not used. However, the call counts for the preceding function are still correct; that is, the static function call counts are not added to the call counts of the external function.

If more than one of the options `-t`, `-c`, `-a`, and `-n` is specified, the last option specified is used and the user is warned.

`LD_LIBRARY_PATH` must not contain `/usr/lib` as a component when compiling a program for profiling. If `LD_LIBRARY_PATH` contains `/usr/lib`, the program will not be linked correctly with the profiling versions of the system libraries in `/usr/lib/libp`. See `gprof(1)`.

Functions such as `mcount()`, `_mcount()`, `moncontrol()`, `_moncontrol()`, `monitor()`, and `_monitor()` may appear in the `prof` report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.

64-bit profiling

64-bit profiling may be used freely with dynamically linked executables, and profiling information is collected for the shared objects if the objects are compiled for profiling. Care must be applied to interpret the profile output, since it is possible for symbols from different shared objects to have the same name. If duplicate names are seen in the profile output, it is better to use the `-s` (summary) option, which prefixes a module id before each symbol that is duplicated. The symbols can then be mapped to appropriate modules by looking at the modules information in the summary.

If the `-a` option is used with a dynamically linked executable, the sorting occurs on a per-shared-object basis. Since there is a high likelihood of symbols from differed shared objects to have the same value, this results in an output that is more understandable. A blank line separates the symbols from different shared objects, if the `-s` option is given.

32-bit profiling

32-bit profiling may be used with dynamically linked executables, but care must be applied. In 32-bit profiling, shared objects cannot be profiled with `prof`. Thus, when a profiled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with `prof`. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the `/usr/lib/libp` directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some `libc` routine, say, `malloc()`. Suppose `malloc()` is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, `prof` will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

NAME	profiles – print execution profiles for a user
SYNOPSIS	profiles [-l] [<i>user</i> ...]
DESCRIPTION	<p>The <code>profiles</code> command prints on standard output the names of the execution profiles that have been assigned to you or to the optionally-specified user or role name. Profiles are a bundling mechanism used to enumerate the commands and authorizations needed to perform a specific function. Along with each listed executable are the process attributes, such as the effective user and group IDs, with which the process runs when started by a privileged command interpreter. The profile shells are <code>pf₀sh</code>, <code>pf₁sh</code>, and <code>pf₂exec</code>. See the <code>pf₂exec(1)</code> man page.</p> <p>Multiple profiles can be combined to construct the appropriate access control. When profiles are assigned, the authorizations are added to the existing set. If the same command appears in multiple profiles, the first occurrence, as determined by the ordering of the profiles, is used for process-attribute settings. For convenience, a wild card can be specified to match all commands.</p> <p>When profiles are interpreted, the profile list is loaded from <code>user_attr(4)</code>. Matching entries in <code>prof_attr(4)</code> provide the authorizations list, and matching entries in <code>exec_attr(4)</code> provide the commands list.</p>
OPTIONS	<p>-l Lists the commands in each profile followed by the special process attributes such as user and group IDs.</p>
EXAMPLES	<p>EXAMPLE 1 Sample output</p> <p>The output of the <code>profiles</code> command has the following form:</p> <pre>example% profiles tester01 tester02 tester01 : Audit Management, All Commands tester02 : Device Management, All Commands example%</pre> <p>EXAMPLE 2 Using the list option</p> <pre>example% profiles -l tester01 tester02 tester01 : Audit Management: /usr/sbin/audit euid=root /usr/sbin/auditconfig euid=root egid=sys All Commands: * tester02 : Device Management: /usr/bin/allocate: euid=root /usr/bin/deallocate: euid=root All Commands * example%</pre>

EXIT STATUS

The following exit values are returned:

0 Successful completion.

1 An error occurred.

FILES

/etc/security/exec_attr

/etc/security/prof_attr

/etc/user_attr

ATTRIBUTES

NAME	ps - report process status
SYNOPSIS	ps [-aAcdefjllPy] [-g <i>grplist</i>] [-n <i>namelist</i>] [-o <i>format</i>] ... [-p <i>proclist</i>] [-s <i>sidlist</i>] [-t <i>term</i>] [-u <i>uidlist</i>] [-U <i>uidlist</i>] [-G <i>gidlist</i>]
DESCRIPTION	<p>The <code>ps</code> command prints information about active processes. Without options, <code>ps</code> prints information about processes that have the same effective user ID and the same controlling terminal as the invoker. The output contains only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the options.</p> <p>Some options accept lists as arguments. Items in a list can be either separated by commas or else enclosed in quotes and separated by commas or spaces. Values for <i>proclist</i> and <i>grplist</i> must be numeric.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a List information about all processes most frequently requested: all those except process group leaders and processes not associated with a terminal. -A List information for all processes. Identical to -e, below. -c Print information in a format that reflects scheduler properties as described in <code>pricntl(1)</code>. The -c option affects the output of the -f and -l options, as described below. -d List information about all processes except session leaders. -e List information about every process now running. -f Generate a full listing. (See below for significance of columns in a full listing.) -g <i>grplist</i> List only process data whose group leader's ID number(s) appears in <i>grplist</i>. (A group leader is a process whose process ID number is identical to its process group ID number.) -G <i>gidlist</i> List information for processes whose real group ID numbers are given in <i>gidlist</i>. The <i>gidlist</i> must be a single argument in the form of a blank- or comma-separated list. -j Print session ID and process group ID. -l Generate a long listing. (See below.) -L Print information about each light weight process (<i>lwp</i>) in each selected process. (See below.)

- `-n namelist` Specify the name of an alternative system *namelist* file in place of the default. This option is accepted for compatibility, but is ignored.
- `-o format` Print information according to the format specification given in *format*. This is fully described in DISPLAY FORMATS. Multiple `-o` options can be specified; the format specification will be interpreted as the space-character-separated concatenation of all the *format* option-arguments.
- `-p proclist` List only process data whose process ID numbers are given in *proclist*.
- `-P` Print the number of the processor to which the process or lwp is bound, if any, under an additional column header, *PSR*.
- `-s sidlist` List information on all session leaders whose IDs appear in *sidlist*.
- `-t term` List only process data associated with *term*. Terminal identifiers are specified as a device file name, and an identifier. For example, `term/a`, or `pts/0`.
- `-u uidlist` List only process data whose effective user ID number or login name is given in *uidlist*. In the listing, the numerical user ID will be printed unless you give the `-f` option, which prints the login name.
- `-U uidlist` List information for processes whose real user ID numbers or login names are given in *uidlist*. The *uidlist* must be a single argument in the form of a blank- or comma-separated list.
- `-y` Under a long listing (`-l`), omit the obsolete *F* and *ADDR* columns and include an *RSS* column to report the resident set size of the process. Under the `-y` option, both *RSS* and *SZ* (see below) will be reported in units of kilobytes instead of pages.

Many of the options shown are used to select processes to list. If any are specified, the default list will be ignored and `ps` will select the processes represented by the inclusive OR of all the selection-criteria options.

DISPLAY FORMATS

Under the `-f` option, `ps` tries to determine the command name and arguments given when the process was created by examining the user block. Failing this, the command name is printed, as it would have appeared without the `-f` option, in square brackets.

The column headings and the meaning of the columns in a `ps` listing are given below; the letters `f` and `l` indicate the option `full` or `long`, respectively) that causes the corresponding heading to appear; `all` means that the heading always appears. Note: These two options determine only what information is provided for a process; they do not determine which processes will be listed.

<code>F (l)</code>	Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.
<code>S (l)</code>	The state of the process: <ul style="list-style-type: none"> <code>O</code> Process is running on a processor. <code>S</code> Sleeping: process is waiting for an event to complete. <code>R</code> Runnable: process is on run queue. <code>Z</code> Zombie state: process terminated and parent not waiting. <code>T</code> Process is stopped, either by a job control signal or because it is being traced.
<code>UID (f,l)</code>	The effective user ID number of the process (the login name is printed under the <code>-f</code> option).
<code>PID (all)</code>	The process ID of the process (this datum is necessary in order to kill a process).
<code>PPID (f,l)</code>	The process ID of the parent process.
<code>C (f,l)</code>	Processor utilization for scheduling (obsolete). Not printed when the <code>-c</code> option is used.
<code>CLS (f,l)</code>	Scheduling class. Printed only when the <code>-c</code> option is used.
<code>PRI (l)</code>	The priority of the process. Without the <code>-c</code> option, higher numbers mean lower priority. With the <code>-c</code> option, higher numbers mean higher priority.
<code>NI (l)</code>	Nice value, used in priority computation. Not printed when the <code>-c</code> option is used. Only processes in the certain scheduling classes have a nice value.
<code>ADDR (l)</code>	The memory address of the process.
<code>SZ (l)</code>	The total size of the process in virtual memory, including all mapped files and devices, in pages. See <code>pagesize(1)</code> .

WCHAN (l)	The address of an event for which the process is sleeping (if blank, the process is running).
STIME (f)	The starting time of the process, given in hours, minutes, and seconds. (A process begun more than twenty-four hours before the <code>ps</code> inquiry is executed is given in months and days.)
TTY (all)	The controlling terminal for the process (the message, <code>?</code> , is printed when there is no controlling terminal).
TIME (all)	The cumulative execution time for the process.
CMD (all)	The command name (the full command name and its arguments, up to a limit of 80 characters, are printed under the <code>-f</code> option).

The following two additional columns are printed when the `-j` option is specified:

PGID	The process ID of the process group leader.
SID	The process ID of the session leader.

The following two additional columns are printed when the `-L` option is specified:

LWP	The lwp ID of the lwp being reported.
NLWP	The number of lwps in the process (if <code>-f</code> is also specified).

Under the `-L` option, one line is printed for each lwp in the process and the time-reporting fields `STIME` and `TIME` show the values for the lwp, not the process. A traditional single-threaded process contains only one lwp.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked `<defunct>`.

`-o format`

The `-o` option allows the output format to be specified under user control.

The format specification must be a list of names presented as a single argument, blank- or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument will be used as the header text. The fields specified will be written in the order specified on the command line, and should be arranged in columns in the output. The field widths will be selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as `-o user=`, the field width will be at least as wide as the default header text. If all header text fields are null, no header line will be written.

The following names are recognized in the POSIX locale:

<code>user</code>	The effective user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>ruser</code>	The real user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>group</code>	The effective group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>rgroup</code>	The real group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
<code>pid</code>	The decimal value of the process ID.
<code>ppid</code>	The decimal value of the parent process ID.
<code>pgid</code>	The decimal value of the process group ID.
<code>pcpu</code>	The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of “recently” in this context is unspecified. The CPU time available is determined in an unspecified manner.
<code>vsz</code>	The total size of the process in virtual memory, in kilobytes.
<code>nice</code>	The decimal value of the system scheduling priority of the process. See <code>nice(1)</code> .
<code>etime</code>	In the POSIX locale, the elapsed time since the process was started, in the form: <code>[[dd-] hh:] mm:ss</code> where <code>dd</code> is the number of days <code>hh</code> is the number of hours <code>mm</code> is the number of minutes <code>ss</code> is the number of seconds The <code>dd</code> field will be a decimal integer. The <code>hh</code> , <code>mm</code> and <code>ss</code> fields will be two-digit decimal integers padded on the left with zeros.

