Normally, the listing is sorted by host name, but this order can be changed by specifying one of the options listed below.

OPTIONS | The following options are supported:

- a Count even those users who have been idle for an hour or more.
- l Sort the display by load average.
- r Reverse the sorting order.
- t Sort the display by up time.
- u Sort the display by number of users.

FILES | /var/spool/rwho/whod.* data files

ATTRIBUTES | See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO | **rwwho(1)**, **in.rwhod(1M)**, **attributes(5)**

NAME | rusage – print resource usage for a command

SYNOPSIS | `/usr/ucb/rusage command`

DESCRIPTION | The `rusage` command is similar to `time(1)`. It runs the given *command*, which must be specified; that is, *command* is not optional as it is in the C shell's timing facility. When the command is complete, `rusage` displays the real (wall clock), the system CPU, and the user CPU times which elapsed during execution of the command, plus other fields in the `rusage` structure, all on one long line. Times are reported in seconds and hundredths of a second.

EXAMPLES | **EXAMPLE 1** The format of `rusage` output

The example below shows the format of `rusage` output.

```
example% rusage wc /usr/share/man/man1/csh (1)
3045 13423 78071 /usr/share/man/man1/csh (1)
2.26 real 0.80 user 0.36 sys 11 pf 38 pr 0 sw 11 rb 0 wb 16 vcx 37
      icx 24 mx 0 ix 1230 id 9 is
example%
```

Each of the fields identified corresponds to an element of the `rusage` structure, as described in `getrusage(3C)`, as follows:

<code>real</code>		elapsed real time
<code>user</code>	<code>ru_utime</code>	user time used
<code>sys</code>	<code>ru_stime</code>	system time used
<code>pf</code>	<code>ru_majflt</code>	page faults requiring physical I/O
<code>pr</code>	<code>ru_minflt</code>	page faults not requiring physical I/O
<code>sw</code>	<code>ru_nswap</code>	swaps
<code>rb</code>	<code>ru_inblock</code>	block input operations
<code>wb</code>	<code>ru_oublock</code>	block output operations
<code>vcx</code>	<code>ru_nvcsw</code>	voluntary context switches
<code>icx</code>	<code>ru_nivcsw</code>	involuntary context switches
<code>mx</code>	<code>ru_maxrss</code>	maximum resident set size
<code>ix</code>	<code>ru_ixrss</code>	currently 0
<code>id</code>	<code>ru_idrss</code>	integral resident set size
<code>is</code>	<code>ru_isrss</code>	currently 0

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

BUGS

When the command being timed is interrupted, the timing values displayed may be inaccurate.

NAME rusers – who is logged in on remote machines

SYNOPSIS **rusers** [-ahilu] *host...*

DESCRIPTION The **rusers** command produces output similar to **who(1)**, but for remote machines. The listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

The default is to print out the names of the users logged in. When the **-l** flag is given, additional information is printed for each user:

```
userid  hostname:terminal  login date  login time  idle time  login host
```

If *hostname* and *login host* are the same value, the *login host* field is not displayed. Likewise, if *hostname* is not idle, the *idle time* is not displayed.

A remote host will only respond if it is running the **rusersd** daemon, which may be started up from **inetd(1M)** or **listen(1M)**.

- OPTIONS**
- a** Give a report for a machine even if no users are logged on.
 - h** Sort alphabetically by host name.
 - i** Sort by idle time.
 - l** Give a longer listing in the style of **who(1)**.
 - u** Sort by number of users.

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

NAME rwho - who is logged in on local machines

SYNOPSIS **rwho** [-a]

DESCRIPTION The `rwho` command produces output similar to `who(1)`, but for all machines on your network. If no report has been received from a machine for 5 minutes, `rwho` assumes the machine is down, and does not report users last known to be logged into that machine.

If a user has not typed to the system for a minute or more, `rwho` reports this idle time. If a user has not typed to the system for an hour or more, the user is omitted from the output of `rwho` unless the `-a` flag is given.

OPTIONS `-a` Report all users whether or not they have typed to the system in the past hour.

FILES `/var/spool/rwho/whod.*` information about other machines

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `finger(1)`, `ruptime(1)`, `who(1)`, `in.rwhod(1M)`, `attributes(5)`

NOTES `rwho` does not work through gateways.

The directory `/var/spool/rwho` must exist on the host from which `rwho` is run.

This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

The `rwho` service daemon, `in.rwhod(1M)`, must be enabled for this command to return useful results.

NAME | sag – system activity graph

SYNOPSIS | **sag** [-e *time*] [-f *file*] [-i *sec*] [-s *time*] [-T *term*] [-x *spec*] [-y *spec*]

DESCRIPTION | The **sag** utility graphically displays the system activity data stored in a binary data file by a previous **sar**(1) run. Any of the **sar** data items may be plotted singly or in combination, as cross plots or versus time. Simple arithmetic combinations of data may be specified. **sag** invokes **sar** and finds the desired data by string-matching the data column header (run **sar** to see what is available). The **sag** utility requires a graphic terminal to draw the graph, and uses **tplot**(1) to produce its output. When running Solaris 2.x and OpenWindows, perform the following steps:

1. Run an "xterm" as a Tektronics terminal: `prompt# xterm -t`
2. In the "xterm" window, run **sag** specifying a tek terminal: `prompt# sag -T tek options`

OPTIONS | The following options are supported and passed through to **sar** (see **sar**(1)):
 -e *time* Select data up to *time*. Default is 18:00.

-f *file* Use *file* as the data source for **sar**. Default is the current daily data file `/usr/adm/sa/sadd`.

-i *sec* Select data at intervals as close as possible to *sec* seconds.

-s *time* Select data later than *time* in the form *hh[:mm]*. Default is 08:00.

-T *term* Produce output suitable for terminal *term*. See **tplot**(1) for known terminals. Default for *term* is `$TERM`.

-x *spec* x axis specification with *spec* in the form:

name[*op name*]*...*[*lo hi*]

name is either a string that will match a column header in the **sar** report, with an optional device name in square brackets, for example, `r+w/s[dsk-1]`, or an integer value. *op* is + - * or / surrounded by blank spaces. Up to five names may be specified. Parentheses are not recognized. Contrary to custom, + and - have precedence over * and /. Evaluation is left to right. Thus, `A/A+B*100` is evaluated as `(A/(A+B))*100`, and `A+B/C+D` is `(A+B)/(C+D)`. *lo* and *hi* are optional numeric scale limits. If unspecified, they are deduced from the data.

Enclose *spec* in double-quotes (" ") if it includes white space.

A single *spec* is permitted for the x axis. If unspecified, *time* is used.

`-y spec` *y* axis specification with *spec* in the same form as for `-x`. Up to 5 *spec* arguments separated by a semi-colon (;) may be given for `-y`. The `-y` default is:

```
-y"%usr0100;%usr+%sys0100;%usr+%sys+%wio0100"
```

EXAMPLES

EXAMPLE 1 Examples of the `sag` command.

To see today's CPU utilization:

```
example$ sag
```

To see activity over 15 minutes of all disk drives:

```
example$ TS='date +%H:%M'
example$ sar -o /tmp/tempfile 60 15
example$ TE='date +%H:%M'
example$ sag -f /tmp/tempfile -s $TS -e $TE -y "r+w/s[dsk]"
```

FILES

`/usr/adm/sa/sadd` daily data file for day `dd`

NAME	sar – system activity reporter
SYNOPSIS	sar [-aAbcdgkmpqruvw] [-o <i>filename</i>] <i>t</i> [<i>n</i>] sar [-aAbcdgkmpqruvw] [-e <i>time</i>] [-f <i>filename</i>] [-i <i>sec</i>] [-s <i>time</i>]
DESCRIPTION	<p>In the first instance, <i>sar</i> samples cumulative activity counters in the operating system at <i>n</i> intervals of <i>t</i> seconds, where <i>t</i> should be 5 or greater. If <i>t</i> is specified with more than one option, all headers are printed together and the output may be difficult to read. (If the sampling interval is less than 5, the activity of <i>sar</i> itself may affect the sample.) If the <i>-o</i> option is specified, it saves the samples in <i>filename</i> in binary format. The default value of <i>n</i> is 1.</p> <p>In the second instance, no sampling interval is specified. <i>sar</i> extracts data from a previously recorded <i>filename</i>, either the one specified by the <i>-f</i> option or, by default, the standard system activity daily data file <i>/var/adm/sa/sadd</i> for the current day <i>dd</i>. The starting and ending times of the report can be bounded using the <i>-e</i> and <i>-s</i> arguments with <i>time</i> specified in the form <i>hh[:mm][:ss]</i>. The <i>-i</i> option selects records at <i>sec</i> second intervals. Otherwise, all intervals found in the data file are reported.</p>
OPTIONS	<p>The following options modify the subsets of information reported by <i>sar</i>.</p> <p><i>-a</i> Report use of file access system routines: <i>iget/s</i>, <i>namei/s</i>, <i>dirblk/s</i></p> <p><i>-A</i> Report all data. Equivalent to <i>-abcdgkmpqruvw</i>.</p> <p><i>-b</i> Report buffer activity:</p> <p style="padding-left: 2em;"><i>bread/s</i>, <i>bwrit/s</i> transfers per second of data between system buffers and disk or other block devices.</p> <p style="padding-left: 2em;"><i>lread/s</i>, <i>lwrit/s</i> accesses of system buffers.</p> <p style="padding-left: 2em;"><i>%rcache</i>, <i>%wcache</i> cache hit ratios, that is, $(1 - \text{bread}/\text{lread})$ as a percentage.</p> <p style="padding-left: 2em;"><i>pread/s</i>, <i>pwrit/s</i> transfers using raw (physical) device mechanism.</p> <p><i>-c</i> Report system calls:</p> <p style="padding-left: 2em;"><i>scall/s</i> system calls of all types.</p>

- sread/s, swrit/s, fork/s, exec/s
specific system calls.
- rchar/s, wchar/s
characters transferred by read and write system calls.
No incoming or outgoing `exec(2)` and `fork(2)` calls are reported.
- d Report activity for each block device (for example, disk or tape drive) with the exception of XDC disks and tape drives. When data is displayed, the device specification *disk-* is generally used to represent a disk drive. The device specification used to represent a tape drive is machine dependent. The activity data reported is:
- %busy, avque
portion of time device was busy servicing a transfer request, average number of requests outstanding during that time.
- read/s, write/s, blks/s
number of read/write transfers from or to device, number of bytes transferred in 512-byte units.
- await
average wait time in milliseconds.
- avserv
average service time in milliseconds.
- For more general system statistics, use `iostat(1M)`, `sar(1M)`, or `vmstat(1M)`.
See *System Administration Guide, Volume 1* for naming conventions for disks.
- e *time* Select data up to *time*. Default is 18:00.
- f *filename* Use *filename* as the data source for `sar`. Default is the current daily data file `/var/adm/sa/sadd`.
- g Report paging activities:
- pgout/s page-out requests per second.
ppgout/s pages paged-out per second.

pgfree/s pages per second placed on the free list by the page stealing daemon.

pgscan/s pages per second scanned by the page stealing daemon.

%ufs_ipf the percentage of UFS inodes taken off the freelist by iget which had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus, this is the percentage of igets with page flushes.

-i *sec* Select data at intervals as close as possible to *sec* seconds.

-k Report kernel memory allocation (KMA) activities:

 sml_mem, alloc, fail
 information about the memory pool reserving and allocating space for small requests: the amount of memory in bytes KMA has for the small pool, the number of bytes allocated to satisfy requests for small amounts of memory, and the number of requests for small amounts of memory that were not satisfied (failed).

 lg_mem, alloc, fail
 information for the large memory pool (analogous to the information for the small memory pool).

 ovsz_alloc, fail
 the amount of memory allocated for oversize requests and the number of oversize requests which could not be satisfied (because oversized memory is allocated dynamically, there is not a pool).

-m Report message and semaphore activities:

 msg/s, sema/s primitives per second.

-o *filename* Save samples in file, *filename*, in binary format.

-p Report paging activities:

 atc/s page faults per second that are satisfied by reclaiming a page currently in memory (attaches per second).

	pgin/s	page-in requests per second.
	ppgin/s	pages paged-in per second.
	pflt/s	page faults from protection errors per second (illegal access to page) or "copy-on-writes".
	vflt/s	address translation page faults per second (valid page not in memory).
	slock/s	faults per second caused by software lock requests requiring physical I/O.
-q		Report average queue length while occupied, and percent of time occupied:
	runq-sz, %runocc	run queue of processes in memory and runnable.
	swpq-sz, %swpocc	these are no longer reported by <i>sar</i> .
-r		Report unused memory pages and disk blocks:
	freemem	average pages available to user processes.
	freeswap	disk blocks available for page swapping.
-s <i>time</i>		Select data later than <i>time</i> in the form <i>hh[:mm]</i> . Default is 08:00.
-u		Report CPU utilization (the default):
	%usr, %sys, %wio, %idle	portion of time running in user mode, running in system mode, idle with some process waiting for block I/O, and otherwise idle.
-v		Report status of process, i-node, file tables:
	proc-sz, inod-sz, file-sz, lock-sz	entries/size for each table, evaluated once at sampling point.

ov
overflows that occur between sampling points for each table.

-w Report system swapping and switching activity:

swpin/s, swpot/s, bswin/s,
bswot/s
number of transfers and number of 512-byte units transferred for swapins and swapouts (including initial loading of some programs).

pswch/s
process switches.

-y Report TTY device activity:

rawch/s, canch/s, outch/s
input character rate, input character rate processed by canon, output character rate.

rcvin/s, xmtin/s, madmin/s
receive, transmit and modem interrupt rates.

EXAMPLES**EXAMPLE 1** Viewing system activity

To see today's CPU activity so far:

```
example% sar
```

EXAMPLE 2 Watching system activity evolve

To watch CPU activity evolve for 10 minutes and save data:

```
example% sar -o temp 60 10
```

EXAMPLE 3 Reviewing disk and tape activity

To later review disk and tape activity from that period:

```
example% sar -d -f temp
```

NAME	sccs – front end for the Source Code Control System (SCCS)
SYNOPSIS	<pre>/usr/ccs/bin/sccs [-r] [-d rootprefix] [-p subdir] subcommand [option...] [file...] /usr/xpg4/bin/sccs [-r] [-d rootprefix] [-p subdir] subcommand [option...] [file...]</pre>
DESCRIPTION	<p>The <code>sccs</code> command is a comprehensive, straightforward front end to the various utility programs of the Source Code Control System (SCCS).</p> <p><code>sccs</code> applies the indicated <i>subcommand</i> to the history file associated with each of the indicated files.</p> <p>The name of an SCCS history file is derived by prepending the 's.' prefix to the filename of a working copy. The <code>sccs</code> command normally expects these 's.' files' to reside in an SCCS subdirectory. Thus, when you supply <code>sccs</code> with a <i>file</i> argument, it normally applies the subcommand to a file named <i>s.file</i> in the SCCS subdirectory. If <i>file</i> is a path name, <code>sccs</code> looks for the history file in the SCCS subdirectory of that file's parent directory. If <i>file</i> is a directory, however, <code>sccs</code> applies the subcommand to every <i>s.file</i> file it contains. Thus, the command:</p> <pre>example% sccs get program.c</pre> <p>would apply the <code>get</code> subcommand to a history file named <code>SCCS/s.program.c</code>, while the command:</p> <pre>example% sccs get SCCS</pre> <p>would apply it to every <i>s.file</i> in the SCCS subdirectory.</p> <p>Options for the <code>sccs</code> command itself must appear before the <i>subcommand</i> argument. Options for a given subcommand must appear after the <i>subcommand</i> argument. These options are specific to each subcommand, and are described along with the subcommands themselves (see <i>Subcommands</i>, below).</p>
Running Setuid	<p>The <code>sccs</code> command also includes the capability to run "setuid" to provide additional protection. However, this does not apply to subcommands such as <code>sccs-admin(1)</code>, since this would allow anyone to change the authorizations of the history file. Commands that would do so always run as the real user.</p>
OPTIONS	<p>The following options are supported:</p>
<code>/usr/ccs/bin/sccs</code>	<code>-d rootprefix</code>
<code>/usr/xpg4/bin/sccs</code>	<pre>-d rootprefix Define the root portion of the path name for SCCS history files. The default root portion is the current directory. rootprefix is prepended to the entire file argument, even if file is an absolute path name. -d overrides any directory specified by the PROJECTDIR environment variable (see ENVIRONMENT, below).</pre>

/usr/ccs/bin/sccs	-p <i>subdir</i>	
/usr/xpg4/bin/sccs	-p <i>subdir</i>	Define the (sub)directory within which a history file is expected to reside. <i>SCCS</i> is the default. (See <i>EXAMPLES</i> , below).
	-r	Run <i>sccs</i> with the real user ID, rather than set to the effective user ID.
OPERANDS		
		The following operands are supported:
	<i>subcommand</i>	An <i>SCCS</i> utility name or the name of one of the pseudo-utilities listed in <i>USAGE</i> .
	<i>options</i>	An option or option-argument to be passed to <i>subcommand</i> .
	<i>operands</i>	An operand to be passed to <i>subcommand</i> .
USAGE		
Subcommands		
		Many of the following <i>sccs</i> subcommands invoke programs that reside in <i>/usr/ccs/bin</i> . Many of these subcommands accept additional arguments that are documented in the reference page for the utility program the subcommand invokes.
	<i>admin</i>	Modify the flags or checksum of an <i>SCCS</i> history file. Refer to <i>sccs-admin(1)</i> for more information about the <i>admin</i> utility. While <i>admin</i> can be used to initialize a history file, you may find that the <i>create</i> subcommand is simpler to use for this purpose.
/usr/ccs/bin/sccs	cdc <i>-rsid</i> [<i>-y</i> [<i>comment</i>]]	
/usr/xpg4/bin/sccs	cdc <i>-rsid</i> <i>-rsid</i> [<i>-y</i> [<i>comment</i>]]	Annotate (change) the delta commentary. Refer to <i>sccs-cdc(1)</i> . The <i>fix</i> subcommand can be used to replace the delta, rather than merely annotating the existing commentary.
/usr/ccs/bin/sccs	-r <i>sid</i>	
/usr/xpg4/bin/sccs	-r <i>sid</i> <i>-rsid</i>	Specify the <i>SCCS</i> delta ID (SID) to which the change notation is to be added. The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the <i>release</i> and <i>level</i> fields, and for branch deltas, the <i>branch</i> and <i>sequence</i> fields. For instance, the SID for the initial delta is normally 1.1.
	-y [<i>comment</i>]"	Specify the comment with which to annotate the delta commentary. If <i>-y</i> is omitted, <i>sccs</i> prompts

for a comment. A null *comment* results in an empty annotation.

`/usr/ccs/bin/sccs`

`check [-b]
[-u[username]]`

`/usr/xpg4/bin/sccs`

`check [-b] [-u [username] | -U]`

Check for files currently being edited. Like `info` and `tell`, but returns an exit code, rather than producing a listing of files. `check` returns a non-zero exit status if anything is being edited.

`-b` Ignore branches.

`/usr/ccs/bin/sccs`

`-u[username]`

`/usr/xpg4/bin/sccs`

`-u [username] | -U`

Check only files being edited by you. When *username* is specified, check only files being edited by that user. For `/usr/xpg4/bin/sccs`, the `-U` option is equivalent to `-u <current_user>`.

`clean [-b]`

Remove everything in the current directory that can be retrieved from an SCCS history. Does not remove files that are being edited.

`-b` Do not check branches to see if they are being edited. '`clean -b`' is dangerous when branch versions are kept in the same directory.

`comb`

Generate scripts to combine deltas. Refer to `sccs-comb(1)`.

`create`

Create (initialize) history files. `create` performs the following steps:

- Renames the original source file to `,program.c` in the current directory.
- Create the history file called `s.program.c` in the SCCS subdirectory.
- Performs an '`sccs get`' on `program.c` to retrieve a read-only copy of the initial version.

`deledit [-s] [-y[comment]]`

Equivalent to an '`sccs delta`' and then an '`sccs edit`'. `deledit` checks in a delta, and checks the file back out again, but leaves the current working copy of the file intact.

`-s` Silent. Do not report delta numbers or statistics.

`-y[comment]` Supply a comment for the delta commentary. If `-y` is omitted, `delta` prompts for a comment. A null `comment` results in an empty comment field for the delta.

`delget [-s] [-y[comment]]`

Perform an 'sccs delta' and then an 'sccs get' to check in a delta and retrieve read-only copies of the resulting new version. See the `deledit` subcommand for a description of `-s` and `-y`. `sccs` performs a delta on all the files specified in the argument list, and then a `get` on all the files. If an error occurs during the delta, the `get` is not performed.

`delta [-s] [-y[comment]]`

Check in pending changes. Records the line-by-line changes introduced while the file was checked out. The effective user ID must be the same as the ID of the person who has the file checked out. Refer to `sccs-delta(1)`. See the `deledit` subcommand for a description of `-s` and `-y`.

`/usr/ccs/bin/sccs`

`diffs [-C]`

`[-I] [-cdate-time]`

`[-rsid] diff-options`

`/usr/xpg4/bin/sccs`

`diffs [-C] [-I] [-cdate-time | -c date-time] [-rsid | -r sid] diff-options`

Compare (in `diff(1)` format) the working copy of a file that is checked out for editing, with a version from the SCCS history. Use the most recent checked-in version by default. The `diffs` subcommand accepts the same options as `diff`.

Any `-r`, `-c`, `-i`, `-x`, and `-t` options are passed to subcommand `get`. Any `-l`, `-s`, `-e`, `-f`, `-h`, and `-b` options are passed to command `diff`. A `-C` option is passed to `diff` as `-c`. An `-I` option is passed to `diff` as `-i`.

`/usr/ccs/bin/sccs`

`-cdate-time`

`/usr/xpg4/bin/sccs`

`-c date-time | -cdate-time`

Use the most recent version checked in before the indicated date and time for comparison. `date-time` takes the form: `yy[mm[dd[hh[mm[ss]]]]]`.

Omitted units default to their maximum possible values; that is `-c7502` is equivalent to `-c750228235959`.

`/usr/ccs/bin/sccs`

`-rsid`

`/usr/xpg4/bin/sccs`

`-r sid | -rsid` Use the version corresponding to the indicated delta for comparison.

`edit`

Retrieve a version of the file for editing. 'sccs edit' extracts a version of the file that is writable by you, and creates a `p.` file in the SCCS subdirectory as lock on the history, so that no one else can check that version in or out. ID keywords are retrieved in unexpanded form.

		edit accepts the same options as <code>get</code> , below. Refer to <code>sccs-get(1)</code> for a list of ID keywords and their definitions.
	<code>enter</code>	Similar to <code>create</code> , but omits the final ' <code>sccs get</code> '. This may be used if an ' <code>sccs edit</code> ' is to be performed immediately after the history file is initialized.
<code>/usr/ccs/bin/sccs</code>	<code>fix -rsid</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>fix -r sid -rsid</code>	Revise a (leaf) delta. Remove the indicated delta from the SCCS history, but leave a working copy of the current version in the directory. This is useful for incorporating trivial updates for which no audit record is needed, or for revising the delta commentary. <code>fix</code> must be followed by a <code>-r</code> option, to specify the SID of the delta to remove. The indicated delta must be the most recent (leaf) delta in its branch. Use <code>fix</code> with caution since it does not leave an audit trail of differences (although the previous commentary is retained within the history file).
<code>/usr/ccs/bin/sccs</code>	<code>get [-ekmps]</code> <code>[-cdate-time] [-r[sid]]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>get [-ekmps] [-c date-time -cdate-time] [-r sid -rsid]</code>	Retrieve a version from the SCCS history. By default, this is a read-only working copy of the most recent version; ID keywords are in expanded form. Refer to <code>sccs-get(1)</code> , which includes a list of ID keywords and their definitions.
	<code>-e</code>	Retrieve a version for editing. Same as <code>sccs edit</code> .
	<code>-k</code>	Retrieve a writable copy but do not check out the file. ID keywords are unexpanded.
	<code>-m</code>	Precede each line with the SID of the delta in which it was added.
	<code>-p</code>	Produce the retrieved version on the standard output. Reports that would normally go to the standard output (delta IDs and statistics) are directed to the standard error.
	<code>-s</code>	Silent. Do not report version numbers or statistics.
<code>/usr/ccs/bin/sccs</code>	<code>-cdate-time</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>-c date-time -cdate-time</code>	

		Retrieve the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form: <i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]]]].
/usr/ccs/bin/sccs	-r [<i>sid</i>]	Retrieve the version corresponding to the indicated SID. If no <i>sid</i> is specified, the latest <i>sid</i> for the specified file is retrieved.
/usr/xpg4/bin/sccs	-r <i>sid</i> -r <i>sid</i>	Retrieve the version corresponding to the indicated SID.
	help	<i>message-code</i> <i>sccs-command</i>
	help <i>stuck</i>	Supply more information about SCCS diagnostics. help displays a brief explanation of the error when you supply the code displayed by an SCCS diagnostic message. If you supply the name of an SCCS command, it prints a usage line. help also recognizes the keyword <i>stuck</i> . Refer to <i>sccs-help</i> (1).
/usr/ccs/bin/sccs	info [-b] [-u[<i>username</i>]]	
/usr/xpg4/bin/sccs	info [-b] [-u [<i>username</i>] -U]	Display a list of files being edited, including the version number checked out, the version to be checked in, the name of the user who holds the lock, and the date and time the file was checked out.
	-b	Ignore branches.
/usr/ccs/bin/sccs	-u [<i>username</i>]	
/usr/xpg4/bin/sccs	-u [<i>username</i>] -U	List only files checked out by you. When <i>username</i> is specified, list only files checked out by that user. For <i>/usr/xpg4/bin/sccs</i> , the -U option is equivalent to -u <i><current_user></i> .
	print	Print the entire history of each named file. Equivalent to an 'sccs prs -e' followed by an 'sccs get -p -m'.
/usr/ccs/bin/sccs	prs [-e1] [-c <i>date-time</i>] [-r <i>sid</i>]	
/usr/xpg4/bin/sccs	prs [-e1] [-c <i>date-time</i> -c <i>date-time</i>] [-r <i>sid</i> -r <i>sid</i>]	Peruse (display) the delta table, or other portion of an <i>s</i> . file. Refer to <i>sccs-prs</i> (1).

	<code>-e</code>	Display delta table information for all deltas earlier than the one specified with <code>-r</code> (or all deltas if none is specified).
	<code>-l</code>	Display information for all deltas later than, and including, that specified by <code>-c</code> or <code>-r</code> .
<code>/usr/ccs/bin/sccs</code> <code>/usr/xpg4/bin/sccs</code>	<code>-c date-time</code>	
	<code>-c date-time -c date-time</code>	Specify the latest delta checked in before the indicated date and time. The <code>date-time</code> argument takes the form: <code>yy[mm[dd[hh[mm[ss]]]]]</code> .
<code>/usr/ccs/bin/sccs</code> <code>/usr/xpg4/bin/sccs</code>	<code>-r sid</code> <code>-r sid -r sid</code>	Specify a given delta by SID.
	<code>prt [-y]</code>	Display the delta table, but omit the MR field (see <code>sccsfile(4)</code> for more information on this field). Refer to <code>sccs-prt(1)</code> .
	<code>-y</code>	Display the most recent delta table entry. The format is a single output line for each file argument, which is convenient for use in a pipeline with <code>awk(1)</code> or <code>sed(1)</code> .
<code>/usr/ccs/bin/sccs</code>	<code>rm del -r sid</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>rm del -r sid</code>	Remove the indicated delta from the history file. That delta must be the most recent (leaf) delta in its branch. Refer to <code>sccs-rm del(1)</code> .
	<code>sact</code>	Show editing activity status of an SCCS file. Refer to <code>sccs-sact(1)</code> .
	<code>sccsdiff -r old-sid -r new-sid diff-options</code>	Compare two versions corresponding to the indicated SIDs (deltas) using <code>diff</code> . Refer to <code>sccs-sccsdiff(1)</code> .
<code>/usr/ccs/bin/sccs</code> <code>/usr/xpg4/bin/sccs</code>	<code>tell [-b]</code> <code>[-u [username]]</code> <code>tell [-b] [-u [username] -U]</code>	Display the list of files that are currently checked out, one file per line.
	<code>-b</code>	Ignore branches.

<code>/usr/ccs/bin/sccs</code>	<code>-u[username]</code>	
<code>/usr/xpg4/bin/sccs</code>	<code>-u [username] -U</code>	List only files checked out to you. When <i>username</i> is specified, list only files checked out to that user. For <code>/usr/xpg4/bin/sccs</code> , the <code>-U</code> option is equivalent to <code>-u <current_user></code> .
	<code>unedit</code>	“Undo” the last edit or ‘get -e’, and return the working copy to its previous condition. <code>unedit</code> backs out all pending changes made since the file was checked out.
	<code>unget</code>	Same as <code>unedit</code> . Refer to <code>sccs-unget(1)</code> .
	<code>val</code>	Validate the history file. Refer to <code>sccs-val(1)</code> .
	<code>what</code>	Display any expanded ID keyword strings contained in a binary (object) or text file. Refer to <code>what(1)</code> for more information.

EXAMPLES**EXAMPLE 1** Checking out, editing, and checking in a file

To check out a copy of `program.c` for editing, edit it, and then check it back in:

```
example% sccs edit program.c
1.1
new delta 1.2
14 lines
example% vi program.c
your editing session

example% sccs delget program.c

comments? clarified cryptic diagnostic
1.2
3 inserted
2 deleted
12 unchanged
1.2
15 lines
```

EXAMPLE 2 Defining the root portion of the command pathname

`sccs` converts the command:

```
example% sccs -d/usr/src/include get stdio.h
```

to:

```
/usr/ccs/bin/get /usr/src/include/SCCS/s.stdio.h
```

EXAMPLE 3 Defining the resident subdirectory

The command:

```
example% sccs -pprivate get include/stdio.h
```

becomes:

```
/usr/ccs/bin/get include/private/s.stdio.h
```

EXAMPLE 4 Initializing a history file

To initialize the history file for a source file named `program.c`, make the SCCS subdirectory, and then use 'sccs create':

```
example% mkdir SCCS
example% sccs create program.c
program.c:
1.1
14 lines
```

After verifying the working copy, you can remove the backup file that starts with a comma:

```
example% diff program.c ,program.c
example% rm ,program.c
```

EXAMPLE 5 Retrieving a file from another directory

To retrieve a file from another directory into the current directory:

```
example% sccs get /usr/src/sccs/cc.c
```

or:

```
example% sccs -p/usr/src/sccs/ get cc.c
```

EXAMPLE 6 Checking out all files

To check out all files under SCCS in the current directory:

```
example% sccs edit SCCS
```

EXAMPLE 7 Checking in all files

To check in all files currently checked out to you:

```
example% sccs delta `sccs tell -u`
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sccs`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

PROJECTDIR If contains an absolute path name (beginning with a slash), `sccs` searches for SCCS history files in the directory given by that variable.

If PROJECTDIR does not begin with a slash, it is taken as the name of a user, and sccs searches the src or source subdirectory of that user's home directory for history files. If such a directory is found, it is used. Otherwise, the value is used as a relative path name.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

FILES

- SCCS SCCS subdirectory
- SCCS/d.file temporary file of differences
- SCCS/p.file lock (permissions) file for checked-out versions
- SCCS/q.file temporary file
- SCCS/s.file SCCS history file
- SCCS/x.file temporary copy of the s.file
- SCCS/z.file temporary lock file
- /usr/ccs/bin/* SCCS utility programs

NAME	sccs-admin, admin – create and administer SCCS history files
SYNOPSIS	<code>/usr/ccs/bin/admin [-bhnz] [-a <i>username</i> <i>groupid</i>]...[-d <i>flag</i>] ... [-e <i>username</i> <i>groupid</i>]...[-f <i>flag</i> [<i>value</i>]] ... [-i [<i>filename</i>]] [-m <i>mr-list</i>] [-r <i>release</i>] [-t [<i>description-file</i>]] [-y [<i>comment</i>]] <i>s.filename</i>...</code>
DESCRIPTION	<p>The <code>admin</code> command creates or modifies the flags and other parameters of SCCS history files. Filenames of SCCS history files begin with the ‘<code>s.</code>’ prefix, and are referred to as <code>s.</code> files, or “history” files.</p> <p>The named <code>s.</code> file is created if it does not exist already. Its parameters are initialized or modified according to the options you specify. Parameters not specified are given default values when the file is initialized, otherwise they remain unchanged.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>admin</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error. The use of ‘<code>-</code>’ as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-b</code> Force encoding of binary data. Files that contain ASCII NUL or other control characters, or that do not end with a NEWLINE, are recognized as binary data files. The contents of such files are stored in the history file in encoded form. See <code>uuencode(1C)</code> for details about the encoding. This option is normally used in conjunction with <code>-i</code> to force <code>admin</code> to encode initial versions not recognized as containing binary data.</p> <p><code>-h</code> Check the structure of an existing <code>s.</code> file (see <code>sccsfile(4)</code>), and compare a newly computed check-sum with one stored in the first line of that file. <code>-h</code> inhibits writing on the file; and so nullifies the effect of any other options.</p> <p><code>-n</code> Create a new SCCS history file.</p> <p><code>-z</code> Recompute the file check-sum and store it in the first line of the <code>s.</code> file. Caution: it is important to verify the contents of the history file (see <code>sccs-val(1)</code>, and the <code>print</code> subcommand in <code>sccs(1)</code>), since using <code>-z</code> on a truly corrupted file may prevent detection of the error.</p> <p><code>-a <i>username</i> <i>groupid</i></code> Add a user name, or a numerical group ID, to the list of users who may check deltas in or out. If the list is empty, any user is allowed to do so.</p>

- d** *flag*
Delete the indicated *flag* from the SCCS file. The **-d** option may be specified only for existing s.files. See **-f** for the list of recognized flags.
- e** *username* | *groupid*
Erase a user name or group ID from the list of users allowed to make deltas.
- f** *flag* [*value*]
Set the indicated *flag* to the (optional) *value* specified. The following flags are recognized:
- | | |
|---|--|
| b | Enable branch deltas. When b is set, branches can be created using the -b option of the SCCS <code>get</code> command (see <code>sccs-get(1)</code>). |
| c
<i>ceil</i> | Set a ceiling on the releases that can be checked out. <i>ceil</i> is a number less than or equal to 9999. If c is not set, the ceiling is 9999. |
| f
<i>floor</i> | Set a floor on the releases that can be checked out. The floor is a number greater than 0 but less than 9999. If f is not set, the floor is 1. |
| d
<i>sid</i> | The default delta number, or SID, to be used by an SCCS <code>get</code> command. |
| i | Treat the 'No id keywords (ge6)' message issued by an SCCS <code>get</code> or <code>delta</code> command as an error rather than a warning. |
| j | Allow concurrent updates. |
| la
l
<i>release</i>
[,
<i>release</i>
...] | Lock the indicated list of releases against deltas. If a is used, lock out deltas to all releases. An SCCS ' <code>get -e</code> ' command fails when applied against a locked release. |
| n | Create empty releases when releases are skipped. These null (empty) deltas serve as anchor points for branch deltas. |
| q
<i>value</i> | Supply a <i>value</i> to which the keyword is to expand when a read-only version is retrieved with the SCCS <code>get</code> command. |

- m*
module
- Supply a value for the module name to which the `sccs-admin.1` keyword is to expand. If the `m` flag is not specified, the value assigned is the name of the SCCS file with the leading `s.` removed.
- t*
type
- Supply a value for the module type to which the keyword is to expand.
- v* [
program
]
- Specify a validation *program* for the MR numbers associated with a new delta. The optional *program* specifies the name of an MR number validity checking *program*. If this flag is set when creating an SCCS file, the `-m` option must also be used, in which case the list of MR *s* may be empty.
- `-i` [*filename*]
- Initialize the history file with text from the indicated file. This text constitutes the initial delta, or set of checked-in changes. If *filename* is omitted, the initial text is obtained from the standard input. Omitting the `-i` option altogether creates an empty `s.` file. You can only initialize one `s.` file with text using `-i`. This option implies the `-n` option.
- `-m` *mr-list*
- Insert the indicated Modification Request (MR) numbers into the commentary for the initial version. When specifying more than one MR number on the command line, *mr-list* takes the form of a quoted, space-separated list. A warning results if the `v` flag is not set or the MR validation fails.
- `-r` *release*
- Specify the release for the initial delta. `-r` may be used only in conjunction with `-i`. The initial delta is inserted into release 1 if this option is omitted. The level of the initial delta is always 1; initial deltas are named 1.1 by default.
- `-t` [*description-file*]
- Insert descriptive text from the file *description-file*. When `-t` is used in conjunction with `-n`, or `-i` to initialize a new `s.file`, the *description-file* must be supplied. When modifying the description for an existing file: a `-t` option without a *description-file* removes the descriptive text, if any; a `-t` option with a *description-file* replaces the existing text.
- `-y` [*comment*]
- Insert the indicated *comment* in the "Comments:" field for the initial delta. Valid only in conjunction with `-i` or `-n`. If `-y` option is omitted, a default

comment line is inserted that notes the date and time the history file was created.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

FILES

- s.* history file
- SCCS/s.* history file in SCCS subdirectory
- z.* temporary lock file

DIAGNOSTICS

Use the `SCCS help` command for explanations (see `sccs-help(1)`).

WARNINGS

The last component of all SCCS filenames must have the 's.' prefix. New SCCS files are given mode 444 (see `chmod(1)`). All writing done by `admin` is to a temporary file with an x. prefix, created with mode 444 for a new SCCS file, or with the same mode as an existing SCCS file. After successful execution of `admin`, the existing s. file is removed and replaced with the x. file. This ensures that changes are made to the SCCS file only when no errors have occurred.

It is recommended that directories containing SCCS files have permission mode 755, and that the s. files themselves have mode 444. The mode for directories allows only the owner to modify the SCCS files contained in the directories, while the mode of the s. files prevents all modifications except those performed using SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner to allow use of a text editor. However, extreme care must be taken when doing this. The edited file should *always* be processed by an 'admin -h' to check for corruption, followed by an 'admin -z' to generate a proper check-sum. Another 'admin -h' is recommended to ensure that the resulting s. file is valid.

`admin` also uses a temporary lock s. file, starting with the 'z.' prefix, to prevent simultaneous updates to the s. file. See `sccs-get(1)` for further information about the 'z. file'.

NAME	sccs-cdc, cdc – change the delta commentary of an SCCS delta
SYNOPSIS	<code>/usr/ccs/bin/cdc -r sid [-m mr-list] [-y [comment]] s.filename...</code>
DESCRIPTION	<p>cdc annotates the delta commentary for the SCCS delta ID (SID) specified by the <code>-r</code> option in each named <code>s.</code> file.</p> <p>If the <code>v</code> flag is set in the <code>s.</code> file, you can also use <code>cdc</code> to update the Modification Request (MR) list.</p> <p>If you checked in the delta, or, if you own the file and directory and have write permission, you can use <code>cdc</code> to annotate the commentary.</p> <p>Rather than replacing the existing commentary, <code>cdc</code> inserts the new comment you supply, followed by a line of the form:</p> <pre>*** CHANGED *** yy / mm / dd hh / mm / ss username</pre> <p>above the existing commentary.</p> <p>If a directory is named as the <code>s.filename</code> argument, the <code>cdc</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). If <code>'-'</code> is given as the <code>s.filename</code> argument, each line of the standard input is taken as the name of an SCCS history file to be processed, and the <code>-m</code> and <code>-y</code> options must be used.</p>
OPTIONS	<p><code>-r</code> <i>sid</i> Specify the SID of the delta to change.</p> <p><code>-m</code> <i>mr-list</i> Specify one or more MR numbers to add or delete. When specifying more than one MR on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. To delete an MR number, precede it with a <code>!</code> character (an empty MR list has no effect). A list of deleted MRs is placed in the comment section of the delta commentary. If <code>-m</code> is not used and the standard input is a terminal, <code>cdc</code> prompts with <code>MRs?</code> for the list (before issuing the <code>comments?</code> prompt). <code>-m</code> is only useful when the <code>v</code> flag is set in the <code>s.</code> file. If that flag has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, <code>cdc</code> terminates and the delta commentary remains unchanged.</p> <p><code>-y</code> [<i>comment</i>] Use <i>comment</i> as the annotation in the delta commentary. The previous comments are retained; the <i>comment</i> is added along with a notation that the commentary was changed. A null <i>comment</i> leaves the commentary unaffected. If <code>-y</code> is not specified and the standard input is a terminal, <code>cdc</code></p>

prompts with `comments?` for the text of the notation to be added. An unescaped NEWLINE character terminates the annotation text.

EXAMPLES

EXAMPLE 1 Changing the annotated commentary

The following command:

```
example% cdc -r1.6 -y"corrected commentary" s.program.c
```

produces the following annotated commentary for delta 1.6 in `s.program.c`:

```
D 1.6 88/07/05 23:21:07 username 9 0 00001/00000/00000
MRs:
COMMENTS:
corrected commentary
*** CHANGED *** 88/07/07 14:09:41 username
performance enhancements in main()
```

FILES

DIAGNOSTICS

Use the `SCCS help` command for explanations (see `sccs-help(1)`).

NAME	sccs-comb, comb – combine SCCS deltas				
SYNOPSIS	/usr/ccs/bin/comb [-os] [-c <i>sid-list</i>] [-p <i>sid</i>] <i>s.filename...</i>				
DESCRIPTION	<p>comb generates a shell script (see <code>sh(1)</code>) that you can use to reconstruct the indicated <code>s.</code> files. This script is written to the standard output.</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the <code>comb</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p> <p>If no options are specified, <code>comb</code> preserves only the most recent (leaf) delta in a branch, and the minimal number of ancestors needed to preserve the history.</p>				
OPTIONS	<p>The following options are supported:</p> <p>-o For each 'get -e' generated, access the reconstructed file at the release of the delta to be created. Otherwise, the reconstructed file is accessed at the most recent ancestor. The use of -o may decrease the size of the reconstructed <code>s.</code> file. It may also alter the shape of the delta tree of the original file.</p> <p>-s Generate scripts to gather statistics, rather than combining deltas. When run, the shell scripts report: the file name, size (in blocks) after combining, original size (also in blocks), and the percentage size change, computed by the formula:</p> $100 * (original - combined) / original$ <p>This option can be used to calculate the space that will be saved, before actually doing the combining.</p> <p>-c <i>sid-list</i> Include the indicated list of deltas. All other deltas are omitted. <i>sid-list</i> is a comma-separated list of SCCS delta IDs (SIDs). To specify a range of deltas, use a '-' separator instead of a comma, between two SIDs in the list.</p> <p>-p <i>SID</i> The SID of the oldest delta to be preserved.</p>				
FILES	<table border="0"> <tr> <td><code>s.COMB</code></td> <td>reconstructed SCCS file</td> </tr> <tr> <td><code>comb?????</code></td> <td>temporary file</td> </tr> </table>	<code>s.COMB</code>	reconstructed SCCS file	<code>comb?????</code>	temporary file
<code>s.COMB</code>	reconstructed SCCS file				
<code>comb?????</code>	temporary file				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO

sccs(1), sccs-admin(1), sccs-cdc(1), sccs-delta(1), sccs-help(1), sccs-prs(1), sccs-prt(1), sccs-rmdel(1), sccs-sccsdiff(1), what(1), sccsfile(4), attributes(5)

DIAGNOSTICS

Use the SCCS `help` command for explanations (see `sccs-help(1)`).

BUGS

`comb` may rearrange the shape of the tree of deltas. It may not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.

NAME	sccs-delta, delta – make a delta to an SCCS file												
SYNOPSIS	<pre>/usr/ccs/bin/delta [-dnps] [-g sid-list -g sid-list][-m mr-list -m mr-list][-r sid -r sid][-y [comment]] s.filename... /usr/xpg4/bin/delta [-dnps] [-g sid-list -g sid-list][-m mr-list -m mr-list][-r sid -r sid][-y [comment]] s.filename...</pre>												
DESCRIPTION	<p>delta checks in a record of the line-by-line differences made to a checked-out version of a file under SCCS control. These changes are taken from the writable working copy that was retrieved using the SCCS <code>get</code> command (see <code>sccs-get(1)</code>). This working copy does not have the 's.' prefix, and is also referred to as a <code>g</code>-file.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>delta</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of '-' as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line (requires <code>-y</code>, and in some cases, <code>-m</code>).</p> <p>delta may issue prompts on the standard output depending upon the options specified and the flags that are set in the <code>s.</code> file (see <code>sccs-admin(1)</code>, and the <code>-m</code> and <code>-y</code> options below, for details).</p> <p>The SID of the delta is not echoed to <code>stdout</code>.</p>												
OPTIONS	<p>The following options are supported:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>-d</code></td> <td>Use command <code>diff(1)</code> instead of <code>bdiff(1)</code>. Returns exit status 2 if <code>s.filename</code> argument is not specified.</td> </tr> <tr> <td style="vertical-align: top;"><code>-n</code></td> <td>Retain the edited <code>g</code>-file, which is normally removed at the completion of processing.</td> </tr> <tr> <td style="vertical-align: top;"><code>-p</code></td> <td>Display line-by-line differences (in <code>diff(1)</code> format) on the standard output.</td> </tr> <tr> <td style="vertical-align: top;"><code>-s</code></td> <td>Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).</td> </tr> <tr> <td style="vertical-align: top;"><code>-g</code> <code>sid-list</code></td> <td>Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. <code>sid-list</code> is a comma-separated list of SID s. To specify a range of</td> </tr> <tr> <td style="vertical-align: top;"><code> -g</code> <code>sid-list</code></td> <td></td> </tr> </table>	<code>-d</code>	Use command <code>diff(1)</code> instead of <code>bdiff(1)</code> . Returns exit status 2 if <code>s.filename</code> argument is not specified.	<code>-n</code>	Retain the edited <code>g</code> -file, which is normally removed at the completion of processing.	<code>-p</code>	Display line-by-line differences (in <code>diff(1)</code> format) on the standard output.	<code>-s</code>	Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).	<code>-g</code> <code>sid-list</code>	Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. <code>sid-list</code> is a comma-separated list of SID s. To specify a range of	<code> -g</code> <code>sid-list</code>	
<code>-d</code>	Use command <code>diff(1)</code> instead of <code>bdiff(1)</code> . Returns exit status 2 if <code>s.filename</code> argument is not specified.												
<code>-n</code>	Retain the edited <code>g</code> -file, which is normally removed at the completion of processing.												
<code>-p</code>	Display line-by-line differences (in <code>diff(1)</code> format) on the standard output.												
<code>-s</code>	Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).												
<code>-g</code> <code>sid-list</code>	Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. <code>sid-list</code> is a comma-separated list of SID s. To specify a range of												
<code> -g</code> <code>sid-list</code>													

<pre> -m mr-list -m mr-list </pre>	<p>deltas, use a ' ' separator instead of a comma, between two SID s in the list.</p> <p>If the SCCS file has the v flag set (see <i>sccs-admin(1)</i>), you must supply one or more Modification Request (MR) numbers for the new delta. When specifying more than one MR number on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. If <i>-m</i> is not used and the standard input is a terminal, <i>delta</i> prompts with <i>MRs?</i> for the list (before issuing the <i>comments?</i> prompt). If the v flag in the <i>s.</i> file has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, <i>delta</i> terminates without checking in the changes.</p>
<pre> -r sid -r sid </pre>	<p>When two or more versions are checked out, specify the version to check in. This SID value can be either the SID specified on the <i>get</i> command line, or the SID of the new version to be checked in as reported by <i>get</i> . A diagnostic results if the specified SID is ambiguous, or if one is required but not supplied.</p>
<pre> -y [comment] </pre>	<p>Supply a comment for the delta table (version log). A null comment is accepted, and produces an empty commentary in the log. If <i>-y</i> is not specified and the standard input is a terminal, <i>delta</i> prompts with 'comments? '. An unescaped NEWLINE terminates the comment.</p>

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	An error occurred and the <i>-d</i> option had not been specified.

2 An error occurred, the `-d` option had been specified, and the `s.filename` argument was not specified.

FILES

DIAGNOSTICS

Use the SCCS `help` command for explanations (see `sccs-help(1)`).

WARNINGS

Lines beginning with an ASCII SOH character (binary 001) cannot be placed in the SCCS file unless the SOH is escaped. This character has special meaning to SCCS (see `sccsfile(4)`) and produces an error.

NAME	sccs-get, get – retrieve a version of an SCCS file
SYNOPSIS	<pre> /usr/ccs/bin/get [-begkmpst] [-l [p]] [-a sequence] [-c date-time -c date-time] [-G g-file] [-i sid-list -i sid-list] [-r [sid]] [-x sid-list -x sid-list] s.filename... /usr/xpg4/bin/get [-begkmpst] [-l [p]] [-a sequence] [-c date-time -c date-time] [-G g-file] [-i sid-list -i sid-list] [-r sid -r sid] [-x sid-list -x sid-list] s.filename... </pre>
DESCRIPTION	<p>The <code>get</code> utility retrieves a working copy from the SCCS history file, according to the specified options.</p> <p>For each <code>s.filename</code> argument, <code>get</code> displays the SCCS delta ID (SID) and number of lines retrieved.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>get</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p> <p>The retrieved file normally has the same filename base as the <code>s.</code> file, less the prefix, and is referred to as the <code>g-</code> file.</p> <p>For each file processed, <code>get</code> responds (on the standard output) with the SID being accessed, and with the number of lines retrieved from the <code>s.</code> file.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-b</code> Create a new branch. Used with the <code>-e</code> option to indicate that the new delta should have an SID in a new branch. Instead of incrementing the level for version to be checked in, <code>get</code> indicates in the <code>p.</code> file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <code>s.</code> file, this option is ignored.</p> <p><code>-e</code> Retrieve a version for editing. With this option, <code>get</code> places a lock on the <code>s.</code> file, so that no one else can check in changes to the version you have checked out. If the <code>j</code> flag is set in the <code>s.</code> file, the lock is advisory: <code>get</code> issues a warning message. Concurrent use of <code>'get -e'</code> for different SIDs is allowed; however, <code>get</code> will not check out a</p>

	version of the file if a writable version is present in the directory. All SCCS file protections stored in the <code>s.</code> file, including the release ceiling, floor, and authorized user list, are honored by <code>'get -e'</code> .
<code>-g</code>	Get the SCCS version ID, without retrieving the version itself. Used to verify the existence of a particular SID.
<code>-k</code>	Suppress expansion of ID keywords. <code>-k</code> is implied by the <code>-e</code> .
<code>-m</code>	Precede each retrieved line with the SID of the delta in which it was added to the file. The SID is separated from the line with a TAB.
<code>-n</code>	Precede each line with the <code>M</code> ID keyword and a TAB. When both the <code>-m</code> and <code>-n</code> options are used, the ID keyword precedes the SID, and the line of text.
<code>-p</code>	Write the text of the retrieved version to the standard output. All messages that normally go to the standard output are written to the standard error instead.
<code>-s</code>	Suppress all output normally written on the standard output. However, fatal error messages (which always go to the standard error) remain unaffected.
<code>-t</code>	Retrieve the most recently created (top) delta in a given release (for example: <code>-r1</code>).
<code>-l</code> <code>[p</code> <code>]</code>	Retrieve a summary of the delta table (version log) and write it to a listing file, with the <code>'l.'</code> prefix (called <code>'l.'</code> file). When <code>-lp</code> is used, write the summary onto the standard output.
<code>-a</code> <i>sequence</i>	Retrieve the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>sccs-comb(1)</code>); for users, <code>-r</code> is an easier way to specify a version. <code>-a</code> supersedes <code>-r</code> when both are used.

<pre> -c date-time -c date-time </pre>	<p>Retrieve the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form:</p> <pre>yy [mm [dd [hh [mm [ss]]]]]</pre> <p>Units omitted from the indicated date and time default to their maximum possible values; that is <code>-c 7502</code> is equivalent to <code>-c 750228235959</code>. Values of <i>yy</i> in the range 69 -99 refer to the twentieth century. Values in the range 00 -68 refer to the twenty-first century. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the <i>date-time</i> specification must be quoted.</p>
<pre> -G newname </pre>	<p>Use <i>newname</i> as the name of the retrieved version.</p>
<pre> -i sid-list -i sid-list </pre>	<p>Specify a list of deltas to include in the retrieved version. The included deltas are noted in the standard output message. <i>sid-list</i> is a comma-separated list of SID s. To specify a range of deltas, use a '-' separator instead of a comma, between two SID s in the list.</p>
<pre> /usr/ccs/bin/get -r [sid] </pre>	<p>Retrieve the version corresponding to the indicated SID (delta).</p> <p>The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the <i>release</i> and <i>level</i> fields, and for branch deltas, the <i>branch</i> and <i>sequence</i> fields. For instance, if 1 . 2 is the SID , 1 is the release, and 2 is the level number. If 1 . 2 . 3 . 4 is the SID, 3 is the branch and 4 is the sequence number.</p> <p>You need not specify the entire SID to retrieve a version with <code>get</code>. When you omit <code>-r</code> altogether, or when you omit both release and level, <code>get</code> normally retrieves the highest release and level. If the <code>d</code> flag is set to an SID in the <code>s.</code> file and you omit the SID , <code>get</code> retrieves the default version indicated by that flag.</p> <p>When you specify a release but omit the level, <code>get</code> retrieves the highest level in that release. If</p>

/usr/xpg4/bin/get

-r
sid
| -r
sid

that release does not exist, `get` retrieves highest level from the next-highest existing release.

Similarly with branches, if you specify a release, level and branch, `get` retrieves the highest sequence in that branch.

Same as for `/usr/ccs/bin/get` except that SID is mandatory.

-x
sid-list
| -x
sid-list

Exclude the indicated deltas from the retrieved version. The excluded deltas are noted in the standard output message. `sid-list` is a comma-separated list of SID s. To specify a range of deltas, use a '-' separator instead of a comma, between two SID s in the list.

OUTPUT**/usr/ccs/bin/get**

The output format for `/usr/ccs/bin/get` is as follows:

```
"%s\ %d lines\ ", <SID>, <number of lines>
```

/usr/xpg4/bin/get

The output format for `/usr/xpg4/bin/get` is as follows:

```
"%s\ %d\ ", <SID>, <number of lines>
```

USAGE**ID Keywords**

In the absence of `-e` or `-k`, `get` expands the following ID keywords by replacing them with the indicated values in the text of the retrieved source.

Keyword	Value
A	Shorthand notation for an ID line with data for <code>what(1)</code> : ZY M IZ
B	SID branch component
C	Current line number. Intended for identifying messages output by the program such as "this shouldn't have happened" type errors. It is <i>not</i> intended to be used on every line to provide sequence numbers.
D	Current date: <code>yy /mm /dd</code>
E	Date newest applied delta was created: <code>yy /mm /dd</code>
F	SCCS <code>s.</code> file name
G	Date newest applied delta was created: <code>mm /dd /yy</code>

<i>Keyword</i>	<i>Value</i>
H	Current date: <i>mm / dd / yy</i>
I	SID of the retrieved version: <i>R.L.B.S</i>
L	SID level component
M	Module name: either the value of the <i>m</i> flag in the <i>s.</i> file (see <i>sccs-admin(1)</i>), or the name of the <i>s.</i> file less the prefix
P	Fully qualified <i>s.</i> file name
Q	Value of the <i>q</i> flag in the <i>s.</i> file
R	SID Release component
S	SID Sequence component
T	Current time: <i>hh : mm : ss</i>
U	Time the newest applied delta was created: <i>hh : mm : ss</i>
W	Shorthand notation for an ID line with data for <i>what</i> : <i>ZM I</i>
Y	Module type: value of the <i>t</i> flag in the <i>s.</i> file
Z	4-character string: '@(#)', recognized by <i>what</i>

ID String

The table below explains how the SCCS identification string is determined for retrieving and creating deltas.

Determination of SCCS Identification String				
SID (1) Specified	-b Option Used (2)	Other Conditions	SID Retrieved	SID of Delta to be Created
none (3)	no	R defaults to mR	mR.mL	mR.(mL+1)
none (3)	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
R	no	R > mR	mR.mL	R.1 (4)
R	no	R = mR	mR.mL	mR.(mL+1)
R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
R	yes	R = mR	mR.mL	mR.mL.(mB+1).1
R	-	R < mR and R does <i>not</i> exist	hR.mL (5)	hR.mL.(mB+1).1
R	-	Trunk succ. (6) in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk succ.	R.L	R.(L+1)

Determination of SCCS Identification String				
SID (1) Specified	-b Option Used (2)	Other Conditions	SID Retrieved	SID of Delta to be Created
R.L	yes	No trunk succ.	R.L	R.L.(mB+1).1
R.L	-	Trunk succ. in release >= R	R.L	R.L.(mB+1).1
R.L.B	no	No branch succ.	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch succ.	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch succ.	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch succ.	R.L.B.S	R.L.(mB+1).1
R.L.B.S	-	Branch succ.	R.L.B.S	R.L.(mB+1).1

- (1) 'R', 'L', 'B', and 'S' are the 'release', 'level', 'branch', and 'sequence' components of the SID, respectively; 'm' means 'maximum'. Thus, for example, 'R.mL' means 'the maximum level number within release R'; 'R.L.(mB+1).1' means 'the first sequence number on the *new* branch (that is, maximum branch number plus one) of level L within release R'. Note: if the SID specified is of the form 'R.L', 'R.L.B', or 'R.L.B.S', each of the specified components *must* exist.
- (2) The -b option is effective only if the b flag is present in the file. An entry of '-' means 'irrelevant'.
- (3) This case applies if the d (default SID) flag is *not* present in the file. If the d flag *is* present in the file, the SID obtained from the d flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.
- (4) Forces creation of the *first* delta in a *new* release.
- (5) 'hR' is the highest *existing* release that is lower than the specified, *nonexistent*, release R.
- (6) Successor.

DIAGNOSTICS

Use the *SCCS help* command for explanations (see *sccs-help(1)*).

BUGS

If the effective user has write permission (either explicitly or implicitly) in the directory containing the SCCS files, but the real user does not, only one file may be named when using *-e*.

NAME sccs-help, help – ask for help regarding SCCS error or warning messages

SYNOPSIS `/usr/ccs/bin/help [argument...]`

DESCRIPTION The `help` utility retrieves information to further explain errors messages and warnings from SCCS commands. It also provides some information about SCCS command usage. If no arguments are given, `help` prompts for one.

An *argument* may be a message number (which normally appears in parentheses following each SCCS error or warning message), or an SCCS command name. `help` responds with an explanation of the message or a usage line for the command.

When all else fails, try `'/usr/ccs/bin/help stuck'`.

FILES `/usr/lib/help` directory containing files of message text

NAME	sccs-prs, prs – display selected portions of an SCCS history
SYNOPSIS	<code>/usr/ccs/bin/prs [-aϵl] [-c <i>date-time</i>] [-d <i>dataspec</i>] [-r <i>sid</i>] <i>s.filename</i>...</code>
DESCRIPTION	<p>The <code>prs</code> utility displays part or all of the SCCS file (see <code>sccsfile(4)</code>) in a user supplied format.</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the <code>prs</code> command applies to all <i>s.</i> files in that directory. Unreadable <i>s.</i> files produce an error; processing continues with the next file (if any). The use of ‘-’ as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s.</i> file per line.</p>
OPTIONS	<p>In the absence of options, <code>prs</code> displays the delta table (version log). In the absence of <code>-d</code>, or <code>-l</code>, <code>prs</code> displays the entry for each delta indicated by the other options.</p> <p><code>-a</code> Includes all deltas, including those marked as removed (see <code>sccs-rmdel(1)</code>).</p> <p><code>-e</code> Requests information for all deltas created <i>earlier</i> than, and including, the delta indicated with <code>-r</code> or <code>-c</code>.</p> <p><code>-l</code> Requests information for all deltas created <i>later</i> than, and including, the delta indicated with <code>-r</code> or <code>-c</code>.</p> <p><code>-c</code> Either options <code>-e</code> or <code>-l</code> must be used with this option. <code>-c</code> <i>date-time</i> displays information on the deltas checked in either prior to and including the date and time indicated by the <i>date-time</i> argument (option <code>-e</code>); or later than and including the date and time indicated (option <code>-l</code>). <i>date-time</i> takes the form:</p> <p style="margin-left: 40px;"><code>yy [mm [dd [hh [mm [ss]]]]]</code></p> <p>Units omitted from the indicated date and time default to their maximum possible values; that is <code>-c 7502</code> is equivalent to <code>-c 750228235959</code>. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the <i>date-time</i> specification must be quoted. Values of <i>yy</i> in the range 69-99 refer to the twentieth century. Values in the range of 00-68 refer to the twenty-first century.</p> <p><code>-d</code> Produce a report according to the indicated data <i>dataspec</i> consists of a (quoted) text string that includes embedded data keywords of the form: ‘: <i>key</i> : ’ (see <code>Data Keywords</code>, below). <code>prs</code> expands these keywords</p>

in the output it produces. To specify a TAB character in the output, use `\\t`; to specify a NEWLINE in the output, use `\\`.

`-r`
`sid` Specifies the SCCS delta ID (SID) of the delta for which information is desired. If no SID is specified, the most recently created delta is used.

USAGE

Data Keywords

Data keywords specify which parts of an SCCS file are to be retrieved. All parts of an SCCS file (see `sccsfile(4)`) have an associated data keyword. A data keyword may appear any number of times in a data specification argument to `-d`. These data keywords are listed in the table below:

Keyword	Data Item	File Section*	Value	Format**
:A:	a format for the what string:	N/A	:Z::Y: :M: :I::Z:	S
:B:	branch number	D	<i>nnnn</i>	S
:BD:	body	B	<i>text</i>	M

DIAGNOSTICS

Use the `SCCS help` command for explanations (see [sccs-help\(1\)](#)).

NAME	sccs-prt, prt – display delta table information from an SCCS file
SYNOPSIS	<code>/usr/ccs/bin/prt [-abdefistu] [-c <i>date-time</i>] [-r <i>date-time</i>] [-y <i>sid</i>] <i>s.filename</i>...</code>
DESCRIPTION	<p>prt prints selected portions of an SCCS file. By default, it prints the delta table (version log).</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the prt command applies to all <i>s.</i> files in that directory. Unreadable <i>s.</i> files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s.</i> file per line.</p>
OPTIONS	<p>If any option other than -y, -c, or -r is supplied, the name of each file being processed (preceded by one NEWLINE and followed by two NEWLINE characters) appears above its contents.</p> <p>If none of the -u, -f, -t, or -b options are used, -d is assumed. -s, -i are mutually exclusive, as are -c and -r.</p> <p>-a Display log entries for all deltas, including those marked as removed.</p> <p>-b Print the body of the <i>s.</i> file.</p> <p>-d Print delta table entries. This is the default.</p> <p>-e Everything. This option implies -d, -i, -u, -f, and -t.</p> <p>-f Print the flags of each named <i>s.</i> file.</p> <p>-i Print the serial numbers of included, excluded, and ignored deltas.</p> <p>-s Print only the first line of the delta table entries; that is, only up to the statistics.</p> <p>-t Print the descriptive text contained in the <i>s.</i> file.</p> <p>-u Print the user-names and/or numerical group IDs of users allowed to make deltas.</p> <p>-c Exclude delta table entries that are specified cutoff date and time. Each entry is printed as a single line, preceded by the name of the SCCS file. This format (also produced by -r, and -y) makes it easy to sort multiple delta tables in chronological order. When both -y and -c, or -y and -r are supplied, prt stops printing when the first of the two conditions is met.</p> <p><i>date-time</i></p>

- `-r` Exclude delta table entries that are newer than the specified
date-time cutoff date and time.
- `-y` Exclude delta table entries made prior to the SID specified. If
sid no delta in the table has the specified SID, the entire table
 is printed. If no SID is specified, the most recent delta
 is printed.

USAGE**Output Format**

The following format is used to print those portions of the `s.` file that are specified by the various options.

- NEWLINE
- Type of delta (D or R)
- SPACE
- SCCS delta ID (SID)
- TAB
- Date and time of creation in the form: *yy / mm / dd hh / mm / ss*
- SPACE
- Username the delta's creator
- TAB
- Serial number of the delta
- SPACE
- Predecessor delta's serial number
- TAB
- Line-by-line change statistics in the form: *inserted / deleted / unchanged*
- NEWLINE
- List of included deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of excluded deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of modification requests (MRs), followed by a NEWLINE (only if any MR numbers were supplied).
- Lines of the delta commentary (if any), followed by a NEWLINE.

EXAMPLES

EXAMPLE 1 Examples of `prt.`

The following command:

```
example% /usr/ccs/bin/prt -y program.c
```

produces a one-line display of the delta table entry for the most recent version:

```
s.program.c: D 1.6 88/07/06 21:39:39 username 5 4
00159/00080/00636 ...
```

DIAGNOSTICS

Use the SCCS help command for explanations (see sccs-help(1)).

NAME	sccs-rmdel, rmdel – remove a delta from an SCCS file				
SYNOPSIS	<code>/usr/ccs/bin/rmdel -r sid s.filename...</code>				
DESCRIPTION	<p>rmdel removes the delta specified by the SCCS delta ID (SID) supplied with <code>-r</code> . The delta to be removed must be the most recent (leaf) delta in its branch. In addition, the SID must <i>not</i> be that of a version checked out for editing: it must not appear in any entry of the version lock file (<code>p.</code> file).</p> <p>If you created the delta, or, if you own the file and directory and have write permission, you can remove it with <code>rmdel</code> .</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>rmdel</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>				
OPTIONS	<p>The following option is supported:</p> <p><code>-r</code> Remove the version corresponding to the indicated SID (delta). <code>sid</code></p>				
FILES	<p><code>p.</code> permissions file <code>file</code></p> <p><code>s.</code> history file <code>file</code></p> <p><code>z.</code> temporary copy of the <code>s.</code> file <code>file</code></p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWsprt</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsprt

NAME sccs-sact, sact – show editing activity status of an SCCS file

SYNOPSIS `/usr/ccs/bin/sact s.filename...`

DESCRIPTION `sact` informs the user of any SCCS files that are checked out for editing. The output for each named file consists of five fields separated by SPACE characters.

- SID of a delta that currently exists in the SCCS file, to which changes will be made to make the new delta
- SID for the new delta to be created
- Username of the person who has the file checked out for editing.
- Date that the version was checked out.
- Time that the version was checked out.

If a directory name is used in place of the *s.filename* argument, the `sact` command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of ‘-’ as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

DIAGNOSTICS Use the SCCS `help` command for explanations (see `sccs-help(1)`).

NAME	sccs-sccsdiff, sccsdiff – compare two versions of an SCCS file				
SYNOPSIS	/usr/ccs/bin/sccsdiff [-p] -r <i>sid</i> -r <i>sid</i> [<i>diff-options</i>] <i>s.filename</i>				
DESCRIPTION	<i>sccsdiff</i> compares two versions of an SCCS file and displays the differences between the two versions. Any number of SCCS files may be specified; the options specified apply to all named <i>s.</i> files.				
OPTIONS	The following options are supported: -p Pipe output for each file through <i>pr</i> (1) . -r <i>sid</i> Specify a version corresponding to the indicated SCCS delta ID (SID) for comparison. Versions are passed to <i>diff</i> (1) in the order given. <i>diff-options</i> Pass options to <i>diff</i> (1) , including: -c , -e , -f , -h , -b and -D .				
FILES	/tmp/get????? temporary files				
ATTRIBUTES	See <i>attributes</i> (5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWsprt</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsprt
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWsprt				
SEE ALSO	<i>diff</i> (1) , <i>sccs</i> (1) , <i>sccs-delta</i> (1) , <i>sccs-get</i> (1) , <i>sccs-help</i> (1) , <i>sccs-prs</i> (1) , <i>sccs-prt</i> (1) , <i>what</i> (1) , <i>sccsfile</i> (4) , <i>attributes</i> (5)				
DIAGNOSTICS	<i>filename</i> If the two versions are the same. : No differences Use the SCCS <i>help</i> command for explanations of other messages (see <i>sccs-help</i> (1)).				

NAME sccs-unget, unget – undo a previous get of an SCCS file

SYNOPSIS `/usr/ccs/bin/unget [-ns] [-r sid] s.filename...`

DESCRIPTION unget undoes the effect of a 'get -e' done prior to the creation of the pending delta.

If a directory name is used in place of the *s.filename* argument, the unget command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

OPTIONS

- n Retain the retrieved version, which is otherwise removed.
- s Suppress display of the SCCS delta ID (SID).
- r *sid* When multiple versions are checked out, specify which pending delta to abort. A diagnostic results if the specified SID is ambiguous, or if it is necessary but omitted from the command line.

DIAGNOSTICS Use the SCCS *help* command for explanations (see *sccs-help(1)*).

NAME	sccs-val, val – validate an SCCS file
SYNOPSIS	<pre>/usr/ccs/bin/val – /usr/ccs/bin/val [-s] [-m name] [-r sid] [-y type] s.filename...</pre>
DESCRIPTION	<p>val determines if the specified <i>s.</i> files meet the characteristics specified by the indicated arguments. val can process up to 50 files on a single command line.</p> <p>val has a special argument, '-', which reads the standard input until the end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.</p> <p>val generates diagnostic messages on the standard output for each command line and file processed and also returns a single 8-bit code upon exit as described below.</p> <p>The 8-bit code returned by val is a disjunction of the possible errors, that is, it can be interpreted as a bit string where (moving from left to right) the bits set are interpreted as follows:</p> <pre>bit 0 = missing file argument bit 1 = unknown or duplicate option bit 2 = corrupted s.file bit 3 = can not open file or file not in s.file format bit 4 = the SCCS delta ID (SID) is invalid or ambiguous bit 5 = the SID does not exist bit 6 = mismatch between and -y argument bit 7 = mismatch between sccs-val.1 -m argument</pre> <p>val can process two or more files on a given command line, and in turn can process multiple command lines (when reading the standard input). In these cases, an aggregate code is returned which is the logical OR of the codes generated for each command line and file processed.</p>
OPTIONS	<p>The following options are supported:</p> <pre>-s Silent. Suppress the normal error or warning messages. -m Compare name with the sccs-val.1 ID keyword in the s. file. name -r Check to see if the indicated SID is ambiguous, invalid, or absent sid from the s. file. -y Compare type with the ID keyword. type</pre>

DIAGNOSTICS

Use the SCCS help command for explanations (see sccs-help(1)).

NAME script – make record of a terminal session

SYNOPSIS **script** [-a] [*filename*]

DESCRIPTION `script` makes a record of everything printed on your screen. The record is written to *filename*. If no file name is given, the record is saved in the file `typescript`.

The `script` command forks and creates a sub-shell, according to the value of `$SHELL`, and records the text from this session. The script ends when the forked shell exits or when CTRL-D is typed.

OPTIONS `-a` Append the session record to *filename*, rather than overwrite it.

NOTES `script` places everything that appears on the screen in *filename*, including prompts.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NAME	sdiff – print differences between two files side-by-side
SYNOPSIS	sdiff [-l] [-s] [-o <i>output</i>] [-w <i>n</i>] <i>filename1 filename2</i>
DESCRIPTION	<code>sdiff</code> uses the output of the <code>diff</code> command to produce a side-by-side listing of two files indicating lines that are different. Lines of the two files are printed with a blank gutter between them if the lines are identical, a < in the gutter if the line appears only in <i>filename1</i> , a > in the gutter if the line appears only in <i>filename2</i> , and a for lines that are different. (See the <code>EXAMPLES</code> section below.)
OPTIONS	<p>-l Print only the left side of any lines that are identical.</p> <p>-s Do not print identical lines.</p> <p>-o <i>output</i> Use the argument <i>output</i> as the name of a third file that is created as a user-controlled merge of <i>filename1</i> and <i>filename2</i>. Identical lines of <i>filename1</i> and <i>filename2</i> are copied to <i>output</i>. Sets of differences, as produced by <code>diff</code>, are printed; where a set of differences share a common gutter character. After printing each set of differences, <code>sdiff</code> prompts the user with a % and waits for one of the following user-typed commands:</p> <p>l Append the left column to the output file.</p> <p>r Append the right column to the output file.</p> <p>s Turn on silent mode; do not print identical lines.</p> <p>v Turn off silent mode.</p> <p>e l Call the editor with the left column.</p> <p>e r Call the editor with the right column.</p> <p>e b Call the editor with the concatenation of left and right.</p> <p>e Call the editor with a zero length file.</p> <p>q Exit from the program.</p> <p>On exit from the editor, the resulting file is concatenated to the end of the <i>output</i> file.</p> <p>-w <i>n</i> Use the argument <i>n</i> as the width of the output line. The default line length is 130 characters.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>sdiff</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 An example of the `sdiff` command.

A sample output of `sdiff` follows.

```
x | y
a | a
b <
c <
d | d
  > c
```

ENVIRONMENT VARIABLES

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `sdiff` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" locale determines how `sdiff` behaves.

`LC_CTYPE` Determines how `sdiff` handles characters. When `LC_CTYPE` is set to a valid value, `sdiff` can display and handle text and filenames containing valid characters for that locale.

ATTRIBUTES

NAME	sed – stream editor
SYNOPSIS	<pre> /usr/bin/sed [-n] script [file...] /usr/bin/sed [-n] [-e script] ... [-f script_file] ... [file...] /usr/xpg4/bin/sed [-n] script [file...] /usr/xpg4/bin/sed [-n] [-e script] ... [-f script_file] ... [file...] </pre>
DESCRIPTION	<p>The <code>sed</code> utility is a stream editor that reads one or more text files, makes editing changes according to a script of editing commands, and writes the results to standard output. The script is obtained from either the <code>script</code> operand string, or a combination of the option-arguments from the <code>-e script</code> and <code>-f script_file</code> options.</p> <p>The <code>sed</code> utility is a text editor. It cannot edit binary files or files containing ASCII NUL (<code>\0</code>) characters or very long lines.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-e script</code> <code>script</code> is an edit command for <code>sed</code>. See <code>USAGE</code> below for more information on the format of <code>script</code>. If there is just one <code>-e</code> option and no <code>-f</code> options, the flag <code>-e</code> may be omitted.</p> <p><code>-f script_file</code> Take the script from <code>script_file</code>. <code>script_file</code> consists of editing commands, one per line.</p> <p><code>-n</code> Suppress the default output.</p> <p>Multiple <code>-e</code> and <code>-f</code> options may be specified. All commands are added to the script in the order specified, regardless of their origin.</p>
OPERANDS	<p>The following operands are supported:</p> <p><code>file</code> A path name of a file whose contents will be read and edited. If multiple <code>file</code> operands are specified, the named files will be read in the order specified and the concatenation will be edited. If no <code>file</code> operands are specified, the standard input will be used.</p> <p><code>script</code> A string to be used as the script of editing commands. The application must not present a <code>script</code> that violates the restrictions of a text file except that the final character need not be a <code>NEWLINE</code> character.</p>
USAGE	<p>A script consists of editing commands, one per line, of the following form:</p> <pre>[address [, address]] command [arguments]</pre> <p>Zero or more blank characters are accepted before the first address and before <code>command</code>. Any number of semicolons are accepted before the first address.</p>

sed Addresses	<p>In normal operation, <code>sed</code> cyclically copies a line of input (less its terminating <code>NEWLINE</code> character) into a <i>pattern space</i> (unless there is something left after a <code>D</code> command), applies in sequence all commands whose <i>addresses</i> select that pattern space, and copies the resulting pattern space to the standard output (except under <code>-n</code>) and deletes the pattern space. Whenever the pattern space is written to standard output or a named file, <code>sed</code> will immediately follow it with a <code>NEWLINE</code> character.</p> <p>Some of the commands use a <i>hold space</i> to save all or part of the <i>pattern space</i> for subsequent retrieval. The <i>pattern</i> and <i>hold spaces</i> will each be able to hold at least 8192 bytes.</p> <p>An <i>address</i> is either empty, a decimal number that counts input lines cumulatively across files, a <code>\$</code> that addresses the last line of input, or a context address, which consists of a <i>regular expression</i> as described on the <code>regex(5)</code> manual page.</p> <p>A command line with no addresses selects every pattern space.</p> <p>A command line with one address selects each pattern space that matches the address.</p> <p>A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second address. Thereafter the process is repeated, looking again for the first address. (If the second address is a number less than or equal to the line number selected by the first address, only the line corresponding to the first address is selected.)</p> <p>Typically, address are separated from each other by a comma (<code>,</code>). They may also be separated by a semicolon (<code>;</code>).</p>
sed Regular Expressions	<p><code>sed</code> supports the basic regular expressions described on the <code>regex(5)</code> manual page, with the following additions:</p> <p><code>\cREc</code> In a context address, the construction <code>\cREc</code>, where <code>c</code> is any character other than a backslash or <code>NEWLINE</code> character, is identical to <code>/RE/</code>. If the character designated by <code>c</code> appears following a backslash, then it is considered to be that literal character, which does not terminate the RE. For example, in the context address <code>\xabc\xdefx</code>, the second <code>x</code> stands for itself, so that the regular expression is <code>abcxdef</code>.</p> <p><code>\n</code> The escape sequence <code>\n</code> matches a <code>NEWLINE</code> character embedded in the pattern space. A literal <code>NEWLINE</code> character must not be used in the regular expression of a context address or in the substitute command.</p> <p>Editing commands can be applied only to non-selected pattern spaces by use of the negation command <code>!</code> (described below).</p>
sed Editing Commands	<p>In the following list of functions the maximum number of permissible addresses for each function is indicated.</p>

The `r` and `w` commands take an optional *rfile* (or *wfile*) parameter, separated from the command letter by one or more blank characters.

Multiple commands can be specified by separating them with a semicolon (`;`) on the same command line.

The *text* argument consists of one or more lines, all but the last of which end with `\` to hide the `NEWLINE`. Each embedded `NEWLINE` character in the text must be preceded by a backslash. Other backslashes in text are removed and the following character is treated literally. Backslashes in text are treated like backslashes in the replacement string of an `s` command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. The use of the *wfile* parameter causes that file to be initially created, if it does not exist, or will replace the contents of an existing file. There can be at most 10 distinct *wfile* arguments.

Regular expressions match entire strings, not just individual lines, but a `NEWLINE` character is matched by `\n` in a `sed` RE; a `NEWLINE` character is not allowed in an RE. Also note that `\n` cannot be used to match a `NEWLINE` character at the end of an input line; `NEWLINE` characters appear in the pattern space as a result of the `N` editing command.

Two of the commands take a *command-list*, which is a list of `sed` commands separated by `NEWLINE` characters, as follows:

```
{ command
  command
}
```

The `{` can be preceded with blank characters and can be followed with white space. The *commands* can be preceded by white space. The terminating `}` must be preceded by a `NEWLINE` character and can be preceded or followed by `<blank>s`. The braces may be preceded or followed by `<blank>s`. The command may be preceded by `<blank>s`, but may not be followed by `<blank>s`.

The following table lists the functions, with the maximum number of permissible addresses.

Max Address	Command	Description
1	a \ <i>text</i>	Append by executing <i>N</i> command or beginning a new cycle. Place <i>text</i> on the output before reading the next input line.
2	b <i>label</i>	Branch to the : command bearing the <i>label</i> . If <i>label</i> is empty, branch to the end of the script. Labels are recognized unique up to eight characters.
2	c \ <i>text</i>	Change. Delete the pattern space. Place <i>text</i> on the output. Start the next cycle.
2	d	Delete the pattern space. Start the next cycle.
2	D	Delete the initial segment of the pattern space through the first new-line. Start the next cycle. (See the <i>N</i> command below.)
2	g	Replace the contents of the pattern space by the contents of the hold space.
2	G	Append the contents of the hold space to the pattern space.
2	h	Replace the contents of the hold space by the contents of the pattern space.
2	H	Append the contents of the pattern space to the hold space.
1	i \ <i>text</i>	Insert. Place <i>text</i> on the standard output.
2	l	/usr/bin/sed: List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded.
		/usr/xpg4/bin/sed: List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded. The characters (\, \a, \b, \f, \r, \t, and \v) are written as the corresponding escape sequences. Non-printable characters not in that table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation dependent.

Max Address	Command	Description
		Long lines are folded, with the point of folding indicated by writing a backslash followed by a <code>NEWLINE</code> ; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line is marked with a <code>\$</code> .
2	<code>n</code>	Copy the pattern space to the standard output if default output is not suppressed. Replace the pattern space with the next line of input.
2	<code>N</code>	Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.) If no next line of input is available, the <code>N</code> command verb shall branch to the end of the script and quit without starting a new cycle and without writing the pattern space.
2	<code>P</code>	Print. Copy the pattern space to the standard output.
2	<code>P</code>	Copy the initial segment of the pattern space through the first new-line to the standard output.
1	<code>q</code>	Quit. Branch to the end of the script. Do not start a new cycle.
2	<code>r rfile</code>	Read the contents of <i>rfile</i> . Place them on the output before reading the next input line. If <i>rfile</i> does not exist or cannot be read, it is treated as if it were an empty file, causing no error condition.
2	<code>t label</code>	Test. Branch to the <code>:</code> command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a <code>t</code> . If <i>label</i> is empty, branch to the end of the script.
2	<code>w wfile</code>	Write. Append the pattern space to <i>wfile</i> . The first occurrence of <i>w</i> will cause <i>wfile</i> to be cleared. Subsequent invocations of <i>w</i> will append. Each time the <code>sed</code> command is used, <i>wfile</i> is overwritten.
2	<code>x</code>	Exchange the contents of the pattern and hold spaces.
2	<code>! command</code>	Don't. Apply the <i>command</i> (or group, if <i>command</i> is <code>{ }</code>) only to lines <i>not</i> selected by the address(es).
0	<code>: label</code>	This command does nothing; it bears a <i>label</i> for <code>b</code> and <code>t</code> commands to branch to.

Max Address	Command	Description
1	=	Place the current line number on the standard output as a line.
2	{ <i>command-list</i> }	Execute <i>command-list</i> only when the pattern space is selected.
0		An empty command is ignored.
0	#	If a # appears as the first character on a line of a script file, then that entire line is treated as a comment, with one exception: if a # appears on the first line and the character after the # is an n, then the default output will be suppressed. The rest of the line after #n is also ignored. A script file must contain at least one non-comment line.

Max Addr	Command (Using <i>strings</i>) and Description
2	<p><i>s/regular expression/replacement/flags</i></p> <p>Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character other than backslash or newline can be used instead of a slash to delimit the RE and the replacement. Within the RE and the replacement, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.</p> <p>An ampersand (&) appearing in the <i>replacement</i> will be replaced by the string matching the RE. The special meaning of & in this context can be suppressed by preceding it by backslash. The characters \n, where <i>n</i> is a digit, will be replaced by the text matched by the corresponding backreference expression. For each backslash (\) encountered in scanning <i>replacement</i> from beginning to end, the following character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than &, \ or digits.</p> <p>A line can be split by substituting a NEWLINE character into it. The application must escape the NEWLINE character in the <i>replacement</i> by preceding it with backslash. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.</p> <p><i>flags</i> is zero or more of:</p> <p><i>n n= 1 - 512</i>. Substitute for just the <i>n</i>th occurrence of the <i>regular expression</i>.</p> <p><i>g</i> Global. Substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one. If both <i>g</i> and <i>n</i> are specified, the results are unspecified.</p>
	<i>p</i> Print the pattern space if a replacement was made.

Max Addr	Command (Using <i>strings</i>) and Description
	<p>P Copy the initial segment of the pattern space through the first new-line to the standard output.</p> <p>w <i>wfile</i> Write. Append the pattern space to <i>wfile</i> if a replacement was made. The first occurrence of <i>w</i> will cause <i>wfile</i> to be cleared. Subsequent invocations of <i>w</i> will append. Each time the <i>sed</i> command is used, <i>wfile</i> is overwritten.</p>
2	<p>y/ <i>string1</i> / <i>string2</i> /</p> <p>Transform. Replace all occurrences of characters in <i>string1</i> with the corresponding characters in <i>string2</i>. <i>string1</i> and <i>string2</i> must have the same number of characters, or if any of the characters in <i>string1</i> appear more than once, the results are undefined. Any character other than backslash or NEWLINE can be used instead of slash to delimit the strings. Within <i>string1</i> and <i>string2</i>, the delimiter itself can be used as a literal character if it is preceded by a backslash. For example, y/abc/ABC/ replaces a with A, b with B, and c with C.</p>

See [largefile\(5\)](#) for the description of the behavior of *sed* when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 An example *sed* script

This *sed* script simulates the BSD `cat -s` command, squeezing excess blank lines from standard input.