<code>time</code>	In the POSIX locale, the cumulative CPU time of the process in the form: [<i>dd-</i>] <i>hh:mm:ss</i> The <i>dd</i> , <i>hh</i> , <i>mm</i> , and <i>ss</i> fields will be as described in the <code>etime</code> specifier.
<code>tty</code>	The name of the controlling terminal of the process (if any) in the same format used by the <code>who(1)</code> command.
<code>comm</code>	The name of the command being executed (<code>argv[0]</code> value) as a string.
<code>args</code>	The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-dependent whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of <code>ps</code> . The Solaris implementation limits the string to 80 bytes; the string is the version of the argument list as it was passed to the command when it started.

The following names are recognized in the Solaris implementation:

<code>f</code>	Flags (hexadecimal and additive) associated with the process.
<code>s</code>	The state of the process.
<code>c</code>	Processor utilization for scheduling (obsolete).
<code>uid</code>	The effective user ID number of the process as a decimal integer.
<code>ruid</code>	The real user ID number of the process as a decimal integer.
<code>gid</code>	The effective group ID number of the process as a decimal integer.
<code>rgid</code>	The real group ID number of the process as a decimal integer.
<code>sid</code>	The process ID of the session leader.
<code>class</code>	The scheduling class of the process.
<code>pri</code>	The priority of the process. Higher numbers mean higher priority.
<code>opri</code>	The obsolete priority of the process. Lower numbers mean higher priority.

<code>lwp</code>	The decimal value of the lwp ID. Requesting this formatting option causes one line to be printed for each lwp in the process.
<code>nlwp</code>	The number of lwps in the process.
<code>psr</code>	The number of the processor to which the process or lwp is bound.
<code>addr</code>	The memory address of the process.
<code>osz</code>	The total size of the process in virtual memory, in pages.
<code>wchan</code>	The address of an event for which the process is sleeping (if <code>-</code> , the process is running).
<code>stime</code>	The starting time or date of the process, printed with no blanks.
<code>rss</code>	The resident set size of the process, in kilobytes.
<code>pmem</code>	The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.
<code>fname</code>	The first 8 bytes of the base name of the process's executable file.

Only `comm` and `args` are allowed to contain blank characters; all others, including the Solaris implementation variables, are not.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

Format Specifier	Default Header	Format Specifier	Default Header
<code>args</code>	COMMAND	<code>ppid</code>	PPID
<code>comm</code>	COMMAND	<code>rgroup</code>	RGROUP
<code>etime</code>	ELAPSED	<code>ruser</code>	RUSER
<code>group</code>	GROUP	<code>time</code>	TIME
<code>nice</code>	NI	<code>tty</code>	TT
<code>pcpu</code>	%CPU	<code>user</code>	USER
<code>pgid</code>	PGID	<code>vsz</code>	VSZ
<code>pid</code>	PID		

The following table lists the Solaris implementation format specifiers and the default header used with each.

Format Specifier	Default Header	Format Specifier	Default Header
addr	ADDR	pri	PRI
c	C	psr	PSR
class	CLS	rgid	RGID
f	F	rss	RSS
fname	COMMAND	ruid	RUID
gid	GID	s	S
lwp	LWP	sid	SID
nlwp	NLWP	stime	STIME
opri	PRI	uid	UID
osz	SZ	wchan	WCHAN
pmem	%MEM		

EXAMPLES

EXAMPLE 1 An example of the `ps` command.

The command:

```
example% ps -o user,pid,ppid=MOM -o args
```

writes the following in the POSIX locale:

```

USER  PID  MOM  COMMAND
helene 34   12  ps -o uid,pid,ppid=MOM -o args

```

The contents of the `COMMAND` field need not be the same due to possible truncation.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ps`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

COLUMNS Override the system-selected horizontal screen size, used to determine the number of text columns to display.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

`/dev/pts/*`

`/dev/term/*` terminal (“tty”) names searcher files

`/etc/passwd` UID information supplier

/proc/* process control files
 /tmp/ps_data internal data structure

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled (see NOTES)

SEE ALSO

`kill(1)`, `nice(1)`, `pagesize(1)`, `pgrep(1)`, `priocntl(1)`, `who(1)`, `getty(1M)`, `proc(4)`, `ttysrch(4)`, `attributes(5)`, `environ(5)`

NOTES

Things can change while `ps` is running; the snap-shot it gives is true only for a split-second, and it may not be accurate by the time you see it. Some data printed for defunct processes is irrelevant.

If no options to select processes are specified, `ps` will report all processes associated with the controlling terminal. If there is no controlling terminal, there will be no report other than the header.

`ps -ef` or `ps -o stime` may not report the actual start of a tty login session, but rather an earlier time, when a `getty` was last respawned on the tty line.

`ps` is CSI-enabled except for login names (usernames).

NAME	ps – display the status of current processes
SYNOPSIS	<code>/usr/ucb/ps [-aceglnrSuUvwx] [-t term] [num]</code>
DESCRIPTION	<p>The <code>ps</code> command displays information about processes. Normally, only those processes that are running with your effective user ID and are attached to a controlling terminal (see <code>termio(7I)</code>) are shown. Additional categories of processes can be added to the display using various options. In particular, the <code>-a</code> option allows you to include processes that are not owned by you (that do not have your user ID), and the <code>-x</code> option allows you to include processes without controlling terminals. When you specify both <code>-a</code> and <code>-x</code>, you get processes owned by anyone, with or without a controlling terminal. The <code>-r</code> option restricts the list of processes printed to running and runnable processes.</p> <p><code>ps</code> displays in tabular form the process ID, under <code>PID</code>; the controlling terminal (if any), under <code>TT</code>; the cpu time used by the process so far, including both user and system time, under <code>TIME</code>; the state of the process, under <code>S</code>; and finally, an indication of the <code>COMMAND</code> that is running.</p> <p>The state is given by a single letter from the following:</p> <ul style="list-style-type: none"> O Process is running on a processor. S Sleeping. Process is waiting for an event to complete. R Runnable. Process is on run queue. Z Zombie state. Process terminated and parent not waiting. T Traced. Process stopped by a signal because parent is tracing it.
OPTIONS	<p>The following options must all be combined to form the first argument:</p> <ul style="list-style-type: none"> <code>-a</code> Include information about processes owned by others. <code>-c</code> Display the command name rather than the command arguments. <code>-e</code> Display the environment as well as the arguments to the command. <code>-g</code> Display all processes. Without this option, <code>ps</code> only prints interesting processes. Processes are deemed to be uninteresting if they are process group leaders. This normally eliminates top-level command interpreters and processes waiting for users to login on free terminals. <code>-l</code> Display a long listing, with fields <code>F</code>, <code>PPID</code>, <code>CP</code>, <code>PRI</code>, <code>NI</code>, <code>SZ</code>, <code>RSS</code> and <code>WCHAN</code> as described below. <code>-n</code> Produce numerical output for some fields. In a user listing, the <code>USER</code> field is replaced by a <code>UID</code> field. <code>-r</code> Restrict output to running and runnable processes.

- S Display accumulated CPU time used by this process and all of its reaped children.
- u Display user-oriented output. This includes fields `USER`, `%CPU`, `%MEM`, `SZ`, `RSS` and `START` as described below.
- U Update a private database where `ps` keeps system information.
- v Display a version of the output containing virtual memory. This includes fields `SIZE`, `%CPU`, `%MEM`, and `RSS`, described below.
- w Use a wide output format (132 columns rather than 80); if repeated, that is, `-ww`, use arbitrarily wide output. This information is used to decide how much of long commands to print.
- x Include processes with no controlling terminal.
- t List only process data associated with the terminal, *term*. Terminal identifiers may be specified in one of two forms: the device's file name (for example, `tty04` or `term/14`) or, if the device's file name starts with `tty`, just the digit identifier (for example, `04`).
- num* A process number may be given, in which case the output is restricted to that process. This option must be supplied last.

DISPLAY FORMATS

Fields that are not common to all output formats:

<code>USER</code>	Name of the owner of the process.
<code>%CPU</code>	CPU use of the process; this is a decaying average over up to a minute of previous (real) time.
<code>NI</code>	Process scheduling increment (see <code>getpriority(3C)</code> and <code>nice(3UCB)</code>).
<code>SIZE</code>	The total size of the process in virtual memory, including all mapped files and devices, in kilobyte units.
<code>SZ</code>	Same as <code>SIZE</code> .
<code>RSS</code>	Real memory (resident set) size of the process, in kilobyte units.
<code>UID</code>	Numerical user-ID of process owner.
<code>PPID</code>	Numerical ID of parent of process.
<code>CP</code>	Short-term CPU utilization factor (used in scheduling).
<code>PRI</code>	The priority of the process (higher numbers mean lower priority).

START The starting time of the process, given in hours, minutes, and seconds. A process begun more than 24 hours before the `ps` inquiry is executed is given in months and days.

WCHAN The address of an event for which the process is sleeping (if blank, the process is running).

%MEM The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.

F Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.

A process that has exited and has a parent, but has not yet been waited for by the parent is marked `<defunct>`; otherwise, `ps` tries to determine the command name and arguments given when the process was created by examining the user block.

FILES

`/dev`
`/dev/kmem` kernel virtual memory
`/dev/mem` memory
`/dev/swap` default swap device
`/dev/sxt/*`
`/dev/tty*`
`/dev/xt/*` terminal (`tty`) names searcher files
`/etc/passwd` UID information supplier
`/etc/ps_data` internal data structure

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NOTES

Things can change while `ps` is running; the picture it gives is only a close approximation to the current state. Some data printed for `defunct` processes is irrelevant.

NAME	pvs – display the internal version information of dynamic objects
SYNOPSIS	pvs [-dlnorsv] [-N <i>name</i>] <i>file</i> ...
DESCRIPTION	<p>pvs displays any internal version information contained within an ELF file. Commonly these files are dynamic executables and shared objects, and possibly relocatable objects. This version information can fall into one of two categories:</p> <ul style="list-style-type: none"> ■ version definitions ■ version dependencies <p>Version <i>definitions</i> describe the interfaces made available by an ELF file. Each version definition is associated to a set of global symbols provided by the file. Version definitions may be assigned to a file during its creation by the link-editor using the -M option and the associated <i>mapfile</i> directives (see the <i>Linker and Libraries Guide</i> for more details).</p> <p>Version <i>dependencies</i> describe the binding requirements of dynamic objects on the version definitions of any shared object dependencies. When a dynamic object is built with a shared object, the link-editor records information within the dynamic object indicating that the shared object is a dependency. This dependency must be satisfied at runtime. If the shared object also contains version <i>definitions</i>, then those version definitions that satisfy the global symbol requirements of the dynamic object will also be recorded in the dynamic object being created. At process initialization, the runtime linker will use any version <i>dependencies</i> as a means of validating the interface requirements of the dynamic objects used to construct the process.</p>
OPTIONS	<p>The following options are supported. If neither the -d or -r options are specified, both will be enabled.</p> <ul style="list-style-type: none"> -d Print version definition information. -l When used with the -s option, print any symbols that have been reduced from global to local binding due to versioning. By convention, these symbol entries are located in the <i>.symtab</i> section, and fall between the <i>FILE</i> symbol representing the output file, and the <i>FILE</i> symbol representing the first input file used to generate the output file. These reduced symbol entries are assigned the fabricated version definition <i>_REDUCED_</i>. No reduced symbols will be printed if the file has been stripped (see <i>strip(1)</i>), or if the symbol entry convention cannot be determined. -n Normalize version definition information. By default, all version definitions within the object are displayed. However, version definitions may inherit other version definitions, and under normalization only the head of each inheritance list is displayed.

- o Create one-line version definition output. By default, file, version definitions, and any symbol output is indented to ease human inspection. This option prefixes each output line with the file and version definition name and may be more useful for analysis with automated tools.
- r Print version dependency (requirements) information.
- s Print the symbols associated with each version definition. Any data symbols are accompanied with the size, in bytes, of the data item.
- v Verbose output. Indicates any weak version definitions, and any version definition inheritance. When used with the `-N` and `-d` options, the inheritance of the base version definition is also shown. When used with the `-s` option, the version symbol definition is also shown.
- `-Nname` Print only the information for the given version definition *name* and any of its inherited version definitions (when used with the `-d` option), or for the given dependency file *name* (when used with the `-r` option).

OPERANDS

The following operands are supported.

`file` The ELF file about which internal version information is displayed.

EXAMPLES

EXAMPLE 1 Examples of `pvs`.

The following example displays the version definitions of `libelf.so.1`:

```
% pvs -d /usr/lib/libelf.so.1
libelf.so.1;
SUNW_1.1
```

A normalized, one-liner display, suitable for creating a *mapfile* version control directive, can be created using the `-n` and `-o` options:

```
% pvs -don /usr/lib/libelf.so.1
/usr/lib/libelf.so.1 - SUNW_1.1;
```

The following example displays the version requirements of `ldd` and `pvs`:

```
% pvs -r /usr/bin/ldd /usr/bin/pvs
/usr/bin/ldd:
libelf.so.1 (SUNW_1.1);
libc.so.1 (SUNW_1.1);
/usr/bin/pvs:
libelf.so.1 (SUNW_1.1);
libc.so.1 (SUNW_1.1);
```

EXIT STATUS

If the requested version information is not found, a non-zero value is returned; otherwise a 0 value is returned.

Version information is determined not found when any of the following is true:

- the `-d` option is specified and no version definitions are found;
- the `-r` option is specified and no version requirements are found;
- neither the `-d` nor `-r` option is specified and no version definitions or version requirements are found.

NAME	pwd – return working directory name						
SYNOPSIS	/usr/bin/pwd						
DESCRIPTION	<p>pwd writes an absolute path name of the current working directory to standard output.</p> <p>Both the Bourne shell, sh(1), and the Korn shell, ksh(1), also have a built-in pwd command.</p>						
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of pwd: LC_MESSAGES and NLSPATH.						
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p> <p>If an error is detected, output will not be written to standard output, a diagnostic message will be written to standard error, and the exit status will not be 0.</p>						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	CSI	enabled
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu						
CSI	enabled						
SEE ALSO	cd(1), ksh(1), sh(1), shell_builtins(1), attributes(5), environ(5)						
DIAGNOSTICS	“Cannot open ..” and “Read error in ..” indicate possible file system trouble and should be referred to a UNIX system administrator.						
NOTES	If you move the current directory or one above it, pwd may not give the correct response. Use the cd(1) command with a full path name to correct this situation.						

NAME ranlib – convert archives to random libraries

SYNOPSIS `/usr/ccs/bin/ranlib archive`

DESCRIPTION ranlib was used in SunOS 4.x to add a table of contents to archive libraries, which converted each archive to a form that could be linked more rapidly. This is no longer needed as the ar(1) command automatically provides all the functionality ranlib used to provide.

This script is provided as a convenience for software developers who need to maintain Makefiles that are portable across a variety of operating systems.

EXIT STATUS ranlib has exit status 0.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NAME	rcp – remote file copy
SYNOPSIS	rcp [-p] <i>filename1 filename2</i> rcp [-pr] <i>filename... directory</i>
DESCRIPTION	<p>The rcp command copies files between machines. Each <i>filename</i> or <i>directory</i> argument is either a remote file name of the form:</p> <p style="padding-left: 2em;"><i>hostname: path</i></p> <p>or a local file name (containing no ":" (colon) characters, or "/" (backslash) before any ":" (colon) characters).</p> <p>The <i>hostname</i> can be an IPv4 or IPv6 address string. See <i>inet(7P)</i> and <i>inet6(7P)</i>. Since IPv6 addresses already contain colons, the <i>hostname</i> should be enclosed in a pair of square brackets. when an IPv6 address is used. Otherwise the first occurrence of a colon can be interpreted as the separator between <i>hostname</i> and <i>path</i>. For example,</p> <p style="padding-left: 2em;">[1080::8:800:200C:417A]:tmp/file</p> <p>If a <i>filename</i> is not a full path name, it is interpreted relative to your home directory on <i>hostname</i>. A <i>path</i> on a remote host may be quoted using \, " , or ' , so that the metacharacters are interpreted remotely.</p> <p>rcp does not prompt for passwords; your current local user name must exist on <i>hostname</i> and allow remote command execution by <i>rsh(1)</i>.</p> <p>rcp handles third party copies, where neither source nor target files are on the current machine. Hostnames may also take the form</p> <p style="padding-left: 2em;"><i>username@hostname: filename</i></p> <p>to use <i>username</i> rather than your current local user name as the user name on the remote host. rcp also supports Internet domain addressing of the remote host, so that:</p> <p style="padding-left: 2em;"><i>username@host . domain: filename</i></p> <p>specifies the username to be used, the hostname, and the domain in which that host resides. File names that are not full path names will be interpreted relative to the home directory of the user named <i>username</i>, on the remote host.</p>

OPTIONS

- p Attempt to give each copy the same modification times, access times, modes, and ACLs if applicable as the original file.
- r Copy each subtree rooted at *filename*; in this case the destination must be a directory.

USAGE

See [largefile\(5\)](#) for the description of the behavior of `rcp` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

The `rcp` command is IPv6-enabled. See [ip6\(7P\)](#).

FILES

`$HOME/.profile`

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

SEE ALSO

[cpio\(1\)](#), [ftp\(1\)](#), [rlogin\(1\)](#), [rsh\(1\)](#), [setfacl\(1\)](#), [tar\(1\)](#), [hosts.equiv\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [inet\(7P\)](#), [inet6\(7P\)](#), [ip6\(7P\)](#)

NOTES

`rcp` is meant to copy between different hosts; attempting to `rcp` a file onto itself, as with:

```
example% rcp tmp/file myhost:/tmp/file
```

results in a severely corrupted file.

`rcp` may not correctly fail when the target of a copy is a file instead of a directory.

`rcp` can become confused by output generated by commands in a `$HOME/.profile` on the remote host.

`rcp` requires that the source host have permission to execute commands on the remote host when doing third-party copies.

`rcp` does not properly handle symbolic links. Use `tar` or `cpio` piped to `rsh` to obtain remote copies of directories containing symbolic links or named pipes. See [tar\(1\)](#) and [cpio\(1\)](#)

If you forget to quote metacharacters intended for the remote host, you will get an incomprehensible error message.

`rcp` will fail if you copy ACLs to a file system that does not support ACLs.

`rcp` is CSI-enabled except for the handling of username, hostname, and domain.

NAME rdist – remote file distribution program

SYNOPSIS **rdist** [-b] [-D] [-h] [-i] [-n] [-q] [-R] [-v] [-w] [-y] [-d *macro = value*]
 [-f *distfile*] [-m *host*] ...
rdist [-b] [-D] [-h] [-i] [-n] [-q] [-R] [-v] [-w] [-y] -c *pathname...* [*login @*]
hostname [: *destpath*]

DESCRIPTION The `rdist` utility maintains copies of files on multiple hosts. It preserves the owner, group, mode, and modification time of the master copies, and can update programs that are executing. (Note: `rdist` does not propagate ownership or mode changes when the file contents have not changed.) Normally, a copy on a remote host is updated if its size or modification time differs from the original on the local host.

There are two forms of the `rdist` command. In the first form shown in the SYNOPSIS section above, `rdist` reads the indicated *distfile* for instructions on updating files and/or directories. If *distfile* is '-', the standard input is used. If no -f option is present, `rdist` first looks in its working directory for *distfile*, and then for `Distfile`, for instructions.

The second form shown in SYNOPSIS uses the -c option and specifies paths as command line options.

In order to be able to use `rdist` across machines, each host machine must have a `/etc/host.equiv` file, or the user must have an entry in the `.rhosts` file in the home directory. See `hosts.equiv(4)` for more information.

OPTIONS The following options are supported:

-b	Binary comparison. Performs a binary comparison and updates files if they differ, rather than merely comparing dates and sizes.
-D	Enables debugging.
-h	Follows symbolic links. Copies the file that the link points to rather than the link itself.
-i	Ignores unresolved links. <code>rdist</code> will normally try to maintain the link structure of files being transferred and warn the user if all the links cannot be found.

-n	Prints the commands without executing them. This option is useful for debugging a distfile.
-q	Quiet mode. Does not display the files being updated on the standard output.
-R	Removes extraneous files. If a directory is being updated, removes files on the remote host that do not correspond to those in the master (local) directory. This is useful for maintaining truly identical copies of directories.
-v	Verifies that the files are up to date on all the hosts. Any files that are out of date are displayed, but no files are updated, nor is any mail sent.
-w	Whole mode. The whole file name is appended to the destination directory name. Normally, only the last component of a name is used when renaming files. This preserves the directory structure of the files being copied, instead of flattening the directory structure. For instance, renaming a list of files such as dir1/dir2 to dir3 would create files dir3/dir1 and dir3/dir2 instead of dir3 and dir3. When the -w option is used with a filename that begins with ~, everything except the home directory is appended to the destination name.
-Y	Younger mode. Does not update remote copies that are

	younger than the master copy, but issues a warning message instead.
<code>-d macro=value</code>	Defines <i>macro</i> to have <i>value</i> . This option is used to define or override macro definitions in the distfile. <i>value</i> can be the empty string, one name, or a list of names surrounded by parentheses and separated by white space.
<code>-c pathname ... [login@]hostname[: destpath]</code>	Copies each <i>pathname</i> to the named host; if <i>destpath</i> is specified, it will not update any <i>pathname</i> on the named host. (Relative filenames are taken as relative to your home directory.) If the ' <i>login@</i> ' prefix is given, the update is performed with the user ID of <i>login</i> . If the ' <i>: destpath</i> ' is given, the remote file is installed as that <i>pathname</i> .
<code>-f distfile</code>	Uses the description file <i>distfile</i> . A '-' as the <i>distfile</i> argument denotes the standard input.
<code>-m host</code>	Limits which machines are to be updated. Multiple <code>-m</code> arguments can be given to limit updates to a subset of the hosts listed in the distfile.