```
sed -n '
# Write non-empty lines.
./ {
    p
    d
}
# Write a single empty line, then look for more empty lines.
/^$/ p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/ {
    N
    s/./ /
    b Empty
}
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
p
'
```

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of *sed*: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

NAME	sed – stream editor								
SYNOPSIS	sed [-n] [-e <i>script</i>] [-f <i>sfilename</i>] [<i>filename</i>] ...								
DESCRIPTION	The <i>sed</i> utility copies the <i>filenames</i> (standard input default) to the standard output, edited according to a script of commands.								
OPTIONS	The following options are supported: -n Suppresses the default output. -e <i>script</i> <i>script</i> is an edit command for <i>sed</i> . If there is just one -e option and no -f options, the -e flag may be omitted. -f <i>sfilename</i> Takes the script from <i>sfilename</i> .								
USAGE sed Scripts	<i>sed</i> scripts consist of editing commands, one per line, of the following form: [<i>address</i> [, <i>address</i>]] <i>function</i> [<i>arguments</i>] In normal operation, <i>sed</i> cyclically copies a line of input into a <i>pattern space</i> (unless there is something left after a D command), sequentially applies all commands with <i>addresses</i> matching that pattern space until reaching the end of the script, copies the pattern space to the standard output (except under -n), and finally, deletes the pattern space. Some commands use a <i>hold space</i> to save all or part of the pattern space for subsequent retrieval. An <i>address</i> is either: <ul style="list-style-type: none"> ■ a decimal number linecount, which is cumulative across input files; ■ a \$, which addresses the last input line; ■ or a context address, which is a <i>/regular expression/</i> as described on the <i>regex(5)</i> manual page, with the following exceptions: \?RE? In a context address, the construction \?regular expression?, where ? is any character, is identical to <i>/regular expression/</i>. Note: in the context address \xabc\xdefx, the second x stands for itself, so that the regular expression is abcxdef. <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 10px;">\n</td> <td>Matches a NEWLINE embedded in the pattern space.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">.</td> <td>Matches any character except the NEWLINE ending the pattern space.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>null</i></td> <td>A command line with no address selects every pattern space.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><i>address</i></td> <td>Selects each pattern space that matches.</td> </tr> </table>	\n	Matches a NEWLINE embedded in the pattern space.	.	Matches any character except the NEWLINE ending the pattern space.	<i>null</i>	A command line with no address selects every pattern space.	<i>address</i>	Selects each pattern space that matches.
\n	Matches a NEWLINE embedded in the pattern space.								
.	Matches any character except the NEWLINE ending the pattern space.								
<i>null</i>	A command line with no address selects every pattern space.								
<i>address</i>	Selects each pattern space that matches.								

	<i>address1</i> , <i>address2</i>	Selects the inclusive range from the first pattern space matching <i>address1</i> to the first pattern space matching <i>address2</i> . Selects only one line if <i>address1</i> is greater than or equal to <i>address2</i> .
Comments		If the first nonwhite character in a line is a '#' (pound sign), <code>sed</code> treats that line as a comment, and ignores it. If, however, the first such line is of the form: #n <code>sed</code> runs as if the <code>-n</code> flag were specified.
Functions		The maximum number of permissible addresses for each function is indicated in parentheses in the list below. An argument denoted <i>text</i> consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Backslashes in <i>text</i> are treated like backslashes in the replacement string of an <code>s</code> command, and may be used to protect initial SPACE and TAB characters against the stripping that is done on every script line. An argument denoted <i>rfilename</i> or <i>wfilename</i> must terminate the command line and must be preceded by exactly one SPACE. Each <i>wfilename</i> is created before processing begins. There can be at most 10 distinct <i>wfilename</i> arguments.
	(1) a \ <i>text</i>	Append: place <i>text</i> on the output before reading the next input line.
	(2) b <i>label</i>	Branch to the ':' command bearing the <i>label</i> . Branch to the end of the script if <i>label</i> is empty.
	(2) c \ <i>text</i>	Change: delete the pattern space. With 0 or 1 address or at the end of a 2 address range, place <i>text</i> on the output. Start the next cycle.
	(2) d	Delete the pattern space. Start the next cycle.
	(2) D	Delete the initial segment of the pattern space through the first NEWLINE. Start the next cycle.
	(2) g	Replace the contents of the pattern space by the contents of the hold space.
	(2) G	Append the contents of the hold space to the pattern space.
	(2) h	Replace the contents of the hold space by the contents of the pattern space.
	(2) H	Append the contents of the pattern space to the hold space.

(1) <i>i</i> \	
<i>text</i>	Insert: place <i>text</i> on the standard output.
(2) <i>l</i>	List the pattern space on the standard output in an unambiguous form. Non-printing characters are spelled in two digit ASCII and long lines are folded.
(2) <i>n</i>	Copy the pattern space to the standard output. Replace the pattern space with the next line of input.
(2) <i>N</i>	Append the next line of input to the pattern space with an embedded newline. (The current line number changes.)
(2) <i>P</i>	Print: copy the pattern space to the standard output.
(2) <i>P</i>	Copy the initial segment of the pattern space through the first NEWLINE to the standard output.
(1) <i>q</i>	Quit: branch to the end of the script. Do not start a new cycle.
(2) <i>r filename</i>	Read the contents of <i>rfilename</i> . Place them on the output before reading the next input line.
(2) <i>s/regular expression/replacement/flags</i>	Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character may be used instead of '/'. For a fuller description see <i>regex(5)</i> . <i>flags</i> is zero or more of:
<i>n</i>	<i>n</i> = 1 – 512. Substitute for just the <i>n</i> th occurrence of the <i>regular expression</i> .
<i>g</i>	Global: substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one.
<i>p</i>	Print the pattern space if a replacement was made.
<i>w filename</i>	Write: append the pattern space to <i>wfilename</i> if a replacement was made.
(2) <i>t label</i>	Test: branch to the ':' command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a <i>t</i> . If <i>label</i> is empty, branch to the end of the script.
(2) <i>w filename</i>	Write: append the pattern space to <i>wfilename</i> .
(2) <i>x</i>	Exchange the contents of the pattern and hold spaces.

- (2) *y/string1/string2/* Transform: replace all occurrences of characters in *string1* with the corresponding character in *string2*. The lengths of *string1* and *string2* must be equal.
- (2) *! function* Do not: apply the *function* (or group, if *function* is '{') only to lines *not* selected by the address(es).
- (0) *: label* This command does nothing; it bears a *label* for *b* and *t* commands to branch to. Note: the maximum length of *label* is seven characters.
- (1) *=* Place the current line number on the standard output as a line.
- (2) *{* Execute the following commands through a matching *}* only when the pattern space is selected. Commands are separated by *;*.
- (0) An empty command is ignored.

Large Files

See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

DIAGNOSTICS

Too many commands

The command list contained more than 200 commands.

Too much command text

The command list was too big for `sed` to handle. Text in the *a*, *c*, and *i* commands, text read in by *r* commands, addresses, regular expressions and replacement strings in *s* commands, and translation tables in *y* commands all require `sed` to store data internally.

Command line too long

A command line was longer than 4000 characters.

Too many line numbers

More than 256 decimal number linecounts were specified as addresses in the command list.

Too many files in *w* commands

More than 10 different files were specified in *w* commands or *w* options for *s* commands in the command list.

Too many labels

More than 50 labels were specified in the command list.

Unrecognized command

A command was not one of the ones recognized by `sed`.

Extra text at end of command
A command had extra text after the end.

Illegal line number
An address was neither a decimal number linecount, a \$, nor a context address.

Space missing before filename
There was no space between an r or w command, or the w option for a s command, and the filename specified for that command.

Too many { 's
There were more { than } in the list of commands to be executed.

Too many } 's
There were more } than { in the list of commands to be executed.

No addresses allowed
A command that takes no addresses had an address specified.

Only one address allowed
A command that takes one address had two addresses specified.

"\digit" out of range
The number in a \n item in a regular expression or a replacement string in an s command was greater than 9.

Bad number
One of the endpoints in a range item in a regular expression (that is, an item of the form {n} or {n,m}) was not a number.

Range endpoint too large
One of the endpoints in a range item in a regular expression was greater than 255.

More than 2 numbers given in \{ \}
More than two endpoints were given in a range expression.

} expected after \
A \< appeared in a range expression and was not followed by a }.

First number exceeds second in \{ \}
The first endpoint in a range expression was greater than the second.

Illegal or missing delimiter
The delimiter at the end of a regular expression was absent.

\(\) imbalance
There were more \(than \), or more \) than \(, in a regular expression.

[] imbalance

There were more [than], or more] than [, in a regular expression.

First RE may not be null

The first regular expression in an address or in a `s` command was null (empty).

Ending delimiter missing on substitution

The ending delimiter in a `s` command was absent.

Ending delimiter missing on string

The ending delimiter in a `y` command was absent.

Transform strings not the same size

The two strings in a `y` command were not the same size.

Suffix too large - 512 max

The suffix in a `s` command, specifying which occurrence of the regular expression should be replaced, was greater than 512.

Label too long

A label in a command was longer than 8 characters.

Duplicate labels

The same label was specified by more than one `:` command.

File name too long

The filename specified in a `r` or `w` command, or in the `w` option for a `s` command, was longer than 1024 characters.

Output line too long

An output line was longer than 4000 characters long.

Too many appends or reads after line *n*

More than 20 `a` or `r` commands were to be executed for line *n*.

Hold space overflowed.

More than 4000 characters were to be stored in the *hold space*.

FILES

usr/ucb/sed

BSD sed

ATTRIBUTES

`awk(1)`, `grep(1)`, `lex(1)`, `attributes(5)`, `largefile(5)`, `regex(5)`

BUGS

There is a combined limit of 200 `-e` and `-f` arguments. In addition, there are various internal size limits which, in rare cases, may overflow. To overcome

these limitations, either combine or break out scripts, or use a pipeline of `sed` commands.

NAME set, unset, setenv, unsetenv, export – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents

SYNOPSIS

sh **set** [--aefhkntuvx *argument*] ...

unset [*name...*]

export [*name...*]

csh **set** [*var* [= *value*]]

set *var* [*n*] = *word*

unset *pattern*

setenv [*VAR* [*word*]]

unsetenv *variable*

ksh **set** [\261aefhkmpstuvx] [\261o *option*] ... [\261A *name*] [*arg...*]

unset [-E] *name...*

****export** [*name* [=*value*]] ...

DESCRIPTION

sh

The **set** built-in command has the following options:

- Do not change any of the flags; useful in setting \$1 to - .
- a Mark variables which are modified or created for export.
- e Exit immediately if a command exits with a non-zero exit status.
- f Disable file name generation.
- h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
- k All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- n Read commands but do not execute them.
- t Exit after reading and executing one command.
- u Treat unset variables as an error when substituting.
- v Print shell input lines as they are read.
- x Print commands and their arguments as they are executed.

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$- . The remaining *argument s* are positional parameters and are assigned, in order, to \$1 , \$2 , If no *argument s* are given the values of all names are printed.

For each *name* , unset removes the corresponding variable or function value. The variables PATH , PS1 , PS2 , MAILCHECK , and IF cannot be unset.

With the export built-in, the given *name s* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. Function names are *not* exported.

csh With no arguments, set displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, set assigns an empty (null) value to the variable *var* . With arguments of the form *var* = *value* set assigns *value* to *var* , where *value* is one of:

word A single word (or quoted string).

(A space-separated list of words enclosed in parentheses.
wordlist
)

Values are command and filename expanded before being assigned. The form set *var* [*n*] = *word* replaces the *n* 'th word in a multiword value with *word* .

unset removes variables whose names match (filename substitution) *pattern* . All variables are removed by 'unset * ' ; this has noticeably distasteful side effects.

With no arguments, setenv displays all environment variables. With the VAR argument, setenv sets the environment variable VAR to an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both VAR and word arguments specified, setenv sets VAR to word , which must be either a single word or a quoted string. The PATH variable can take multiple word arguments, separated by colons (see EXAMPLES). The most commonly used environment variables, USER , TERM , and PATH , are automatically imported to and exported from the csh variables user , term , and path . Use setenv if you need to change these variables. In addition, the shell sets the PWD environment variable from the csh variable cwd whenever the latter changes.

The environment variables LC_CTYPE , LC_MESSAGES , LC_TIME , LC_COLLATE , LC_NUMERIC , and LC_MONETARY take immediate effect when changed within the C shell. See environ(5) for descriptions of these environment variables.

`unsetenv` removes *variable* from the environment. As with `unset`, pattern matching is not performed.

ksh

The flags for the `set` built-in have meaning as follows:

- A Array assignment. Unset the variable *name* and assign values sequentially from the list *arg*. If +A is used, the variable *name* is not unset first.
- a All subsequent variables that are defined are automatically exported.
- e If a command has a non-zero exit status, execute the `ERR` trap, if set, and exit. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o The following argument can be one of the following option names:

<code>allexport</code>	Same as <code>-a</code> .
<code>errexit</code>	Same as <code>-e</code> .
<code>bgnice</code>	All background jobs are run at a lower priority. This is the default mode. <code>emacs</code> Puts you in an <code>emacs</code> style in-line editor for command entry.
<code>gmacs</code>	Puts you in a <code>gmacs</code> style in-line editor for command entry.
<code>ignoreeof</code>	The shell will not exit on end-of-file. The command <code>exit</code> must be used.

keyword	Same as <code>-k</code> .
markdirs	All directory names resulting from file name generation have a trailing <code>/</code> appended.
monitor	Same as <code>-m</code> .
noclobber	Prevents redirection <code>></code> from truncating existing files. Require <code>> </code> to truncate a file when turned on.
noexec	Same as <code>-n</code> .
noglob	Same as <code>-f</code> .
nolog	Do not save function definitions in history file.
nounset	Same as <code>-u</code> .
privileged	Same as <code>-p</code> .
verbose	Same as <code>-v</code> .
trackall	Same as <code>-h</code> .
vi	Puts you in insert mode of a <code>vi</code> style in-line editor until you hit escape character <code>033</code> . This puts you in control mode. A return sends the line.
viraw	Each character is processed as it is typed in <code>vi</code> mode.
xtrace	Same as <code>-x</code> .

If no option name is supplied then the current option settings are printed.

`-p` Disables processing of the `$HOME/.profile` file and uses the file `/etc/suid_profile` instead of the `ENV` file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.

- s Sort the positional parameters lexicographically.
- t Exit after reading and executing one command.
- u Treat unset parameters as an error when substituting.
- v Print shell input lines as they are read.
- x Print commands and their arguments as they are executed.
- Turns off `-x` and `-v` flags and stops examining arguments for flags.
- Do not change any of the flags; useful in setting `$1` to a value beginning with `-`. If no arguments follow this flag then the positional parameters are unset.

Using `+` rather than `-` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in `$-`. Unless `-A` is specified, the remaining arguments are positional parameters and are assigned, in order, to `$1 $2 ...`. If no arguments are given then the names and values of all variables are printed on the standard output.

The variables given by the list of *name s* are unassigned, i.e., their values and attributes are erased. `readonly` variables cannot be unset. If the `-f`, flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned.

When using `unset`, the variables given by the list of *name s* are unassigned, i.e., their values and attributes are erased. `readonly` variables cannot be unset. If the `-f`, flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned.

With the `export` built-in, the given *name s* are marked for automatic export to the environment of subsequently-executed commands.

On this man page, `ksh(1)` commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.

3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

EXAMPLES**csh**

The following example sets the `PATH` variable to search for files in the `/bin`, `/usr/bin`, `/usr/sbin`, and `/usr/ucb/bin` directories, in that order.

```
setenv PATH "/bin:/usr/bin:/usr/sbin:usr/ucb/bin"
```

NAME	set, unset – set and unset local or global environment variables
SYNOPSIS	<pre>set [-l variable [=value]] ... set [-e variable [=value]] ... set [-f file variable [=value] ...] ... unset -l variable... unset -f file variable...</pre>
DESCRIPTION	<p>The <code>set</code> command sets <code>variable</code> in the environment, or adds <code>variable = value</code> to <code>file</code>. If <code>variable</code> is not equated it to a value, <code>set</code> expects the value to be on <code>stdin</code>. The <code>unset</code> command removes <code>variable</code>. Note that the FMLI predefined, read-only variables (such as <code>ARG1</code>), may not be set or unset.</p> <p>Note that at least one of the above options must be used for each variable being set or unset. If you set a variable with the <code>-f filename</code> option, you must thereafter include <code>filename</code> in references to that variable. For example, <code>\$((file) VARIABLE)</code>.</p> <p>FMLI inherits the UNIX environment when invoked.</p>
OPTIONS	<pre>-l Sets or unsets the specified variable in the local environment. Variables set with -l will not be inherited by processes invoked from FMLI. -e Sets the specified variable in the UNIX environment. Variables set with -e will be inherited by any processes started from FMLI. Note that these variables cannot be unset. -f Sets or unsets the specified variable in the global environment. The file argument file is the name, or pathname, of a file containing lines of the form variable = value. file will be created if it does not already exist. Note that no space intervenes between -f and file.</pre>
EXAMPLES	<p>EXAMPLE 1 A sample output of <code>set</code> command.</p> <p>Storing a selection made in a menu:</p> <pre>name=Selection 2 action='set -l SELECTION=2'close</pre>
NOTES	<p>Variables set to be available to the UNIX environment (those set using the <code>-e</code> option) can only be set for the current <code>fmli</code> process and the processes it calls.</p> <p>When using the <code>-f</code> option, unless <code>file</code> is unique to the process, other users of FMLI on the same machine will be able to expand these variables, depending on the read/write permissions on <code>file</code>.</p>

A variable set in one frame may be referenced or unset in any other frame.
This includes local variables.

NAME setcolor – redefine or create a color

SYNOPSIS **setcolor** *color red_level green_level blue_level*

DESCRIPTION The `setcolor` command takes four arguments: *color*, which must be a string naming the color; and the arguments *red_level*, *green_level*, and *blue_level*, which must be integer values defining, respectively, the intensity of the red, green, and blue components of *color*. Intensities must be in the range of 0 to 1000. If you are redefining an existing color, you must use its current name (default color names are: black, blue, green, cyan, red, magenta, yellow, and white). `setcolor` returns the color's name string.

EXAMPLES **EXAMPLE 1** A sample output of `setcolor` command.

The following is an example of the arguments that `setcolor` takes:

```
`setcolor blue 100 24 300`
```

NAME	setfacl – modify the Access Control List (ACL) for a file or files						
SYNOPSIS	setfacl [-r] -s <i>acl_entries</i> <i>file</i> setfacl [-r] -m <i>d</i> <i>acl_entries</i> <i>file</i> setfacl [-r] -f <i>acl_filefile</i>						
DESCRIPTION	<p>For each file specified, <code>setfacl</code> will either replace its entire ACL, including the default ACL on a directory, or it will add, modify, or delete one or more ACL entries, including default entries on directories.</p> <p>Setting an ACL on a file also modifies the file's permission bits. The <code>user</code> entry modifies the file owner permission bits. If you don't specify a <code>mask</code> entry, the <code>group</code> entry modifies the file group owner permission bits. If you specify a <code>mask</code> entry, the file group owner permission bits are modified based on the intersection (bitwise AND) of the <code>group</code> and <code>mask</code> entries. The <code>other</code> entry modifies the other permission bits.</p> <p>If you use the <code>chmod(1)</code> command to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions may change the effective permissions for additional users and groups who have ACL entries on the file.</p> <p>A directory may contain default ACL entries. If a file or directory is created in a directory that contains default ACL entries, the newly created file will have permissions generated according to the intersection of the default ACL entries and the permissions requested at creation time. The <code>umask(1)</code> will not be applied if the directory contains default ACL entries. If a default ACL is specified for a specific user (or users), the file will have a regular ACL created; otherwise, only the mode bits will be initialized according to the intersection described above. The default ACL should be thought of as the maximum discretionary access permissions that may be granted.</p>						
<i>acl_entries</i> Syntax	<p>For the <code>-m</code> and <code>-s</code> options, <i>acl_entries</i> are one or more comma-separated ACL entries.</p> <p>An ACL entry consists of the following fields separated by colons:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><i>entry_type</i></td> <td>Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).</td> </tr> <tr> <td style="padding-right: 20px;"><i>uid</i> or <i>gid</i></td> <td>User name or user identification number. Or, group name or group identification number.</td> </tr> <tr> <td style="padding-right: 20px;"><i>perms</i></td> <td>Represents the permissions that are set on <i>entry_type</i>. <i>perms</i> can be indicated by the symbolic characters <code>rxw</code> or a number (the same</td> </tr> </table>	<i>entry_type</i>	Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).	<i>uid</i> or <i>gid</i>	User name or user identification number. Or, group name or group identification number.	<i>perms</i>	Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters <code>rxw</code> or a number (the same
<i>entry_type</i>	Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).						
<i>uid</i> or <i>gid</i>	User name or user identification number. Or, group name or group identification number.						
<i>perms</i>	Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters <code>rxw</code> or a number (the same						

permissions numbers used with the `chmod` command).

The following table shows the valid ACL entries (default entries may only be specified for directories):

ACL Entry	Description
<code>u[ser]::perms</code>	File owner permissions.
<code>g[roup]::perms</code>	File group owner permissions.
<code>o[ther]::perms</code>	Permissions for users other than the file owner or members of file group owner.
<code>m[ask]::perms</code>	The ACL mask. The mask entry indicates the maximum permissions allowed for users (other than the owner) and for groups. The mask is a quick way to change permissions on all the users and groups.
<code>u[ser]:uid:perms</code>	Permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.
<code>g[roup]:gid:perms</code>	Permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.
<code>d[efault]:u[ser]::perms</code>	Default file owner permissions.
<code>d[efault]:g[roup]::perms</code>	Default file group owner permissions.
<code>d[efault]:o[ther]::perms</code>	Default permissions for users other than the file owner or members of the file group owner.
<code>d[efault]:m[ask]::perms</code>	Default ACL mask.
<code>d[efault]:u[ser]:uid:perms</code>	Default permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.
<code>d[efault]:g[roup]:gid:perms</code>	Default permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.

For the `-d` option, *acl_entries* are one or more comma-separated ACL entries without permissions. Note that the entries for file owner, file group owner, ACL mask, and others may not be deleted.

OPTIONS

The options have the following meaning:

`-s acl_entries`

Set a file's ACL. All old ACL entries are removed and replaced with the newly specified ACL. The entries need not be in any specific order. They will be sorted by the command before being applied to the file.

Required entries:

- Exactly one `user` entry specified for the file owner.
- Exactly one `group` entry for the file group owner.
- Exactly one `other` entry specified.

If there are additional user and group entries:

- Exactly one `mask` entry specified for the ACL mask that indicates the maximum permissions allowed for users (other than the owner) and groups.
- Must not be duplicate `user` entries with the same `uid`.
- Must not be duplicate `group` entries with the same `gid`.

If `file` is a directory, the following default ACL entries may be specified:

- Exactly one default `user` entry for the file owner.
- Exactly one default `group` entry for the file group owner.
- Exactly one default `mask` entry for the ACL mask.
- Exactly one default `other` entry.

There may be additional default `user` entries and additional default `group` entries specified, but there may not be duplicate additional default `user` entries with the same `uid`, or duplicate default `group` entries with the same `gid`.

`-m acl_entries`

Add one or more new ACL entries to the file, and/or modify one or more existing ACL entries on the file. If an entry already exists for a specified `uid` or `gid`, the specified permissions will replace the current permissions. If an entry does not exist for the specified `uid` or `gid`, an entry will be created.

`-d acl_entries`

Delete one or more entries from the file. The entries for the file owner, the file group owner, and others may not be deleted from the ACL. Note that deleting an entry does not necessarily have the same effect as removing all permissions from the entry.

`-f acl_file`

Set a file's ACL with the ACL entries contained in the file named `acl_file`. The same constraints on specified entries hold as with the `-s` option. The entries are not required to be in any specific order in the file. Also, if you specify a dash '-' for `acl_file`, standard input is used to set the file's ACL.

The character '#' in `acl_file` may be used to indicate a comment. All characters, starting with the '#' until the end of the line, will be ignored. Note that if the `acl_file` has been created as the output of the `getfacl(1)`

command, any effective permissions, which will follow a "#", will be ignored.

-r

Recalculate the permissions for the ACL mask entry. The permissions specified in the ACL mask entry are ignored and replaced by the maximum permissions necessary to grant the access to all additional user, file group owner, and additional group entries in the ACL. The permissions in the additional user, file group owner, and additional group entries are left unchanged.

EXAMPLES

EXAMPLE 1 Adding read permission only

The following example adds one ACL entry to file `abc`, which gives user `shea` read permission only.

```
setfacl -m user:shea:r— abc
```

EXAMPLE 2 Replacing a file's entire ACL

The following example replaces the entire ACL for the file `abc`, which gives `shea` read access, the file owner all access, the file group owner read access only, the ACL mask read/write access, and others no access.

```
setfacl -s user:shea:rw-,user::rw-,group::r--,mask:r--,other:— abc
```

Note that after this command, the file permission bits are `rw-r-----`. Even though the file group owner was set with read/write permissions, the ACL mask entry limits it to have only read permissions. The mask entry also specifies the maximum permissions available to all additional user and group ACL entries. Once again, even though the user `shea` was set with all access, the mask limits it to have only read permissions. The ACL mask entry is a quick way to limit or open access to all the user and group entries in an ACL. For example, by changing the mask entry to read/write, both the file group owner and user `shea` would be given read/write access.

EXAMPLE 3 Setting the same ACL on two files

The following example sets the same ACL on file `abc` as the file `xyz`.

```
getfacl xyz | setfacl -f - abc
```

FILES

<code>/etc/passwd</code>	password file
<code>/etc/group</code>	group file

NAME	sh, jsh – standard and job control shell and command interpreter
SYNOPSIS	<pre>/usr/bin/sh [-acefhiknprstuvx] [argument...]</pre> <pre>/usr/xpg4/bin/sh [\\261 abCefhikmnoprstuvx] [\\261 o option ...] [-c string]</pre> <pre> [arg...]</pre> <pre>/usr/bin/jsh [-acefhiknprstuvx] [argument...]</pre>
DESCRIPTION	<p>The <code>/usr/bin/sh</code> utility is a command programming language that executes commands read from a terminal or a file.</p> <p>The <code>/usr/xpg4/bin/sh</code> utility is identical to <code>/usr/bin/ksh</code>. See <code>ksh(1)</code>.</p> <p>The <code>jsh</code> utility is an interface to the shell that provides all of the functionality of <code>sh</code> and enables job control (see <code>Job Control</code> section below).</p>
Definitions	<p>Arguments to the shell are listed in the <code>Invocation</code> section below.</p> <p>A <i>blank</i> is a tab or a space. A <i>name</i> is a sequence of ASCII letters, digits, or underscores, beginning with a letter or an underscore. A <i>parameter</i> is a name, a digit, or any of the characters <code>*</code>, <code>@</code>, <code>#</code>, <code>?</code>, <code>-</code>, <code>\$</code>, and <code>!</code>.</p>
USAGE	
Commands	<p>A <i>simple-command</i> is a sequence of non-blank <i>word</i>s separated by <i>blank</i>s. The first <i>word</i> specifies the name of the command to be executed. Except as specified below, the remaining <i>word</i>s are passed as arguments to the invoked command. The command name is passed as argument 0 (see <code>exec(2)</code>). The <i>value</i> of a <i>simple-command</i> is its exit status if it terminates normally, or (octal) <code>200 +status</code> if it terminates abnormally; see <code>signal(3HEAD)</code> for a list of status values.</p> <p>A <i>pipeline</i> is a sequence of one or more <i>command</i>s separated by <code> </code>. The standard output of each <i>command</i> but the last is connected by a <code>pipe(2)</code> to the standard input of the next <i>command</i>. Each <i>command</i> is run as a separate process; the shell waits for the last <i>command</i> to terminate. The exit status of a <i>pipeline</i> is the exit status of the last <i>command</i> in the <i>pipeline</i>.</p> <p>A <i>list</i> is a sequence of one or more <i>pipeline</i>s separated by <code>;</code>, <code>&</code>, <code>&&</code>, or <code> </code>, and optionally terminated by <code>;</code> or <code>&</code>. Of these four symbols, <code>;</code> and <code>&</code> have equal precedence, which is lower than that of <code>&&</code> and <code> </code>. The symbols <code>&&</code> and <code> </code> also have equal precedence. A semicolon (<code>;</code>) causes sequential execution of the preceding <i>pipeline</i> (that is, the shell waits for the <i>pipeline</i> to finish before executing any commands following the semicolon); an ampersand (<code>&</code>) causes asynchronous execution of the preceding <i>pipeline</i> (that is, the shell does <i>not</i> wait for that <i>pipeline</i> to finish). The symbol <code>&&</code> (<code> </code>) causes the <i>list</i> following it to be executed only if the preceding <i>pipeline</i> returns a zero (non-zero) exit status. An arbitrary number of newlines may appear in a <i>list</i>, instead of semicolons, to delimit commands.</p>

A command is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last *simple-command* executed in the command.

```
for name [ in word ... ] do list done
```

Each time a `for` command is executed, *name* is set to the next *word* taken from the `in word` list. If `in word ...` is omitted, then the `for` command executes the `do list` once for each positional parameter that is set (see Parameter Substitution section below). Execution ends when there are no more words in the list.

```
case word in [ pattern [ | pattern ] ) list ; ; ] ... esac
```

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see File Name Generation section) except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.

```
if list ; then list ; [ elif list ; then list ; ] ... [ else list ; ] fi
```

The *list* following `if` is executed and, if it returns a zero exit status, the *list* following the first `then` is executed. Otherwise, the *list* following `elif` is executed and, if its value is zero, the *list* following the next `then` is executed. Failing that, the `else list` is executed. If no `else list` or `then list` is executed, then the `if` command returns a zero exit status.

```
while
list
do
list
done
```

A `while` command repeatedly executes the `while list` and, if the exit status of the last command in the list is zero, executes the `do list`; otherwise the loop terminates. If no commands in the `do list` are executed, then the `while` command returns a zero exit status; `until` may be used in place of `while` to negate the loop termination test.

```
(
list
)
```

Execute *list* in a sub-shell.

```
{
list
; }
```

list is executed in the current (that is, parent) shell. The `{` must be followed by a space.

```

name
( ) {
list
; }

```

Define a function which is referenced by *name*. The body of the function is the *list* of commands between { and }. The { must be followed by a space. Execution of functions is described below (see Execution section). The { and } are unnecessary if the body of the function is a command as defined above, under Commands.

The following words are only recognized as the first word of a command and when not quoted:

```
if then else elif fi case esac for while until do done { }
```

Comments Lines

A word beginning with # causes that word and all the following characters up to a newline to be ignored.

Command Substitution

The shell reads commands from the string between two grave accents (` `) and the standard output from these commands may be used as all or part of a word. Trailing newlines from the standard output are removed.

No interpretation is done on the string before the string is read, except to remove backslashes (\) used to escape other characters. Backslashes may be used to escape a grave accent (`) or another backslash (\) and are removed before the command string is read. Escaping grave accents allows nested command substitution. If the command substitution lies within a pair of double quotes (" . . . ` . . . ` . . . "), a backslash used to escape a double quote (\ ") will be removed; otherwise, it will be left intact.

If a backslash is used to escape a newline character (\ newline), both the backslash and the newline are removed (see the later section on Quoting). In addition, backslashes used to escape dollar signs (\ \$) are removed. Since no parameter substitution is done on the command string before it is read, inserting a backslash to escape a dollar sign has no effect. Backslashes that precede characters other than \ , ` , " , newline , and \$ are left intact when the command string is read.

Parameter Substitution

The character \$ is used to introduce substitutable *parameters*. There are two types of parameters, positional and keyword. If *parameter* is a digit, it is a positional parameter. Positional parameters may be assigned values by *set*. Keyword parameters (also known as variables) may be assigned values by writing:

```
name = value [ name = value ] ...
```

Pattern-matching is not performed on *value*. There cannot be a function and a variable with the same *name*.

```

${
parameter
}

```

The value, if any, of the parameter is substituted. The braces are required only when *parameter* is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If *parameter* is * or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.

```

${
parameter
:-
word
}

```

If *parameter* is set and is non-null, substitute its value; otherwise substitute *word*.

```

${
parameter
:=
word
}

```

If *parameter* is not set or is null set it to *word*; the value of the parameter is substituted. Positional parameters may not be assigned in this way.

```

${
parameter
:?
word
}

```

If *parameter* is set and is non-null, substitute its value; otherwise, print *word* and exit from the shell. If *word* is omitted, the message "parameter null or not set" is printed.

```

${
parameter
:+
word
}

```

If *parameter* is set and is non-null, substitute *word*; otherwise substitute nothing.

In the above, *word* is not evaluated unless it is to be used as the substituted string, so that, in the following example, `pwd` is executed only if `d` is not set or is null:

```
echo ${d:-`pwd`}
```

If the colon (:) is omitted from the above expressions, the shell only checks whether *parameter* is set or not.

The following parameters are automatically set by the shell.

#	The number of positional parameters in decimal.
-	Flags supplied to the shell on invocation or by the <code>set</code> command.
?	The decimal value returned by the last synchronously executed command.
\$	The process number of this shell.
!	The process number of the last background command invoked.

The following parameters are used by the shell. The parameters in this section are also referred to as environment variables.

HOME	The default argument (home directory) for the <code>cd</code> command, set to the user's login directory by <code>login(1)</code> from the password file (see <code>passwd(4)</code>).
PATH	The search path for commands (see <code>Execution</code> section below).
CDPATH	The search path for the <code>cd</code> command.
MAIL	If this parameter is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> parameter is not set, the shell informs the user of the arrival of mail in the specified file.
MAILCHECK	This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the <code>MAILPATH</code> or <code>MAIL</code> parameters. The default value is 600 seconds (10 minutes). If set to 0, the shell will check before each prompt.
MAILPATH	A colon (:) separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by % and a

	message that will be printed when the modification time changes. The default message is, you have mail .
PS1	Primary prompt string, by default "\$ ".
PS2	Secondary prompt string, by default "> ".
IFS	Internal field separators, normally space , tab , and newline (see Blank Interpretation section).
SHACCT	If this parameter is set to the name of a file writable by the user, the shell will write an accounting record in the file for each shell procedure executed.
SHELL	When the shell is invoked, it scans the environment (see Environment section below) for this name.

See environ(5) for descriptions of the following environment variables that affect the execution of sh : LC_CTYPE and LC_MESSAGES .

The shell gives default values to PATH , PS1 , PS2 , MAILCHECK , and IFS . HOME and MAIL are set by login(1) .

Blank Interpretation

After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in IFS) and split into distinct arguments where such characters are found. Explicit null arguments (" " or ' ') are retained. Implicit null arguments (those resulting from parameters that have no values) are removed.

Input/Output Redirection

A command's input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a command and are not passed on as arguments to the invoked command. Note: Parameter and command substitution occurs before word or digit is used.

- < word Use file word as standard input (file descriptor 0).
- > word Use file word as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.

>>
word

Use file *word* as standard output. If the file exists, output is appended to it (by first seeking to the EOF); otherwise, the file is created.

<>
word

Open file *word* for reading and writing as standard input.

<<
[-
]*word*

After parameter and command substitution is done on *word*, the shell input is read up to the first line that literally matches the resulting *word*, or to an EOF. If, however, - is appended to << :

- 1) leading tabs are stripped from *word* before the shell input is read (but after parameter and command substitution is done on *word*),
- 2) leading tabs are stripped from the shell input as it is read and before each line is compared with *word*, and
- 3) shell input is read up to the first line that literally matches the resulting *word*, or to an EOF.

If any character of *word* is quoted (see *Quoting* section later), no additional processing is done to the shell input. If no characters of *word* are quoted:

- 1) parameter and command substitution occurs,
- 2) (escaped) \ewline s are removed, and
- 3) \\ must be used to quote the characters \\, \$, and `.

The resulting document becomes the standard input.

<&
digit

Use the file associated with file descriptor *digit* as standard input. Similarly for the standard output using >& *digit* .

<&-

The standard input is closed. Similarly for the standard output using >&- .

If any of the above is preceded by a digit, the file descriptor which will be associated with the file is that specified by the digit (instead of the default 0 or 1). For example:

... 2>&1

associates file descriptor 2 with the file currently associated with file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates redirections left-to-right. For example:

... 1> xxx 2>&1

first associates file descriptor 1 with file *xxx* . It associates file descriptor 2 with the file associated with file descriptor 1 (that is, *xxx*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file *xxx* .

Using the terminology introduced on the first page, under `Commands` , if a `command` is composed of several *simple commands* , redirection will be evaluated for the entire `command` before it is evaluated for each *simple command* . That is, the shell evaluates redirection for the entire *list* , then each *pipeline* within the *list* , then each `command` within each *pipeline* , then each *list* within each `command` .

If a command is followed by & the default standard input for the command is the empty file `/dev/null` . Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

File Name Generation

Before a command is executed, each command *word* is scanned for the characters `*` , `?` , and `[]` . If one of these characters appears the word is regarded as a *pattern* . The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. The character `.` at the start of a file name or immediately following a `/` , as well as the character `/` itself, must be matched explicitly.

*	Matches any string, including the null string.
?	Matches any single character.
[...]	Matches any one of the enclosed characters. A pair of characters separated by - matches any character lexically between the pair, inclusive. If the first character following the opening [is a ! , any character not enclosed is matched.

Note that all quoted characters (see below) must be matched explicitly in a filename.

Quoting

The following characters have a special meaning to the shell and cause termination of a word unless quoted:

```
; & ( ) | ^ < > newline space tab
```

A character may be *quoted* (that is, made to stand for itself) by preceding it with a backslash (\\) or inserting it between a pair of quote marks (' ' or " "). During processing, the shell may quote certain characters to prevent them from taking on a special meaning. Backslashes used to quote a single character are removed from the word before the command is executed. The pair \ ewline is removed from a word before command and parameter substitution.

All characters enclosed between a pair of single quote marks (' '), except a single quote, are quoted by the shell. Backslash has no special meaning inside a pair of single quotes. A single quote may be quoted inside a pair of double quote marks (for example, " ' "), but a single quote can not be quoted inside a pair of single quotes.

Inside a pair of double quote marks (" "), parameter and command substitution occurs and the shell quotes the results to avoid blank interpretation and file name generation. If \$* is within a pair of double quotes, the positional parameters are substituted and quoted, separated by quoted spaces (" \$1 \$2 ... "); however, if \$@ is within a pair of double quotes, the positional parameters are substituted and quoted, separated by unquoted spaces (" \$1 " "\$2" ...). \\ quotes the characters \\, \ , , and \$. The pair \ ewline is removed before parameter and command substitution. If a backslash precedes characters other than \\, \ , , \$, and newline, then the backslash itself is quoted by the shell.

Prompting

When used interactively, the shell prompts with the value of PS1 before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (that is, the value of PS2) is issued.

Environment

The *environment* (see `environ(5)`) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the `export` command is used to bind the shell's parameter to the environment (see also `set -a`). A parameter may be removed from the environment with the `unset` command. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by `unset`, plus any modifications or additions, all of which must be noted in `export` commands.

The environment for any *simple-command* may be augmented by prefixing it with one or more assignments to parameters. Thus:

```
TERM =450 command
```

and

```
(export TERM ; TERM =450; command )
```

are equivalent as far as the execution of `command` is concerned if `command` is not a Special Command. If `command` is a Special Command, then

```
TERM =450 command
```

will modify the `TERM` variable in the current shell.

If the `-k` flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name. The following example first prints

```
a=b c and c :
```

```
echo a=b c
```

```
a=b c
```

```
set -k
```

```
echo a=b c
```

```
c
```

Signals

The `INTERRUPT` and `QUIT` signals for an invoked command are ignored if the command is followed by `&`; otherwise signals have the values inherited by the

shell from its parent, with the exception of signal 11 (but see also the `trap` command below).

Execution

Each time a command is executed, the command substitution, parameter substitution, blank interpretation, input/output redirection, and filename generation listed above are carried out. If the command name matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of shell script files, which require a sub-shell for invocation). If the command name does not match the name of a defined function, but matches one of the *Special Commands* listed below, it is executed in the shell process.

The positional parameters `$1`, `$2`, ... are set to the arguments of the function. If the command name matches neither a *Special Command* nor the name of a defined function, a new process is created and an attempt is made to execute the command via `exec(2)`.

The shell parameter `PATH` defines the search path for the directory containing the command. Alternative directory names are separated by a colon (`:`). The default path is `/usr/bin`. The current directory is specified by a null path name, which can appear immediately after the equal sign, between two colon delimiters anywhere in the path list, or at the end of the path list. If the command name contains a `/` the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an `a.out` file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. A parenthesized command is also executed in a sub-shell.

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary *execs* later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the `PATH` variable is changed or the `hash -r` command is executed (see below).

Special Commands

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional *Special Commands* are added to the shell's environment (see `Job Control` section below).

`:`

No effect; the command does nothing. A zero exit code is returned.

`. filename`

Read and execute commands from *filename* and return. The search path specified by `PATH` is used to find the directory containing *filename*.

`bg [% jobid ...]`

When Job Control is enabled, the `bg` command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in

the background. If % *jobid* is omitted the current job is assumed. (See Job Control section below for more detail.)

break [*n*]

Exit from the enclosing `for` or `while` loop, if any. If *n* is specified, break *n* levels.

cd [*argument*]

Change the current directory to *argument*. The shell parameter `HOME` is the default *argument*. The shell parameter `CDPATH` defines the search path for the directory containing *argument*. Alternative directory names are separated by a colon (:). The default path is `<null>` (specifying the current directory). Note: The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *argument* begins with a / the search path is not used. Otherwise, each directory in the path is searched for *argument*.

chdir [*dir*]

`chdir` changes the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the `CDPATH` variable. If *dir* is the name of a shell variable whose value starts with a /, change to the directory named by that value.

continue [*n*]

Resume the next iteration of the enclosing `for` or `while` loop. If *n* is specified, resume at the *n*-th enclosing loop.

echo [*arguments* ...]

The words in *arguments* are written to the shell's standard output, separated by space characters. See `echo(1)` for fuller usage and description.

eval [*argument* ...]

The arguments are read as input to the shell and the resulting command(s) executed.

exec [*argument* ...]

The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

exit [*n*]

Causes the calling shell or shell script to exit with the exit status specified by *n*. If *n* is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)

export [*name* ...]

The given *name s* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell's execution.) Function names are *not* exported.

`fg [% jobid ...]`

When Job Control is enabled, the `fg` command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If `% jobid` is omitted the current job is assumed. (See `Job Control` section below for more detail.)

`getopts`

Use in shell scripts to support command syntax standards (see `intro(1)`); it parses positional parameters and checks for legal options. See `getoptcvt(1)` for usage and description.

`hash [-r] [name ...]`

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The `-r` option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

`jobs [-p |-l] [% jobid ...]`

`jobs -x command [arguments]`

Reports all jobs that are stopped or executing in the background. If `% jobid` is omitted, all jobs that are stopped or running in the background will be reported. (See `Job Control` section below for more detail.)

`kill [-sig] % job ...`

`kill -l`

Sends either the `TERM` (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal(3HEAD)` stripped of the prefix "SIG" with the exception that `SIGCHD` is named `CHLD`). If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process will be sent a `CONT` (continue) signal if it is stopped. The argument *job* can be the process id of a process that is

not a member of one of the active jobs. See `Job Control` section below for a description of the format of *job*. In the second form, `kill -l`, the signal numbers and names are listed. (See `kill(1)`).

`login [argument ...]`

Equivalent to `'exec login argument ...'` See `login(1)` for usage and description.

`newgrp [argument]`

Equivalent to `exec newgrp argument`. See `newgrp(1)` for usage and description.

`pwd`

Print the current working directory. See `pwd(1)` for usage and description.

`read name ...`

One line is read from the standard input and, using the internal field separator, `IFS` (normally space or tab), to delimit word boundaries, the first word is assigned to the first *name*, the second word to the second *name*, and so forth, with leftover words assigned to the last *name*. Lines can be continued using `\ewline`. Characters other than `newline` can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to *names*, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.

`readonly [name ...]`

The given *names* are marked `readonly` and the values of these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all `readonly` names is printed.

`return [n]`

Causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed.

`set [-aefhkntuvx [argument ...]]`

- a Mark variables which are modified or created for export.
- e Exit immediately if a command exits with a non-zero exit status.
- f Disable file name generation.
- h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).

- k All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- n Read commands but do not execute them.
- t Exit after reading and executing one command.
- u Treat unset variables as an error when substituting.
- v Print shell input lines as they are read.
- x Print commands and their arguments as they are executed.
- Do not change any of the flags; useful in setting \$1 to - .

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$- . The remaining arguments are positional parameters and are assigned, in order, to \$1 , \$2 , If no arguments are given the values of all names are printed.

`shift [n]`

The positional parameters from \$ n +1 ... are renamed \$1 If n is not given, it is assumed to be 1.

`stop pid ...`

Halt execution of the process number *pid* . (see `ps(1)`).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`test`

Evaluate conditional expressions. See `test(1)` for usage and description.

`times`

Print the accumulated user and system times for processes run from the shell.

`trap [argument n [n2 ...]]`

The command *argument* is to be read and executed when the shell receives numeric or symbolic signal(s) (*n*) . (Note: *argument* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *argument* is absent all trap(s) *n* are reset to their original values. If *argument* is the null string this signal is ignored by the shell and by the commands it invokes. If *n* is 0 the command *argument* is executed on exit

from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.

```
type [ name ... ]
```

For each *name*, indicate how it would be interpreted if used as a command name.

```
ulimit [-[HS][a | cdfnstv ]]
```

```
ulimit [-[HS][c | d | f | n | s | t | v]] limit
```

`ulimit` prints or sets hard or soft resource limits. These limits are described in `getrlimit(2)`.

If `limit` is not present, `ulimit` prints the specified limits. Any number of limits may be printed at one time. The `-a` option prints all limits.

If `limit` is present, `ulimit` sets the specified limit to `limit`. The string `unlimited` requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see `su(1M)`.

The `-H` option specifies a hard limit. The `-S` option specifies a soft limit. If neither option is specified, `ulimit` will set both limits and print the soft limit.

The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

- `-c` maximum core file size (in 512-byte blocks)
- `-d` maximum size of data segment or heap (in kbytes)
- `-f` maximum file size (in 512-byte blocks)
- `-n` maximum file descriptor plus 1
- `-s` maximum size of stack segment (in kbytes)
- `-t` maximum CPU time (in seconds)
- `-v` maximum size of virtual memory (in kbytes)

Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` utility. See `swap(1M)`.

Example of `ulimit`: to limit the size of a core file dump to 0
Megabytes, type the following:

```
ulimit -c 0
```

`umask [nnn]`

The user file-creation mask is set to *nnn* (see `umask(1)`). If *nnn* is omitted, the current value of the mask is printed.

`unset [name ...]`

For each *name*, remove the corresponding variable or function value. The variables `PATH`, `PS1`, `PS2`, `MAILCHECK`, and `IFS` cannot be unset.

`wait [n]`

Wait for your background process whose process id is *n* and report its termination status. If *n* is omitted, all your shell's currently active background processes are waited for and the return code will be zero.

Invocation

If the shell is invoked through `exec(2)` and the first character of argument zero is `-`, commands are initially read from `/etc/profile` and from `$HOME/.profile`, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as `/usr/bin/sh`. The flags below are interpreted by the shell on invocation only. Note: Unless the `-c` or `-s` flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

- `-c` *string* If the `-c` flag is present commands are read from *string*.
- `-i` If the `-i` flag is present or if the shell input and output are attached to a terminal, this shell is *interactive*. In this case `TERMINATE` is ignored (so that `kill 0` does not kill an interactive shell) and `INTERRUPT` is caught and ignored (so that `wait` is interruptible). In all cases, `QUIT` is ignored by the shell.
- `-p` If the `-p` flag is present, the shell will not set the effective user and group IDs to the real user and group IDs.
- `-r` If the `-r` flag is present the shell is a restricted shell (see `rsh(1M)`).
- `-s` If the `-s` flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for *Special Commands*) is written to file descriptor 2.

The remaining flags and arguments are described under the `set` command above.

Job Control (jsh)

When the shell is invoked as `jsh`, Job Control is enabled in addition to all of the functionality described previously for `sh`. Typically Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled every command or pipeline the user enters at the terminal is called a *job*. All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows: 1) a job in the foreground has read and write access to the controlling terminal; 2) a job in the background is denied read access and has conditional write access to the controlling terminal (see `stty(1)`); 3) a stopped job is a job that has been placed in a suspended state, usually as a result of a `SIGTSTP` signal (see `signal(3HEAD)`).

Every job that the shell starts is assigned a positive integer, called a *job number* which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

`% jobid`

where, *jobid* may be specified in any of the following formats:

`%` for the current job

or `+`

`-` for the previous job

`? <string>` specify the job for which the command line uniquely contains *string*.

`n` for job number *n*, where *n* is a job number

`pref` where *pref* is a unique prefix of the command name (for example, if the command `ls -l name` were running in the background, it could be referred to as `%ls`); *pref* cannot contain blanks unless it is quoted.

When Job Control is enabled, the following commands are added to the user's environment to manipulate jobs:

`bg [% jobid ...]`

Resumes the execution of a stopped job in the background. If `% jobid` is omitted the current job is assumed.

`fg [% jobid ...]`

Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If *% jobid* is omitted the current job is assumed.

`jobs [-p |-l] [% jobid ...]`

`jobs -x command [arguments]`

Reports all jobs that are stopped or executing in the background. If *% jobid* is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of `jobs` :

`-l` Report the process group ID and working directory of the jobs.

`-p` Report only the process group ID of the jobs.

`-x` Replace any *jobid* found in `command` or `arguments` with the corresponding process group ID, and then execute `command` passing it `arguments` .

`kill [-signal] % jobid`

Builtin version of `kill` to provide the functionality of the `kill` command for processes identified with a *jobid* .

`stop % jobid ...`

Stops the execution of a background job(s).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`wait [% jobid ...]`

`wait` builtin accepts a job identifier. If *% jobid* is omitted `wait` behaves as described above under `Special Commands` .

Large File Behavior

See `largefile(5)` for the description of the behavior of `sh` and `jsh` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXIT STATUS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above).

jsh Only

If the shell is invoked as `jsh` and an attempt is made to exit the shell while there are stopped jobs, the shell issues one warning:

There are stopped jobs.

This is the only message. If another exit attempt is made, and there are still stopped jobs they will be sent a `SIGHUP` signal from the kernel and the shell is exited.

FILES

\$HOME
 /.profile

 /dev/null

 /etc/profile

 /tmp/sh*

WARNINGS

The use of `setuid` shell scripts is *strongly* discouraged.

NOTES

Words used for filenames in input/output redirection are not interpreted for filename generation (see File Name Generation section above). For example, `cat file1 >a*` will create a file named `a*`.

Because commands in pipelines are run as separate processes, variables set in a pipeline have no effect on the parent shell.

If you get the error message `cannot fork,too many processes`, try using the `wait(1)` command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. (There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.)

Only the last process in a pipeline can be waited for.

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to `exec` the original command. Use the `hash` command to correct this situation.

The Bourne shell has a limitation on the effective UID for a process. If this UID is less than 100 (and not equal to the process' real UID), then the UID is reset to the process' real UID.

Because the shell implements both foreground and background jobs in the same process group, they all receive the same signals, which can lead to unexpected behavior. It is, therefore, recommended that other job control shells be used, especially in an interactive environment.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

NAME	shell – run a command using shell				
SYNOPSIS	shell <i>command</i> [<i>command</i>] ...				
DESCRIPTION	The <code>shell</code> function concatenate its arguments, separating each by a space, and passes this string to the shell (<code>\$SHELL</code> if set, otherwise <code>/usr/bin/sh</code>).				
EXAMPLES	<p>EXAMPLE 1 A sample output of <code>shell</code> command.</p> <p>Since the Form and Menu Language does not directly support background processing, the <code>shell</code> function can be used instead.</p> <pre>\shell "build prog > /dev/null &"\</pre> <p>If you want the user to continue to be able to interact with the application while the background job is running, the output of an executable run by <code>shell</code> in the background must be redirected: to a file if you want to save the output, or to <code>/dev/null</code> if you don't want to save it (or if there is no output), otherwise your application may appear to be hung until the background job finishes processing.</p> <p><code>shell</code> can also be used to execute a command that has the same name as an FMLI built-in function.</p>				
NOTES	The arguments to <code>shell</code> will be concatenate using spaces, which may or may not do what is expected. The variables set in local environments will not be expanded by the shell because "local" means "local to the current process."

NAME shell_builtins – shell command interpreter built-in functions

DESCRIPTION

The shell command interpreters `sh(1)`, `csh(1)`, and `ksh(1)` have special built-in functions which are interpreted by the shell as commands. Many of these built-in commands are implemented by more than one of the shells, and some are unique to a particular shell. These are:

command	built into
alias	csh, ksh
bg	csh, ksh, sh
break	csh, ksh, sh
case	csh, ksh, sh
cd	csh, ksh, sh
chdir	csh, sh

while	sh, ksh, sh

**Bourne Shell, sh,
Special Commands**

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional *Special Commands* are added to the shell's environment.

Additional to these built-in reserved command words, sh also uses:

- : No effect; the command does nothing. A zero exit code is returned.
- .*filename* Read and execute commands from *filename* and return. The search path specified by PATH is used to find the directory containing *filename*.

C shell, cs

Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell.

Additional to these built-in reserved command words, cs also uses:

- : Null command. This command is interpreted, but performs no action.

**Korn Shell, ksh,
Special Commands**

Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.

Commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

Additional to these built-in reserved command words, ksh also uses:

- * : [*arg*...] The command only expands parameters.
- * .*file* [*arg*...] Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed. the loop termination test.

NAME shift – shell built-in function to traverse either a shell's argument list or a list of field-separated words

SYNOPSIS

sh **shift** [*n*]

csh **shift** [*variable*]

ksh * **shift** [*n*]

DESCRIPTION

sh The positional parameters from $\$n+1 \dots$ are renamed $\$1 \dots$. If *n* is not given, it is assumed to be 1.

csh The components of *argv*, or *variable*, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.

ksh The positional parameters from $\$n+1 \dots$ are renamed $\$1 \dots$, default *n* is 1. The parameter *n* can be any arithmetic expression that evaluates to a non-negative number less than or equal to $\$#$.

On this man page, **ksh(1)** commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	shutdown – close down the system at a given time				
SYNOPSIS	<code>/usr/ucb/shutdown [-fhknr] time [warning-message...]</code>				
DESCRIPTION	<p>shutdown provides an automated procedure to notify users when the system is to be shut down. <code>time</code> specifies when shutdown will bring the system down; it may be the word <code>now</code> (indicating an immediate shutdown), or it may specify a future time in one of two formats: <code>+number</code> and <code>hour: min</code>. The first form brings the system down in <code>number</code> minutes, and the second brings the system down at the time of day indicated in 24-hour notation.</p> <p>At intervals that get closer as the apocalypse approaches, warning messages are displayed at terminals of all logged-in users, and of users who have remote mounts on that machine.</p> <p>At shutdown time a message is written to the system log daemon, <code>syslogd(1M)</code>, containing the time of shutdown, the instigator of the shutdown, and the reason. Then a terminate signal is sent to <code>init</code>, which brings the system down to single-user mode.</p>				
OPTIONS	<p>As an alternative to the above procedure, these options can be specified:</p> <ul style="list-style-type: none"> <code>-f</code> Arrange, in the manner of <code>fastboot(1B)</code>, that when the system is rebooted, the file systems will not be checked. <code>-h</code> Execute <code>halt(1M)</code>. <code>-k</code> Simulate shutdown of the system. Do not actually shut down the system. <code>-n</code> Prevent the normal <code>sync(2)</code> before stopping. <code>-r</code> Execute <code>reboot(1M)</code>. 				
FILES	<code>/etc/rmtab</code> remote mounted file system table				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWscpu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>fastboot(1B)</code> , <code>login(1)</code> , <code>halt(1M)</code> , <code>reboot(1M)</code> , <code>syslogd(1M)</code> , <code>sync(2)</code> , <code>rmtab(4)</code> , <code>attributes(5)</code>				
NOTES	Only allows you to bring the system down between <code>now</code> and <code>23:59</code> if you use the absolute time for shutdown.				

NAME	size – print section sizes in bytes of object files
SYNOPSIS	size [-f] [-F] [-n] [-o] [-v] [-x] <i>filename...</i>
DESCRIPTION	<p>The <code>size</code> command produces segment or section size information in bytes for each loaded section in ELF object files. <code>size</code> prints out the size of the text, data, and bss (uninitialized data) segments (or sections) and their total.</p> <p><code>size</code> processes ELF object files entered on the command line. If an archive file is input to the <code>size</code> command, the information for each object file in the archive is displayed.</p> <p>When calculating segment information, the <code>size</code> command prints out the total file size of the non-writable segments, the total file size of the writable segments, and the total memory size of the writable segments minus the total file size of the writable segments.</p> <p>If it cannot calculate segment information, <code>size</code> calculates section information. When calculating section information, it prints out the total size of sections that are allocatable, non-writable, and not <code>NOBITS</code>, the total size of the sections that are allocatable, writable, and not <code>NOBITS</code>, and the total size of the writable sections of type <code>NOBITS</code>. <code>NOBITS</code> sections do not actually take up space in the <i>filename</i>.</p> <p>If <code>size</code> cannot calculate either segment or section information, it prints an error message and stops processing the file.</p>
OPTIONS	<p>-f Print out the size of each allocatable section, the name of the section, and the total of the section sizes. If there is no section data, <code>size</code> prints out an error message and stops processing the file.</p> <p>-F Print out the size of each loadable segment, the permission flags of the segment, then the total of the loadable segment sizes. If there is no segment data, <code>size</code> prints an error message and stops processing the file.</p> <p>-n Print out non-loadable segment or non-allocatable section sizes. If segment data exists, <code>size</code> prints out the memory size of each loadable segment or file size of each non-loadable segment, the permission flags, and the total size of the segments. If there is no segment data, <code>size</code> prints out, for each allocatable and non-allocatable section, the memory size, the section name, and the total size of the sections. If there is no segment or section data, <code>size</code> prints an error message and stops processing.</p> <p>-o Print numbers in octal, not decimal.</p> <p>-v Print the version information for the <code>size</code> command on the standard error output.</p>

`-x` Print numbers in hexadecimal; not decimal.

EXAMPLES

EXAMPLE 1 Examples of `size`.

The examples below are typical `size` output.

```
example% size filename
2724 + 88 + 0 = 2812
```

```
example% size -f filename
26(.text) + 5(.init) + 5(.fini) = 36
```

```
example% size -F filename
2724(r-x) + 88(rwx) + 0(rwx) = 2812    (If statically linked)
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO

`as(1)`, `cc(1B)`, `ld(1)`, `a.out(4)`, `ar(4)`, `attributes(5)`

NOTES

Since the size of bss sections is not known until link-edit time, the `size` command will not give the true total size of pre-linked objects.

NAME	sleep – suspend execution for an interval				
SYNOPSIS	sleep <i>time</i>				
DESCRIPTION	The <code>sleep</code> utility will suspend execution for at least the integral number of seconds specified by the <code>time</code> operand.				
OPERANDS	The following operands are supported: <i>time</i> A non-negative decimal integer specifying the number of seconds for which to suspend execution.				
EXAMPLES	EXAMPLE 1 Example of the <code>sleep</code> command. To execute a command after a certain amount of time: (<code>sleep 105; command</code>)& or to execute a command every so often: while true do <i>command</i> sleep 37 done				
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sleep</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .				
EXIT STATUS	The following exit values are returned: 0 The execution was successfully suspended for at least <code>time</code> seconds, or a <code>SIGALRM</code> signal was received (see <code>NOTES</code>). >0 An error has occurred.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>wait(1)</code> , <code>alarm(2)</code> , <code>sleep(3C)</code> , <code>wait(3UCB)</code> , <code>attributes(5)</code> , <code>environ(5)</code>				
NOTES	If the <code>sleep</code> utility receives a <code>SIGALRM</code> signal, one of the following actions will be taken: <ul style="list-style-type: none"> ■ Terminate normally with a zero exit status. ■ Effectively ignore the signal. The <code>sleep</code> utility will take the standard action for all other signals.				

NAME	smart2cfg – Compaq Smart-2 EISA/PCI and Smart-2SL PCI Array Controller ioctl utility
SYNOPSIS	smart2cfg -c [<i>controller_num</i>] smart2cfg -d [<i>controller_num</i>] smart2cfg -h smart2cfg -l <i>logical_drive_num</i> [<i>controller_num</i>] smart2cfg -p <i>physical_drive_num bus_num</i> [<i>controller_num</i>]
DESCRIPTION	smart2cfg issues controller-specific ioctls to the Compaq Smart-2 EISA/PCI and Smart-2SL PCI array controller using the smartii(7D) driver. smart2cfg provides information about the Smart-2 and Smart-2SL controllers installed on the system, the Logical and Physical drives as well as the details of the ReadWrite cache present on each controller. The utility is text based and is driven by command line arguments. smart2cfg and the smartii(7D) driver communicate using ioctls. smart2cfg also supports multiple commands.
OPTIONS	-c <i>controller_num</i> Print cache details of the cache on controller <i>controller_num</i> . -d <i>controller_num</i> Print details of all the physical disks, all the logical drives, and the cache on controller <i>controller_num</i> . -h On-line help for the smart2cfg utility. -l <i>logical_drive_num controller_num</i> Print logical drive details of the drive <i>logical_drive_num</i> on controller <i>controller_num</i> . -p <i>physical_drive_num bus_num controller_num</i> Print physical drive details of the disk <i>physical_drive_num</i> on bus <i>bus_num</i> on controller <i>controller_num</i> .
EXAMPLES	EXAMPLE 1 Examples of smart2cfg . Details of the physical disk with SCSI ID 0, on Bus 0, on controller 0: <pre>smart2cfg -p 0 0 0</pre> Logical drive details of logical drive 0 on controller 0: <pre>smart2cfg -l 0 0</pre> Cache details of controller 0:

```
smart2cfg -c 0
```

Information of all physical disks, logical drives, and cache on controller 0:

```
smart2cfg -d
```

Details of the disk with SCSI ID 0, on Bus 0, on controller 0, and logical drive details of logical drive 0 on controller 1:

```
smart2cfg -p 0 0 0 -l 0 1
```

FILES

NAME solregis – Solaris user registration

SYNOPSIS /usr/dt/bin/solregis [-dc]

DESCRIPTION The `solregis` command initiates the Solaris user registration procedure. This allows users to register with Sun Microsystems and receive information about Solaris. Normally, `solregis` is executed in conditional mode as a part of desktop login so that users are prompted at desktop start up time to register, unless they have already done so.

OPTIONS The following options are supported:

- d Delay display of the initial screen until a window manager has asserted control of the X display.
- c Conditional mode. If specified, `solregis` will exit without any dialog displayed if: (1) `$HOME/.solregis/disable` exists, (2) `DISABLE=1` is specified in `/etc/default/solregis`, or (3) the user has already registered.

USAGE The following resources can control the behavior and appearance of `solregis`:

Name	Class	Value Type	Default
<code>disable</code>	Disable	Boolean	False
<code>localeChoices</code>	LocaleChoices	Int	1
<code>action0</code>	Action	String	/usr/dt/bin/hotjava
<code>initialURL0</code>	URL	String	file:///usr/dt/app-config \ /solregis/EReg.html
<code>localeChoicen</code>	LocaleChoice	String	null
<code>actionn</code>	Action	String	null for n>0
<code>initialURLn</code>	URL	String	null for n>0
<code>printContext</code>	PrintContext	String	thisorgunit

`disable` If TRUE, when executed in conditional mode `solregis` simply exits without displaying anything.

`localeChoices` Specifies the number of `localeChoicen`, `actionn` and `initialURLn` sets. The first set is 0, so if `localeChoices` is 1, `localeChoice0`, `action0`, and `initialURL0` are the only

	active resources. If <code>localeChoices</code> is 1, none of the <code>localeChoicen</code> strings are displayed, and <code>action0</code> , and so forth, are used. If <code>localeChoices</code> is greater than 1, each <code>localeChoicen</code> string is made an element in an exclusive choice list and the index of the selected item controls which <code>actionn</code> and <code>initialURLn</code> resources are applied.
<code>localeChoicen</code>	Specifies the string presented to the user for this choice.
<code>actionn</code>	Specifies the file name of the command to be executed (normally expected to be a World Wide Web browser) when the user selects "Register Now", or the special string "print". If "print" is specified, the <code>initialURLn</code> string must be a file name on the local system, naming a file which is to be printed after prompting the user for a print destination.
<code>initialURLn</code>	Specifies the argument to be passed to <code>actionn</code> for initial registration. This will normally be the Universal Resource Locator for the initial page to be displayed by the World Wide Web browser.
<code>printContext</code>	XFN naming context under which the printers to display to the user if the special "print" action are named, in the service/printer context. For example, if the default <code>printContext</code> "thisorgunit" is used, the printers in <code>thisorgunit/service/printer</code> are displayed.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `solregis`: `HOME`, `LANG`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

FILES

`/etc/default/solregis`
Default values.

`/$HOME/.solregis/uprops`
User registration information.

```
/$HOME/.solregis/disable
  Users disabled from registration.

/usr/dt/app-defaults/C/Solregis
  Default locale resources.

/usr/dt/app-defaults/$LANG/Solregis
  Default localized resources.

/etc/dt/app-defaults/C/Solregis

NAME	sort – sort, merge, or sequence check text files
SYNOPSIS	<pre> /usr/bin/sort [-bcdfimMnru] [-k keydef] [-o output] [-S kmem] [-t char] [-T directory] [-y [kmem]] [-z recsz] [+pos1 [-pos2]] [file...] /usr/xpg4/bin/sort [-bcdfimMnru] [-k keydef] [-o output] [-S kmem] [-t char] [-T directory] [-y [kmem]] [-z recsz] [+pos1 [-pos2]] [file...] </pre>
DESCRIPTION	<p>The <code>sort</code> command sorts lines of all the named files together and writes the result on the standard output.</p> <p>Comparisons are based on one or more sort keys extracted from each line of input. By default, there is one sort key, the entire input line. Lines are ordered according to the collating sequence of the current locale.</p>
OPTIONS	The following options alter the default behavior:
<code>/usr/bin/sort</code>	<pre> -c Checks that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. The exit code is set and no output is produced unless the file is out of sort. </pre>
<code>/usr/xpg4/bin/sort</code>	<pre> -c Same as /usr/bin/sort except no output is produced under any circumstances. -m Merges only. The input files are assumed to be already sorted. -u Unique: suppresses all but one in each set of lines having equal keys. If used with the -c option, checks that there are no lines with duplicate keys in addition to checking that the input file is sorted. -o output Specifies the name of an output file to be used instead of the standard output. This file can be the same as one of the input files. -S kmem Specifies the maximum amount of swap-based memory used for sorting, in kilobytes (the default unit). kmem can also be specified directly as a number of bytes (b), kilobytes (k), megabytes (m), gigabytes (g), or terabytes (t); or as a percentage (%) of the installed physical memory. -T directory Specifies the directory in which to place temporary files. -y kmem (obsolete). This option was used to specify the amount of main memory initially used by sort. Its functionality is not appropriate for a virtual memory system; memory usage for sort is now specified using the -S option. </pre>

`-z recsz` (obsolete). This option was used to prevent abnormal termination when lines longer than the system-dependent default buffer size are encountered. Because `sort` automatically allocates buffers large enough to hold the longest line, this option has no effect.

Ordering Options

The default sort order depends on the value of `LC_COLLATE`. If `LC_COLLATE` is set to `C`, sorting will be in ASCII order. If `LC_COLLATE` is set to `en_US`, sorting is case insensitive except when the two strings are otherwise equal and one has an uppercase letter earlier than the other. Other locales will have other sort orders.

The following options override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules are applied globally to all sort keys. When attached to a specific key (see `Sort Key Options`), the specified ordering options override all global ordering options for that key. In the obsolescent forms, if one or more of these options follows a `+pos1` option, it will affect only the key field specified by that preceding option.

`-d` "Dictionary" order: only letters, digits, and blanks (spaces and tabs) are significant in comparisons.

`-f` Folds lower-case letters into upper case.

`-i` Ignores non-printable characters.

`-M` Compares as months. The first three non-blank characters of the field are folded to upper case and compared. For example, in English the sorting order is "JAN" < "FEB" < ... < "DEC". Invalid fields compare low to "JAN". The `-M` option implies the `-b` option (see below).

`-n` Restricts the sort key to an initial numeric string, consisting of optional blank characters, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which will be sorted by arithmetic value. An empty digit string is treated as zero. Leading zeros and signs on zeros do not affect ordering.

`-r` Reverses the sense of comparisons.

Field Separator Options

The treatment of field separators can be altered using the following options:

`-b` Ignores leading blank characters when determining the starting and ending positions of a restricted sort key. If the `-b` option is specified before the first sort key option, it is applied to all sort key options. Otherwise, the `-b` option can be attached independently to each `-k field_start, field_end`, or `+pos1` or `-pos2` option-argument (see below).

Sort Key Options**-t** *char*

Use *char* as the field separator character. *char* is not considered to be part of a field (although it can be included in a sort key). Each occurrence of *char* is significant (for example, *<char><char>* delimits an empty field). If **-t** is not specified, blank characters are used as default field separators; each maximal non-empty sequence of blank characters that follows a non-blank character is a field separator.

Sort keys can be specified using the options:

-k *keydef*

The *keydef* argument is a restricted sort key field definition. The format of this definition is:

```
-k field_start [type] [, field_end [type] ]
```

where:

field_start and *field_end*

define a key field restricted to a portion of the line.

type

is a modifier from the list of characters `bdfiMnr`. The `b` modifier behaves like the `-b` option, but applies only to the *field_start* or *field_end* to which it is attached and characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.) The other modifiers behave like the corresponding options, but apply only to the key field to which they are attached. They have this effect if specified with *field_start*, *field_end* or both. If any modifier is attached to a *field_start* or to a *field_end*, no option applies to either.

When there are multiple key fields, later keys are compared only after all earlier keys compare equal. Except when the `-u` option is specified, lines that otherwise compare equal are ordered as if none of the options `-d`, `-f`, `-i`, `-n` or `-k` were present (but with `-r` still in effect, if it was specified) and with all bytes in the lines significant to the comparison.

The notation:

```
-k field_start[type][, field_end[type]]
```

defines a key field that begins at *field_start* and ends at *field_end* inclusive, unless *field_start* falls beyond the end of the line or after *field_end*, in which case the key field is empty. A missing *field_end* means the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option `-t`, any preceding field separator.

The *field_start* portion of the *keydef* option-argument has the form:

```
field_number[.first_character]
```

Fields and characters within fields are numbered starting with 1. *field_number* and *first_character*, interpreted as positive decimal integers, specify the first character to be used as part of a sort key. If *first_character* is omitted, it refers to the first character of the field.

The *field_end* portion of the *keydef* option-argument has the form:

```
field_number[.last_character]
```

The *field_number* is as described above for *field_start*. *last_character*, interpreted as a non-negative decimal integer, specifies the last character to be used as part of the sort key. If *last_character* evaluates to zero or *last_character* is omitted, it refers to the last character of the field specified by *field_number*.

If the `-b` option or `b` type modifier is in effect, characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.)

[+*pos1* [-*pos2*]] (obsolete). Provide functionality equivalent to the `-kkeydef` option.

pos1 and *pos2* each have the form *m.n* optionally followed by one or more of the flags *bdfiMnr*. A starting position specified by *+m.n* is interpreted to mean the *n*+1st character in the *m*+1st field. A missing *.n* means *.0*, indicating the first character of the *m*+1st field. If the *b* flag is in effect *n* is counted from the first non-blank in the *m*+1st field; *+m.0b* refers to the first non-blank character in the *m*+1st field.

A last position specified by *-m.n* is interpreted to mean the *n*th character (including separators) after the last character of the *m*th field. A missing *.n* means *.0*, indicating the last character of the *m*th field. If the *b* flag is in effect *n* is counted from the last leading blank in the *m*+1st field; *-m.1b* refers to the first non-blank in the *m*+1st field.

The fully specified *+pos1 -pos2* form with type modifiers *T* and *U*:

+w.xT -y.zU

is equivalent to:

undefined (z==0 & *U* contains *b* & *-t* is present)

-k w+1.x+1T,y.0U (z==0 otherwise)

-k w+1.x+1T,y+1.zU (z > 0)

Implementations support at least nine occurrences of the sort keys (the *-k* option and obsolescent *+pos1* and *-pos2*) which are significant in command line order. If no sort key is specified, a default sort key of the entire line is used.

OPERANDS

The following operand is supported:

file A path name of a file to be sorted, merged or checked. If no *file* operands are specified, or if a *file* operand is *-*, the standard input will be used.

USAGE

See *largefile(5)* for the description of the behavior of *sort* when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

EXAMPLES

In the following examples, first the preferred and then the obsolete way of specifying *sort* keys are given as an aid to understanding the relationship between the two forms.

EXAMPLE 1 Sorting with the second field as a sort key

Either of the following commands sorts the contents of `infile` with the second field as the sort key:

```
example% sort -k 2,2 infile
example% sort +1 -2 infile
```

EXAMPLE 2 Sorting in reverse order

Either of the following commands sorts, in reverse order, the contents of `infile1` and `infile2`, placing the output in `outfile` and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