USAGE**White Space Characters**

NEWLINE, TAB, and SPACE characters are all treated as white space; a mapping continues across input lines until the start of the next mapping: either a single *filename* followed by a '->' or the opening parenthesis of a filename list.

Comments

Comments begin with # and end with a NEWLINE.

Distfiles

The distfile contains a sequence of entries that specify the files to be copied, the destination files to be copied, the destination hosts, and what operations to perform to do the updating. Each entry has one of the following formats:

```

variable_name '=' name_list
[ label: ] source_list '->' destination_list command_list
[ label: ] source_list '::' time_stamp_file command_list

```

The first format is used for defining variables. The second format is used for distributing files to other hosts. The third format is used for making lists of files that have been changed since some given date. The source list specifies a list of files and/or directories on the local host that are to be used as the master copy for distribution. The destination list is the list of hosts to which these files are to be copied. Each file in the source list is added to a list of changes if the file is out of date on the host that is being updated (second format) or if the file is newer than the time stamp file (third format). Labels are optional. They are used to identify a command for partial updates. The colon (:) is used after an optional label, while the double colon (::) is used for making lists of files that have been changed since a certain date (specified by the date/time of the *time_stamp* file). Typically, only `notify` is used with the '::<' format of the command line.

Macros

`rdist` has a limited macro facility. Macros are only expanded in filename or hostname lists, and in the argument lists of certain primitives. Macros cannot be used to stand for primitives or their options, or the '->' or '::<' symbols.

A macro definition is a line of the form:

```
macro = value
```

A macro reference is a string of the form:

```
$(macro)
```

although (as with `make(1S)`) the braces can be omitted if the macro name consists of just one character.

Metacharacters

The shell meta-characters: [,], {, }, *, and ? are recognized and expanded (on the local host only) just as they are with `cs(1)`. Metacharacters can be escaped by prepending a backslash.

The ~ character is also expanded in the same way as with `cs`; however, it is expanded separately on the local and destination hosts.

Filenames

File names that do not begin with '/' or '~' are taken to be relative to user's home directory on each destination host; they are *not* relative to the current working directory. Multiple file names must be enclosed within parentheses.

Primitives

The following primitives can be used to specify actions `rdist` is to take when updating remote copies of each file.

```
install [-b] [-h] [-i] [-R] [-v] [-w] [-y] [newname]
```

Copy out of date files and directories (recursively). If no *newname* operand is given, the name of the local file is given to the remote host's copy. If absent from the remote host, parent directories in a filename's path are created. To help prevent disasters, a non-empty directory on a target host is not replaced with a regular file or a symbolic link by *rdist*. However, when using the *-R* option, a non-empty directory is removed if the corresponding filename is completely absent on the master host.

The options for *install* have the same semantics as their command line counterparts, but are limited in scope to a particular map. The login name used on the destination host is the same as the local host unless the destination name is of the format *login@host*. In that case, the update is performed under the username *login*.

notify address ...

Send mail to the indicated email *address* of the form:

user@host

that lists the files updated and any errors that may have occurred. If an address does not contain a '@*host*' suffix, *rdist* uses the name of the destination host to complete the address.

except filename ...

Omit from updates the files named as arguments.

except_pat pattern ...

Omit from updates the filenames that match each regular-expression *pattern* (see *ed(1)* for more information on regular expressions). Note that '\ ' and '\$' characters must be escaped in the distfile. Shell variables can also be used within a pattern, however shell filename expansion is not supported.

special [filename] ... "command-line "

Specify a Bourne shell, *sh(1)* command line to execute on the remote host after each named file is updated. If no *filename* argument is present, the *command-line* is performed for every updated file, with the shell variable *FILE* set to the file's name on the local host. The quotation marks allow *command-line* to span input lines in the distfile; multiple shell commands must be separated by semicolons (;).

The default working directory for the shell executing each *command-line* is the user's home directory on the remote host.

IPv6

The *ftp* command is IPv6-enabled. See *ip6(7P)*.

EXAMPLES

EXAMPLE 1 A sample distfile

The following sample distfile instructs `rdist` to maintain identical copies of a shared library, a shared-library initialized data file, several include files, and a directory, on hosts named `hermes` and `magus`. On `magus`, commands are executed as super-user. `rdist` notifies `merlin@druid` whenever it discovers that a local file has changed relative to a timestamp file. (Parentheses are used when the source or destination list contains zero or more names separated by white-space.)

```
HOSTS = ( hermes root@magus )

FILES = ( /usr/local/lib/libcant.so.1.1
          /usrlocal/lib/libcant.sa.1.1 /usr/local/include/{*.h}
          /usr/local/bin )

({FILES}) -> ({HOSTS})
install -R ;
${FILES} :: /usr/local/lib/timestamp
notify merlin@druid ;
```

FILES

- ~/.rhosts user's trusted hosts and users
- /etc/host.equiv system trusted hosts and users
- /tmp/rdist* temporary file for update lists

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`cs(1)`, `ed(1)`, `make(1S)`, `sh(1)`, `stat(2)`, `hosts.equiv(4)`, `attributes(5)`, `ip6(7P)`

DIAGNOSTICS

A complaint about mismatch of `rdist` version numbers may really stem from some problem with starting your shell, for example, you are in too many groups.

WARNINGS

The super-user does not have its accustomed access privileges on NFS mounted file systems. Using `rdist` to copy to such a file system may fail, or the copies may be owned by user "nobody".

BUGS

Source files must reside or be mounted on the local host.

There is no easy way to have a special command executed only once after all files in a directory have been updated.

Variable expansion only works for name lists; there should be a general macro facility.

`rdist` aborts on files that have a negative modification time (before Jan 1, 1970). There should be a “force” option to allow replacement of non-empty directories by regular files or symlinks. A means of updating file modes and owners of otherwise identical files is also needed.

NAME	read – read a line from standard input
SYNOPSIS	<code>/usr/bin/read [-r] var...</code>
sh	<code>read name...</code>
csh	<code>set variable = \$<</code>
ksh	<code>read [-prs] [n] [name ? prompt] [name...]</code>
DESCRIPTION	<p>The <code>read</code> utility will read a single line from standard input.</p> <p>By default, unless the <code>-r</code> option is specified, backslash (<code>\</code>) acts as an escape character. If standard input is a terminal device and the invoking shell is interactive, <code>read</code> will prompt for a continuation line when:</p> <ul style="list-style-type: none"> ■ The shell reads an input line ending with a backslash, unless the <code>-r</code> option is specified. ■ A here-document is not terminated after a newline character is entered. <p>The line will be split into fields as in the shell; the first field will be assigned to the first variable <code>var</code>, the second field to the second variable <code>var</code>, and so forth. If there are fewer <code>var</code> operands specified than there are fields, the leftover fields and their intervening separators will be assigned to the last <code>var</code>. If there are fewer fields than <code>vars</code>, the remaining <code>vars</code> will be set to empty strings.</p> <p>The setting of variables specified by the <code>var</code> operands will affect the current shell execution environment. If it is called in a subshell or separate utility execution environment, such as one of the following:</p> <pre>(read foo) nohup read ... find . -exec read ... \;</pre> <p>it will not affect the shell variables in the caller's environment.</p> <p>The standard input must be a text file.</p>
sh	<p>One line is read from the standard input and, using the internal field separator, <code>IFS</code> (normally space or tab), to delimit word boundaries, the first word is assigned to the first <code>name</code>, the second word to the second <code>name</code>, etc., with leftover words assigned to the last <code>name</code>. Lines can be continued using <code>\newline</code>. Characters other than <code>newline</code> can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to <code>names</code>, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.</p>

cs

The notation:

```
set variable = $<
```

loads one line of standard input as the value for *variable*. (See `cs(1)`).

ks

The shell input mechanism. One line is read and is broken up into fields using the characters in `IFS` as separators. The escape character, (`\`), is used to remove any special meaning for the next character and for line continuation. In raw mode, `-r`, the `\` character is not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, etc., with leftover fields assigned to the last *name*. The `-p` option causes the input line to be taken from the input pipe of a process spawned by the shell using `|&`. If the `-s` flag is present, the input will be saved as a command in the history file. The flag `-u` can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the `exec` special command. The default value of *n* is 0. If *name* is omitted then `REPLY` is used as the default *name*. The exit status is 0 unless the input file is not open for reading or an end-of-file is encountered. An end-of-file with the `-p` option causes cleanup for this process so that another can be spawned. If the first argument contains a `?`, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is 0 unless an end-of-file is encountered.

OPTIONS

The following option is supported:

`-r` Do not treat a backslash character in any special way. Consider each backslash to be part of the input line.

OPERANDS

The following operand is supported:

var The name of an existing or non-existing shell variable.

EXAMPLES

EXAMPLE 1 An example of the `read` command.

The following example for `/usr/bin/read` prints a file with the first field of each line moved to the end of the line.

```
while read -r xx yy
do
    printf "%s %s\n" "$yy" "$xx"
done < input_file
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `read`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`IFS` Determine the internal field separators used to delimit fields.

`PS2` Provide the prompt string that an interactive shell will write to standard error when a line ending with a backslash is read and the `-r`

option was not specified, or if a here-document is not terminated after a newline character is entered.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 End-of-file was detected or an error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME readfile, longline – reads file, gets longest line

SYNOPSIS **readfile** *filename*
longline [*filename*]

DESCRIPTION The `readfile` function reads *filename* and copies it to *stdout*. No translation of NEWLINE is done. It keeps track of the longest line it reads and if there is a subsequent call to `longline`, the length of that line, including the NEWLINE character, is returned.

The `longline` function returns the length, including the NEWLINE character, of the longest line in *filename*. If *filename* is not specified, it uses the file named in the last call to `readfile`.

EXAMPLES **EXAMPLE 1** Here is a typical use of `readfile` and `longline` in a text frame definition file:

Here is a typical use of `readfile` and `longline` in a text frame definition file:

```
.
.
.
text=`readfile myfile`
columns=`longline`
.
.
.
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `cat(1)`, `attributes(5)`

DIAGNOSTICS If *filename* does not exist, `readfile` will return `FALSE` (that is, the expression will have an error return).

`longline` returns 0 if a `readfile` has not previously been issued.

NOTES More than one descriptor can call `readfile` in the same frame definition file. In text frames, if one of those calls is made from the `text` descriptor, then a subsequent use of `longline` will always get the longest line of the file read by the `readfile` associated with the `text` descriptor, even if it was not the most recent use of `readfile`.

NAME readonly – shell built-in function to protect the value of the given variable from reassignment

SYNOPSIS

sh **readonly** [*name*...]

ksh ****readonly** [*name* [= *value*] ...]

DESCRIPTION

sh The given *names* are marked `readonly` and the values of these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all `readonly` names is printed.

ksh The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.