```
example% sort -r -o outfile -k 2.2,2.2 infile1 infile2
example% sort -r -o outfile +1.1 -1.2 infile1 infile2
```

EXAMPLE 3 Sorting using a specified character in one of the files

Either of the following commands sorts the contents of `infile1` and `infile2` using the second non-blank character of the second field as the sort key:

```
example% sort -k 2.2b,2.2b infile1 infile2
example% sort +1.1b -1.2b infile1 infile2
```

EXAMPLE 4 Sorting by numeric user ID

Either of the following commands prints the `passwd(4)` file (user database) sorted by the numeric user ID (the third colon-separated field):

```
example% sort -t : -k 3,3n /etc/passwd
example% sort -t : +2 -3n /etc/passwd
```

EXAMPLE 5 Printing sorted lines excluding lines that duplicate a field

Either of the following commands prints the lines of the already sorted file `infile`, suppressing all but one occurrence of lines having the same third field:

```
example% sort -um -k 3.1,3.0 infile
example% sort -um +2.0 -3.0 infile
```

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sort`: `LC_COLLATE`, `LC_MESSAGES`, and `NLSPATH`.

`LC_CTYPE` Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single- versus multi-byte characters in arguments and input files) and the behavior of character classification for the `-b`, `-d`, `-f`, `-i` and `-n` options.

LC_NUMERIC Determine the locale for the definition of the radix character and thousands separator for the `-n` option.

EXIT STATUS

The following exit values are returned:

- 0 All input files were output successfully, or `-c` was specified and the input file was correctly sorted.
- 1 Under the `-c` option, the file was not ordered as specified, or if the `-c` and `-u` options were both specified, two input lines were found with equal keys.
- >1 An error occurred.

FILES

`/var/tmp/stm???` temporary files

ATTRIBUTES

`/usr/bin/sort`

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled

`/usr/xpg4/bin/sort`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled

SEE ALSO

`comm(1)`, `join(1)`, `uniq(1)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

DIAGNOSTICS

Comments and exits with non-zero status for various trouble conditions (for example, when input lines are too long), and for disorders discovered under the `-c` option.

NOTES

When the last line of an input file is missing a new-line character, `sort` appends one, prints a warning message, and continues.

`sort` does not guarantee preservation of relative line ordering on equal keys.

One can tune `sort` performance for a specific scenario using the `-S` option. However, one should note in particular that `sort` has greater knowledge of how to use a finite amount of memory for sorting than the virtual memory system. Thus, a `sort` invoked to request an extremely large amount of memory via the `-S` option will perform extremely poorly.

NAME	sortbib – sort a bibliographic database
SYNOPSIS	sortbib [-s <i>KEYS</i>] <i>database</i> ...
DESCRIPTION	<p>sortbib sorts files of records containing <i>refer</i> key-letters by user-specified keys. Records may be separated by blank lines, or by ‘. [’ and ‘.]’ delimiters, but the two styles may not be mixed together. This program reads through each <i>database</i> and pulls out key fields, which are sorted separately. The sorted key fields contain the file pointer, byte offset, and length of corresponding records. These records are delivered using disk seeks and reads, so <i>sortbib</i> may not be used in a pipeline to read standard input.</p> <p>The most common key-letters and their meanings are given below.</p> <ul style="list-style-type: none"> %A Author’s name %B Book containing article referenced %C City (place of publication) %D Date of publication %E Editor of book containing article referenced %F Footnote number or label (supplied by <i>refer</i>) %G Government order number %H Header commentary, printed before reference %I Issuer (publisher) %J Journal containing article %K Keywords to use in locating reference %L Label field used by -k option of <i>refer</i> %M Bell Labs Memorandum (undefined) %N Number within volume %O Other commentary, printed at end of reference %P Page number(s) %Q Corporate or Foreign Author (unreversed) %R Report, paper, or thesis (unpublished) %S Series title %T Title of article or book %V Volume number

%X Abstract — used by `roffbib`, not by `refer`

%Y,Z Ignored by `refer`

By default, `sortbib` alphabetizes by the first %A and the %D fields, which contain the senior author and date.

`sortbib` sorts on the last word on the %A line, which is assumed to be the author's last name. A word in the final position, such as 'jr.' or 'ed.', will be ignored if the name beforehand ends with a comma. Authors with two-word last names or unusual constructions can be sorted correctly by using the `nroff` convention '\0' in place of a blank. A %Q field is considered to be the same as %A, except sorting begins with the first, not the last, word. `sortbib` sorts on the last word of the %D line, usually the year. It also ignores leading articles (like 'A' or 'The') when sorting by titles in the %T or %J fields; it will ignore articles of any modern European language. If a sort-significant field is absent from a record, `sortbib` places that record before other records containing that field.

No more than 16 databases may be sorted together at one time. Records longer than 4096 characters will be truncated.

OPTIONS

`-sKEYS` Specify new *KEYS*. For instance, `-sATD` will sort by author, title, and date, while `-sA+D` will sort by all authors, and date. Sort keys past the fourth are not meaningful.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

SEE ALSO

`addbib(1)`, `indxbib(1)`, `lookbib(1)`, `refer(1)`, `roffbib(1)`, `attributes(5)`

BUGS

Records with missing author fields should probably be sorted by title.

NAME	sotruss – trace shared library procedure calls
SYNOPSIS	<code>/usr/bin/sotruss [-f] [-F bindfromlist] [-T bindtolist] [-o outputfile] executable</code> <code>[executable arguments...]</code>
DESCRIPTION	sotruss executes the specified command and produces a trace of the library calls that it performs. Each line of the trace output reports what bindings are occurring between dynamic objects as each procedure call is executed. sotruss traces all of the procedure calls that occur between dynamic objects via the <i>Procedure Linkage Table</i> , so only those procedure calls which are bound via the <i>Procedure Linkage Table</i> will be traced. See <i>Linker and Libraries Guide</i>
OPTIONS	<p><code>-F bindfromlist</code> A colon-separated list of libraries that are to be traced. Only calls from these libraries will be traced. The default is to trace calls from the main executable only.</p> <p><code>-T bindtolist</code> A colon-separated list of libraries that are to be traced. Only calls to these libraries will be traced. The default is to trace all calls.</p> <p><code>-o outputfile</code> sotruss output will be directed to the <i>outputfile</i>. If this option is combined with the <code>-f</code> option then the <i>pid</i> of the executing program will be placed at the end of the filename. By default sotruss output is placed on <code>stderr</code>.</p> <p><code>-f</code> Follow all children created by <code>fork()</code> and print truss output on each child process. This option will also cause a <i>pid</i> to be output on each truss output line.</p>
EXAMPLES	<p>EXAMPLE 1 An example of sotruss.</p> <p>A simple example shows the tracing of a simple <code>ls</code> command:</p> <pre>% sotruss ls more ls -> libc.so.1:*atexit(0xef7d7d1c, 0x23c00, 0x0) ls -> libc.so.1:*atexit(0x1392c, 0xef7d7d1c, 0xef621bb0) ls -> libc.so.1:*setlocale(0x6, 0x1396c, 0xef621ba8) ls -> libc.so.1:*textdomain(0x13970, 0x1396c, 0xef621ba8) ls -> libc.so.1:*time(0x0, 0xef61f6fc, 0xef621ba8) ls -> libc.so.1:*isatty(0x1, 0xef61f6fc, 0x0) ls -> libc.so.1:*getopt(0x1, 0xfffff8fc, 0x13980) ls -> libc.so.1:*malloc(0x100, 0x0, 0x0) ls -> libc.so.1:*malloc(0x9000, 0x0, 0x0) ls -> libc.so.1:*lstat64(0x23ee8, 0xfffff7a0, 0x0) . . . ls -> libc.so.1:*printf(0x13a64, 0x26208, 0x23ef0) ls -> libc.so.1:*printf(0x13a64, 0x26448, 0x23ef0) ls -> libc.so.1:*exit(0x0, 0x24220, 0x2421c)</pre>

Linker and Libraries Guide

NAME	spell, hashmake, spellin, hashcheck – report spelling errors						
SYNOPSIS	<pre>spell [-bilvx] [+ local_file] [file] ... /usr/lib/spell/hashmake /usr/lib/spell/spellin n /usr/lib/spell/hashcheck spelling_list</pre>						
DESCRIPTION	<p>The <code>spell</code> command collects words from the named <code>file s</code> and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, or suffixes) from words in the spelling list are written to the standard output.</p> <p>If there are no <code>file</code> arguments, words to check are collected from the standard input. <code>spell</code> ignores most <code>troff(1)</code>, <code>tbl(1)</code>, and <code>eqn(1)</code> constructs. Copies of all output words are accumulated in the history file (<code>spellhist</code>), and a <code>stop</code> list filters out misspellings (for example, <code>their=thy-y+ier</code>) that would otherwise pass.</p> <p>By default, <code>spell</code> (like <code>deroff(1)</code>) follows chains of included files (<code>.so</code> and <code>.nx troff(1)</code> requests), unless the names of such included files begin with <code>/usr/lib</code>.</p> <p>The standard spelling list is based on many sources, and while more haphazard than an ordinary dictionary, is also more effective in respect to proper names and popular technical words. Coverage of the specialized vocabularies of biology, medicine and chemistry is light.</p> <p>Three programs help maintain and check the hash lists used by <code>spell</code>:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>hashmake</code></td> <td>Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.</td> </tr> <tr> <td><code>spellin</code></td> <td>Reads <code>n</code> hash codes from the standard input and writes a compressed spelling list on the standard output.</td> </tr> <tr> <td><code>hashcheck</code></td> <td>Reads a compressed <code>spelling_list</code> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.</td> </tr> </table>	<code>hashmake</code>	Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.	<code>spellin</code>	Reads <code>n</code> hash codes from the standard input and writes a compressed spelling list on the standard output.	<code>hashcheck</code>	Reads a compressed <code>spelling_list</code> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.
<code>hashmake</code>	Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.						
<code>spellin</code>	Reads <code>n</code> hash codes from the standard input and writes a compressed spelling list on the standard output.						
<code>hashcheck</code>	Reads a compressed <code>spelling_list</code> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.						
OPTIONS	<p>The following options are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>-b</code></td> <td>Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon <code>-ise</code> in words like "standardise."</td> </tr> <tr> <td><code>-i</code></td> <td>Cause <code>deroff(1)</code> to ignore <code>.so</code> and <code>.nx</code> commands. If <code>deroff(1)</code> is not present on the system, then this option is ignored.</td> </tr> </table>	<code>-b</code>	Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon <code>-ise</code> in words like "standardise."	<code>-i</code>	Cause <code>deroff(1)</code> to ignore <code>.so</code> and <code>.nx</code> commands. If <code>deroff(1)</code> is not present on the system, then this option is ignored.		
<code>-b</code>	Check British spelling. Besides preferring "centre," "colour," "programme," "speciality," "travelled," and so forth, this option insists upon <code>-ise</code> in words like "standardise."						
<code>-i</code>	Cause <code>deroff(1)</code> to ignore <code>.so</code> and <code>.nx</code> commands. If <code>deroff(1)</code> is not present on the system, then this option is ignored.						

- l Follow the chains of *all* included files.
- v Print all words not literally in the spelling list, as well as plausible derivations from the words in the spelling list.
- x Print every plausible stem, one per line, with = preceding each word.
- + Specify a set of words that are correct spellings (in addition to `spell`'s own spelling list) for each job. *local_file* is the name of a user-provided file that contains a sorted list of words, one per line. Words found in *local_file* are removed from `spell`'s output. Use `sort(1)` to order *local_file* in ASCII collating sequence. If this ordering is not followed, some entries in *local_file* may be ignored.

OPERANDS

The following operands are supported:
file A path name of a text file to check for spelling errors. If no files are named, words are collected from the standard input.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `spell`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:
 0 Successful completion.
 >0 An error occurred.

FILES

- `D_SPELL=/usr/lib/spell/hlist[ab]` hashed spelling lists, American & British
- `S_SPELL=/usr/lib/spell/hstop` hashed stop list
- `H_SPELL=/var/adm/spellhist` history file
- `/usr/share/lib/dict/words` master dictionary

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO

`deroff(1)`, `eqn(1)`, `sort(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `environ(5)`

NOTES

Misspelled words can be monitored by default by setting the `H_SPELL` variable in `/usr/bin/spell` to the name of a file that has permission mode 666.
`spell` works only on English words defined in the U.S. ASCII codeset.

BUGS

Because copies of all output are accumulated in the `spellhist` file, `spellhist` may grow quite large and require purging.

The spelling list's coverage is uneven; new installations may wish to monitor the output for several months to gather local additions.

British spelling was done by an American.

NAME	spline – interpolate smooth curve				
SYNOPSIS	spline [-aknp x] ...				
DESCRIPTION	<code>spline</code> takes pairs of numbers from the standard input as abscissas and ordinates of a function. It produces a similar set, which is approximately equally spaced and includes the input set, on the standard output. The cubic spline output (R. W. Hamming, <i>Numerical Methods for Scientists and Engineers</i> , 2nd ed., 349ff) has two continuous derivatives, and sufficiently many points to look smooth when plotted, for example by <code>graph(1)</code> .				
OPTIONS	<p>-a Supply abscissas automatically (they are missing from the input); spacing is given by the next argument, or is assumed to be 1 if next argument is not a number.</p> <p>-k The constant k used in the boundary value computation (<i>2nd deriv. at end</i>) = k*(<i>2nd deriv. next to end</i>) is set by the next argument. By default $k = 0$.</p> <p>-n Space output points so that approximately n intervals occur between the lower and upper x limits. (Default $n = 100$.)</p> <p>-p Make output periodic, that is, match derivatives at ends. First and last input values should normally agree.</p> <p>-x Next 1 (or 2) arguments are lower (and upper) x limits. Normally these limits are calculated from the data. Automatic abscissas start at lower limit (default 0).</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	<code>graph(1)</code> , <code>attributes(5)</code> R. W. Hamming, <i>Numerical Methods for Scientists and Engineers</i> , 2nd ed.				
DIAGNOSTICS	When data is not strictly monotonic in x , <code>spline</code> reproduces the input without interpolating extra points.				
BUGS	A limit of 1000 input points is enforced silently.				

NAME	split – split a file into pieces
SYNOPSIS	split [-linecount -l <i>linecount</i>] [-a <i>suffixlength</i>] [<i>file</i> [<i>name</i>]] split [-b <i>n</i> <i>nk</i> <i>nm</i>] [-a <i>suffixlength</i>] [<i>file</i> [<i>name</i>]]
DESCRIPTION	The <code>split</code> utility reads <i>file</i> and writes it in <i>linecount</i> -line pieces into a set of output-files. The name of the first output-file is <i>name</i> with <code>aa</code> appended, and so on lexicographically, up to <code>zz</code> (a maximum of 676 files). The maximum length of <i>name</i> is 2 characters less than the maximum filename length allowed by the filesystem. See <code>statvfs(2)</code> . If no output name is given, <code>x</code> is used as the default (output-files will be called <code>xaa</code> , <code>xab</code> , and so forth).
OPTIONS	The following options are supported: <i>-linecount</i> -l <i>linecount</i> Number of lines in each piece. Defaults to 1000 lines. <i>-a suffixlength</i> Uses <i>suffixlength</i> letters to form the suffix portion of the filenames of the split file. If <code>-a</code> is not specified, the default suffix length is 2. If the sum of the <i>name</i> operand and the <i>suffixlength</i> option-argument would create a filename exceeding <code>NAME_MAX</code> bytes, an error will result; <code>split</code> will exit with a diagnostic message and no files will be created. <i>-b n</i> Splits a file into pieces <i>n</i> bytes in size. <i>-b nk</i> Splits a file into pieces <i>n</i> *1024 bytes in size. <i>-b nm</i> Splits a file into pieces <i>n</i> *1 048 576 bytes in size.
OPERANDS	The following operands are supported: <i>file</i> The path name of the ordinary file to be split. If no input file is given or <i>file</i> is <code>-</code> , the standard input will be used. <i>name</i> The prefix to be used for each of the files resulting from the <code>split</code> operation. If no <i>name</i> argument is given, <code>x</code> will be used as the prefix of the output files. The combined length of the basename of <i>prefix</i> and <i>suffixlength</i> cannot exceed <code>NAME_MAX</code> bytes; see OPTIONS .
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>split</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>split</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	The following exit values are returned: 0 Successful completion.

>0 An error occurred.

NAME	srchtxt – display contents of, or search for a text string in, message data bases
SYNOPSIS	srchtxt [-s] [-l <i>locale</i>] [-m <i>msgfile</i> , ...] [<i>text</i>]
DESCRIPTION	<p>The <code>srchtxt</code> utility is used to display all the text strings in message data bases, or to search for a text string in message data bases (see <code>mkmsgs(1)</code>). These data bases are files in the directory <code>/usr/lib/locale/<i>locale</i>/LC_MESSAGES</code> (see <code>setlocale(3C)</code>), unless a file name given with the <code>-m</code> option contains a <code>/</code>. The directory <code>locale</code> can be viewed as the name of the language in which the text strings are written. If the <code>-l</code> option is not specified, the files accessed will be determined by the value of the environment variable <code>LC_MESSAGES</code>. If <code>LC_MESSAGES</code> is not set, the files accessed will be determined by the value of the environment variable <code>LANG</code>. If <code>LANG</code> is not set, the files accessed will be in the directory <code>/usr/lib/locale//C/LC_MESSAGES</code>, which contains default strings.</p> <p>If no <i>text</i> argument is present, then all the text strings in the files accessed will be displayed.</p> <p>If the <code>-s</code> option is not specified, the displayed text is prefixed by message sequence numbers. The message sequence numbers are enclosed in angle brackets: <code><msgfile:msgnum></code>.</p> <p><i>msgfile</i> name of the file where the displayed text occurred</p> <p><i>msgnum</i> sequence number in <i>msgfile</i> where the displayed text occurred</p> <p>This display is in the format used by <code>gettext(1)</code> and <code>gettext(3C)</code>.</p>
OPTIONS	<p><code>-s</code> Suppress printing of the message sequence numbers of the messages being displayed.</p> <p><code>-l <i>locale</i></code> Access files in the directory <code>/usr/lib/locale/<i>locale</i>/LC_MESSAGES</code>. If <code>-m <i>msgfile</i></code> is also supplied, <code>LOCALE</code> is ignored for <i>msgfiles</i> containing a <code>/</code>.</p> <p><code>-m <i>msgfile</i></code> Access files specified by one or more <i>msgfiles</i>. If <i>msgfile</i> contains a <code>/</code> character, then <i>msgfile</i> is interpreted as a pathname; otherwise, it will be assumed to be in the directory determined as described above. To specify more than one <i>msgfile</i>, separate the file names using commas.</p> <p><i>text</i> Search for the text string specified by <i>text</i> and display each one that matches. <i>text</i> can take the form of a regular expression; see <code>regex(5)</code>.</p>

EXAMPLES**EXAMPLE 1** Using srchtxt

If message files have been installed in a locale named `french` by using `mkmsgs(1)`, then you could display the entire set of text strings in the `french` locale (`/usr/lib/locale/french/LC_MESSAGES/*`) by typing:

```
example% srchtxt -l french
```

EXAMPLE 2 Using srchtxt

If a set of error messages associated with the operating system have been installed in the file `UX` in the `french` locale (`/usr/lib/locale/french/LC_MESSAGE/UX`), then, using the value of the `LANG` environment variable to determine the locale to be searched, you could search that file in that locale for all error messages dealing with files by typing:

```
example% setenv LANG=french; export LANG
example% srchtxt -m UX "[Ff]ichier"
```

If `/usr/lib/locale/french/LC_MESSAGES/UX` contained the following strings:

```
Erreur E/S\n
Liste d'arguments trop longue\n
Fichier inexistant\n
Argument invalide\n
Trop de fichiers ouverts\n
Fichier trop long\n
Trop de liens\n
Argument hors du domaine\n
Identificateur supprim\n
Etreinte fatale\n
.\n
.\n
.
```

then the following strings would be displayed:

```
<UX:3>Fichier inexistant\n
<UX:5>Trop de fichiers ouverts\n
<UX:6>Fichier trop long\n
```

EXAMPLE 3 Using srchtxt

If a set of error messages associated with the operating system have been installed in the file `UX` and a set of error messages associated with the `INGRESS` data base product have been installed in the file `ingress`, both in the `german` locale, then you could search for the pattern `[Dd]atei` in both the files `UX` and `ingress` in the `german` locale by typing:

```
example% srchtxt -l german -m UX,ingress "[Dd]atei"
```

**ENVIRONMENT
VARIABLES**

See [environ\(5\)](#) for a description of the LC_CTYPE environment variable that affects the execution of `srchtxt`.

FILES

`/usr/lib/locale/C/LC_MESSAGES/*`
default files created by [mkmsgs\(1\)](#)

`/usr/lib/locale/locale/LC_MESSAGES/*`
message files created by [mkmsgs\(1\)](#)

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc

SEE ALSO

[exstr\(1\)](#), [gettxt\(1\)](#), [locale\(1\)](#), [mkmsgs\(1\)](#), [gettxt\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [locale\(5\)](#), [regexp\(5\)](#)

DIAGNOSTICS

The error messages produced by `srchtxt` are intended to be self-explanatory. They indicate an error in the command line or errors encountered while searching for a particular locale and/or message file.

NAME	strchg, strconf – change or query stream configuration
SYNOPSIS	strchg <i>-h module1</i> [, <i>module2...</i>] strchg <i>-p</i> [<i>-a</i> <i>-u module</i>] strchg <i>-f filename</i> strconf [<i>-m</i> <i>-t module</i>]
DESCRIPTION	<p>These commands are used to alter or query the configuration of the stream associated with the user's standard input. The <i>strchg</i> command pushes modules on and/or pops modules off the stream. The <i>strconf</i> command queries the configuration of the stream. Only the super-user or owner of a STREAMS device may alter the configuration of that stream.</p> <p>Invoked without any arguments, <i>strconf</i> prints a list of all the modules in the stream as well as the topmost driver. The list is printed with one name per line where the first name printed is the topmost module on the stream (if one exists) and the last item printed is the name of the driver.</p>
OPTIONS	<p>The following options apply to <i>strchg</i> and, <i>-h</i> , <i>-f</i> , and <i>-p</i> are mutually exclusive.</p> <p><i>-h module1</i> [,<i>module2 ...</i>] Mnemonic for <i>push</i> , pushes modules onto a stream. It takes as arguments the names of one or more pushable streams modules. These modules are pushed in order; that is, <i>module1</i> is pushed first, <i>module2</i> is pushed second, etc.</p> <p><i>-p</i> Mnemonic for <i>pop</i> , pops modules off the stream. With the <i>-p</i> option alone, <i>strchg</i> pops the topmost module from the stream.</p> <p><i>-a module</i> Pop all the modules above the topmost driver off the stream. This option requires the <i>-p</i> option.</p> <p><i>-u module</i> All modules above, but not including <i>module</i> are popped off the stream. This option requires the <i>-p</i> option.</p> <p><i>-f filename</i> Specify a <i>filename</i> that contains a list of modules representing the desired configuration of the stream. Each module name must appear on a separate line where the first name represents the topmost module and the last name represents the module that should be closest to the driver. <i>strchg</i> will determine the current configuration of the stream and pop and push the necessary modules in order to end up with the desired configuration.</p> <p>The following options apply to <i>strconf</i> and, <i>-m</i> and <i>-t</i> are mutually exclusive.</p>

`-m` *module* Determine if the named *module* is present on a stream. If it is, `strconf` prints the message `yes` and returns zero. If not, `strconf` prints the message `no` and returns a non-zero value. The `-t` and `-m` options are mutually exclusive.

`-t` *module* Print only the topmost module (if one exists). The `-t` and `-m` options are mutually exclusive.

EXAMPLES**EXAMPLE 1** Using the `strchg` Command

The following command pushes the module `ldterm` on the stream associated with the user's standard input:

```
example% strchg -h ldterm
```

The following command pops the topmost module from the stream associated with `/dev/term/24`. The user must be the owner of this device or the super user.

```
example% strchg -p < /dev/term/24
```

If the file `fileconf` contains the following:

```
ttcompat
ldterm
ptem
```

then the command

```
example% strchg -f fileconf
```

will configure the user's standard input stream so that the module `ptem` is pushed over the driver, followed by `ldterm` and `ttcompat` closest to the stream head.

The `strconf` command with no arguments lists the modules and topmost driver on the stream; for a stream that has only the module `ldterm` pushed above the `zs` driver, it would produce the following output:

```
ldterm
zs
```

The following command asks if `ldterm` is on the stream:

```
example% strconf -m ldterm
```

and produces the following output while returning an exit status of 0:

```
yes
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`attributes(5)`, `streamio(7I)`

DIAGNOSTICS

`strchg` returns zero on success. It prints an error message and returns non-zero status for various error conditions, including usage error, bad module name, too many modules to push, failure of an `ioctl` on the stream, or failure to open *filename* from the `-f` option.

`strconf` returns zero on success (for the `-m` or `-t` option, "success" means the named or topmost module is present). It returns a non-zero status if invoked with the `-m` or `-t` option and the module is not present. It prints an error message and returns non-zero status for various error conditions, including usage error or failure of an `ioctl` on the stream.

NOTES

If the user is neither the owner of the stream nor the super-user, the `strchg` command will fail. If the user does not have read permissions on the stream and is not the super user, the `strconf` command will fail.

If modules are pushed in the wrong order, one could end up with a stream that does not function as expected. For `ttys`, if the line discipline module is not pushed in the correct place, one could have a terminal that does not respond to any commands.

NAME	strings – find printable strings in an object or binary file														
SYNOPSIS	strings [-a -][-t <i>format</i> -o][-n <i>number</i> - <i>number</i>][<i>file</i> ...]														
DESCRIPTION	The <i>strings</i> utility looks for ASCII strings in a binary file. A string is any sequence of 4 or more printing characters ending with a newline or a null character. <i>strings</i> is useful for identifying random object files and many other things.														
OPTIONS	The following options are supported: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">-a -</td> <td>Look everywhere in the file for strings. If this flag is omitted, <i>strings</i> only looks in the initialized data space of object files.</td> </tr> <tr> <td style="vertical-align: top;">-n <i>number</i> -<i>number</i></td> <td>Use a <i>number</i> as the minimum string length rather than the default, which is 4.</td> </tr> <tr> <td style="vertical-align: top;">-o</td> <td>Equivalent to -t d option.</td> </tr> <tr> <td style="vertical-align: top;">-t <i>format</i></td> <td>Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the <i>format</i> option-argument: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">d</td> <td>The offset will be written in decimal.</td> </tr> <tr> <td style="vertical-align: top;">o</td> <td>The offset will be written in octal.</td> </tr> <tr> <td style="vertical-align: top;">x</td> <td>The offset will be written in hexadecimal.</td> </tr> </table> </td> </tr> </table>	-a -	Look everywhere in the file for strings. If this flag is omitted, <i>strings</i> only looks in the initialized data space of object files.	-n <i>number</i> - <i>number</i>	Use a <i>number</i> as the minimum string length rather than the default, which is 4.	-o	Equivalent to -t d option.	-t <i>format</i>	Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the <i>format</i> option-argument: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">d</td> <td>The offset will be written in decimal.</td> </tr> <tr> <td style="vertical-align: top;">o</td> <td>The offset will be written in octal.</td> </tr> <tr> <td style="vertical-align: top;">x</td> <td>The offset will be written in hexadecimal.</td> </tr> </table>	d	The offset will be written in decimal.	o	The offset will be written in octal.	x	The offset will be written in hexadecimal.
-a -	Look everywhere in the file for strings. If this flag is omitted, <i>strings</i> only looks in the initialized data space of object files.														
-n <i>number</i> - <i>number</i>	Use a <i>number</i> as the minimum string length rather than the default, which is 4.														
-o	Equivalent to -t d option.														
-t <i>format</i>	Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the <i>format</i> option-argument: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">d</td> <td>The offset will be written in decimal.</td> </tr> <tr> <td style="vertical-align: top;">o</td> <td>The offset will be written in octal.</td> </tr> <tr> <td style="vertical-align: top;">x</td> <td>The offset will be written in hexadecimal.</td> </tr> </table>	d	The offset will be written in decimal.	o	The offset will be written in octal.	x	The offset will be written in hexadecimal.								
d	The offset will be written in decimal.														
o	The offset will be written in octal.														
x	The offset will be written in hexadecimal.														
OPERANDS	The following operand is supported: <i>file</i> A path name of a regular file to be used as input. If no <i>file</i> operand is specified, the <i>strings</i> utility will read from the standard input.														
ENVIRONMENT VARIABLES	See <i>environ</i> (5) for descriptions of the following environment variables that affect the execution of <i>strings</i> : LC_CTYPE, LC_MESSAGES, and NLSPATH.														
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.														
ATTRIBUTES	See <i>attributes</i> (5) for descriptions of the following attributes:														
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWtoo</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWtoo	CSI	Enabled								
ATTRIBUTE TYPE	ATTRIBUTE VALUE														
Availability	SUNWtoo														
CSI	Enabled														

SEE ALSO

od(1), attributes(5), environ(5)

NOTES

The algorithm for identifying strings is extremely primitive.

For backwards compatibility, the options `-a` and `-` are interchangeable.

NAME	strip – strip symbol table, debugging and line number information from an object file
SYNOPSIS	<code>/usr/ccs/bin/strip [-blrVx] file...</code>
DESCRIPTION	<p>The <code>strip</code> command removes the symbol table, debugging information, and line number information from ELF object files. Once this stripping process has been done, no symbolic debugging access will be available for that file; therefore, this command is normally run only on production modules that have been debugged and tested.</p> <p>If <code>strip</code> is executed on a common archive file (see <code>ar(3HEAD)</code>) in addition to processing the members, <code>strip</code> will remove the archive symbol table. The archive symbol table must be restored by executing the <code>ar(1)</code> command with the <code>-s</code> option before the archive can be linked by the <code>ld(1)</code> command. <code>strip</code> will produce appropriate warning messages when this situation arises.</p> <p><code>strip</code> is used to reduce the file storage overhead taken by the object file.</p>
OPTIONS	<p>The amount of information stripped from the ELF object file can be controlled by using any of the following options:</p> <ul style="list-style-type: none"> <code>-b</code> Same effect as the default behavior. This option is obsolete and will be removed in the next release. <code>-l</code> Strip line number information only; do not strip the symbol table or debugging information. <code>-r</code> Same effect as the default behavior. This option is obsolete and will be removed in the next release. <code>-V</code> Print, on standard error, the version number of <code>strip</code>. <code>-x</code> Do not strip the symbol table; debugging and line number information may be stripped.
OPERANDS	<p>The following operand is supported:</p> <p><code>file</code> A path name referring to an executable file.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>strip</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful completion. >0 An error occurred.
FILES	<code>/tmp/strip*</code> temporary files
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO

ar(1), as(1), ld(1), elf(3ELF), tmpnam(3C), a.out(4), ar(3HEAD),
attributes(5), environ(5)

NOTES

The symbol table section will not be removed if it is contained within a segment, or the file is either a relocatable or dynamic shared object.

The line number and debugging sections will not be removed if they are contained within a segment, or their associated relocation section is contained within a segment.

NAME	stty – set the options for a terminal												
SYNOPSIS	<pre> /usr/bin/stty [-a] [-g] /usr/bin/stty [modes] /usr/xpg4/bin/stty [-a -g] /usr/xpg4/bin/stty [modes] </pre>												
DESCRIPTION	<p>The <code>stty</code> command sets certain terminal I/O options for the device that is the current standard input; without arguments, it reports the settings of certain options.</p> <p>In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding control character (for example, “^h” is CTRL-H; in this case, recall that CTRL-H is the same as the “back-space” key). The sequence “^” means that an option has a null value.</p> <p>See <code>termio(7I)</code> for detailed information about the modes listed from <code>Control Modes through Local Modes</code>. For detailed information about the modes listed under <code>Hardware Flow Control Modes and Clock Modes</code>, below, see <code>termiox(7I)</code>.</p> <p>Operands described in the <code>Combination Modes</code> section are implemented using options in the earlier sections. Note that many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options may not be supported by all hardware interfaces.</p>												
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> –a Write to standard output all of the option settings for the terminal. –g Report current settings in a form that can be used as an argument to another <code>stty</code> command. Emits <code>termios</code>-type output if the underlying driver supports it; otherwise, it emits <code>termio</code>-type output. 												
OPERANDS	<p>The following <i>mode</i> operands are supported:</p>												
Control Modes	<table border="0"> <tr> <td style="padding-right: 20px;"><code>parenb(-parenb)</code></td> <td>Enable (disable) parity generation and detection.</td> </tr> <tr> <td style="padding-right: 20px;"><code>parext(-parext)</code></td> <td>Enable (disable) extended parity generation and detection for mark and space parity.</td> </tr> <tr> <td style="padding-right: 20px;"><code>parodd(-parodd)</code></td> <td>Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.</td> </tr> <tr> <td style="padding-right: 20px;"><code>cs5 cs6 cs7 cs8</code></td> <td>Select character size (see <code>termio(7I)</code>).</td> </tr> <tr> <td style="padding-right: 20px;"><code>0</code></td> <td>Hang up line immediately.</td> </tr> <tr> <td style="padding-right: 20px;"><code>hupcl (-hupcl)</code></td> <td>Hang up (do not hang up) connection on last close.</td> </tr> </table>	<code>parenb(-parenb)</code>	Enable (disable) parity generation and detection.	<code>parext(-parext)</code>	Enable (disable) extended parity generation and detection for mark and space parity.	<code>parodd(-parodd)</code>	Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.	<code>cs5 cs6 cs7 cs8</code>	Select character size (see <code>termio(7I)</code>).	<code>0</code>	Hang up line immediately.	<code>hupcl (-hupcl)</code>	Hang up (do not hang up) connection on last close.
<code>parenb(-parenb)</code>	Enable (disable) parity generation and detection.												
<code>parext(-parext)</code>	Enable (disable) extended parity generation and detection for mark and space parity.												
<code>parodd(-parodd)</code>	Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.												
<code>cs5 cs6 cs7 cs8</code>	Select character size (see <code>termio(7I)</code>).												
<code>0</code>	Hang up line immediately.												
<code>hupcl (-hupcl)</code>	Hang up (do not hang up) connection on last close.												

hup (-hup)	Same as hupcl(-hupcl).
cstopb (-cstopb)	Use two (one) stop bits per character.
cread (-cread)	Enable (disable) the receiver.
crtsets (-crtsets)	Enable output hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.
crtsexoff (-crtsexoff)	Enable input hardware flow control. Raise the RTS (Request to Send) modem control line to receive data. Suspends input when RTS is low.
cllocal (-cllocal)	Assume a line without (with) modem control.
loblk (-loblk)	Block (do not block) output from a non-current layer.
defeucw	Set the widths of characters to the values defined in the current locale specified by LC_CTYPE. Width is expressed in terms of bytes per character, and screen or display columns per character.
110 300 600 1200 1800 2400 4800 9600 19200 38400 357600 76800 115200 153600 230400 307200 460800	Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)
ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800	Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to 0, the input baud rate will be specified by the value of the output baud rate.
ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800	Set terminal output baud rate to the number given, if possible. (Not all

		hardware supports split baud rates.) If the output baud rate is set to 0, the line will be hung up immediately.
Input Modes	<code>ignbrk (-ignbrk)</code>	Ignore (do not ignore) break on input.
	<code>brkint (-brkint)</code>	Signal (do not signal) INTR on break.
	<code>ignpar (-ignpar)</code>	Ignore (do not ignore) parity errors.
	<code>parmrk (-parmrk)</code>	Mark (do not mark) parity errors (see <code>termio(7I)</code>).
	<code>inpck (-inpck)</code>	Enable (disable) input parity checking.
	<code>istrip (-istrip)</code>	Strip (do not strip) input characters to seven bits.
	<code>inlcr (-inlcr)</code>	Map (do not map) NL to CR on input.
	<code>igncr (-igncr)</code>	Ignore (do not ignore) CR on input.
	<code>icrnl (-icrnl)</code>	Map (do not map) CR to NL on input.
	<code>iuclc (-iuclc)</code>	Map (do not map) upper-case alphabetic to lower case on input.
	<code>ixon (-ixon)</code>	Enable (disable) START/STOP output control. Output is stopped by sending STOP control character and started by sending the START control character.
	<code>ixany (-ixany)</code>	Allow any character (only DC1) to restart output.
	<code>ixoff (-ixoff)</code>	Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
	<code>imaxbel (-imaxbel)</code>	Echo (do not echo) BEL when the input line is too long.
Output Modes	<code>opost (-opost)</code>	Post-process output (do not post-process output; ignore all other output modes).
	<code>olcuc (-olcuc)</code>	Map (do not map) lower-case alphabetic to upper case on output.
	<code>onlcr (-onlcr)</code>	Map (do not map) NL to CR-NL on output.
	<code>ocrnl (-ocrnl)</code>	Map (do not map) CR to NL on output.
	<code>onocr (-onocr)</code>	Do not (do) output CRs at column zero.

	onlret (-onlret)	On the terminal NL performs (does not perform) the CR function.
	ofill (-ofill)	Use fill characters (use timing) for delays.
	ofdel (-ofdel)	Fill characters are DELs (NULs).
	cr0 cr1 cr2 cr3	Select style of delay for carriage returns (see termio(7I)).
	nl0 nl1	Select style of delay for line-feeds (see termio(7I)).
	tab0 tab1 tab2 tab3	Select style of delay for horizontal tabs (see termio(7I)).
	bs0 bs1	Select style of delay for backspaces (see termio(7I)).
	ff0 ff1	Select style of delay for form-feeds (see termio(7I)).
	vt0 vt1	Select style of delay for vertical tabs (see termio(7I)).
Local Modes	isig(-isig)	Enable (disable) the checking of characters against the special control characters INTR, QUIT, SWTCH, and SUSP.
	icanon (-icanon)	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
	xcase (-xcase)	Canonical (unprocessed) upper/lower-case presentation.
	echo (-echo)	Echo back (do not echo back) every character typed.
	echoe (-echoe)	Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode will erase the ERASEed character on many CRT terminals; however, it does not keep track of column position and, as a result, it may be confusing for escaped characters, tabs, and backspaces.
	echok(-echok)	Echo (do not echo) NL after KILL character.
	lfkc (-lfkc)	The same as echok(-echok); obsolete.
	echonl (-echonl)	Echo (do not echo) NL.

	<code>noflsh (-noflsh)</code>	Disable (enable) flush after INTR, QUIT, or SUSP.
	<code>stwrap (-stwrap)</code>	Disable (enable) truncation of lines longer than 79 characters on a synchronous line.
	<code>tostop (-tostop)</code>	Send (do not send) SIGTTOU when background processes write to the terminal.
	<code>echoctl (-echoctl)</code>	Echo (do not echo) control characters as <i>^char</i> , delete as <i>^?</i> .
	<code>echoprnt (-echoprnt)</code>	Echo (do not echo) erase character as character is "erased".
	<code>echoke (-echoke)</code>	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
	<code>flusho (-flusho)</code>	Output is (is not) being flushed.
	<code>pendin (-pendin)</code>	Retype (do not retype) pending input at next read or input character.
	<code>iexten (-iexten)</code>	Enable (disable) special control characters not currently controlled by <code>icanon</code> , <code>isig</code> , <code>ixon</code> , or <code>ixoff</code> : <code>VEOLZ</code> , <code>VSWTCH</code> , <code>VREPRINT</code> , <code>VDISCARD</code> , <code>VDSUSP</code> , <code>VWERASE</code> , and <code>VLNEXT</code> .
	<code>stflush (-stflush)</code>	Enable (disable) flush on a synchronous line after every <code>write(2)</code> .
	<code>stappl (-stappl)</code>	Use application mode (use line mode) on a synchronous line.
Hardware Flow Control Modes	<code>rtsxoff (-rtsxoff)</code>	Enable (disable) RTS hardware flow control on input.
	<code>ctsxon (-ctsxon)</code>	Enable (disable) CTS hardware flow control on output.
	<code>dtrxoff (-dtrxoff)</code>	Enable (disable) DTR hardware flow control on input.
	<code>cdxon (-cdxon)</code>	Enable (disable) CD hardware flow control on output.
	<code>isxoff (-isxoff)</code>	Enable (disable) isochronous hardware flow control on input.
Clock Modes	<code>xcibrg</code>	Get transmit clock from internal baud rate generator.
	<code>xctset</code>	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.

xcrset	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
rcibrgr	Get receive clock from internal baud rate generator.
rctset	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
rcrset	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
tsetcoff	Transmitter signal element timing clock not provided.
tsetcrbrg	Output receive baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
tsetctbrg	Output transmit baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
tsetctset	Output transmitter signal element timing (DCE source) on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
tsetcrset	Output receiver signal element timing (DCE source) on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
rsetcoff	Receiver signal element timing clock not provided.
rsetcrbrg	Output receive baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
rsetctbrg	Output transmit baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
rsetctset	Output transmitter signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
rsetcrset	Output receiver signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

Control Assignments

control-character *c* Set *control-character* to *c*, where:

control-character

is `ctab`, `discard`, `dsusp`, `eof`, `eol`, `eol2`, `erase`, `intr`, `kill`, `lnext`, `quit`, `reprint`, `start`, `stop`, `susp`, `swtch`, or `werase` (`ctab` is used with `-stappl`, see `termio(7I)`).

c

If *c* is a single character, the control character will be set to that character.

In the POSIX locale, if *c* is preceded by a caret (^) indicating an escape from the shell and is one of those listed in the `^c` column of the following table, then its value used (in the Value column) is the corresponding control character (for example, “`^d`” is a CTRL-D). “`^?`” is interpreted as DEL and “`^-`” is interpreted as undefined.

<code>^c</code>	Value	<code>^c</code>	Value	<code>^c</code>	Value
a, A	<SOH>	l, L	<FF>	w, W	<ETB>
b, B	<STX>	m, M	<CR>	x, X	<CAN>
c, C	<ETX>	n, N	<SO>	y, Y	
d, D	<EOT>	o, O	<SI>	z, Z	<SUB>
e, E	<ENQ>	p, P	<DLE>	[<ESC>
f, F	<ACK>	q, Q	<DC1>	\	<FS>
g, G	<BEL>	r, R	<DC2>]	<GS>
h, H	<BS>	s, S	<DC3>	^	<RS>
i, I	<HT>	t, T	<DC4>	-	<US>
j, J	<LF>	u, U	<NAK>	?	
k, K	<VT>	v, V	<SYN>		

`min number`
`time number`

Set the value of `min` or `time` to *number*. `MIN` and `TIME` are used in Non-Canonical mode input processing (`-icanon`).

`line i`

Set line discipline to *i* ($0 < i < 127$).

Combination Modes	<i>saved settings</i>	Set the current terminal characteristics to the saved settings produced by the <code>-g</code> option.
	<code>evenp</code> or <code>parity</code>	Enable <code>parenb</code> and <code>cs7</code> , or disable <code>parodd</code> .
	<code>oddp</code>	Enable <code>parenb</code> , <code>cs7</code> , and <code>parodd</code> .
	<code>spacep</code>	Enable <code>parenb</code> , <code>cs7</code> , and <code>parext</code> .
	<code>markp</code>	Enable <code>parenb</code> , <code>cs7</code> , <code>parodd</code> , and <code>parext</code> .
	<code>-parity</code> , or <code>-evenp</code>	Disable <code>parenb</code> , and set <code>cs8</code> .
	<code>-oddp</code>	Disable <code>parenb</code> and <code>parodd</code> , and set <code>cs8</code> .
	<code>-spacep</code>	Disable <code>parenb</code> and <code>parext</code> , and set <code>cs8</code> .
	<code>-markp</code>	Disable <code>parenb</code> , <code>parodd</code> , and <code>parext</code> , and set <code>cs8</code> .
	<code>raw</code> (<code>-raw</code> or <code>cooked</code>)	Enable (disable) raw input and output. Raw mode is equivalent to setting: <pre>stty cs8 -icanon min 1 time 0 -isig -xcase \ -inpck -opost</pre>
/usr/bin/stty	<code>nl</code> (<code>-nl</code>)	Unset (set) <code>icrnl</code> , <code>onlcr</code> . In addition <code>-nl</code> unsets <code>inlcr</code> , <code>igncr</code> , <code>ocrnl</code> , and <code>onlret</code> .
/usr/xpg4/bin/stty	<code>nl</code> (<code>-nl</code>)	Set (unset) <code>icrnl</code> . In addition, <code>-nl</code> unsets <code>inlcr</code> , <code>igncr</code> , <code>ocrnl</code> , and <code>onlret</code> ; <code>-nl</code> sets <code>onlcr</code> , and <code>nl</code> unsets <code>onlcr</code> .
	<code>lcase</code> (<code>-lcase</code>)	Set (unset) <code>xcase</code> , <code>iuclc</code> , and <code>olcuc</code> .
	<code>LCASE</code> (<code>-LCASE</code>)	Same as <code>lcase</code> (<code>-lcase</code>).
	<code>tabs</code> (<code>-tabs</code> or <code>tab3</code>)	Preserve (expand to spaces) tabs when printing.
	<code>ek</code>	Reset ERASE and KILL characters back to normal <code>#</code> and <code>@</code> .
	<code>sane</code>	Resets all modes to some reasonable values.
	<code>term</code>	Set all modes suitable for the terminal type <code>term</code> , where <code>term</code> is one of <code>tty33</code> , <code>tty37</code> , <code>vt05</code> , <code>tn300</code> , <code>ti700</code> , or <code>tek</code> .
	<code>async</code>	Set normal asynchronous communications where clock settings are <code>xcibrg</code> , <code>rcibrg</code> , <code>tsetcoff</code> and <code>rsetcoff</code> .
Window Size	<code>rows</code> <i>n</i>	Set window size to <i>n</i> rows.

`columns n` Set window size to *n* columns.

`cols n` Set window size to *n* columns. Note that `cols` is a shorthand alias for `columns`.

`ypixels n` Set vertical window size to *n* pixels.

`xpixels n` Set horizontal window size to *n* pixels.

USAGE

The `-g` flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program may:

```
saveterm="$(stty -g)"      # save terminal state
stty (new settings)      # set new state
...                      # ...
stty $saveterm           # restore terminal state
```

Since the `-a` format is so loosely specified, scripts that save and restore terminal settings should use the `-g` option.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `stty`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

`/usr/bin/stty`

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`/usr/xpg4/bin/stty`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

SEE ALSO

`tabs(1)`, `ioctl(2)`, `write(2)`, `getwidth(3C)`, `attributes(5)`, `environ(5)`, `ldterm(7M)`, `termio(7I)`, `termiox(7I)`

NAME	stty – set the options for a terminal
SYNOPSIS	<code>/usr/ucb/stty [-a] [-g] [-h] [modes]</code>
DESCRIPTION	<code>stty</code> sets certain terminal I/O options for the device that is the current standard output; without arguments, it reports the settings of certain options.
OPTIONS	<p>In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding CTRL character (for example, “^h” is CTRL-H; in this case, recall that CTRL-H is the same as the “back-space” key.) The sequence “^’” means that an option has a null value.</p> <p>–a Report all of the option settings.</p> <p>–g Report current settings in a form that can be used as an argument to another <code>stty</code> command.</p> <p>–h Report all the option settings with the control characters in an easy to read column format.</p> <p>Options in the last group are implemented using options in the previous groups. Note: Many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options may not be supported by all hardware interfaces. The options are selected from the following:</p>
Special Requests	<p>all Reports the same option settings as <code>stty</code> without arguments, but with the control characters in column format.</p> <p>everything Everything <code>stty</code> knows about is printed. Same as –h option.</p> <p>speed The terminal speed alone is reported on the standard output.</p> <p>size The terminal (window) sizes are printed on the standard output, first rows and then columns. This option is only appropriate if currently running a window system.</p> <p> size and speed always report on the settings of <code>/dev/tty</code>, and always report the settings to the standard output.</p>
Control Modes	<p>parenb (–parenb) Enable (disable) parity generation and detection.</p> <p>parext (–parext) Enable (disable) extended parity generation and detection for mark and space parity.</p> <p>parodd (–parodd) Select odd (even) parity, or mark (space) parity if <code>parext</code> is enabled.</p> <p>cs5 cs6 cs7 cs8 Select character size (see <code>termio(7I)</code>).</p>

0
 Hang up line immediately.

110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb
 Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)

ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb
 Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to zero, the input baud rate will be specified by the value of the output baud rate.

ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb
 Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the baud rate is set to zero, the line will be hung up immediately.

hupcl (-hupcl)
 Hang up (do not hang up) connection on last close.

hup (-hup)
 Same as hupcl (-hupcl).

cstopb (-cstopb)
 Use two (one) stop bits per character.

cread (-cread)
 Enable (disable) the receiver.

clocal (-clocal)
 Assume a line without (with) modem control.

crtsets (-crtsets)
 Enable hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.

loblk (-loblk)
 Block (do not block) output from a non-current layer.

Input Modes

ignbrk (-ignbrk) Ignore (do not ignore) break on input.

brkint (-brkint) Signal (do not signal) INTR on break.

ignpar (-ignpar) Ignore (do not ignore) parity errors.

parmrk (-parmrk) Mark (do not mark) parity errors (see `termio(7I)`).

inpck (-inpck) Enable (disable) input parity checking.

	<code>istrip (-istrip)</code>	Strip (do not strip) input characters to seven bits.
	<code>inlcr (-inlcr)</code>	Map (do not map) NL to CR on input.
	<code>igncr (-igncr)</code>	Ignore (do not ignore) CR on input.
	<code>icrnl (-icrnl)</code>	Map (do not map) CR to NL on input.
	<code>iuclc (-iuclc)</code>	Map (do not map) upper-case alphabets to lower case on input.
	<code>ixon (-ixon)</code>	Enable (disable) START/STOP output control. Output is stopped by sending an STOP and started by sending an START.
	<code>ixany (-ixany)</code>	Allow any character (only START) to restart output.
	<code>decctlq (-decctlq)</code>	Same as <code>-ixany</code> .
	<code>ixoff (-ixoff)</code>	Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
	<code>tandem (-tandem)</code>	Same as <code>ixoff</code> .
	<code>imaxbel (-imaxbel)</code>	Echo (do not echo) BEL when the input line is too long.
	<code>iexten (-iexten)</code>	Enable (disable) extended (implementation-defined) functions for input data.
Output Modes	<code>opost (-opost)</code>	Post-process output (do not post-process output; ignore all other output modes).
	<code>olcuc (-olcuc)</code>	Map (do not map) lower-case alphabets to upper case on output.
	<code>onlcr (-onlcr)</code>	Map (do not map) NL to CR-NL on output.
	<code>ocrnl (-ocrnl)</code>	Map (do not map) CR to NL on output.
	<code>onocr (-onocr)</code>	Do not (do) output CRs at column zero.
	<code>onlret (-onlret)</code>	On the terminal NL performs (does not perform) the CR function.
	<code>ofill (-ofill)</code>	Use fill characters (use timing) for delays.
	<code>ofdel (-ofdel)</code>	Fill characters are DELs (NULs).

	cr0 cr1 cr2 cr3	Select style of delay for carriage returns (see <code>termio(7I)</code>).
	nl0 nl1	Select style of delay for line-feeds (see <code>termio(7I)</code>).
	tab0 tab1 tab2 tab3	Select style of delay for horizontal tabs (see <code>termio(7I)</code>).
	bs0 bs1	Select style of delay for backspaces (see <code>termio(7I)</code>).
	ff0 ff1	Select style of delay for form-feeds (see <code>termio(7I)</code>).
	vt0 vt1	Select style of delay for vertical tabs (see <code>termio(7I)</code>).
Local Modes	<code>isig (-isig)</code>	Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SWTCH.
	<code>icanon (-icanon)</code>	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
	<code>cbreak (-cbreak)</code>	Equivalent to <code>-icanon min 1 time 0</code> .
	<code>xcase (-xcase)</code>	Canonical (unprocessed) upper/lower-case presentation.
	<code>echo (-echo)</code>	Echo back (do not echo back) every character typed.
	<code>echoe (-echoe)</code>	Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode will erase the ERASEed character on many CRT terminals; however, it does <i>not</i> keep track of column position and, as a result, may be confusing on escaped characters, tabs, and backspaces.
	<code>crterase (-crterase)</code>	Same as <code>echoe</code> .
	<code>echok (-echok)</code>	Echo (do not echo) NL after KILL character.
	<code>lfkc (-lfkc)</code>	The same as <code>echok (-echok)</code> ; obsolete.
	<code>echonl (-echonl)</code>	Echo (do not echo) NL.
	<code>noflsh (-noflsh)</code>	Disable (enable) flush after INTR, QUIT, or SWTCH.

	stwrap (-stwrap)	Disable (enable) truncation of lines longer than 79 characters on a synchronous line. (Does not apply to the 3B2.)
	tostop (-tostop)	Send (do not send) SIGTTOU for background processes.
	echoctl (-echoctl)	Echo (do not echo) control characters as <i>^char</i> , delete as <i>^?</i>
	ctlecho (-ctlecho)	Same as echoctl.
	echoprnt (-echoprnt)	Echo (do not echo) erase character as character is "erased".
	prterase (-prterase)	Same as echoprnt.
	echoke (-echoke)	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
	crtkill (-crtkill)	Same as echoke.
	flusho (-flusho)	Output is (is not) being flushed.
	pendin (-pendin)	Retype (do not retype) pending input at next read or input character.
	stflush (-stflush)	Enable (disable) flush on a synchronous line after every <i>write(2)</i> . (Does not apply to the 3B2.)
	stappl (-stappl)	Use application mode (use line mode) on a synchronous line. (Does not apply to the 3B2.)
Hardware Flow Control Modes	rtsxoff (-rtsxoff)	Enable (disable) RTS hardware flow control on input.
	ctsxon (-ctsxon)	Enable (disable) CTS hardware flow control on output.
	dterxoff (-dterxoff)	Enable (disable) DTER hardware flow control on input.
	rlsdxon (-rlsdxon)	Enable (disable) RLSD hardware flow control on output.
	isxoff (-isxoff)	Enable (disable) isochronous hardware flow control on input.
Clock Modes	xcibrg	Get transmit clock from internal baud rate generator.

	xctset	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	xcrset	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	rcibrgr	Get receive clock from internal baud rate generator.
	rctset	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	rcrset	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	tsetcoff	Transmitter signal element timing clock not provided.
	tsetcrc	Output receive clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	tsetcxc	Output transmit clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	rsetcoff	Receiver signal element timing clock not provided.
	rsetcrc	Output receive clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
	rsetcxc	Output transmit clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
Control Assignments	<i>control-character c</i>	Set <i>control-character</i> to <i>c</i> , where <i>control-character</i> is <i>intr</i> , <i>quit</i> , <i>erase</i> , <i>kill</i> , <i>eof</i> , <i>eol</i> , <i>eol2</i> , <i>swtch</i> , <i>start</i> , <i>stop</i> , <i>susp</i> , <i>dsusp</i> , <i>rprnt</i> , <i>flush</i> , <i>werase</i> , <i>lnext</i> <i>min</i> , <i>ctab</i> , <i>time</i> , or <i>brk</i> (<i>ctab</i> is used with <i>-stappl</i> ; <i>min</i> and <i>time</i> are used with <i>-icanon</i> ; see <i>termio(7I)</i>). If <i>c</i> is preceded by an (escaped from the shell) caret (^), then the value used is the corresponding CTRL

Combination Modes

	character (for example, “^d” is a CTRL-d); “^?” is interpreted as DEL and “^_” is interpreted as undefined.
line <i>i</i>	Set line discipline to <i>i</i> ($0 < i < 127$).
evenp or parity	Enable parenb and cs7.
-evenp, or -parity	Disable parenb, and set cs8.
even (-even)	Same as evenp (-evenp).
oddp	Enable parenb, cs7, and parodd.
-oddp	Disable parenb and parodd, and set cs8.
odd (-odd)	Same as oddp (-oddp).
spacep	Enable parenb, cs7, and parext.
-spacep	Disable parenb and parext, and set cs8.
markp	Enable parenb, cs7, parodd, and parext.
-markp	Disable parenb, parodd, and parext, and set cs8.
raw (-raw or cooked)	Enable (disable) raw input and output (no ERASE, KILL, INTR, QUIT, SWTCH, EOT, or output post processing).
nl (-nl)	Unset (set) icrnl, onlcr. In addition -nl unsets inlcr, igncr, ocrnl, and onlret.
lcase (-lcase)	Set (unset) xcase, iuclc, and olcuc.
LCASE (-LCASE)	Same as lcase (-lcase).
tabs (-tabs or tab3)	Preserve (expand to spaces) tabs when printing.
ek	Reset ERASE and KILL characters back to normal # and @.
sane	Resets all modes to some reasonable values.
term	Set all modes suitable for the terminal type <i>term</i> , where <i>term</i> is one of tty33, tty37, vt05, tn300, ti700, or tek.
async	Set normal asynchronous communications where clock settings are xcibrg, rcibrg, tsetcoff and rsetcoff.

	litout (-litout)	Disable (enable) parenb, istrip, and opost, and set cs8 (cs7).
	pass8 (-pass8)	Disable (enable) parenb and istrip, and set cs8 (cs7).
	crt	Set options for a CRT (echoe, echoctl, and, if >= 1200 baud, echoke.)
	dec	Set all modes suitable for Digital Equipment Corp. operating systems users ERASE, KILL, and INTR characters to ^?, ^U, and ^C, decctlq, and crt.)
Window Size	rows <i>n</i>	Set window size to <i>n</i> rows.
	columns <i>n</i>	Set window size to <i>n</i> columns.
	cols <i>n</i>	An alias for columns <i>n</i> .
	ypixels <i>n</i>	Set vertical window size to <i>n</i> pixels.
	xpixels <i>n</i>	Set horizontal window size to <i>n</i> pixels.

NAME	sum – print checksum and block count for a file						
SYNOPSIS	sum [-r] [<i>file</i> ...]						
DESCRIPTION	The <code>sum</code> utility calculates and prints a 16-bit checksum for the named file and the number of 512-byte blocks in the file. It is typically used to look for bad spots, or to validate a file communicated over some transmission line.						
OPTIONS	The following options are supported: -r Use an alternate (machine-dependent) algorithm in computing the checksum.						
OPERANDS	The following operands are supported: <i>file</i> A path name of a file. If no files are named, the standard input is used.						
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>sum</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sum</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following exit values are returned. 0 Successful completion. >0 An error occurred.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu	CSI	enabled

CSI	enabled						
SEE ALSO	<code>cksum(1)</code> , <code>sum(1B)</code> , <code>wc(1)</code> , <code>attributes(5)</code> , <code>environ(5)</code> , <code>largefile(5)</code>						
DIAGNOSTICS	“Read error” is indistinguishable from end of file on most devices; check the block count.						
NOTES	Portable applications should use <code>cksum(1)</code> . <code>sum</code> and <code>usr/ucb/sum</code> (see <code>sum(1B)</code>) return different checksums.						

NAME	sum – calculate a checksum for a file				
SYNOPSIS	<i>/usr/ucb/sum file...</i>				
DESCRIPTION	sum calculates and displays a 16-bit checksum for the named file and displays the size of the file in kilobytes. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. The checksum is calculated by an algorithm which may yield different results on machines with 16-bit ints and machines with 32-bit ints, so it cannot always be used to validate that a file has been transferred between machines with different-sized ints.				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>sum</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWscpu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>sum(1)</code> , <code>wc(1)</code> , <code>attributes(5)</code> , <code>largefile(5)</code>				
DIAGNOSTICS	Read error is indistinguishable from EOF on most devices; check the block count.				
NOTES	sum and <code>/usr/bin/sum</code> (see <code>sum(1)</code>) return different checksums. This utility is obsolete.				

NAME suspend – shell built-in function to halt the current shell

SYNOPSIS

sh suspend

csh suspend

ksh suspend

DESCRIPTION

sh Stops the execution of the current shell (but not if it is the login shell).

csh Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z. This is most often used to stop shells started by su.

ksh Stops the execution of the current shell (but not if it is the login shell).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME symorder – rearrange a list of symbols

SYNOPSIS **symorder** [-s] *objectfile symbolfile*

DESCRIPTION *symorder* was used in SunOS 4.x specifically to cut down on the overhead of getting symbols from *vmunix*. This is no longer applicable as kernel symbol entries are dynamically obtained through */dev/ksyms*.

This script is provided as a convenience for software developers who need to maintain scripts that are portable across a variety of operating systems.

EXIT STATUS *symorder* has exit status 0.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

NAME	sysV-make – maintain, update, and regenerate groups of programs
SYNOPSIS	<code>/usr/lib/svr4.make [-f <i>makefile</i>] [-eiknpqrst] [<i>names</i>]</code>
DESCRIPTION	<p>This is the “vanilla” System V version of <code>make</code>. If the environment variable <code>USE_SVR4_MAKE</code> is set, then the command <code>make</code> will invoke this version of <code>make</code>. (See also the <code>ENVIRONMENT</code> section.)</p> <p><code>make</code> allows the programmer to maintain, update, and regenerate groups of computer programs. <code>make</code> executes commands in <i>makefile</i> to update one or more target <i>names</i> (<i>names</i> are typically programs). If the <code>-f</code> option is not present, then <i>makefile</i>, <code>Makefile</code>, and the Source Code Control System (SCCS) files <code>s.makefile</code> and <code>s.Makefile</code> are tried in order. If <i>makefile</i> is ‘-’ the standard input is taken. More than one <code>-f <i>makefile</i></code> argument pair may appear.</p> <p><code>make</code> updates a target only if its dependents are newer than the target. All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be outdated.</p> <p>The following list of four directives can be included in <i>makefile</i> to extend the options provided by <code>make</code>. They are used in <i>makefile</i> as if they were targets:</p> <ul style="list-style-type: none"> <code>.DEFAULT:</code> If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name <code>.DEFAULT</code> are used if it exists. <code>.IGNORE:</code> Same effect as the <code>-i</code> option. <code>.PRECIOUS:</code> Dependents of the <code>.PRECIOUS</code> entry will not be removed when quit or interrupt are hit. <code>.SILENT:</code> Same effect as the <code>-s</code> option. <p>Options The options for <code>make</code> are listed below:</p> <ul style="list-style-type: none"> <code>-e</code> Environment variables override assignments within makefiles. <code>-f <i>makefile</i></code> Description filename (<i>makefile</i> is assumed to be the name of a description file). <code>-i</code> Ignore error codes returned by invoked commands. <code>-k</code> Abandon work on the current entry if it fails, but continue on other branches that do not depend on that entry. <code>-n</code> No execute mode. Print commands, but do not execute them. Even command lines beginning with an ‘@’ are printed. <code>-p</code> Print out the complete set of macro definitions and target descriptions.

- `-q` Question. `make` returns a zero or non-zero status code depending on whether or not the target file has been updated.
- `-r` Do not use the built-in rules.
- `-s` Silent mode. Do not print command lines before executing.
- `-t` Touch the target files (causing them to be updated) rather than issue the usual commands.

Creating the makefile

The makefile invoked with the `-f` option is a carefully structured file of explicit instructions for updating and regenerating programs, and contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a `:`, then a (possibly null) list of prerequisite files or dependencies. Text following a `;` and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or `#` begins a new dependency or macro definition. Shell commands may be continued across lines with a backslash-new-line (`\-NEWLINE`) sequence. Everything printed by `make` (except the initial TAB) is passed directly to the shell as is. Thus,

```
echo a\  
b
```

will produce

```
ab
```

exactly the same as the shell would.

Number-sign (`#`) and `NEWLINE` surround comments including contained `'\-NEWLINE'` sequences.

The following makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) and a common file `incl.h`:

```
pgm: a.o b.o  
    cc a.o b.o -o pgm  
a.o: incl.h a.c  
    cc -c a.c  
b.o: incl.h b.c  
    cc -c b.c
```

Command lines are executed one at a time, each by its own shell. The `SHELL` environment variable can be used to specify which shell `make` should use to execute commands. The default is `/usr/bin/sh`. The first one or two characters in a command can be the following: '@', '-', '@-', or '-@'. If '@' is present, printing of the command is suppressed. If '-' is present, `make` ignores an error. A line is printed when it is executed unless the `-s` option is present, or the entry `.SILENT:` is included in *makefile*, or unless the initial character sequence contains a @. The `-n` option specifies printing without execution; however, if the command line has the string `$(MAKE)` in it, the line is always executed (see the discussion of the `MAKEFLAGS` macro in the `make Environment` sub-section below). The `-t` (touch) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate `make`. If the `-i` option is present, if the entry `.IGNORE:` is included in *makefile*, or if the initial character sequence of the command contains '-', the error is ignored. If the `-k` option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

Interrupt and quit cause the target to be deleted unless the target is a dependent of the directive `.PRECIOUS`.

make Environment

The environment is read by `make`. All variables are assumed to be macro definitions and are processed as such. The environment variables are processed before any *makefile* and after the internal rules; thus, macro assignments in a *makefile* override environment variables. The `-e` option causes the environment to override the macro assignments in a *makefile*. Suffixes and their associated rules in the *makefile* will override any identical suffixes in the built-in rules.

The `MAKEFLAGS` environment variable is processed by `make` as containing any legal input option (except `-f` and `-p`) defined for the command line. Further, upon invocation, `make` "invents" the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, `MAKEFLAGS` always contains the current input options. This feature proves very useful for "super-makes". In fact, as noted above, when the `-n` option is used, the command `$(MAKE)` is executed anyway; hence, one can perform a `make -n` recursively on a whole software system to see what would have been executed. This result is possible because the `-n` is put in `MAKEFLAGS` and passed to further invocations of `$(MAKE)`. This usage is one way of debugging all of the *makefiles* for a software project without actually doing anything.

Include Files

If the string *include* appears as the first seven letters of a line in a *makefile*, and is followed by a blank or a tab, the rest of the line is assumed to be a filename and will be read by the current invocation, after substituting for any macros.

Macros Entries of the form *string1* = *string2* are macro definitions. *string2* is defined as all characters up to a comment character or an unescaped NEWLINE. Subsequent appearances of $\$(string1[:subst1=[subst2]])$ are replaced by *string2*. The parentheses are optional if a single-character macro name is used and there is no substitute sequence. The optional *:subst1=subst2* is a substitute sequence. If it is specified, all non-overlapping occurrences of *subst1* in the named macro are replaced by *subst2*. Strings (for the purposes of this type of substitution) are delimited by BLANKs, TABs, NEWLINE characters, and beginnings of lines. An example of the use of the substitute sequence is shown in the `Libraries` sub-section below.

Internal Macros There are five internally maintained macros that are useful for writing rules for building targets.

$\$*$ The macro $\$*$ stands for the filename part of the current dependent with the suffix deleted. It is evaluated only for inference rules.

$\$@$ The $\$@$ macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.

$\$<$ The $\$<$ macro is only evaluated for inference rules or the `.DEFAULT` rule. It is the module that is outdated with respect to the target (the “manufactured” dependent file name). Thus, in the `.c.o` rule, the $\$<$ macro would evaluate to the `.c` file. An example for making optimized `.o` files from `.c` files is:

```
.c.o:
    cc -c -O  $\$*$ .c
```

or:

```
.c.o:
    cc -c -O  $\$<$ 
```

$\$?$ The $\$?$ macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are outdated with respect to the target, and essentially those modules that must be rebuilt.

$\$%$ The $\$%$ macro is only evaluated when the target is an archive library member of the form `lib(file.o)`. In this case, $\$@$ evaluates to `lib` and $\$%$ evaluates to the library member, `file.o`.

Four of the five macros can have alternative forms. When an upper case `D` or `F` is appended to any of the four macros, the meaning is changed to “directory part” for `D` and “file part” for `F`. Thus, $\$(@D)$ refers to the directory part of the string

Suffixes

\$. If there is no directory part, ./ is generated. The only macro excluded from this alternative form is \$?.

Certain names (for instance, those ending with .o) have inferable prerequisites such as .c, .s, etc. If no update commands for such a file appear in *makefile*, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, *make* has inference rules that allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

.c	.c~	.f	.f~	.s	.s~	.sh	.sh~	.C	.C~
.c.a	.c.o	.c~.a	.c~.c	.c~.o	.f.a	.f.o	.f~.a	.f~.f	.f~.o
.h~.h	.l.c	.l.o	.l~.c	.l~.l	.l~.o	.s.a	.s.o	.s~.a	.s~.o
.s~.s	.sh~.sh	.y.c	.y.o	.y~.c	.y~.o	.y~.y	.C.a	.C.o	.C~.a
.C~.C	.C~.o	.L.C	.L.o	.L~.C	.L~.L	.L~.o	.Y.C	.Y.o	.Y~.C
.Y~.o	.Y~.Y								

The internal rules for *make* are contained in the source file *make.rules* for the *make* program. These rules can be locally modified. To print out the rules compiled into the *make* on any machine in a form suitable for recompilation, the following command is used:

```
make -pf - 2>/dev/null </dev/null
```

A tilde in the above rules refers to an SCCS file (see *sccsfile(4)*). Thus, the rule *.c~.o* would transform an SCCS C source file into an object file (.o). Because the *s.* of the SCCS files is a prefix, it is incompatible with the *make* suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (for example, *.c:*) is the definition of how to build *x* from *x.c*. In effect, the other suffix is null. This feature is useful for building targets from only one source file, for example, shell procedures and simple C programs.

Additional suffixes are given as the dependency list for *.SUFFIXES*. Order is significant: the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

```
.SUFFIXES: .o .c .c~ .y .y~ .l .l~ .s .s~ .sh .sh~ .h .h~
.f .f~ .C .C~ .Y .Y~ .L .L~
```

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; `.SUFFIXES:` with no dependencies clears the list of suffixes.

Inference Rules

The first example can be done more briefly.

```
pgm: a.o b.o
      cc a.o b.o -o pgm
a.o b.o: incl.h
```

This abbreviation is possible because `make` has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, `CFLAGS`, `LFLAGS`, and `YFLAGS` are used for compiler options to `cc(1B)`. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix `.o` from a file with suffix `.c` is specified as an entry with `.c.o:` as the target and no dependents. Shell commands associated with the target define the rule for making a `.o` file from a `.c` file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

Libraries

If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus, `lib(file.o)` and `$(LIB)(file.o)` both refer to an archive library that contains `file.o`. (This example assumes the `LIB` macro has been previously defined.) The expression `$(LIB)(file1.o file2.o)` is not legal. Rules pertaining to archive libraries have the form `.XX.a` where the `XX` is the suffix from which the archive member is to be made. An unfortunate by-product of the current implementation requires the `XX` to be different from the suffix of the archive member. Thus, one cannot have `lib(file.o)` depend upon `file.o` explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
      @echo lib is now up-to-date
.c.a:
      $(CC) -c $(CFLAGS) $<
      $(AR) $(ARFLAGS) $@ $*.o
      rm -f $*.o
```

In fact, the `.c.a` rule listed above is built into `make` and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
    $(CC) -c $(CFLAGS) $(?:.o=.c)
$(AR) $(ARFLAGS) lib $?
rm $?
@echo lib is now up-to-date
.c.a:;
```

Here the substitution mode of the macro expansions is used. The `$?` list is defined to be the set of object filenames (inside `lib`) whose C source files are outdated. The substitution mode translates the `.o` to `.c`. (Unfortunately, one cannot as yet transform to `.c~`; however, this transformation may become possible in the future.) Also note the disabling of the `.c.a:` rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

ENVIRONMENT VARIABLES

USE_SVR4_MAKE If this environment variable is set, then the `make` command will invoke this System V version of `make`. If this variable is not set, then the default version of `make(1S)` is invoked.

`USE_SVR4_MAKE` can be set as follows (Bourne shell):

```
$ USE_SVR4_MAKE='''; export USE_SVR4_MAKE
```

or (C shell):

```
% setenv USE_SVR4_MAKE
```

FILES

- [Mm]akefile
- s.[Mm]akefile default makefiles
- /usr/bin/sh default shell for make
- /usr/share/lib/make/make.rules default rules for make

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO

`cc(1B)`, `cd(1)`, `make(1S)`, `sh(1)`, `printf(3C)`, `sccsfile(4)`, `attributes(5)`

NOTES

Some commands return non-zero status inappropriately; use `-i` or the `'-'` command line prefix to overcome the difficulty.

Filenames containing the characters `'='`, `':'`, and `'@'` will not work. Commands that are directly executed by the shell, notably `cd(1)`, are ineffectual across NEWLINES in `make`. The syntax `lib(file1.o file2.o file3.o)` is illegal. You cannot build `lib(file.o)` from `file.o`.

NAME	tabs - set tabs on a terminal
SYNOPSIS	<p>tabs <i>[[</i>-n <i>--file</i>] <i>[-code</i>] <i>-a</i> <i>-a2</i> <i>-c</i> <i>-c2</i> <i>-c3</i> <i>-f</i> <i>-p</i> <i>-s</i> <i>-u</i> <i>][+m [n]] [-T type]</i></p> <p>tabs <i>[-T type] [+ m [n]] n1 [, n2 ,...]</i></p>
DESCRIPTION	<p>tabs sets the tab stops on the user's terminal according to a tab specification, after clearing any previous settings. The user's terminal must have remotely settable hardware tabs.</p>
OPTIONS	<p>The following options are supported. If a given flag occurs more than once, the last value given takes effect:</p> <p><i>-T type</i> tabs needs to know the type of terminal in order to set tabs and margins. <i>type</i> is a name listed in <i>term(5)</i>. If no <i>-T</i> flag is supplied, tabs uses the value of the environment variable <i>TERM</i>. If the value of <i>TERM</i> is NULL or <i>TERM</i> is not defined in the environment (see <i>environ(5)</i>), tabs uses <i>ansi+tabs</i> as the terminal type to provide a sequence that will work for many terminals.</p> <p><i>+m[n]</i> The margin argument may be used for some terminals. It causes all tabs to be moved over <i>n</i> columns by making column <i>n+1</i> the left margin. If <i>+m</i> is given without a value of <i>n</i>, the value assumed is 10. For a TermiNet, the first value in the tab list should be 1, or the margin will move even further to the right. The normal (leftmost) margin on most terminals is obtained by <i>+m0</i>. The margin for most terminals is reset only when the <i>+m</i> flag is given explicitly.</p>
Tab Specification	<p>Four types of tab specification are accepted. They are described below: canned, repetitive (<i>-n</i>), arbitrary (<i>n1,n2,...</i>), and file (<i>-file</i>).</p> <p>If no tab specification is given, the default value is <i>-8</i>, that is, UNIX system "standard" tabs. The lowest column number is 1. Note: For tabs, column 1 always refers to the leftmost column on a terminal, even one whose column markers begin at 0, for example, the DASI 300, DASI 300s, and DASI 450.</p>
<i>Canned -code</i>	<p>Use one of the codes listed below to select a canned set of tabs. If more than one code is specified, the last code option will be used. The legal codes and their meanings are as follows:</p> <p><i>-a</i> 1, 10, 16, 36, 72 Assembler, IBM S/370, first format</p> <p><i>-a2</i> 1, 10, 16, 40, 72 Assembler, IBM S/370, second format</p> <p><i>-c</i> 1, 8, 12, 16, 20, 55</p>

		COBOL, normal format
	-c2	1, 6, 10, 14, 49
		COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows (see <code>fspec(4)</code>):
		<code><:t-c2 m6 s66 d:></code>
	-c3	1, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62, 67
		COBOL compact format (columns 1-6 omitted), with more tabs than -c2. This is the recommended format for COBOL. The appropriate format specification is (see <code>fspec(4)</code>):
		<code><:t-c3 m6 s66 d:></code>
	-f	1, 7, 11, 15, 19, 23
		FORTRAN

		UNIVAC 1100 Assembler
<i>Repetitive</i>	-n	A <i>repetitive</i> specification requests tabs at columns $1+n$, $1+2*n$, etc., where n is a single-digit decimal number. Of particular importance is the value 8: this represents the UNIX system “standard” tab setting, and is the most likely tab setting to be found at a terminal. When -0 is used, the tab stops are cleared and no new ones are set.
<i>Arbitrary</i>		See OPERANDS.
<i>File</i>	-file	If the name of a file is given, <code>tabs</code> reads the first line of the file, searching for a format specification (see <code>fspec(4)</code>). If it finds one there, it sets the tab stops according to it, otherwise it sets them as -8. This type of specification may be used to make sure that a tabbed file is printed with correct tab settings, and would be used with the <code>pr</code> command:

```
example% tabs - file; pr file
```

Tab and margin setting is performed via the standard output.

OPERANDS

The following operand is supported:

n1[,*n2*,...] The *arbitrary* format consists of tab-stop values separated by commas or spaces. The tab-stop values must be positive decimal integers in ascending order. Up to 40 numbers are allowed. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the formats 1,10,20,30, and 1,10,+10,+10 are considered identical.

EXAMPLES**EXAMPLE 1** Using the `tabs` Command

The following command is an example using `-code` (*canned* specification) to set tabs to the settings required by the IBM assembler: columns 1, 10, 16, 36, 72:

```
example% tabs -a
```

The next command is an example of using `-n` (*repetitive* specification), where *n* is 8, causes tabs to be set every eighth position: 1+(1*8), 1+(2*8), ... which evaluate to columns 9, 17, ...:

```
example% tabs -8
```

This command uses *n1,n2,...* (*arbitrary* specification) to set tabs at columns 1, 8, and 36:

```
example% tabs 1,8,36
```

The last command is an example of using `-file` (*file* specification) to indicate that tabs should be set according to the first line of `$HOME/fspec.list/att4425` (see `fspec(4)`).

```
example% tabs - $HOME/fspec.list/att4425
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tabs`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

TERM Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, terminal type `ansi+tabs` will be used.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

`expand(1)`, `newform(1)`, `pr(1)`, `stty(1)`, `tput(1)`, `fspec(4)`, `terminfo(4)`,
`attributes(5)`, `environ(5)`, `term(5)`

NOTES

There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.

`tabs` clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.

The *tabspec* used with the `tabs` command is different from the one used with the `newform` command. For example, `tabs -8` sets every eighth position; whereas `newform -i-8` indicates that tabs are set every eighth position.

NAME	tail – deliver the last part of a file
SYNOPSIS	<pre> /usr/bin/tail [± number [lbc]] [file] /usr/bin/tail [-lbc] [file] /usr/bin/tail [± number [lbc]] [file] /usr/bin/tail [-lbc] [file] /usr/xpg4/bin/tail [-f -r][-c number -n number][file] /usr/xpg4/bin/tail [± number [l b c][f]] [file] /usr/xpg4/bin/tail [± number [l] [f r]] [file] </pre>
DESCRIPTION	<p>The <code>tail</code> utility copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.</p> <p>Copying begins at a point in the file indicated by the <code>-c number</code>, <code>-n number</code>, or <code>± number</code> options (if <code>+ number</code> is specified, begins at distance <code>number</code> from the beginning; if <code>- number</code> is specified, from the end of the input; if <code>number</code> is <code>NULL</code>, the value 10 is assumed). <code>number</code> is counted in units of lines or byte according to the <code>-c</code> or <code>-n</code> options, or lines, blocks, or bytes, according to the appended option <code>l</code>, <code>b</code>, or <code>c</code>. When no units are specified, counting is by lines.</p>
OPTIONS	<p>The following options are supported for both <code>/usr/bin/tail</code> and <code>/usr/xpg4/bin/tail</code>. The <code>-r</code> and <code>-f</code> options are mutually exclusive. If both are specified on the command line, the <code>-f</code> option will be ignored.</p> <ul style="list-style-type: none"> <code>-b</code> Units of blocks. <code>-c</code> Units of bytes. <code>-f</code> Follow. If the input-file is not a pipe, the program will not terminate after the line of the input-file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input-file. Thus it may be used to monitor the growth of a file that is being written by some other process. <code>-l</code> Units of lines. <code>-r</code> Reverse. Copies lines from the specified starting point in the file in reverse order. The default for <code>r</code> is to print the entire file in reverse order.
<code>/usr/xpg4/bin/tail</code>	<p>The following options are supported for <code>/usr/xpg4/bin/tail</code> only:</p> <ul style="list-style-type: none"> <code>-c number</code> The <code>number</code> option-argument must be a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying: <ul style="list-style-type: none"> <code>+</code> Copying starts relative to the beginning of the file.

- Copying starts relative to the end of the file.

none Copying starts relative to the end of the file.

The origin for counting is 1; that is, `-c+1` represents the first byte of the file, `-c-1` the last.

`-n number` Equivalent to `-cnumber`, except the starting location in the file is measured in lines instead of bytes. The origin for counting is 1; that is, `-n+1` represents the first line of the file, `-n-1` the last.

OPERANDS

The following operand is supported:

file A path name of an input file. If no *file* operands are specified, the standard input will be used.

USAGE

See `largefile(5)` for the description of the behavior of `tail` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 Using the `tail` Command

The following command will print the last ten lines of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed.