On this man page, `ksh(1)` commands that are preceded by one or two `**` (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by `**` that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`ksh(1)`, `sh(1)`, `typeset(1)`, `attributes(5)`

NAME	refer – expand and insert references from a bibliographic database
SYNOPSIS	refer [-ben] [-ar] [-cstring] [-kx] [-lm,n] [-p filename] [-skeys] filename...
DESCRIPTION	<p>refer is a preprocessor for <code>nroff(1)</code>, or <code>troff(1)</code>, that finds and formats references. The input files (standard input by default) are copied to the standard output, except for lines between <code>. [</code> and <code>.]</code> command lines. Such lines are assumed to contain keywords as for <code>lookbib(1)</code>, and are replaced by information from a bibliographic data base. The user can avoid the search, override fields from it, or add new fields. The reference data, from whatever source, is assigned to a set of <code>troff</code> strings. Macro packages such as <code>ms(5)</code> print the finished reference text from these strings. A flag is placed in the text at the point of reference. By default, the references are indicated by numbers.</p> <p>When <code>refer</code> is used with <code>eqn(1)</code>, <code>neqn</code>, or <code>tbl(1)</code>, <code>refer</code> should be used first in the sequence, to minimize the volume of data passed through pipes.</p>
OPTIONS	<p><code>-b</code> Bare mode — do not put any flags in text (neither numbers or labels).</p> <p><code>-e</code> Accumulate references instead of leaving the references where encountered, until a sequence of the form:</p> <pre style="margin-left: 40px;">. [\$LIST\$.]</pre> <p>is encountered, and then write out all references collected so far. Collapse references to the same source.</p> <p><code>-n</code> Do not search the default file.</p> <p><code>-ar</code> Reverse the first <i>r</i> author names (Jones, J. A. instead of J. A. Jones). If <i>r</i> is omitted, all author names are reversed.</p> <p><code>-cstring</code> Capitalize (with SMALL CAPS) the fields whose key-letters are in <i>string</i>.</p> <p><code>-kx</code> Instead of numbering references, use labels as specified in a reference data line beginning with the characters <code>%x</code>; By default, <i>x</i> is <code>L</code>.</p> <p><code>-lm,n</code> Instead of numbering references, use labels from the senior author's last name and the year of publication. Only the first <i>m</i> letters of the last name and the last <i>n</i> digits of the date</p>

are used. If either of *m* or *n* is omitted, the entire name or date, respectively, is used.

- `-p filename` Take the next argument as a file of references to be searched. The default file is searched last.
- `-skeys` Sort references by fields whose key-letters are in the *keys* string, and permute reference numbers in the text accordingly. Using this option implies the `-e` option. The key-letters in *keys* may be followed by a number indicating how many such fields are used, with a + sign taken as a very large number. The default is AD, which sorts on the senior author and date. To sort on all authors and then the date, for instance, use the options `'-sA+T'`.

FILES

NAME	regcmp – regular expression compile
SYNOPSIS	regcmp [-] <i>filename</i> ...
DESCRIPTION	The <code>regcmp</code> command performs a function similar to <code>regcmp</code> and, in most cases, precludes the need for calling <code>regcmp</code> from C programs. Bypassing <code>regcmp</code> saves on both execution time and program size. The command <code>regcmp</code> compiles the regular expressions in <i>filename</i> and places the output in <i>filename.i</i> .
OPTIONS	– If the <code>-</code> option is used, the output is placed in <i>filename.c</i> . The format of entries in <i>filename</i> is a name (C variable) followed by one or more blanks followed by one or more regular expressions enclosed in double quotes. The output of <code>regcmp</code> is C source code. Compiled regular expressions are represented as <code>extern char</code> vectors. <i>filename.i</i> files may thus be <code>#included</code> in C programs, or <i>filename.c</i> files may be compiled and later loaded. In the C program that uses the <code>regcmp</code> output, <code>regex(abc, line)</code> applies the regular expression named <code>abc</code> to <code>line</code> . Diagnostics are self-explanatory.
EXAMPLES	<p>EXAMPLE 1 Examples of the <code>regcmp</code> command.</p> <pre>name "([A-Za-z][A-Za-z0-9_]*)\$0" telno "\({0,1}([2-9][01][1-9])\$0\){0,1}*" "([2-9][0-9]{2})\$1[-]{0,1}" "([0-9]{4})\$2"</pre> <p>The three arguments to <code>telno</code> shown above must all be entered on one line.</p> <p>In the C program that uses the <code>regcmp</code> output, <pre>regex(telno, line, area, exch, rest)</pre> applies the regular expression named <code>telno</code> to <code>line</code>.</p>
ENVIRONMENT VARIABLES	<p>A general description of the usage of the <code>LC_*</code> environmental variables can be found in <code>environ(5)</code>.</p> <p>LC_CTYPE Determines how <code>regcmp</code> handles characters. When <code>LC_CTYPE</code> is set to a valid value, <code>regcmp</code> can display and handle text and filenames containing valid characters for that locale.</p> <p>LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).</p>

NAME regex – match patterns against a string

SYNOPSIS **regex** [-e] [-v "string"] [pattern template] ... pattern [template]

DESCRIPTION The `regex` command takes a string from the standard input, and a list of *pattern* / *template* pairs, and runs `regex()` to compare the string against each *pattern* until there is a match. When a match occurs, `regex` writes the corresponding *template* to the standard output and returns `TRUE`. The last (or only) *pattern* does not need a template. If that is the pattern that matches the string, the function simply returns `TRUE`. If no match is found, `regex` returns `FALSE`.

The argument *pattern* is a regular expression of the form described in `regex()`. In most cases, *pattern* should be enclosed in single quotes to turn off special meanings of characters. Note that only the final *pattern* in the list may lack a *template*.

The argument *template* may contain the strings `$m0` through `$m9`, which will be expanded to the part of *pattern* enclosed in `(. . .)$0` through `(. . .)$9` constructs (see examples below). Note that if you use this feature, you must be sure to enclose *template* in single quotes so that FMLI does not expand `$m0` through `$m9` at parse time. This feature gives `regex` much of the power of `cut(1)`, `paste(1)`, and `grep(1)`, and some of the capabilities of `sed(1)`. If there is no *template*, the default is `$m0$m1$m2$m3$m4$m5$m6$m7$m8$m9`.

OPTIONS The following options are supported:

`-e` Evaluates the corresponding template and writes the result to the standard output.

`-v "string"` Uses *string* instead of the standard input to match against patterns.

EXAMPLES **EXAMPLE 1** Cutting letters out of a string

To cut the 4th through 8th letters out of a string (this example will output `string` and return `TRUE`):

```
'regex -v "my string is nice" '^.{3}(.{5})$0' '$m0''
```

EXAMPLE 2 Validating input in a form

In a form, to validate input to field 5 as an integer:

```
valid='regex -v "$F5" '^[0-9]+$''
```

EXAMPLE 3 Translating an environment variable in a form

In a form, to translate an environment variable which contains one of the numbers 1, 2, 3, 4, 5 to the letters a, b, c, d, e:

```
value='regex -v "$VAR1" 1 a 2 b 3 c 4 d 5 e '.*' 'Error''
```

Note the use of the pattern `'.*'` to mean "anything else".

EXAMPLE 4 Using backquoted expressions

In the example below, all three lines constitute a single backquoted expression. This expression, by itself, could be put in a menu definition file. Since backquoted expressions are expanded as they are parsed, and output from a backquoted expression (the `cat` command, in this example) becomes part of the definition file being parsed, this expression would read `/etc/passwd` and make a dynamic menu of all the login ids on the system.

```
`cat /etc/passwd | regex '^([:]*)$0.*$' `
name=$m0
action='message "$m0 is a user"```
```

DIAGNOSTICS

If none of the patterns match, `regex` returns `FALSE`, otherwise `TRUE`.

NOTES

Patterns and templates must often be enclosed in single quotes to turn off the special meanings of characters. Especially if you use the `$m0` through `$m9` variables in the template, since FMLI will expand the variables (usually to `""`) before `regex` even sees them.

Single characters in character classes (inside `[]`) must be listed before character ranges, otherwise they will not be recognized. For example, `[a-zA-Z_ /]` will not find underscores (`_`) or slashes (`/`), but `[_ /a-zA-Z]` will.

The regular expressions accepted by `regcmp` differ slightly from other utilities (that is, `sed`, `grep`, `awk`, `ed`, and so forth).

`regex` with the `-e` option forces subsequent commands to be ignored. In other words, if a backquoted statement appears as follows:

```
`regex -e ...; command1; command2`
```

`command1` and `command2` would never be executed. However, dividing the expression into two:

```
`regex -e ...``command1; command2`
```

would yield the desired result.

NAME reinit – runs an initialization file

SYNOPSIS **reinit** *filename*

DESCRIPTION The `reinit` command is used to change the values of descriptors defined in the initialization file that was named when `fml` was invoked and/or define additional descriptors. FMLI will parse and evaluate the descriptors in *filename*, and then continue running the current application. The argument *filename* must be the name of a valid FMLI initialization file.

The `reinit` command does not re-display the introductory frame or change the layout of screen labels for function keys.

NAME	renice – alter priority of running processes
SYNOPSIS	<p>renice [-n <i>increment</i>] [-g -p -u]<i>ID</i>...</p> <p>renice <i>priority</i> [-p] <i>pid</i>... [-g <i>gid</i>...] [-p <i>pid</i>...] [-u <i>user</i>...]</p> <p>renice <i>priority</i> -g <i>gid</i>... [-g <i>gid</i>...] [-p <i>pid</i>...] [-u <i>user</i>...]</p> <p>renice <i>priority</i> -u <i>user</i>... [-g <i>gid</i>...] [-p <i>pid</i>...] [-u <i>user</i>...]</p>
DESCRIPTION	<p>The <code>renice</code> command alters the scheduling priority of one or more running processes. By default, the processes to be affected are specified by their process IDs.</p> <p>If the first operand is a number within the valid range of priorities (-20 to 20), <code>renice</code> will treat it as a <i>priority</i> (as in all but the first synopsis form); otherwise, <code>renice</code> will treat it as an <i>ID</i> (as in the first synopsis form).</p>
Altering Process Priority	<p>Users other than the privileged user may only alter the priority of processes they own, and can only monotonically increase their “nice value” within the range 0 to 19. This prevents overriding administrative fiats. The privileged user may alter the priority of any process and set the priority to any value in the range -20 to 19. Useful priorities are: 19 (the affected processes will run only when nothing else in the system wants to), 0 (the “base” scheduling priority) and any negative value (to make things go very fast). 20 is an acceptable nice value, but will be rounded down to 19.</p>
OPTIONS	<p><code>renice</code> supports the following option features:</p> <ul style="list-style-type: none"> ■ The first operand, <i>priority</i>, must precede the options and can have the appearance of a multi-digit option. ■ The -g, -p and -u options can each take multiple option-arguments. ■ The <i>pid</i> option-argument can be used without its -p option. <p>The following options are supported:</p> <p>-g Interpret all operands or just the <i>gid</i> arguments as unsigned decimal integer process group IDs.</p> <p>-n<i>increment</i> Specify how the system scheduling priority of the specified process or processes is to be adjusted. The <i>increment</i> option-argument is a positive or negative decimal integer that will be used to modify the system scheduling priority of the specified process or processes. Positive <i>increment</i> values cause a lower system scheduling priority. Negative <i>increment</i> values may require appropriate privileges and will cause a higher system scheduling priority.</p>

-p Interpret all operands or just the *pid* arguments as unsigned decimal integer process IDs. The **-p** option is the default if no options are specified.

-u Interpret all operands or just the *user* argument as users. If a user exists with a user name equal to the operand, then the user ID of that user will be used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it will be used as the numeric user ID of the user.

OPERANDS

The following operands are supported:

ID A process ID, process group ID or user name/user ID, depending on the option selected.

priority The value specified is taken as the actual system scheduling priority, rather than as an increment to the existing system scheduling priority. Specifying a scheduling priority higher than that of the existing process may require appropriate privileges.

EXAMPLES

EXAMPLE 1 Examples of *renice*.

Adjust the system scheduling priority so that process IDs 987 and 32 would have a lower scheduling priority:

```
example% renice -n 5 -p 987 32
```

Adjust the system scheduling priority so that group IDs 324 and 76 would have a higher scheduling priority, if the user has the appropriate privileges to do so:

```
example% renice -n -4 -g 324 76
```

Adjust the system scheduling priority so that numeric user ID 8 and user *sas* would have a lower scheduling priority:

```
example% renice -n 4 -u 8 sas
```

ENVIRONMENT VARIABLES

See *environ(5)* for descriptions of the following environment variables that affect the execution of *renice*: *LC_CTYPE*, *LC_MESSAGES*, and *NLSPATH*.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

/etc/passwd map user names to user ID's

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`nice(1)`, `passwd(1)`, `priocntl(1)`, `attributes(5)`, `environ(5)`

NOTES

If you make the priority very negative, then the process cannot be interrupted.

To regain control you must make the priority greater than 0.

Users other than the privileged user cannot increase scheduling priorities of their own processes, even if they were the ones that decreased the priorities in the first place.

The `priocntl` command subsumes the function of `renice`.

NAME reset – reset the current form field to its default values

SYNOPSIS reset

DESCRIPTION The `reset` function changes the entry in a field of a form to its default value; that is, the value displayed when the form was opened.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

NAME	rlogin – remote login
SYNOPSIS	rlogin [-8EL] [-ec] [-l <i>username</i>] <i>hostname</i>
DESCRIPTION	<p>rlogin establishes a remote login session from your terminal to the remote machine named <i>hostname</i>.</p> <p>Hostnames are listed in the <i>hosts</i> database, which may be contained in the <i>/etc/hosts</i> and <i>/etc/inet/ipnodes</i> files, the Network Information Service (NIS) <i>hosts</i> map, the Internet domain name server, or a combination of these. Each host has one official name (the first name in the database entry), and optionally one or more nicknames. Either official hostnames or nicknames may be specified in <i>hostname</i>.</p> <p>Each remote machine may have a file named <i>/etc/hosts.equiv</i> containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may rlogin from the machines listed in the remote machine's <i>/etc/hosts.equiv</i> file without supplying a password. Individual users may set up a similar private equivalence list with the file <i>.rhosts</i> in their home directories. Each line in this file contains two names: a <i>hostname</i> and a <i>username</i> separated by a space. An entry in a remote user's <i>.rhosts</i> file permits the user named <i>username</i> who is logged into <i>hostname</i> to log in to the remote machine as the remote user without supplying a password. If the name of the local host is not found in the <i>/etc/hosts.equiv</i> file on the remote machine, and the local username and hostname are not found in the remote user's <i>.rhosts</i> file, then the remote machine will prompt for a password. Hostnames listed in <i>/etc/hosts.equiv</i> and <i>.rhosts</i> files must be the official hostnames listed in the hosts database; nicknames may not be used in either of these files.</p> <p>For security reasons, the <i>.rhosts</i> file must be owned by either the remote user or by root.</p> <p>The remote terminal type is the same as your local terminal type (as given in your environment <i>TERM</i> variable). The terminal or window size is also copied to the remote system if the server supports the option, and changes in size are reflected as well. All echoing takes place at the remote site, so that (except for delays) the remote login is transparent. Flow control using CTRL-S and CTRL-Q and flushing of input and output on interrupts are handled properly.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -8 Pass eight-bit data across the net instead of seven-bit data. -ec Specify a different escape character, <i>c</i>, for the line used to disconnect from the remote host. -E Stop any character from being recognized as an escape character.

Escape Sequences

- l *username* Specify a different *username* for the remote login. If you do not use this option, the remote username used is the same as your local username.
 - L Allow the *rlogin* session to be run in “litout” mode.
- Lines that you type which start with the tilde character are “escape sequences” (the escape character can be changed using the `-e` option):
- ~. Disconnect from the remote host. This is not the same as a logout, because the local host breaks the connection with no warning to the remote end.
 - ~suspend Suspend the login session (only if you are using a shell with Job Control). *suspend* is your “suspend” character, usually CTRL-Z; see *tty(1)*.
 - ~dsuspend Suspend the input half of the login, but output will still be seen (only if you are using a shell with Job Control). *dsuspend* is your “deferred suspend” character, usually CTRL-Y; see *tty(1)*.

OPERANDS

hostname The remote machine on which *rlogin* establishes the remote login session.

FILES

- /etc/passwd* contains information about users’ accounts
- /usr/hosts/** for *hostname* version of the command
- /etc/hosts.equiv* list of trusted hostnames with shared usernames
- /etc/nologin* message displayed to users attempting to login during machine shutdown
- \$HOME/.rhosts* private list of trusted hostname/username combinations
- /etc/hosts* hosts database
- /etc/inet/ipnodes* hosts database

ATTRIBUTES

See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

rsh(1), *stty(1)*, *tty(1)*, *in.named(1M)*, *hosts(4)*, *ipnodes(4)*, *hosts.equiv(4)*, *nologin(4)*, *attributes(5)*

DIAGNOSTICS

The following message indicates that the machine is in the process of being shutdown and logins have been disabled:

```
NO LOGINS: System going down in N minutes
```

NOTES

When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed.

This implementation can only use the TCP network service.

NAME	rm, rmdir - remove directory entries
SYNOPSIS	<pre> /usr/bin/rm [-f] [-i] file... /usr/bin/rm -rR [-f] [-i] dirname... [file...] /usr/xpg4/bin/rm [-fiRr] file... /usr/bin/rmdir [-ps] dirname... </pre>
DESCRIPTION	<p>The <code>rm</code> utility removes the directory entry specified by each <i>file</i> argument. If a file has no write permission and the standard input is a terminal, the full set of permissions (in octal) for the file are printed followed by a question mark. This is a prompt for confirmation. If the answer begins with <i>y</i> (for yes), the file is deleted, otherwise the file remains.</p> <p>If <i>file</i> is a symbolic link, the link will be removed, but the file or directory to which it refers will not be deleted. Users do not need write permission to remove a symbolic link, provided they have write permissions in the directory.</p> <p>If multiple <i>file</i>s are specified and removal of a <i>file</i> fails for any reason, <code>rm</code> will write a diagnostic message to standard error, do nothing more to the current <i>file</i>, and go on to any remaining <i>file</i>s.</p> <p>If the standard input is not a terminal, the utility will operate as if the <code>-f</code> option is in effect.</p>
<code>/usr/bin/rmdir</code>	<p>The <code>rmdir</code> utility will remove the directory entry specified by each <i>dirname</i> operand, which must refer to an empty directory.</p> <p>Directories will be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of <code>rmdir</code>, the subdirectory must be specified before the parent directory so that the parent directory will be empty when <code>rmdir</code> tries to remove it.</p>
OPTIONS	<p>The following options are supported for <code>/usr/bin/rm</code> and <code>/usr/xpg4/bin/rm</code>:</p> <p><code>-r</code> Recursively remove directories and subdirectories in the argument list. The directory will be emptied of files and removed. The user is normally prompted for removal of any write-protected files which the directory contains. The write-protected files are removed without prompting, however, if the <code>-f</code> option is used, or if the standard input is not a terminal and the <code>-i</code> option is not used.</p> <p>Symbolic links that are encountered with this option will not be traversed.</p>

If the removal of a non-empty, write-protected directory is attempted, the utility will always fail (even if the `-f` option is used), resulting in an error message.

`-R` Same as `-r` option.

`/usr/bin/rm`

The following options are supported for `/usr/bin/rm` only:

`-f` Remove all files (whether write-protected or not) in a directory without prompting the user. In a write-protected directory, however, files are never removed (whatever their permissions are), but no messages are displayed. If the removal of a write-protected directory is attempted, this option will not suppress an error message.

`-i` Interactive. With this option, `rm` prompts for confirmation before removing any files. It overrides the `-f` option and remains in effect even if the standard input is not a terminal.

`/usr/xpg4/bin/rm`

The following options are supported for `/usr/xpg4/bin/rm` only:

`-f` Do not prompt for confirmation. Do not write diagnostic messages or modify the exit status in the case of non-existent operands. Any previous occurrences of the `-i` option will be ignored.

`-i` Prompt for confirmation. Any occurrences of the `-f` option will be ignored.

`/usr/bin/rmdir`

The following options are supported for `/usr/bin/rmdir` only:

`-p` Allow users to remove the directory *dirname* and its parent directories which become empty. A message is printed to standard error if all or part of the path could not be removed.

`-s` Suppress the message printed on the standard error when `-p` is in effect.

OPERANDS

The following operands are supported:

file A path name of a directory entry to be removed.

dirname A path name of an empty directory to be removed.

USAGE

See `largefile(5)` for the description of the behavior of `rm` and `rmdir` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

`/usr/bin/rm`

`/usr/xpg4/bin/rm`

The following command:

```
example% rm a.out core
```

removes the directory entries: `a.out` and `core`.

The following command:

```
example% rm -rf junk
```

removes the directory `junk` and all its contents, without prompting.

`/usr/bin/rmdir`

If a directory `a` in the current directory is empty except that it contains a directory `b` and `a/b` is empty except that it contains a directory `c`,

```
example% rmdir -p a/b/c
```

will remove all three directories.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `rm` and `rmdir`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 If the `-f` option was not specified, all the named directory entries were removed; otherwise, all the existing named directory entries were removed.
- >0 An error occurred.

ATTRIBUTES

`/usr/bin/rm`
`/usr/bin/rmdir`

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

`/usr/xpg4/bin/rm`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled

SEE ALSO

`rmdir(2)`, `unlink(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

DIAGNOSTICS

All messages are generally self-explanatory.

It is forbidden to remove the files ". " and ". ." in order to avoid the consequences of inadvertently doing something like the following:

```
rm -r .*
```

NOTES

A - permits the user to mark explicitly the end of any command line options, allowing `rm` to recognize file arguments that begin with a - . As an aid to BSD migration, `rm` will accept - as a synonym for - . This migration aid may disappear in a future release. If a - and a - both appear on the same command line, the second will be interpreted as a file.