```
example% tail -f fred
```

The next command will print the last 15 bytes of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed:

```
example% tail -15cf fred
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tail`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

`/usr/bin/tail`

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

`/usr/xpg4/bin/tail`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled

SEE ALSO

cat(1), head(1), more(1), pg(1), dd(1M), attributes(5), environ(5), largefile(5), XPG4(5)

NOTES

Piped tails relative to the end of the file are stored in a buffer, and thus are limited in length. Various kinds of anomalous behavior may happen with character special files.

NAME	talk – talk to another user
SYNOPSIS	talk <i>address</i> [<i>terminal</i>]
DESCRIPTION	<p>The <code>talk</code> utility is a two-way, screen-oriented communication program.</p> <p>When first invoked, <code>talk</code> sends a message similar to:</p> <pre>Message from TalkDaemon@ her_machine at time ... talk: connection requested by your_address talk: respond with: talk your_address</pre> <p>to the specified <i>address</i>. At this point, the recipient of the message can reply by typing:</p> <pre>talk your_address</pre> <p>Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters are processed as follows:</p> <ul style="list-style-type: none"> ■ Typing the alert character will alert the recipient's terminal. ■ Typing CTRL-L will cause the sender's screen regions to be refreshed. ■ Typing the erase and kill characters will affect the sender's terminal in the manner described by the <code>termios(3C)</code> interface. ■ Typing the interrupt or end-of-file (EOF) characters will terminate the local <code>talk</code> utility. Once the <code>talk</code> session has been terminated on one side, the other side of the <code>talk</code> session will be notified that the <code>talk</code> session has been terminated and will be able to do nothing except exit. ■ Typing characters from <code>LC_CTYPE</code> classifications <code>print</code> or <code>space</code> will cause those characters to be sent to the recipient's terminal. ■ When and only when the <code>stty iexten</code> local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable. ■ Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a caret (^) followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'. <p>Permission to be a recipient of a <code>talk</code> message can be denied or granted by use of the <code>mesg(1)</code> utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. Certain commands, such as <code>pr(1)</code>, disallow messages in order to prevent interference with their output.</p>

`talk` will fail when the user lacks the appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for `talk`. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

OPERANDS

The following operands are supported:

address The recipient of the `talk` session. One form of *address* is the *username*, as returned by the `who(1)` utility. If you wish to talk to someone on your own machine, then *username* is just the person's login name. If you wish to talk to a user on another host, then *username* is one of the following forms:

```
host! user
host . user
host: user
user@host
```

although *user@host* is perhaps preferred.

terminal If the recipient is logged in more than once, *terminal* can be used to indicate the appropriate terminal name. If *terminal* is not specified, the `talk` message will be displayed on one or more accessible terminals in use by the recipient. The format of *terminal* will be the same as that returned by `who`.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `talk`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`TERM` Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified terminal type will be used.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred, or `talk` was invoked on a terminal incapable of supporting it.

FILES

`/etc/hosts` host name database

`/var/adm/utmp` user and accounting information for `talk`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

mail(1), mesg(1), pr(1), stty(1), who(1), write(1), termios(3C),
attributes(5), environ(5)

NOTES

Typing CTRL-L redraws the screen, while the erase, kill, and word kill characters will work in `talk` as normal. To exit, type an interrupt character; `talk` then moves the cursor to the bottom of the screen and restores the terminal to its previous state.

NAME	tar – create tape archives and add or extract files
SYNOPSIS	<pre>tar c [bBeEfFhiklnopPqvwx [0-7]] [block] [tarfile] [exclude-file] {-I include-file -C directory file file}... tar r [bBeEfFhiklnqv [0-7]] [block] {-I include-file -C directory file file}... tar t [BefFhiklnqvX [0-7]] [tarfile] [exclude-file] {-I include-file file}... tar u [bBeEfFhiklnqv [0-7]] [block] [tarfile] file... tar x [BefFhiklmnopqvwx [0-7]] [tarfile] [exclude-file] [file...]</pre>
DESCRIPTION	<p>The <code>tar</code> command archives and extracts files to and from a single file called a <i>tarfile</i>. A <i>tarfile</i> is usually a magnetic tape, but it can be any file. <code>tar</code>'s actions are controlled by the <i>key</i> argument. The <i>key</i> is a string of characters containing exactly one function letter (<code>c</code>, <code>r</code>, <code>t</code>, <code>u</code>, or <code>x</code>) and zero or more function modifiers (letters or digits), depending on the function letter used. The <i>key</i> string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the <i>key</i> string.</p> <p>The <code>-I include-file</code>, <code>-C directory file</code>, and <code>file</code> arguments specify which files or directories are to be archived or extracted. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory. Arguments appearing within braces (<code>{ }</code>) indicate that one of the arguments must be specified.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-I include-file</code> Opens <i>include-file</i> containing a list of files, one per line, and treats it as if each file appeared separately on the command line. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the included file, the entire line (apart from the newline) will be used to match against the initial string of files to include. In the case where excluded files (see <code>x</code> function modifier) are also specified, they take precedence over all included files. If a file is specified in both the <i>exclude-file</i> and the <i>include-file</i> (or on the command line), it will be excluded.</p> <p><code>-C directory file</code> Performs a <code>chdir</code> (see <code>cd(1)</code>) operation on <i>directory</i> and performs the <code>c</code> (create) or <code>r</code> (replace) operation on <i>file</i>. Use short relative path names for <i>file</i>. If <i>file</i> is '.', archive all files in <i>directory</i>. This option enables archiving files</p>

from multiple directories not related by a close common parent.

OPERANDS

The following operands are supported:

file A path name of a regular file or directory to be archived (when the *c*, *r* or *u* functions are specified), extracted (*x*) or listed (*t*). When *file* is the path name of a directory, the action applies to all of the files and (recursively) subdirectories of that directory.

When a file is archived, and the *E* flag (see *Function Modifiers*) is not specified, the filename cannot exceed 256 characters. In addition, it must be possible to split the name between parent directory names so that the prefix is no longer than 155 characters and the name is no longer than 100 characters. If *E* is specified, a name of up to *PATH_MAX* characters may be specified.

For example, a file whose basename is longer than 100 characters could not be archived without using the *E* flag. A file whose directory portion is 200 characters and whose basename is 50 characters could be archived (without using *E*) if a slash appears in the directory name somewhere in character positions 151-156.

Function Letters

The function portion of the key is specified by one of the following letters:

- c* Create. Writing begins at the beginning of the tarfile, instead of at the end.
- r* Replace. The named *files* are written at the end of the tarfile. A file created with extended headers must be updated with extended headers (see *E* flag under *Function Modifiers*). A file created without extended headers cannot be modified with extended headers.
- t* Table of Contents. The names of the specified files are listed each time they occur in the tarfile. If no *file* argument is given, the names of all files in the tarfile are listed. With the *v* function modifier, additional information for the specified files is displayed.
- u* Update. The named *files* are written at the end of the tarfile if they are not already in the tarfile, or if they have been modified since last written to that tarfile. An update can be rather slow. A tarfile created on a 5.x system cannot be updated on a 4.x system. A file created with extended headers must be updated with extended headers (see *E* flag under *Function Modifiers*). A file created without extended headers cannot be modified with extended headers.
- x* Extract or restore. The named *files* are extracted from the tarfile and written to the directory specified in the tarfile, relative to the current directory. Use the relative path names of files and directories to be

extracted. If a named file matches a directory whose contents has been written to the tarfile, this directory is recursively extracted. The owner, modification time, and mode are restored (if possible); otherwise, to restore owner, you must be the super-user. Character-special and block-special devices (created by `mknod(1M)`) can only be extracted by the super-user. If no `file` argument is given, the entire content of the tarfile is extracted. If the tarfile contains several files with the same name, each file is written to the appropriate directory, overwriting the previous one. Filename substitution wildcards cannot be used for extracting files from the archive; rather, use a command of the form:

```
tar xvf... /dev/rmt/0 `tar tf... /dev/rmt/0 | grep 'pattern'`
```

When extracting tapes created with the `r` or `u` functions, directory modification times may not be set correctly. These same functions cannot be used with many tape drives due to tape drive limitations such as the absence of backspace or append capabilities.

When using the `r`, `u`, or `x` functions or the `X` function modifier, the named files must match exactly the corresponding files in the *tarfile*. For example, to extract `./thisfile`, you must specify `./thisfile`, and not `thisfile`. The `t` function displays how each file was archived.

Function Modifiers

The characters below may be used in conjunction with the letter that selects the desired function.

b Blocking Factor. Use when reading or writing to raw magnetic archives (see `f` below). The *block* argument specifies the number of 512-byte tape blocks to be included in each read or write operation performed on the tarfile. The minimum is 1, the default is 20. The maximum value is a function of the amount of memory available and the blocking requirements of the specific tape device involved (see `mtio(7I)` for details.) The maximum cannot exceed `INT_MAX/512` (4194303).

When a tape archive is being read, its actual blocking factor will be automatically detected, provided that it is less than or equal to the nominal blocking factor (the value of the *block* argument, or the default value if the `b` modifier is not specified). If the actual blocking factor is greater than the nominal blocking factor, a read error will result. See Example 5 in `EXAMPLES`.

B Block. Force `tar` to perform multiple reads (if necessary) to read exactly enough bytes to fill a block. This function

- modifier enables `tar` to work across the Ethernet, since pipes and sockets return partial blocks even when more data is coming. When reading from standard input, `'-'`, this function modifier is selected by default to ensure that `tar` can recover from short reads.
- e** Error. Exit immediately with a positive exit status if any unexpected errors occur. The `SYSV3` environment variable overrides the default behavior. (See `ENVIRONMENT` section below.)
- E** Write a tarfile with extended headers. (Used with `c`, `r`, or `u` options; ignored with `t` or `x` options.) When a tarfile is written with extended headers, the modification time is maintained with a granularity of microseconds rather than seconds. In addition, filenames no longer than `PATH_MAX` characters that could not be archived without `E`, and file sizes greater than 8GB, are supported. The `E` flag is required whenever the larger files and/or files with longer names, or whose `UID/GID` exceed 2097151, are to be archived, or if time granularity of microseconds is desired.
- f** File. Use the *tarfile* argument as the name of the tarfile. If `f` is specified, `/etc/default/tar` is not searched. If `f` is omitted, `tar` will use the device indicated by the `TAPE` environment variable, if set; otherwise, it will use the default values defined in `/etc/default/tar`. If the name of the tarfile is `'-'`, `tar` writes to the standard output or reads from the standard input, whichever is appropriate. `tar` can be used as the head or tail of a pipeline. `tar` can also be used to move hierarchies with the command:
- ```
example% cd fromdir; tar cf - . | (cd todir; tar xfbp -)
```
- F** With one `F` argument, `tar` excludes all directories named `SCCS` and `RCS` from the tarfile. With two arguments, `FF`, `tar` excludes all directories named `SCCS` and `RCS`, all files with `.o` as their suffix, and all files named `errs`, `core`, and `a.out`. The `SYSV3` environment variable overrides the default behavior. (See `ENVIRONMENT` section below.)
- h** Follow symbolic links as if they were normal files or directories. Normally, `tar` does not follow symbolic links.
- i** Ignore directory checksum errors.

|   |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| k | <i>size</i> | Requires <code>tar</code> to use the <code>size</code> argument as the size of an archive in kilobytes. This is useful when the archive is intended for a fixed size device such as floppy disks. Large files are then split across volumes if they do not fit in the specified size.                                                                                                                                                                                                                                                                                                                                                |
| l |             | Link. Output error message if unable to resolve all links to the files being archived. If <code>l</code> is not specified, no error messages are printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| m |             | Modify. The modification time of the file is the time of extraction. This function modifier is valid only with the <code>x</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| n |             | The file being read is a non-tape device. Reading of the archive is faster since <code>tar</code> can randomly seek around the archive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| o |             | Ownership. Assign to extracted files the user and group identifiers of the user running the program, rather than those on tarfile. This is the default behavior for users other than root. If the <code>o</code> function modifier is not set and the user is root, the extracted files will take on the group and user identifiers of the files on tarfile (see <code>chown(1)</code> for more information). The <code>o</code> function modifier is only valid with the <code>x</code> function.                                                                                                                                   |
| p |             | Restore the named files to their original modes, and ACLs if applicable, ignoring the present <code>umask(1)</code> . This is the default behavior if invoked as super-user with the <code>x</code> function letter specified. If super-user, SETUID and sticky information are also extracted, and files are restored with their original owners and permissions, rather than owned by root. When this function modifier is used with the <code>c</code> function, ACLs are created in the tarfile along with other information. Errors will occur when a tarfile with ACLs is extracted by previous versions of <code>tar</code> . |
| P |             | Suppress the addition of a trailing "/" on directory entries in the archive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| q |             | Stop after extracting the first occurrence of the named file. <code>tar</code> will normally continue reading the archive after finding an occurrence of a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| v |             | Verbose. Output the name of each file preceded by the function letter. With the <code>t</code> function, <code>v</code> provides additional                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

- information about the tarfile entries. The listing is similar to the format produced by the `-l` option of the `ls(1)` command.
- w** What. Output the action to be taken and the name of the file, then await the user's confirmation. If the response is affirmative, the action is performed; otherwise, the action is not performed. This function modifier cannot be used with the `t` function.
- x** Exclude. Use the *exclude-file* argument as a file containing a list of relative path names for files (or directories) to be excluded from the tarfile when using the functions `c`, `x`, or `t`. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the excluded file, the entire line (apart from the newline) will be used to match against the initial string of files to exclude. Multiple `x` arguments may be used, with one *exclude-file* per argument. In the case where included files (see `-I include-file` option) are also specified, the excluded files take precedence over all included files. If a file is specified in both the *exclude-file* and the *include-file* (or on the command line), it will be excluded.
- [0-7] Select an alternative drive on which the tape is mounted. The default entries are specified in `/etc/default/tar`. If no digit or `f` function modifier is specified, the entry in `/etc/default/tar` with digit "0" is the default.

**USAGE**

See `largefile(5)` for the description of the behavior of `tar` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

The automatic determination of the actual blocking factor may be fooled when reading from a pipe or a socket (see the `B` function modifier below).

1/4" streaming tape has an inherent blocking factor of one 512-byte block. It can be read or written using any blocking factor.

This function modifier works for archives on disk files and block special devices, among others, but is intended principally for tape devices.

For information on `tar` header format, see `archives(4)`.

**EXAMPLES**

**EXAMPLE 1** Using the `tar` Command to Create an Archive of Your Home Directory

The following is an example using `tar` to create an archive of your home directory on a tape mounted on drive `/dev/rmt/0`:

```
example% cd
example% tar cvf /dev/rmt/0 .
messages from tar
```

The `c` function letter means create the archive; the `v` function modifier outputs messages explaining what `tar` is doing; the `f` function modifier indicates that the tarfile is being specified (`/dev/rmt/0` in this example). The dot (`.`) at the end of the command line indicates the current directory and is the argument of the `f` function modifier.

Display the table of contents of the tarfile with the following command:

```
example% tar tvf /dev/rmt/0
```

The output will be similar to the following for the POSIX locale:

```
rw-r--r-- 1677/40 2123 Nov 7 18:15 1985 ./test.c
...
example%
```

The columns have the following meanings:

- column 1 is the access permissions to `./test.c`
- column 2 is the *user-id/group-id* of `./test.c`
- column 3 is the size of `./test.c` in bytes
- column 4 is the modification date of `./test.c`. When the `LC_TIME` category is not set to the POSIX locale, a different format and date order field may be used.
- column 5 is the name of `./test.c`

To extract files from the archive:

```
example% tar xvf /dev/rmt/0
messages from tar
example%
```

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. To have `tar` read the first and second archives from a tape with multiple archives on it, the *non-rewinding* version of the tape device name must be used with the `f` function modifier, as follows:

```
example% tar xvfp /dev/rmt/0n read first archive from tape
messages from tar example% tar xvfp /dev/rmt/0n read second archive from tape
messages from tar example%
```

Note that in some earlier releases, the above scenario did not work correctly, and intervention with `mt(1)` between `tar` invocations was necessary. To emulate the old behavior, use the non-rewind device name containing the letter `b` for BSD behavior. See the `Close Operations` section of the `mtio(7I)` manual page.

**EXAMPLE 2** Using Tar To Archive Files From /usr/include And From /etc To Default Tape Drive 0:

To archive files from /usr/include and from /etc to default tape drive 0:

```
example% tar c -C /usr include -C /etc .
```

The table of contents from the resulting tarfile would produce output like the following:

```
include/
include/a.out.h
and all the other files in /usr/include ...
./chown and all the other files in /etc
```

To extract all files in the include directory:

```
example% tar xv include
x include/, 0 bytes, 0 tape blocksand all files under include...
```

**EXAMPLE 3** Using tar to Transfer Files Across the Network

The following is an example using tar to transfer files across the network.

First, here is how to archive files from the local machine ( example) to a tape on a remote system ( host):

```
example% tar cvfb - 20 files | rsh host dd of=/dev/rmt/0 obs=20b
messages from tar
example%
```

In the example above, we are *creating a tarfile* with the `c` key letter, asking for *verbose output* from tar with the `v` function modifier, specifying the name of the output *tarfile* using the `f` function modifier (the standard output is where the *tarfile* appears, as indicated by the `'-'` sign), and specifying the blocksize (20) with the `b` function modifier. If you want to change the blocksize, you must change the blocksize arguments both on the tar command *and* on the dd command.

**EXAMPLE 4** Using Tar To Retrieve Files From A Tape On The Remote System Back To The Local System:

The following is an example that uses tar to retrieve files from a tape on the remote system back to the local system:

```
example% rsh -n host dd if=/dev/rmt/0 bs=20b | tar xvBfb - 20 files
messages from tar
example%
```

In the example above, we are *extracting* from the *tarfile* with the `x` key letter, asking for *verbose output* from tar with the `v` function modifier, telling tar it is reading from a pipe with the `B` function modifier, specifying the name of the input *tarfile* using the `f` function modifier (the standard input is where the *tarfile* appears, as indicated by the `'-'` sign), and specifying the blocksize (20) with the `b` function modifier.

**EXAMPLE 5** Creating An Archive Of The Home Directory On /dev/rmt/0 With A Blocking Factor Of 19

The following example creates an archive of the home directory on /dev/rmt/0 with an actual blocking factor of 19:

```
example% tar cvfb /dev/rmt/0 19 $HOME
```

To recognize this archive's actual blocking factor without using the `b` function modifier:

```
example% tar tvf /dev/rmt/0
tar: blocksize = 19
...
```

To recognize this archive's actual blocking factor using a larger nominal blocking factor:

```
example% tar tvf /dev/rmt/0 30
tar: blocksize = 19
...
```

Attempt to recognize this archive's actual blocking factor using a nominal blocking factor that is too small:

```
example% tar tvf /dev/rmt/0 10
tar: tape read error
```

**ENVIRONMENT VARIABLES**

**SYSV3** This variable is used to override the default behavior of `tar`, provide compatibility with INTERACTIVE UNIX Systems and SCO UNIX installation scripts, and should not be used in new scripts. (It is intended for compatibility purposes only.) When set, the following options behave differently:

- `-F filename` Uses *filename* to obtain a list of command line switches and files on which to operate.
- `-e` Prevents files from being split across volumes. If there is insufficient room on one volume, `tar` prompts for a new volume. If the file will not fit on the new volume, `tar` exits with an error.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tar`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES**

```
/dev/rmt/[0-7][b][n]
/dev/rmt/[0-7]l[b][n]
/dev/rmt/[0-7]m[b][n]
```

```

/dev/rmt/[0-7]h[b][n]
/dev/rmt/[0-7]u[b][n]
/dev/rmt/[0-7]c[b][n]
/etc/default/tar

```

Settings may look like this:

```

archive0=/dev/rmt/0
archive1=/dev/rmt/0n
archive2=/dev/rmt/1
archive3=/dev/rmt/1n
archive4=/dev/rmt/0
archive5=/dev/rmt/0n
archive6=/dev/rmt/1
archive7=/dev/rmt/1n

```

```

/tmp/tar*

```

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

## SEE ALSO

`ar(1)`, `basename(1)`, `cd(1)`, `chown(1)`, `cpio(1)`, `csh(1)`, `dirname(1)`, `ls(1)`, `mt(1)`, `pax(1)`, `setfacl(1)`, `umask(1)`, `mknod(1M)`, `vold(1M)`, `archives(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `mtio(7I)`

## DIAGNOSTICS

Diagnostic messages are output for bad key characters and tape read/write errors, and for insufficient memory to hold the link tables.

## NOTES

There is no way to access the *n*-th occurrence of a file.

Tape errors are handled ungracefully.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, `/dev/rdiskette`) may not succeed. See `vold(1M)` for further details.

The `tar` archive format allows UIDs and GIDs up to 2097151 to be stored in the archive header. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.

If an archive is created that contains files whose names were created by processes running in multiple locales, a single locale that uses a full 8-bit codeset (for example, the `en_US` locale) should be used both to create the archive and to extract files from the archive.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | tbl – format tables for nroff or troff                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>tbl</b> [-me] [-mm] [-ms] [ <i>filename</i> ] ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | tbl is a preprocessor for formatting tables for nroff(1) or troff(1). The input <i>filenames</i> are copied to the standard output, except that lines between .TS and .TE command lines are assumed to describe tables and are reformatted.<br><br>If no arguments are given, tbl reads the standard input, so tbl may be used as a filter. When tbl is used with eqn(1) or neqn, the tbl command should be first, to minimize the volume of data passed through pipes.                                                                                                                                                    |
| <b>OPTIONS</b>     | -me    Copy the -me macro package to the front of the output file.<br>-mm    Copy the -mm macro package to the front of the output file.<br>-ms    Copy the -ms macro package to the front of the output file.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> Using tbl<br><br>As an example, letting '@' (at-sign) represent a TAB, which should be typed as an actual TAB character in the input file<br><br><pre>.TS c s s c c s c c c l n n. | <b>SYNOPSIS</b>    | <b>tcopy</b> <i>source</i> [ <i>destination</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>tcopy copies the magnetic tape mounted on the tape drive specified by the <i>source</i> argument. The only assumption made about the contents of a tape is that there are two tape marks at the end.</p> <p>When only a source drive is specified, tcopy scans the tape, and displays information about the sizes of records and tape files. If a destination is specified, tcopy makes a copies the source tape onto the <i>destination</i> tape, with blocking preserved. As it copies, tcopy produces the same output as it does when only scanning a tape.</p> |                |                 |              |         |

| <b>SEE ALSO</b>    | mt(1), ioctl(2), attributes(5)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>NOTES</b>       | tcopy will only run on systems supporting an associated set of ioctl(2) requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>NAME</b>                  | tee – replicate the standard output                                                                                                                                                                                                      |                |                 |              |         |     |         |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|-----|---------|
| <b>SYNOPSIS</b>              | <b>tee</b> [-ai] [ <i>file</i> ...]                                                                                                                                                                                                      |                |                 |              |         |     |         |
| <b>DESCRIPTION</b>           | The <code>tee</code> utility will copy standard input to standard output, making a copy in zero or more files. <code>tee</code> will not buffer its output. The options determine if the specified files are overwritten or appended to. |                |                 |              |         |     |         |
| <b>OPTIONS</b>               | The following options are supported.<br>-a     Append the output to the files rather than overwriting them.<br>-i     Ignore interrupts.                                                                                                 |                |                 |              |         |     |         |
| <b>OPERANDS</b>              | The following operands are supported:<br><i>file</i> A path name of an output file. Processing of at least 13 <i>file</i> operands will be supported.                                                                                    |                |                 |              |         |     |         |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>tee</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                        |                |                 |              |         |     |         |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>tee</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                        |                |                 |              |         |     |         |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br>0       The standard input was successfully copied to all output files.<br>>0     The number of files that could not be opened or whose status could not be obtained.                         |                |                 |              |         |     |         |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                             |                |                 |              |         |     |         |

| <b>NAME</b>        | telnet – user interface to a remote system using the TELNET protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>telnet</b> [-8ELcdr] [-e <i>escape_char</i> ] [-l <i>user</i> ] [-n <i>file</i> ] [[!] @hop1 [@hop2... ] @<br>] <i>host</i> [ <i>port</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>telnet communicates with another host using the TELNET protocol. If telnet is invoked without arguments, it enters command mode, indicated by its prompt, <code>telnet&gt;</code>. In this mode, it accepts and executes its associated commands. See USAGE , telnet Commands, below. If it is invoked with arguments, it performs an <code>open</code> command with those arguments.</p> <p>If for example a <i>host</i> is specified as <code>@hop1@hop2@host</code>, the connection goes through hosts <i>hop1</i> and <i>hop2</i>, using loose source routing to end at <i>host</i>. If a leading <code>!</code> is used, the connection follows strict source routing. Note that when telnet uses IPv6, it can only use loose source routing, and the connection ignores the <code>!</code>.</p> <p>Once a connection has been opened, telnet enters input mode. In this mode, text typed is sent to the remote host. The input mode entered will be either "line mode", "character at a time", or "old line by line", depending upon what the remote system supports.</p> <p>In "line mode", character processing is done on the local system, under the control of the remote system. When input editing or character echoing is to be disabled, the remote system will relay that information. The remote system will also relay changes to any special characters that happen on the remote system, so that they can take effect on the local system.</p> <p>In "character at a time" mode, most text typed is immediately sent to the remote host for processing.</p> <p>In "old line by line" mode, all text is echoed locally, and (normally) only completed lines are sent to the remote host. The "local echo character" (initially <code>^E</code>) may be used to turn off and on the local echo. (Use this mostly to enter passwords without the password being echoed.)</p> <p>If the "line mode" option is enabled, or if the <code>localchars</code> toggle is TRUE (the default in "old line by line" mode), the user's <code>quit</code>, <code>intr</code>, and <code>flush</code> characters are trapped locally, and sent as TELNET protocol sequences to the remote side. If "line mode" has ever been enabled, then the user's <code>susp</code> and <code>eof</code> are also sent as TELNET protocol sequences. <code>quit</code> is then sent as a TELNET ABORT instead of BREAK. The options <code>toggle autoflush</code> and <code>toggle autosynch</code> cause this action to flush subsequent output to the terminal (until the remote host acknowledges the TELNET sequence); and to flush previous terminal input, in the case of <code>quit</code> and <code>intr</code>.</p> <p>While connected to a remote host, the user can enter telnet command mode by typing the telnet escape character (initially <code>^]</code>). When in command mode, the</p> |

normal terminal editing conventions are available. Pressing RETURN at the telnet command prompt causes telnet to exit command mode.

## OPTIONS

The following options are supported:

- 8                Specifies an 8-bit data path. Negotiating the TELNET BINARY option is attempted for both input and output.
- c                Disables the reading of the user's telnetrc file. (See the toggle skiprc command on this reference page.)
- d                Sets the initial value of the debug toggle to TRUE.
- e *escape\_char* Sets the initial escape character to *escape\_char*. *escape\_char* may also be a two character sequence consisting of '^' followed by one character. If the second character is '?', the DEL character is selected. Otherwise, the second character is converted to a control character and used as the escape character. If the escape character is the null string (that is, -e ), it is disabled.
- E                Stops any character from being recognized as an escape character.
- l *user*                When connecting to a remote system that understands the ENVIRON option, then *user* will be sent to the remote system as the value for the ENVIRON variable USER.
- L                Specifies an 8-bit data path on output. This causes the BINARY option to be negotiated on output.
- n *tracefile*        Opens *tracefile* for recording trace information. See the set *tracefile* command below.
- r                Specifies a user interface similar to rlogin. In this mode, the escape character is set to the tilde (~) character, unless modified by the -e option. The rlogin escape character is only recognized when it is preceded by a carriage return. In this mode, the telnet escape character, normally '^]', must still precede a telnet command. The rlogin escape character can also be followed by '.\r' or '^Z', and, like rlogin(1), closes or suspends the connection, respectively. This option is an uncommitted interface and may change in the future.

## USAGE

### telnet Commands

The commands described in this section are available with telnet. It is necessary to type only enough of each command to uniquely identify it. (This

is also true for arguments to the `mode`, `set`, `toggle`, `unset`, `environ`, and `display` commands.)

`open` [ `-l user` ] [ `!@hop1` [`@hop2 ...`]`@host` [ `port` ]

Open a connection to the named host. If no port number is specified, `telnet` will attempt to contact a TELNET server at the default port. The host specification may be either a host name (see `hosts(4)`, `ipnodes(4)`) or an Internet address specified in the "dot notation" (see `inet(7P)` or `inet6(7P)`). If the `host` is specified as `@hop1@hop2@host`, the connection goes through hosts `hop1` and `hop2`, using loose source routing to end at `host`. The "@" symbol is required as a separator between the hosts specified. If a leading ! is used with IPv4, the connection follows strict source routing.

The `-l` option passes the `user` as the value of the `ENVIRON` variable `USER` to the remote system.

`close`

Close any open TELNET session and exit `telnet`. An EOF (in command mode) will also close a session and exit.

`quit`

Same as `close`.

`z`

Suspend `telnet`. This command only works when the user is using a shell that supports job control, such as `sh(1)`.

`mode type`

The remote host is asked for permission to go into the requested mode. If the remote host is capable of entering that mode, the requested mode will be entered. The argument `type` is one of the following:

|                           |                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>character</code>    | Disable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then enter "character at a time" mode.        |
| <code>line</code>         | Enable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then attempt to enter "old-line-by-line" mode. |
| <code>isig (-isig)</code> | Attempt to enable (disable) the TRAPSIG mode of the LINEMODE option. This requires that the LINEMODE option be enabled.                           |

|                                   |                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>edit (-edit)</code>         | Attempt to enable (disable) the <code>EDIT</code> mode of the <code>LINEMODE</code> option. This requires that the <code>LINEMODE</code> option be enabled.                                                                                                                                                                   |
| <code>softtabs (-softtabs)</code> | Attempt to enable (disable) the <code>SOFT_TAB</code> mode of the <code>LINEMODE</code> option. This requires that the <code>LINEMODE</code> option be enabled.                                                                                                                                                               |

This requires that the <code>LINEMODE</code> option be enabled.                                                                                                                                                               |
| <code>?</code>                    | Prints out help information for the <code>mode</code> command.                                                                                                                                                                                                                                                                |
| <code>status</code>               | Show the current status of <code>telnet</code> . This includes the peer one is connected to, as well as the current mode.                                                                                                                                                                                                     |
| <code>display</code>              | [ <i>argument...</i> ] Display all, or some, of the <code>set</code> and <code>toggle</code> values (see <code>toggle argument...</code> ).                                                                                                                                                                                   |
| <code>?</code>                    | [ <i>command</i> ] Get help. With no arguments, <code>telnet</code> prints a help summary. If a command is specified, <code>telnet</code> will print the help information for just that command.                                                                                                                              |
| <code>send argument . . .</code>  | Send one or more special character sequences to the remote host. The following are the arguments that can be specified (more than one argument may be specified at a time):                                                                                                                                                   |
| <code>escape</code>               | Send the current <code>telnet</code> escape character (initially <code>^</code> ).                                                                                                                                                                                                                                            |
| <code>synch</code>                | Send the <code>TELNET SYNCH</code> sequence. This sequence discards all previously typed, but not yet read, input on the remote system. This sequence is sent as <code>TCP urgent</code> data and may not work if the remote system is a 4.2 BSD system. If it does not work, a lower case "r" may be echoed on the terminal. |
| <code>brk or break</code>         | Send the <code>TELNET BRK (Break)</code> sequence, which may have significance to the remote system.                                                                                                                                                                                                                          |
| <code>ip</code>                   | Send the <code>TELNET IP (Interrupt Process)</code> sequence, which aborts the currently running process on the remote system.                                                                                                                                                                                                |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>abort</code>                  | Send the TELNET ABORT (Abort Process) sequence.                                                                                                                                                                                                                                                                                                                                                                             |
| <code>ao</code>                     | Send the TELNET AO (Abort Output) sequence, which flushes all output from the remote system to the user's terminal.                                                                                                                                                                                                                                                                                                         |
| <code>ayt</code>                    | Send the TELNET AYT (Are You There) sequence, to which the remote system may or may not respond.                                                                                                                                                                                                                                                                                                                            |
| <code>ec</code>                     | Send the TELNET EC (Erase Character) sequence, which erases the last character entered.                                                                                                                                                                                                                                                                                                                                     |
| <code>el</code>                     | Send the TELNET EL (Erase Line) sequence, which should cause the remote system to erase the line currently being entered.                                                                                                                                                                                                                                                                                                   |
| <code>eof</code>                    | Send the TELNET EOF (End Of File) sequence.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>eor</code>                    | Send the TELNET EOR (End Of Record) sequence.                                                                                                                                                                                                                                                                                                                                                                               |
| <code>ga</code>                     | Send the TELNET GA (Go Ahead) sequence, which probably has no significance for the remote system.                                                                                                                                                                                                                                                                                                                           |
| <code>getstatus</code>              | If the remote side supports the TELNET STATUS command, <code>getstatus</code> will send the subnegotiation to request that the server send its current option status.                                                                                                                                                                                                                                                       |
| <code>nop</code>                    | Send the TELNET NOP (No Operation) sequence.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>susp</code>                   | Send the TELNET SUSP (Suspend Process) sequence.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>do option</code>              | Send the TELNET protocol option negotiation indicated. Option may be the text name of the protocol option, or the number corresponding to the option. The command will be silently ignored if the option negotiation indicated is not valid in the current state. If the <i>option</i> is given as 'help' or '?', the list of option names known is listed. This command is mostly useful for unusual debugging situations. |
| <code>dont option</code>            |                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>will option</code>            |                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>wont option</code>            |                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>?</code>                      | Print out help information for the <code>send</code> command.                                                                                                                                                                                                                                                                                                                                                               |
| <code>set argument [ value ]</code> | Set any one of a number of <code>telnet</code> variables to a specific value. The special value "off" turns off the function associated with the variable. The values                                                                                                                                                                                                                                                       |
| <code>unset argument</code>         |                                                                                                                                                                                                                                                                                                                                                                                                                             |

of variables may be interrogated with the `display` command. If *value* is omitted, the value is taken to be true, or "on". If the `unset` form is used, the value is taken to be false, or "off." The variables that may be specified are:

|                          |                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>echo</code>        | This is the value (initially <code>^E</code> ) that, when in "line by line" mode, toggles between local echoing of entered characters for normal processing, and suppressing echoing of entered characters, for example, entering a password.                                                                                                  |
| <code>escape</code>      | This is the telnet escape character (initially <code>^]</code> ) that enters telnet command mode when connected to a remote system.                                                                                                                                                                                                            |
| <code>interrupt</code>   | If telnet is in <code>localchars</code> mode (see <code>toggle</code> , <code>localchars</code> ) and the interrupt character is typed, a TELNET IP sequence (see <code>send</code> and <code>ip</code> ) is sent to the remote host. The initial value for the interrupt character is taken to be the terminal's <code>intr</code> character. |
| <code>quit</code>        | If telnet is in <code>localchars</code> mode and the quit character is typed, a TELNET BRK sequence (see <code>send</code> , <code>brk</code> ) is sent to the remote host. The initial value for the quit character is taken to be the terminal's <code>quit</code> character.                                                                |
| <code>flushoutput</code> | If telnet is in <code>localchars</code> mode and the flushoutput character is typed, a TELNET AO sequence (see <code>send</code> , <code>ao</code> ) is sent to the remote host. The initial value for the flush character is taken to be the terminal's <code>flush</code> character.                                                         |
| <code>erase</code>       | If telnet is in <code>localchars</code> mode <i>and</i> operating in "character at a time" mode, then when the erase character is typed, a TELNET EC sequence (see <code>send</code> , <code>ec</code> ) is sent to the remote system. The initial value for the erase character is taken to be the terminal's <code>erase</code> character.   |
| <code>kill</code>        | If telnet is in <code>localchars</code> mode <i>and</i> operating in "character at a time" mode, then when the kill character is typed, a TELNET EL sequence (see <code>send</code> , <code>el</code> ) is sent to the remote system. The initial value for the kill character is taken to be the terminal's <code>kill</code> character.      |
| <code>eof</code>         | If telnet is operating in "line by line" mode, entering the <code>eof</code> character as the first character on a line sends this                                                                                                                                                                                                             |

|                |                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | character to the remote system. The initial value of eof is taken to be the terminal's eof character.                                                                                                                                                                                                                                                                                         |
| ayt            | If telnet is in localchars mode, or LINEMODE is enabled, and the status character is typed, a TELNET AYT ("Are You There") sequence is sent to the remote host. (See send, ayt above.) The initial value for ayt is the terminal's status character.                                                                                                                                          |
| forw1<br>forw2 | If telnet is operating in LINEMODE, and the forw1 or forw2 characters are typed, this causes the forwarding of partial lines to the remote system. The initial values for the forwarding characters come from the terminal's eol and eol2 characters.                                                                                                                                         |
| lnext          | If telnet is operating in LINEMODE or "old line by line" mode, then the lnext character is assumed to be the terminal's lnext character. The initial value for the lnext character is taken to be the terminal's lnext character.                                                                                                                                                             |
| reprint        | If telnet is operating in LINEMODE or "old line by line" mode, then the reprint character is assumed to be the terminal's reprint character. The initial value for reprint is taken to be the terminal's reprint character.                                                                                                                                                                   |
| rlogin         | This is the rlogin escape character. If set, the normal telnet escape character is ignored, unless it is preceded by this character at the beginning of a line. The rlogin character, at the beginning of a line followed by a "." closes the connection. When followed by a ^Z, the rlogin command suspends the telnet command. The initial state is to disable the rlogin escape character. |
| start          | If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the start character is taken to be the terminal's start character. The initial value for the kill character is taken to be the terminal's start character.                                                                                                                                                                    |
| stop           | If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the stop character is taken to be the terminal's stop character. The initial value for the kill character is taken to be the terminal's stop character.                                                                                                                                                                       |
| susp           | If telnet is in localchars mode, or LINEMODE is enabled, and the suspend character is typed, a TELNET                                                                                                                                                                                                                                                                                         |

|                        |                                                                                                                                                                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | SUSP sequence (see <code>send</code> , <code>susp</code> above) is sent to the remote host. The initial value for the <code>suspend</code> character is taken to be the terminal's <code>suspend</code> character.                                                                                      |
| <code>tracefile</code> | This is the file to which the output, generated when the <code>netdata</code> or the <code>debug</code> option is <code>TRUE</code> , will be written. If <code>tracefile</code> is set to "-", then tracing information will be written to standard output (the default).                              |
| <code>worderase</code> | If <code>telnet</code> is operating in <code>LINEMODE</code> or "old line by line" mode, then this character is taken to be the terminal's <code>worderase</code> character. The initial value for the <code>worderase</code> character is taken to be the terminal's <code>worderase</code> character. |
| <code>?</code>         | Displays the legal <code>set</code> and <code>unset</code> commands.                                                                                                                                                                                                                                    |