NAME	roffbib – format and print a bibliographic database
SYNOPSIS	roffbib [-e] [-h] [-m <i>filename</i>] [-np] [-olist] [-Q] [-ra <i>N</i>] [-s <i>N</i>] [-T <i>term</i>] [-v] [-x] [<i>filename</i>] ...
DESCRIPTION	roffbib prints out all records in a bibliographic database, in bibliography format rather than as footnotes or endnotes. Generally it is used in conjunction with sortbib(1): example% sortbib database roffbib
OPTIONS	roffbib accepts all options understood by nroff(1) except -i and -q. -e Produce equally-spaced words in adjusted lines using full terminal resolution. -h Use output tabs during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths. -m <i>filename</i> Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files. There should be a space between the -m and the macro filename. This set of macros will replace the ones defined in /usr/share/lib/tmac/tmac.bib. -np Number first generated page <i>p</i> . -olist Print only page numbers that appear in the comma-separated list of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i> ; an initial - <i>N</i> means from the beginning to page <i>N</i> ; a final <i>N-</i> means from page <i>N</i> to end. -Q Queue output for the phototypesetter. Page offset is set to 1 inch. -ra <i>N</i> Set register <i>a</i> (one-character) to <i>N</i> . The command-line argument -r <i>N</i> 1 will number the references starting at 1. Four command-line registers control formatting style of the bibliography, much like the number registers of ms(5). The flag -rV2 will double space the bibliography, while -rV1 will double space references but single space annotation paragraphs. The line length can be changed from the default 6.5 inches to 6 inches with the -rL6i argument, and the page offset can be set from the default of 0 to one inch by specifying -rO1i (capital O, not zero).

- `-sN` Halt prior to every *N* pages for paper loading or changing (default *N*=1). To resume, enter NEWLINE or RETURN.
- `-Tterm` Specify *term* as the terminal type.
- `-V` Send output to the Versatec. Page offset is set to 1 inch.
- `-x` If abstracts or comments are entered following the `%X` field key, `roffbib` will format them into paragraphs for an annotated bibliography. Several `%X` fields may be given if several annotation paragraphs are desired.

FILES

`/usr/share/lib/tmac/tmac.bib` file of macros used by `nroff/troff`

ATTRIBUTES

BUGS

Users have to rewrite macros to create customized formats.

NAME	roles – print roles granted to a user
SYNOPSIS	roles [<i>user</i> ...]
DESCRIPTION	<p>The command <code>roles</code> prints on standard output the roles that you or the optionally-specified user have been granted. Roles are special accounts that correspond to a functional responsibility rather than to an actual person (referred to as a normal user).</p> <p>Each user may have zero or more roles. Roles have most of the attributes of normal users and are identified like normal users in <code>passwd(4)</code> and <code>shadow(4)</code>. Each role must have an entry in the <code>user_attr(4)</code> file that identifies it as a role. Roles can have their own authorizations and profiles. See <code>auths(1)</code> and <code>profiles(1)</code>.</p> <p>Roles are not allowed to log into a system as a primary user. Instead, a user must log in as him or herself and assume the role. The actions of a role are attributable to the normal user. When auditing is enabled, the audited events of the role contain the audit ID of the original user who assumed the role.</p> <p>Roles must have valid passwords and one of the shells that interprets profiles: either <code>pfsh</code>, <code>pfksh</code>, or <code>pfsh</code>. See <code>pfexec(1)</code>.</p> <p>Role assumption may be performed using <code>su(1M)</code>, <code>rlogin(1)</code>, or some other service that supports the <code>PAM_RUSER</code> variable. Successful assumption requires knowledge of the role's password and membership in the role. Role assignments are specified in <code>user_attr(4)</code>.</p>
EXAMPLES	<p>EXAMPLE 1 Sample output</p> <p>The output of the <code>roles</code> command has the following form:</p> <pre>example% roles tester01 tester02 tester01 : admin tester02 : secadmin, root example%</pre>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>
FILES	<pre>/etc/user_attr /etc/security/auth_attr /etc/security/prof_attr</pre>

NAME	rpcgen - an RPC protocol compiler
SYNOPSIS	<p>rpcgen <i>infile</i></p> <p>rpcgen [-a] [-A] [-b] [-C] [-D <i>name</i> [= <i>value</i>]] [-i <i>size</i>] [-I [-K <i>seconds</i>]] [-L] [-M] [-N] [-T] [-Y <i>pathname</i>] <i>infile</i></p> <p>rpcgen [-c -h -l -m -t -Sc -Ss -Sm][-o <i>outfile</i>] [<i>infile</i>]</p> <p>rpcgen [-s <i>nettype</i>] [-o <i>outfile</i>] [<i>infile</i>]</p> <p>rpcgen [-n <i>netid</i>] [-o <i>outfile</i>] [<i>infile</i>]</p>
DESCRIPTION	<p>rpcgen is a tool that generates C code to implement an RPC protocol. The input to rpcgen is a language similar to C known as RPC Language (Remote Procedure Call Language).</p> <p>The rpcgen utility is normally used as in the first synopsis where it takes an input file and generates three output files. If the <i>infile</i> is named <i>proto.x</i>, then rpcgen generates a header in <i>proto.h</i>, XDR routines in <i>proto_xdr.c</i>, server-side stubs in <i>proto_svc.c</i>, and client-side stubs in <i>proto_clnt.c</i>. With the -T option, it also generates the RPC dispatch table in <i>proto_tbl.i</i>.</p> <p>rpcgen can also generate sample client and server files that can be customized to suit a particular application. The -Sc, -Ss, and -Sm options generate sample client, server and makefile, respectively. The -a option generates all files, including sample files. If the <i>infile</i> is <i>proto.x</i>, then the client side sample file is written to <i>proto_client.c</i>, the server side sample file to <i>proto_server.c</i> and the sample makefile to <i>makefile.proto</i>.</p> <p>The server created can be started both by the port monitors (for example, <i>inetd</i> or <i>listen</i>) or by itself. When it is started by a port monitor, it creates servers only for the transport for which the file descriptor 0 was passed. The name of the transport must be specified by setting up the environment variable <i>PM_TRANSPORT</i>. When the server generated by rpcgen is executed, it creates server handles for all the transports specified in the <i>NETPATH</i> environment variable, or if it is unset, it creates server handles for all the visible transports from the <i>/etc/netconfig</i> file. Note: the transports are chosen at run time and not at compile time. When the server is self-started, it backgrounds itself by default. A special define symbol <i>RPC_SVC_FG</i> can be used to run the server process in foreground.</p> <p>The second synopsis provides special features which allow for the creation of more sophisticated RPC servers. These features include support for user-provided <i>#defines</i> and RPC dispatch tables. The entries in the RPC dispatch table contain:</p> <ul style="list-style-type: none"> ■ pointers to the service routine corresponding to that procedure ■ a pointer to the input and output arguments

- the size of these routines

A server can use the dispatch table to check authorization and then to execute the service routine; a client library may use it to deal with the details of storage management and XDR data conversion.

The other three synopses shown above are used when one does not want to generate all the output files, but only a particular one. See the `EXAMPLES` section below for examples of `rpcgen` usage. When `rpcgen` is executed with the `-s` option, it creates servers for that particular class of transports. When executed with the `-n` option, it creates a server for the transport specified by *netid*. If *infile* is not specified, `rpcgen` accepts the standard input.

All the options mentioned in the second synopsis can be used with the other three synopses, but the changes will be made only to the specified output file.

The C preprocessor `cc -E` is run on the input file before it is actually interpreted by `rpcgen`. For each type of output file, `rpcgen` defines a special preprocessor symbol for use by the `rpcgen` programmer:

<code>RPC_HDR</code>	defined when compiling into headers
<code>RPC_XDR</code>	defined when compiling into XDR routines
<code>RPC_SVC</code>	defined when compiling into server-side stubs
<code>RPC_CLNT</code>	defined when compiling into client-side stubs
<code>RPC_TBL</code>	defined when compiling into RPC dispatch tables

Any line beginning with “%” is passed directly into the output file, uninterpreted by `rpcgen`, except that the leading “%” is stripped off. To specify the path name of the C preprocessor, use the `-Y` flag.

For every data type referred to in *infile*, `rpcgen` assumes that there exists a routine with the string `xdr_` prepended to the name of the data type. If this routine does not exist in the RPC/XDR library, it must be provided. Providing an undefined data type allows customization of XDR routines.

OPTIONS

The following options are supported:

- `-a` Generate all files, including sample files.
- `-A` Enable the Automatic MT mode in the server main program. In this mode, the RPC library automatically creates threads to service client requests. This option generates multithread-safe stubs by implicitly turning on the `-M` option. Server multithreading modes and parameters can be set using the `rpc_control(3NSL)` call. `rpcgen` generated code does not change the default values for the Automatic MT mode.

-b	Backward compatibility mode. Generate transport-specific RPC code for older versions of the operating system.
-c	Compile into XDR routines.
-C	Generate header and stub files which can be used with ANSI C compilers. Headers generated with this flag can also be used with C++ programs.
-Dname[=value]	Define a symbol <i>name</i> . Equivalent to the <code>#define</code> directive in the source. If no <i>value</i> is given, <i>value</i> is defined as 1. This option may be specified more than once.
-h	Compile into C data-definitions (a header). The <code>-T</code> option can be used in conjunction to produce a header which supports RPC dispatch tables.
-i <i>size</i>	Size at which to start generating inline code. This option is useful for optimization. The default <i>size</i> is 5.
-I	<p>Compile support for <code>inetd(1M)</code> in the server side stubs. Such servers can be self-started or can be started by <code>inetd</code>. When the server is self-started, it backgrounds itself by default. A special define symbol <code>RPC_SVC_FG</code> can be used to run the server process in foreground, or the user may simply compile without the <code>-I</code> option.</p> <p>If there are no pending client requests, the <code>inetd</code> servers exit after 120 seconds (default). The default can be changed with the <code>-K</code> option. All of the error messages for <code>inetd</code> servers are always logged with <code>syslog(3C)</code>.</p> <p>Note: This option is supported for backward compatibility only. It should always be used in conjunction with the <code>-b</code> option which generates backward compatibility code. By default (that is, when <code>-b</code> is not specified), <code>rpcgen</code> generates servers that can be invoked through portmonitors.</p>
-K <i>seconds</i>	<p>By default, services created using <code>rpcgen</code> and invoked through port monitors wait 120 seconds after servicing a request before exiting. That interval can be changed using the <code>-K</code> flag. To create a server that exits immediately upon servicing a request, use <code>-K 0</code>. To create a server that never exits, the appropriate argument is <code>-K -1</code>.</p> <p>When monitoring for a server, some portmonitors, like <code>listen(1M)</code>, <i>always</i> spawn a new process in response to a service request. If it is known that a server will be used</p>

- with such a monitor, the server should exit immediately on completion. For such servers, `rpcgen` should be used with `-K 0`.
- `-l` Compile into client-side stubs.
 - `-L` When the servers are started in foreground, use `syslog(3C)` to log the server errors instead of printing them on the standard error.
 - `-m` Compile into server-side stubs, but do not generate a “main” routine. This option is useful for doing callback-routines and for users who need to write their own “main” routine to do initialization.
 - `-M` Generate multithread-safe stubs for passing arguments and results between `rpcgen`-generated code and user written code. This option is useful for users who want to use threads in their code.
 - `-N` This option allows procedures to have multiple arguments. It also uses the style of parameter passing that closely resembles C. So, when passing an argument to a remote procedure, you do not have to pass a pointer to the argument, but can pass the argument itself. This behavior is different from the old style of `rpcgen`-generated code. To maintain backward compatibility, this option is not the default.
 - `-n netid` Compile into server-side stubs for the transport specified by *netid*. There should be an entry for *netid* in the `netconfig` database. This option may be specified more than once, so as to compile a server that serves multiple transports.
 - `-o outfile` Specify the name of the output file. If none is specified, standard output is used (`-c`, `-h`, `-l`, `-m`, `-n`, `-s`, `-Sc`, `-Sm`, `-Ss`, and `-t` modes only).
 - `-s nettype` Compile into server-side stubs for all the transports belonging to the class *nettype*. The supported classes are `netpath`, `visible`, `circuit_n`, `circuit_v`, `datagram_n`, `datagram_v`, `tcp`, and `udp` (see `rpc(3NSL)` for the meanings associated with these classes). This option may be specified more than once. Note: the transports are chosen at run time and not at compile time.
 - `-Sc` Generate sample client code that uses remote procedure calls.

`-Sm` Generate a sample Makefile which can be used for compiling the application.

`-Ss` Generate sample server code that uses remote procedure calls.

`-t` Compile into RPC dispatch table.

`-T` Generate the code to support RPC dispatch tables.

The options `-c`, `-h`, `-l`, `-m`, `-s`, `-Sc`, `-Sm`, `-Ss`, and `-t` are used exclusively to generate a particular type of file, while the options `-D` and `-T` are global and can be used with the other options.

`-Y pathname` Give the name of the directory where `rpcgen` will start looking for the C preprocessor.

OPERANDS

The following operand is supported:

infile input file

EXAMPLES

EXAMPLE 1 Generating the output files and dispatch table

The following entry

```
example% rpcgen -T prot.x
```

generates all the five files: `prot.h`, `prot_clnt.c`, `prot_svc.c`, `prot_xdr.c`, and `prot_tbl.i`.

EXAMPLE 2 Sending headers to standard output

The following example sends the C data-definitions (header) to the standard output:

```
example% rpcgen -h prot.x
```

EXAMPLE 3 Sending a test version

To send the test version of the `-DTEST`, server side stubs for all the transport belonging to the class `datagram_n` to standard output, use:

```
example% rpcgen -s datagram_n -DTEST prot.x
```

EXAMPLE 4 Creating server side stubs

To create the server side stubs for the transport indicated by `netid tcp`, use:

```
example% rpcgen -n tcp -o prot_svc.c prot.x
```

EXIT STATUS

0 Successful operation.

>0 An error occurred.

NAME	rsh, remsh, remote_shell – remote shell
SYNOPSIS	<p>rsh [-n] [-l <i>username</i>] <i>hostname</i> <i>command</i></p> <p>rsh <i>hostname</i> [-n] [-l <i>username</i>] <i>command</i></p> <p>remsh [-n] [-l <i>username</i>] <i>hostname</i> <i>command</i></p> <p>remsh <i>hostname</i> [-n] [-l <i>username</i>] <i>command</i></p> <p><i>hostname</i> [-n] [-l <i>username</i>] <i>command</i></p>
DESCRIPTION	<p>rsh connects to the specified <i>hostname</i> and executes the specified <i>command</i>. rsh copies its standard input to the remote command, the standard output of the remote command to its standard output, and the standard error of the remote command to its standard error. Interrupt, quit, and terminate signals are propagated to the remote command; rsh normally terminates when the remote command does.</p> <p>If you omit <i>command</i>, instead of executing a single command, rsh logs you in on the remote host using rlogin(1).</p> <p>Shell metacharacters which are not quoted are interpreted on the local machine, while quoted metacharacters are interpreted on the remote machine. See EXAMPLES.</p>
OPTIONS	<p>The following options are supported:</p> <p>-l Use <i>username</i> as the remote username instead of your local username. In the absence of this option, the remote <i>username</i> is the same as your local username.</p> <p>-n Redirect the input of rsh to /dev/null. You sometimes need this option to avoid unfortunate interactions between rsh and the shell which invokes it. For example, if you are running rsh and invoke a rsh in the background without redirecting its input away from the terminal, it will block even if no reads are posted by the remote command. The -n option will prevent this.</p> <p>The type of remote shell (sh, rsh, or other) is determined by the user's entry in the file /etc/passwd on the remote system.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>command</i> The command to be executed on the specified <i>hostname</i>.</p>
USAGE	<p>See largefile(5) for the description of the behavior of rsh and remsh when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).</p> <p>The rsh and remsh commands are IPv6-enabled. See ip6(7P).</p>

Hostnames are given in the *hosts* database, which may be contained in the */etc/hosts* file, the Internet domain name database, or both. Each host has one official name (the first name in the database entry) and optionally one or more nicknames. Official hostnames or nicknames may be given as *hostname*.

If the name of the file from which *rsh* is executed is anything other than *rsh*, *rsh* takes this name as its *hostname* argument. This allows you to create a symbolic link to *rsh* in the name of a host which, when executed, will invoke a remote shell on that host. By creating a directory and populating it with symbolic links in the names of commonly used hosts, then including the directory in your shell's search path, you can run *rsh* by typing *hostname* to your shell.

If *rsh* is invoked with the basename *remsh*, *rsh* will check for the existence of the file */usr/bin/remsh*. If this file exists, *rsh* will behave as if *remsh* is an alias for *rsh*. If */usr/bin/remsh* does not exist, *rsh* will behave as if *remsh* is a host name.

Each remote machine may have a file named */etc/hosts.equiv* containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may run *rsh* from the machines listed in the remote machine's */etc/hosts* file. Individual users may set up a similar private equivalence list with the file *.rhosts* in their home directories. Each line in this file contains two names: a *hostname* and a *username* separated by a space. The entry permits the user named *username* who is logged into *hostname* to use *rsh* to access the remote machine as the remote user. If the name of the local host is not found in the */etc/hosts.equiv* file on the remote machine, and the local username and hostname are not found in the remote user's *.rhosts* file, then the access is denied. The hostnames listed in the */etc/hosts.equiv* and *.rhosts* files must be the official hostnames listed in the *hosts* database; nicknames may not be used in either of these files.

rsh will not prompt for a password if access is denied on the remote machine unless the *command* argument is omitted.

EXAMPLES

EXAMPLE 1 Using *rsh* to append files.

The following command:

```
example% rsh lizard cat lizard.file >> example.file
```

appends the remote file *lizard.file* from the machine called "lizard" to the file called *example.file* on the machine called "example," while the command:

```
example% rsh lizard cat lizard.file ">>" lizard.file2
```

appends the file *lizard.file* on the machine called "lizard" to the file *lizard.file2* which also resides on the machine called "lizard."

EXIT STATUS

The following exit values are returned:

0 Successful completion.

1 An error occurred.

FILES

`/etc/hosts` Internet host table

`/etc/hosts.equiv` trusted remote hosts and users

`/etc/passwd` system password file

ATTRIBUTES

NOTES

When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

You cannot run an interactive command (such as `vi(1)`); use `rlogin` if you wish to do so.

Stop signals stop the local `rsh` process only; this is arguably wrong, but currently hard to fix for reasons too complicated to explain here.

The current local environment is not passed to the remote shell.

Sometimes the `-n` option is needed for reasons that are less than obvious. For example, the command:

```
example% rsh somehost dd if=/dev/nrmt0 bs=20b | tar xvpBf -
```

will put your shell into a strange state. Evidently, what happens is that the `tar` terminates before the `rsh`. The `rsh` then tries to write into the “broken pipe” and, instead of terminating neatly, proceeds to compete with your shell for its standard input. Invoking `rsh` with the `-n` option avoids such incidents.

This bug occurs only when `rsh` is at the beginning of a pipeline and is not reading standard input. Do not use the `-n` if `rsh` actually needs to read standard input. For example,

```
example% tar cf - . | rsh sundial dd of=/dev/rmt0 obs=20b
```

does not produce the bug. If you were to use the `-n` in a case like this, `rsh` would incorrectly read from `/dev/null` instead of from the pipe.

NAME	run – run an executable
SYNOPSIS	run [-s] [-e] [-n] [-t <i>string</i>] <i>program</i>
DESCRIPTION	The <code>run</code> command runs <i>program</i> , using the <code>PATH</code> variable to find it. By default, when <i>program</i> has completed, the user is prompted (Press ENTER to continue:), before being returned to FMLI. The argument <i>program</i> is a system executable followed by its options (if any).
OPTIONS	<p>The following options are supported:</p> <p><code>-e</code> If <code>-e</code> is specified, the user will be prompted before returning to FMLI only if there is an error condition</p> <p><code>-n</code> If <code>-n</code> is specified, the user will never be prompted before returning to FMLI (useful for programs like <code>vi</code>, in which the user must do some specific action to exit in the first place).</p> <p><code>-s</code> The <code>-s</code> option means "silent", implying that the screen will not have to be repainted when <i>program</i> has completed. Note that the <code>-s</code> option should only be used when <i>program</i> does not write to the terminal. In addition, when <code>-s</code> is used, <i>program</i> cannot be interrupted, even if it recognizes interrupts.</p> <p><code>-tstring</code> If <code>-t</code> is specified, <i>string</i> is the name this process will have in the pop-up menu generated by the <code>frm-list</code> command. This feature requires the executable <code>facesuspend</code> (see <code>face(1)</code>) to suspend the process and return to the FMLI application.</p>
EXAMPLES	<p>EXAMPLE 1 Sample output of run command</p> <p>Here is a menu that uses <code>run</code>:</p> <pre> menu="Edit special System files" name="Password file" action='run -e vi /etc/passwd\' name="Group file" action='run -e vi /etc/group\' name="My .profile" action='run -n vi \$HOME/.profile\' </pre>

NAME | rup – show host status of remote machines (RPC version)

SYNOPSIS | **rup** [-hlt]
rup [host...]

DESCRIPTION | rup gives a status similar to uptime for remote machines. It broadcasts on the local network, and displays the responses it receives.

Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

When *host* arguments are given, rather than broadcasting rup will only query the list of specified hosts.

A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd(1M).

OPTIONS | -h Sort the display alphabetically by host name.
 -l Sort the display by load average.
 -t Sort the display by up time.

FILES | /etc/servers

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO | ruptime(1), inetd(1M), attributes(5)

BUGS | Broadcasting does not work through gateways.

NAME | ruptime - show host status of local machines

SYNOPSIS | **ruptime** [-alrtu]

DESCRIPTION | **ruptime** gives a status line like **uptime** for each machine on the local network; these are formed from packets broadcast by each host on the network once a minute.

Machines for which no status report has been received for 5 minutes are shown as being down.