`slc state`

The `slc` (Set Local Characters) command is used to set or change the state of special characters when the `TELNET LINEMODE` option has been enabled. Special characters are characters that get mapped to `TELNET` commands sequences (like `ip` or `quit`) or line editing characters (like `erase` and `kill`). By default, the local special characters are exported. The following values for `state` are valid:

|                     |                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>check</code>  | Verifies the settings for the current special characters. The remote side is requested to send all the current special character settings. If there are any discrepancies with the local side, the local settings will switch to the remote values. |
| <code>export</code> | Switches to the local defaults for the special characters. The local default characters are those of the local terminal at the time when <code>telnet</code> was started.                                                                           |
| <code>import</code> | Switches to the remote defaults for the special characters. The remote default characters are those of the remote system at the time when the <code>TELNET</code> connection was established.                                                       |
| <code>?</code>      | Prints out help information for the <code>slc</code> command.                                                                                                                                                                                       |

`toggle argument...`

Toggle between `TRUE` and `FALSE` the various flags that control how `telnet` responds to events. More than one argument may be specified. The state

of these flags may be interrogated with the `display` command. Valid arguments are:

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>autoflush</code> | If <code>autoflush</code> and <code>localchars</code> are both <code>TRUE</code> , then when the <code>ao</code> , <code>intr</code> , or <code>quit</code> characters are recognized (and transformed into <code>TELNET</code> sequences; see <code>set</code> for details), <code>telnet</code> refuses to display any data on the user's terminal until the remote system acknowledges (using a <code>TELNET</code> Timing Mark option) that it has processed those <code>TELNET</code> sequences. The initial value for this toggle is <code>TRUE</code> if the terminal user has not done an "stty noflsh". Otherwise, the value is <code>FALSE</code> (see <code>stty(1)</code> ). |
| <code>autosynch</code> | If <code>autosynch</code> and <code>localchars</code> are both <code>TRUE</code> , then when either the <code>interrupt</code> or <code>quit</code> characters are typed (see <code>set</code> for descriptions of <code>interrupt</code> and <code>quit</code> ), the resulting <code>TELNET</code> sequence sent is followed by the <code>TELNET SYNCH</code> sequence. This procedure <i>should</i> cause the remote system to begin throwing away all previously typed input until both of the <code>TELNET</code> sequences have been read and acted upon. The initial value of this toggle is <code>FALSE</code> .                                                                 |
| <code>binary</code>    | Enable or disable the <code>TELNET BINARY</code> option on both input and output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>inbinary</code>  | Enable or disable the <code>TELNET BINARY</code> option on input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>outbinary</code> | Enable or disable the <code>TELNET BINARY</code> option on output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>crlf</code>      | Determines how carriage returns are sent. If the value is <code>TRUE</code> , then carriage returns will be sent as <code>&lt;CR&gt;&lt;LF&gt;</code> . If the value is <code>FALSE</code> , then carriage returns will be sent as <code>&lt;CR&gt;&lt;NUL&gt;</code> . The initial value for this toggle is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                        |
| <code>crmod</code>     | Toggle <code>RETURN</code> mode. When this mode is enabled, most <code>RETURN</code> characters received from the remote host will be mapped into a <code>RETURN</code> followed by a line feed. This mode does not affect those characters typed by the user, only those received from the remote host. This mode is useful only for remote hosts that send <code>RETURN</code> but never send <code>LINEFEED</code> . The initial value for this toggle is <code>FALSE</code> .                                                                                                                                                                                                        |
| <code>debug</code>     | Toggle socket level debugging (only available to the super-user). The initial value for this toggle is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| localchars | If this toggle is TRUE, then the flush, interrupt, quit, erase, and kill characters (see set) are recognized locally, and transformed into appropriate TELNET control sequences, respectively ao, ip, brk, ec, and el (see send). The initial value for this toggle is TRUE in "line by line" mode, and FALSE in "character at a time" mode. When the LINEMODE option is enabled, the value of localchars is ignored, and assumed always to be TRUE. If LINEMODE has ever been enabled, then quit is sent as abort, and eof and suspend are sent as eof and susp (see send above). |
| netdata    | Toggle the display of all network data (in hexadecimal format). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| options    | Toggle the display of some internal TELNET protocol processing (having to do with telnet options). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| prettydump | When the netdata toggle is enabled, if prettydump is enabled, the output from the netdata command will be formatted in a more user readable format. Spaces are put between each character in the output. The beginning of any TELNET escape sequence is preceded by an asterisk (*) to aid in locating them.                                                                                                                                                                                                                                                                       |
| skiprc     | When the skiprc toggle is TRUE, TELNET skips the reading of the .telnetrc file in the user's home directory when connections are opened. The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                               |
| termdata   | Toggles the display of all terminal data (in hexadecimal format). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ?          | Display the legal toggle commands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

*environ argument...*

The `environ` command is used to manipulate variables that may be sent through the TELNET ENVIRON option. The initial set of variables is taken from the users environment. Only the DISPLAY and PRINTER variables are exported by default. Valid arguments for the `environ` command are:

|                                   |                                                                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>define variablevalue</code> | Define <i>variable</i> to have a value of <i>value</i> . Any variables defined by this command are automatically exported. The <i>value</i> may be |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|

enclosed in single or double quotes, so that tabs and spaces may be included.

`undefine variable` Remove *variable* from the list of environment variables.

`export variable` Mark the *variable* to be exported to the remote side.

`unexport variable` Mark the *variable* to not be exported unless explicitly requested by the remote side.

`list` List the current set of environment variables. Those marked with an asterisk (\*) will be sent automatically. Other variables will be sent only if explicitly requested.

`?` Prints out help information for the `environ` command.

**logout**

Sends the telnet logout option to the remote side. This command is similar to a `close` command. However, if the remote side does not support the `logout` option, nothing happens. If, however, the remote side does support the `logout` option, this command should cause the remote side to close the TELNET connection. If the remote side also supports the concept of suspending a user's session for later reattachment, the `logout` argument indicates that the remote side should terminate the session immediately.

**FILES**

`$HOME/.telnetrc` file that contains commands to be executed before initiating a telnet session

`/etc/nologin` file that contains a message displayed to users attempting to login during machine shutdown

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`rlogin(1)`, `sh(1)`, `stty(1)`, `hosts(4)`, `ipnodes(4)`, `nologin(4)`, `telnetrc(4)`, `attributes(5)`, `inet(7P)`, `inet6(7P)`

**DIAGNOSTICS**

NO LOGINS: System going down in *N* minutes

The machine is in the process of being shut down and logins have been disabled.

**NOTES**

On some remote systems, echo has to be turned off manually when in "line by line" mode.

In "old line by line" mode, or `LINEMODE`, the terminal's EOF character is only recognized (and sent to the remote system) when it is the first character on a line.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | test – condition evaluation command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>/usr/ucb/test</b> <i>expression</i><br><i>expression</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>test evaluates the expression <i>expression</i> and, if its value is true, sets 0 (true) exit status; otherwise, a non-zero (false) exit status is set. test also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to the test command; normally these items are separated by spaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Primitives</b>  | <p>The following primitives are used to construct <i>expression</i>:</p> <ul style="list-style-type: none"> <li>-r <i>filename</i> True if <i>filename</i> exists and is readable.</li> <li>-w <i>filename</i> True if <i>filename</i> exists and is writable.</li> <li>-x <i>filename</i> True if <i>filename</i> exists and is executable.</li> <li>-f <i>filename</i> True if <i>filename</i> exists and is a regular file. Alternatively, if /usr/bin/sh users specify /usr/ucb before /usr/bin in their PATH environment variable, then test will return true if <i>filename</i> exists and is (not-a-directory). This is also the default for /usr/bin/csh users.</li> <li>-d <i>filename</i> True if <i>filename</i> exists and is a directory.</li> <li>-c <i>filename</i> True if <i>filename</i> exists and is a character special file.</li> <li>-b <i>filename</i> True if <i>filename</i> exists and is a block special file.</li> <li>-p <i>filename</i> True if <i>filename</i> exists and is a named pipe (fifo).</li> <li>-u <i>filename</i> True if <i>filename</i> exists and its set-user- ID bit is set.</li> <li>-g <i>filename</i> True if <i>filename</i> exists and its set-group- ID bit is set.</li> <li>-k <i>filename</i> True if <i>filename</i> exists and its sticky bit is set.</li> <li>-s <i>filename</i> True if <i>filename</i> exists and has a size greater than zero.</li> <li>-t[ <i>fil-des</i> ] True if the open file whose file descriptor number is <i>fil-des</i> (1 by default) is associated with a terminal device.</li> <li>-z <i>s1</i> True if the length of string <i>s1</i> is zero.</li> <li>-n <i>s1</i> True if the length of the string <i>s1</i> is non-zero.</li> <li><i>s1</i> = <i>s2</i> True if strings <i>s1</i> and <i>s2</i> are identical.</li> </ul> |

*s1* != *s2* True if strings *s1* and *s2* are *not* identical.  
*s1* True if *s1* is *not* the null string.  
*n1* -eq *n2* True if the integers *n1* and *n2* are algebraically equal. Any of the comparisons -ne, -gt, -ge, -lt, and -le may be used in place of -eq.

**Operators**

These primaries may be combined with the following operators:

! Unary negation operator.  
-a Binary *and* operator.  
-o Binary *or* operator (-a has higher precedence than -o).  
(*expression*) Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO**

find(1), sh(1), attributes(5)

**NOTES**

The not-a-directory alternative to the -f option is a transition aid for BSD applications and may not be supported in future releases.

If you test a file you own (the -r , -w , or -x tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The = and != operators have a higher precedence than the -r through -n operators, and = and != always expect arguments; therefore, = and != cannot be used with the -r through -n operators.

If more than one argument follows the -r through -n operators, only the first argument is examined; the others are ignored, unless a -a or a -o is the second argument.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | test – condition evaluation command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>test</b> <i>expression</i><br><i>expression</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p><b>test</b> evaluates the expression <i>expression</i> and if its value is true, sets a 0 (TRUE) exit status; otherwise, a non-zero (FALSE) exit status is set; <b>test</b> also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to <b>test</b>. Normally these items are separated by spaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Primitives</b>  | <p>The following primitives are used to construct <i>expression</i>:</p> <ul style="list-style-type: none"> <li><code>-r filename</code> True if <i>filename</i> exists and is readable.</li> <li><code>-w filename</code> True if <i>filename</i> exists and is writable.</li> <li><code>-x filename</code> True if <i>filename</i> exists and is executable.</li> <li><code>-f filename</code> True if <i>filename</i> exists and is a regular file.</li> <li><code>-d filename</code> True if <i>filename</i> exists and is a directory.</li> <li><code>-c filename</code> True if <i>filename</i> exists and is a character special file.</li> <li><code>-b filename</code> True if <i>filename</i> exists and is a block special file.</li> <li><code>-p filename</code> True if <i>filename</i> exists and is a named pipe (FIFO).</li> <li><code>-u filename</code> True if <i>filename</i> exists and its set-user-ID bit is set.</li> <li><code>-g filename</code> True if <i>filename</i> exists and its set-group-ID bit is set.</li> <li><code>-k filename</code> True if <i>filename</i> exists and its sticky bit is set.</li> <li><code>-s filename</code> True if <i>filename</i> exists and has a size greater than 0.</li> </ul> |

`-t [ fildev ]` True if the open file whose file descriptor number is *fildev* (1 by default) is associated with a terminal device.

`-z s1` True if the length of string *s1* is 0.

`-n s1` True if the length of the string *s1* is non-zero.

`s1 = s2` True if strings *s1* and *s2* are identical.

`s1 != s2` True if strings *s1* and *s2* are *not* identical.

`s1` True if *s1* is *not* the null string.

`n1 -eq n2` True if the integers *n1* and *n2* are algebraically equal. Any of the comparisons `-ne`, `-gt`, `-ge`, `-lt`, and `-le` may be used in place of `-eq`.

**Operators**

These primaries may be combined with the following operators:

`!` Unary negation operator.

`-a` Binary *and* operator.

`-o` Binary *or* operator (`-a` has higher precedence than `-o`).

`'(expression)'` Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`find(1)`, `sh(1)`, `attributes(5)`

**NOTES**

If you test a file you own (the `-r`, `-w`, or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The = and != operators have a higher precedence than the -r through -n operators, and = and != always expect arguments; therefore, = and != cannot be used with the -r through -n operators.

If more than one argument follows the -r through -n operators, only the first argument is examined; the others are ignored, unless a -a or a -o is the second argument.

| <b>DESCRIPTION</b> | tftp is the user interface to the Internet TFTP (Trivial File Transfer Protocol), which allows users to transfer files to and from a remote machine. The remote <i>host</i> may be specified on the command line, in which case tftp uses <i>host</i> as the default host for future transfers (see the <code>connect</code> command below).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>USAGE</b>       | Once tftp is running, it issues the prompt tftp> and recognizes the following commands:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Commands</b>    | <p><code>connect</code> <i>host-name</i> [<i>port</i>]</p> <p>Set the <i>host</i> (and optionally <i>port</i>) for transfers. The TFTP protocol, unlike the FTP protocol, does not maintain connections between transfers; thus, the <code>connect</code> command does not actually create a connection, but merely remembers what host is to be used for transfers. You do not have to use the <code>connect</code> command; the remote host can be specified as part of the <code>get</code> or <code>put</code> commands.</p> <p><code>mode</code> <i>transfer-mode</i></p> <p>Set the mode for transfers; <i>transfer-mode</i> may be one of <code>ascii</code> or <code>binary</code>. The default is <code>ascii</code>.</p> <p><code>put</code> <i>filename</i></p> <p><code>put</code> <i>localfile remotefile</i></p> <p><code>put</code> <i>filename1 filename2 . . . filenameN remote-directory</i></p> <p>Transfer a file, or a set of files, to the specified remote file or directory. The destination can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:</p> <p style="padding-left: 40px;"><i>host: filename</i></p> <p>to specify both a <i>host</i> and <i>filename</i> at the same time. If the latter form is used, the specified host becomes the default for future transfers. If the remote-directory form is used, the remote host is assumed to be running the UNIX system.</p> <p>The <i>host</i> can be a host name (see <code>hosts(4)</code> or <code>ipnodes(4)</code>) or an IPv4 or IPv6 address string (see <code>inet(7P)</code> or <code>inet6(7P)</code>). Since IPv6 addresses already contain ":"s, the <i>host</i> should be enclosed in square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon will be interpreted as the separator between the <i>host</i> and the <i>filename</i>. For example,</p> <p style="padding-left: 40px;">[1080::8:800:200c:417A]:myfile</p> |

Files may be written only if they already exist and are publicly writable.  
See `in.tftpd(1M)`.

`get filename`

`get remotename localname`

`get filename1 filename2 filename3 ... filenameN`

Get a file or set of files (three or more) from the specified remote *sources*.  
*source* can be in one of two forms: a filename on the remote host if the  
host has already been specified, or a string of the form:

*host: filename*

to specify both a host and filename at the same time. If the latter form is  
used, the last host specified becomes the default for future transfers. See  
the `put` command regarding specifying a *host*.

`quit`

Exit tftp. An EOF also exits.

`verbose`

Toggle verbose mode.

`trace`

Toggle packet tracing.

`status`

Show current status.

`rexmt retransmission-timeout`

Set the per-packet retransmission timeout, in seconds.

`timeout total-transmission-timeout`

Set the total transmission timeout, in seconds.

`ascii`

Shorthand for mode `ascii`.

`binary`

Shorthand for mode `binary`.

`? [ command-name ... ]`

Print help information.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`in.tftpd(1M)`, `hosts(4)`, `ipnodes(4)`, `attributes(5)`, `inet(7P)`, `inet6(7P)`

**NOTES**

The default *transfer-mode* is `ascii`. This differs from pre-SunOS 4.0 and pre-4.3BSD systems, so explicit action must be taken when transferring non-ASCII binary files such as executable commands.

Because there is no user-login or validation within the TFTP protocol, many remote sites restrict file access in various ways. Approved methods for file access are specific to each site, and therefore cannot be documented here.

When using the `get` command to transfer multiple files from a remote host, three or more files must be specified. If two files are specified, the second file is used as a local file.

| <b>NAME</b>        | time – time a simple command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>time</b> [-p] <i>utility</i> [ <i>argument</i> .. ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <code>time</code> utility invokes <i>utility</i> operand with <i>argument</i>, and writes a message to standard error that lists timing statistics for <i>utility</i>. The message includes the following information:</p> <ul style="list-style-type: none"> <li>■ The elapsed (real) time between invocation of <i>utility</i> and its termination.</li> <li>■ The User CPU time, equivalent to the sum of the <code>tms_utime</code> and <code>tms_cstime</code> fields returned by the <code>times(2)</code> function for the process in which <i>utility</i> is executed.</li> <li>■ The System CPU time, equivalent to the sum of the <code>tms_stime</code> and <code>tms_cstime</code> fields returned by the <code>times()</code> function for the process in which <i>utility</i> is executed.</li> </ul> <p>When <code>time</code> is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities <code>a</code> and <code>c</code>, respectively.</p> <pre style="margin-left: 2em;">time a   b   c { time a }   b   c a   b   time c a   b   (time c)</pre> |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <p>-p Write the timing output to standard error in the following format:</p> <pre style="margin-left: 2em;">real %f\nuser %f\nsys %f\n &lt; real seconds&gt; , &lt;user seconds&gt; , &lt;system seconds&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>utility</i> The name of the utility that is to be invoked.</p> <p><i>argument</i> Any string to be supplied as an argument when invoking <i>utility</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>USAGE</b>       | <p>The <code>time</code> utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**EXAMPLES****EXAMPLE 1** Using The `time` Command

It is frequently desirable to apply `time` to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the `time` applies to everything in the file.

Alternatively, the following command can be used to apply `time` to a complex command:

```
time sh -c 'complex-command-line'
```

**EXAMPLE 2** Using `time` In The `cs` Shell

The following two examples show the differences between the `cs` version of `time` and the version in `/usr/bin/time`. These examples assume that `cs` is the shell in use.

```
example% time find / -name csh.1 -print
/usr/share/man/man1/csh.1
95.0u 692.0s 1:17:52 16% 0+0k 0+0io 0pf+0w
```

See `cs(1)` for an explanation of the format of `time` output.

```
example% /usr/bin/time find / -name csh.1 -print
/usr/share/man/man1/csh.1
real 1:23:31.5
user 1:33.2
sys 11:28.2
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `time`: `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, `NLSPATH`, and `PATH`.

**EXIT STATUS**

If `utility` is invoked, the exit status of `time` will be the exit status of `utility`; otherwise, the `time` utility will exit with one of the following values:

1-125           An error occurred in the `time` utility.  
126             `utility` was found but could not be invoked.  
127             `utility` could not be found.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`cs(1)`, `shell_builtins(1)`, `timex(1)`, `times(2)`, `attributes(5)`, `environ(5)`

**NOTES**

When the time command is run on a multiprocessor machine, the total of the values printed for `user` and `sys` can exceed `real`. This is because on a multiprocessor machine it is possible to divide the task between the various processors.

When the command being timed is interrupted, the timing values displayed may not always be accurate.

**BUGS**

Elapsed time is accurate to the second, while the CPU times are measured to the 100th second. Thus the sum of the CPU times can be up to a second larger than the elapsed time.

**NAME** times – shell built-in function to report time usages of the current shell

**SYNOPSIS**

**sh** **times**

**ksh** **times**

**DESCRIPTION**

**sh** Print the accumulated user and system times for processes run from the shell.

**ksh** Print the accumulated user and system times for the shell and for processes run from the shell.

On this man page, `ksh(1)` commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

| <b>NAME</b>        | timex - time a command; report process data and system activity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>timex</b> [-o] [-p [-fhkmrt] ] [-s] <i>command</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The given <code>command</code> is executed; the elapsed time, user time and system time spent in execution are reported in seconds. Optionally, process accounting data for the <code>command</code> and all its children can be listed or summarized, and total system activity during the execution interval can be reported.</p> <p>The output of <code>timex</code> is written on standard error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-o Report the total number of blocks read or written and total characters transferred by <code>command</code> and all its children. This option works only if the process accounting software is installed.</li> <li>-p List process accounting records for <code>command</code> and all its children. This option works only if the process accounting software is installed. Suboptions <code>f</code>, <code>h</code>, <code>k</code>, <code>m</code>, <code>r</code>, and <code>t</code> modify the data items reported. The options are as follows: <ul style="list-style-type: none"> <li>-f Print the <code>fork(2)</code>/<code>exec(2)</code> flag and system exit status columns in the output.</li> <li>-h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This "hog factor" is computed as (total CPU time)/(elapsed time).</li> <li>-k Instead of memory size, show total kcore-minutes.</li> <li>-m Show mean core size (the default).</li> <li>-r Show CPU factor (user time/(system-time + user-time)).</li> <li>-t Show separate system and user CPU times. The number of blocks read or written and the number of characters transferred are always reported.</li> </ul> </li> <li>-s Report total system activity (not just that due to <code>command</code>) that occurred during the execution interval of <code>command</code>. All the data items listed in <code>sar(1)</code> are reported.</li> </ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of <code>timex</code>.</p> <p>A simple example:</p> <pre>example% timex -ops sleep 60</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

A terminal session of arbitrary complexity can be measured by timing a sub-shell:

```
example% timex -opskmt sh
 session commands
EOT
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWaccu        |

**SEE ALSO**

`sar(1)`, `time(1)`, `exec(2)`, `fork(2)`, `times(2)`, `attributes(5)`

**NOTES**

Process records associated with `command` are selected from the accounting file `/var/adm/pacct` by inference, since process genealogy is not available. Background processes having the same user ID, terminal ID, and execution time window will be spuriously included.

| <b>NAME</b>        | tip - connect to remote system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>tip</b> [-v] [-speed-entry] {hostname   phone-number   device}                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>tip</code> utility establishes a full-duplex terminal connection to a remote host. Once the connection is established, a remote session using <code>tip</code> behaves like an interactive session on a local terminal.</p> <p>The <code>remote</code> file contains entries describing remote systems and line speeds used by <code>tip</code>.</p> <p>Each host has a default baud rate for the connection, or you can specify a speed with the <code>-speed-entry</code> command line argument.</p> <p>When <code>phone-number</code> is specified, <code>tip</code> looks for an entry in the <code>remote</code> file of the form:</p> <pre>tip -speed-entry</pre> <p>When it finds such an entry, it sets the connection speed accordingly. If it finds no such entry, <code>tip</code> interprets <code>-speed-entry</code> as if it were a system name, resulting in an error message.</p> <p>If you omit <code>-speed-entry</code>, <code>tip</code> uses the <code>tip0</code> entry to set a speed for the connection.</p> <p>When <code>device</code> is specified, <code>tip</code> attempts to open that device, but will do so using the access privileges of the user, rather than <code>tip</code>'s usual access privileges (<code>setuid uucp</code>). The user must have read/write access to the device. The <code>tip</code> utility interprets any character string beginning with the slash character (<code>/</code>) as a device name.</p> <p>When establishing the connection <code>tip</code> sends a connection message to the remote system. The default value for this message can be found in the <code>remote</code> file.</p> <p>When <code>tip</code> attempts to connect to a remote system, it opens the associated device with an exclusive-open <code>ioctl(2)</code> call. Thus only one user at a time may access a device. This is to prevent multiple processes from sampling the terminal line. In addition, <code>tip</code> honors the locking protocol used by <code>uucp(1C)</code>.</p> <p>When <code>tip</code> starts up it reads commands from the file <code>.tiprc</code> in your home directory.</p> |
| <b>OPTIONS</b>     | <code>-v</code> Display commands from the <code>.tiprc</code> file as they are executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>USAGE</b>       | Typed characters are normally transmitted directly to the remote machine (which does the echoing as well).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Commands

At any time that `tip` prompts for an argument (for example, during setup of a file transfer) the line typed may be edited with the standard erase and kill characters. A null line in response to a prompt, or an interrupt, aborts the dialogue and returns you to the remote machine.

A tilde ( `~` ) appearing as the first character of a line is an escape signal which directs `tip` to perform some special action. `tip` recognizes the following escape sequences:

`~^D`

`~.`

Drop the connection and exit (you may still be logged in on the remote machine).

`~c [name]`

Change directory to *name* (no argument implies change to your home directory).

`~!`

Escape to an interactive shell on the local machine (exiting the shell returns you to `tip`).

`~>`

Copy file from local to remote.

`~<`

Copy file from remote to local.

`~p from [ to ]`

Send a file to a remote host running the UNIX system. When you use the `put` command, the remote system runs the command string

```
cat > to
```

while `tip` sends it the *from* file. If the *to* file is not specified, the *from* file name is used. This command is actually a UNIX-system-specific version of the '`~>`' command.

`~t from [ to ]`

Take a file from a remote host running the UNIX system. As in the `put` command the *to* file defaults to the *from* file name if it is not specified. The remote host executes the command string

```
cat from ; echo ^A
```

to send the file to `tip`.

`~|`

Pipe the output from a remote command to a local process. The command string sent to the local system is processed by the shell.

`~C`

Connect a program to the remote machine. The command string sent to the program is processed

|     |                                                                                                                                                                                                                                                     |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     | by the shell. The program inherits file descriptors 0 as remote line input, 1 as remote line output, and 2 as tty standard error.                                                                                                                   |
| ~\$ | Pipe the output from a local process to the remote host. The command string sent to the local system is processed by the shell.                                                                                                                     |
| ~#  | Send a BREAK to the remote system.                                                                                                                                                                                                                  |
| ~s  | Set a variable (see the discussion below).                                                                                                                                                                                                          |
| ~^Z | Stop <code>tip</code> (only available when run under a shell that supports job control, such as the C shell).                                                                                                                                       |
| ~^Y | Stop only the "local side" of <code>tip</code> (only available when run under a shell that supports job control, such as the C shell); the "remote side" of <code>tip</code> , the side that displays output from the remote host, is left running. |
| ~?  | Get a summary of the tilde escapes.                                                                                                                                                                                                                 |

Copying files requires some cooperation on the part of the remote host. When a `~>` or `~<` escape is used to send a file, `tip` prompts for a file name (to be transmitted or received) and a command to be sent to the remote system, in case the file is being transferred from the remote system. While `tip` is transferring a file the number of lines transferred will be continuously displayed on the screen. A file transfer may be aborted with an interrupt.

#### Auto-call Units

`tip` may be used to dial up remote systems using a number of auto-call unit's (ACU's). When the remote system description contains the `du` capability, `tip` uses the call-unit (`cu`), ACU type (`at`), and phone numbers (`pn`) supplied. Normally `tip` displays verbose messages as it dials.

Depending on the type of auto-dialer being used to establish a connection the remote host may have garbage characters sent to it upon connection. The user should never assume that the first characters typed to the foreign host are the first ones presented to it. The recommended practice is to immediately type a `kill` character upon establishing a connection (most UNIX systems either support `@` or `CTRL-U` as the initial kill character).

`tip` currently supports the Ventel MD-212+ modem and DC Hayes-compatible modems.

When `tip` initializes a Hayes-compatible modem for dialing, it sets up the modem to auto-answer. Normally, after the conversation is complete, `tip` drops DTR, which causes the modem to "hang up."

Most modems can be configured such that when DTR drops, they re-initialize themselves to a preprogrammed state. This can be used to reset the modem and disable auto-answer, if desired.

Additionally, it is possible to start the phone number with a Hayes S command so that you can configure the modem before dialing. For example, to disable auto-answer, set up all the phone numbers in `/etc/remote` using something like `pn=S0=0DT5551212`. The `S0=0` disables auto-answer.

**Remote Host  
Description**

Descriptions of remote hosts are normally located in the system-wide file `/etc/remote`. However, a user may maintain personal description files (and phone numbers) by defining and exporting the REMOTE shell variable. The `remote` file must be readable by `tip`, but a secondary file describing phone numbers may be maintained readable only by the user. This secondary phone number file is `/etc/phones`, unless the shell variable PHONES is defined and exported. The phone number file contains lines of the form:

*system-name phone-number*

Each phone number found for a system is tried until either a connection is established, or an end of file is reached. Phone numbers are constructed from `'0123456789-=*'`, where the '=' and '\*' are used to indicate a second dial tone should be waited for (ACU dependent).

**tip Internal Variables**

`tip` maintains a set of variables which are used in normal operation. Some of these variables are read-only to normal users (root is allowed to change anything of interest). Variables may be displayed and set through the `~s` escape. The syntax for variables is patterned after `vi(1)` and `mail(1)`. Supplying `all` as an argument to the `~s` escape displays all variables that the user can read. Alternatively, the user may request display of a particular variable by attaching a ? to the end. For example `'~s escape?'` displays the current escape character.

Variables are numeric (num), string (str), character (char), or Boolean (bool) values. Boolean variables are set merely by specifying their name. They may be reset by prepending a ! to the name. Other variable types are set by appending an = and the value. The entire assignment must not have any blanks in it. A single set command may be used to interrogate as well as set a number of variables.

Variables may be initialized at run time by placing set commands (without the `~s` prefix) in a `.tiprc` file in one's home directory. The `-v` option makes `tip` display the sets as they are made. Comments preceded by a # sign can appear in the `.tiprc` file.

Finally, the variable names must either be completely specified or an abbreviation may be given. The following list details those variables known to `tip`.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| beautify    | (bool) Discard unprintable characters when a session is being scripted; abbreviated <code>be</code> . If the <code>nb</code> capability is present, <code>beautify</code> is initially set to <code>off</code> ; otherwise, <code>beautify</code> is initially set to <code>on</code> .                                                                                                                                                                                                                |
| baudrate    | (num) The baud rate at which the connection was established; abbreviated <code>ba</code> . If a baud rate was specified on the command line, <code>baudrate</code> is initially set to the specified value; otherwise, if the <code>br</code> capability is present, <code>baudrate</code> is initially set to the value of that capability; otherwise, <code>baudrate</code> is set to 300 baud. Once <code>tip</code> has been started, <code>baudrate</code> can only be changed by the super-user. |
| dialtimeout | (num) When dialing a phone number, the time (in seconds) to wait for a connection to be established; abbreviated <code>dial</code> . <code>dialtimeout</code> is initially set to 60 seconds, and can only be changed by the super-user.                                                                                                                                                                                                                                                               |
| disconnect  | (str) The string to send to the remote host to disconnect from it; abbreviated <code>di</code> . If the <code>di</code> capability is present, <code>disconnect</code> is initially set to the value of that capability; otherwise, <code>disconnect</code> is set to a null string ("").                                                                                                                                                                                                              |
| echocheck   | (bool) Synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted; abbreviated <code>ec</code> . If the <code>ec</code> capability is present, <code>echocheck</code> is initially set to <code>on</code> ; otherwise, <code>echocheck</code> is initially set to <code>off</code> .                                                                                                                                                              |
| eofread     | (str) The set of characters which signify an end-of-transmission during a <code>~&lt;</code> file transfer command; abbreviated <code>eofr</code> . If the <code>ie</code> capability is present, <code>eofread</code> is initially set to the value of that capability; otherwise, <code>eofread</code> is set to a null string ("").                                                                                                                                                                 |
| eofwrite    | (str) The string sent to indicate end-of-transmission during a <code>~&gt;</code> file transfer command; abbreviated <code>eofw</code> . If the <code>oe</code> capability is present, <code>eofread</code> is initially set to the value of that capability; otherwise, <code>eofread</code> is set to a null string ("").                                                                                                                                                                            |
| eol         | (str) The set of characters which indicate an end-of-line. <code>tip</code> will recognize escape characters only after an end-of-line. If the <code>e1</code> capability is present, <code>eol</code> is initially set to the value of that capability; otherwise, <code>eol</code> is set to a null string ("").                                                                                                                                                                                     |

|              |                                                                                                                                                                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| escape       | (char) The command prefix (escape) character; abbreviated <code>es</code> . If the <code>es</code> capability is present, <code>escape</code> is initially set to the value of that capability; otherwise, <code>escape</code> is set to <code>'~'</code> .                                                                                        |
| etimeout     | (num) The amount of time, in seconds, that <code>tip</code> should wait for the echo-check response when <code>echocheck</code> is set; abbreviated <code>et</code> . If the <code>et</code> capability is present, <code>etimeout</code> is initially set to the value of that capability; otherwise, <code>etimeout</code> is set to 10 seconds. |
| exceptions   | (str) The set of characters which should not be discarded due to the beautification switch; abbreviated <code>ex</code> . If the <code>ex</code> capability is present, <code>exceptions</code> is initially set to the value of that capability; otherwise, <code>exceptions</code> is set to <code>'\t\n\f\b'</code> .                           |
| force        | (char) The character used to force literal data transmission; abbreviated <code>fo</code> . If the <code>fo</code> capability is present, <code>force</code> is initially set to the value of that capability; otherwise, <code>force</code> is set to <code>\377</code> (which disables it).                                                      |
| framesize    | (num) The amount of data (in bytes) to buffer between file system writes when receiving files; abbreviated <code>fr</code> . If the <code>fs</code> capability is present, <code>framesize</code> is initially set to the value of that capability; otherwise, <code>framesize</code> is set to 1024.                                              |
| halfduplex   | (bool) Do local echoing because the host is half-duplex; abbreviated <code>hdx</code> . If the <code>hd</code> capability is present, <code>halfduplex</code> is initially set to <code>on</code> ; otherwise, <code>halfduplex</code> is initially set to <code>off</code> .                                                                      |
| hardwareflow | (bool) Do hardware flow control; abbreviated <code>hf</code> . If the <code>hf</code> capability is present, <code>hardwareflow</code> is initially set to <code>on</code> ; otherwise, <code>hardwareflowcontrol</code> is initially set to <code>off</code> .                                                                                    |
| host         | (str) The name of the host to which you are connected; abbreviated <code>ho</code> . <code>host</code> is permanently set to the name given on the command line or in the <code>HOST</code> environment variable.                                                                                                                                  |
| localecho    | (bool) A synonym for <code>halfduplex</code> ; abbreviated <code>le</code> .                                                                                                                                                                                                                                                                       |
| log          | (str) The name of the file to which to log information about outgoing phone calls. <code>log</code> is initially set to <code>/var/adm/aculog</code> , and can only be inspected or changed by the super-user.                                                                                                                                     |
| parity       | (str) The parity to be generated and checked when talking to the remote host; abbreviated <code>par</code> . The possible values are:                                                                                                                                                                                                              |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>none&gt;</p> <p>zero Parity is not checked on input, and the parity bit is set to zero on output.</p> <p>one Parity is not checked on input, and the parity bit is set to one on output.</p> <p>even Even parity is checked for on input and generated on output.</p> <p>odd Odd parity is checked for on input and generated on output.</p>                                                                                                         |
|           | <p>If the <code>pa</code> capability is present, <code>parity</code> is initially set to the value of that capability; otherwise, <code>parity</code> is set to <code>none</code>.</p>                                                                                                                                                                                                                                                                  |
| phones    | <p>The file in which to find hidden phone numbers. If the environment variable <code>PHONES</code> is set, <code>phones</code> is set to the value of <code>PHONES</code>; otherwise, <code>phones</code> is set to <code>/etc/phones</code>. The value of <code>phones</code> cannot be changed from within <code>tip</code>.</p>                                                                                                                      |
| prompt    | <p>(char) The character which indicates an end-of-line on the remote host; abbreviated <code>pr</code>. This value is used to synchronize during data transfers. The count of lines transferred during a file transfer command is based on receipt of this character. If the <code>pr</code> capability is present, <code>prompt</code> is initially set to the value of that capability; otherwise, <code>prompt</code> is set to <code>\n</code>.</p> |
| raise     | <p>(bool) Upper case mapping mode; abbreviated <code>ra</code>. When this mode is enabled, all lower case letters will be mapped to upper case by <code>tip</code> for transmission to the remote machine. If the <code>ra</code> capability is present, <code>raise</code> is initially set to <code>on</code>; otherwise, <code>raise</code> is initially set to <code>off</code>.</p>                                                                |
| raisechar | <p>(char) The input character used to toggle upper case mapping mode; abbreviated <code>rc</code>. If the <code>rc</code> capability is present, <code>raisechar</code> is initially set to the value of that capability; otherwise, <code>raisechar</code> is set to <code>\377</code> (which disables it).</p>                                                                                                                                        |
| rawftp    | <p>(bool) Send all characters during file transfers; do not filter non-printable characters, and do not do translations like <code>\n</code> to <code>\r</code>. Abbreviated <code>raw</code>. If the <code>rw</code> capability is present,</p>                                                                                                                                                                                                        |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <code>rawftp</code> is initially set to <code>on</code> ; otherwise, <code>rawftp</code> is initially set to <code>off</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>record</code>    | (str) The name of the file in which a session script is recorded; abbreviated <code>rec</code> . If the <code>re</code> capability is present, <code>record</code> is initially set to the value of that capability; otherwise, <code>record</code> is set to <code>tip.record</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>remote</code>    | The file in which to find descriptions of remote systems. If the environment variable <code>REMOTE</code> is set, <code>remote</code> is set to the value of <code>REMOTE</code> ; otherwise, <code>remote</code> is set to <code>/etc/remote</code> . The value of <code>remote</code> cannot be changed from within <code>tip</code> .                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>script</code>    | (bool) Session scripting mode; abbreviated <code>sc</code> . When <code>script</code> is <code>on</code> , <code>tip</code> will record everything transmitted by the remote machine in the script record file specified in <code>record</code> . If the <code>beautify</code> switch is <code>on</code> , only printable ASCII characters will be included in the script file (those characters between 040 and 0177). The variable <code>exceptions</code> is used to indicate characters which are an exception to the normal beautification rules. If the <code>sc</code> capability is present, <code>script</code> is initially set to <code>on</code> ; otherwise, <code>script</code> is initially set to <code>off</code> . |
| <code>tabexpand</code> | (bool) Expand TAB characters to SPACE characters during file transfers; abbreviated <code>tab</code> . When <code>tabexpand</code> is <code>on</code> , each <code>tab</code> is expanded to 8 SPACE characters. If the <code>tb</code> capability is present, <code>tabexpand</code> is initially set to <code>on</code> ; otherwise, <code>tabexpand</code> is initially set to <code>off</code> .                                                                                                                                                                                                                                                                                                                                 |
| <code>tandem</code>    | (bool) Use XON/XOFF flow control to limit the rate that data is sent by the remote host; abbreviated <code>ta</code> . If the <code>nt</code> capability is present, <code>tandem</code> is initially set to <code>off</code> ; otherwise, <code>tandem</code> is initially set to <code>on</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>verbose</code>   | (bool) Verbose mode; abbreviated <code>verb</code> ; When verbose mode is enabled, <code>tip</code> prints messages while dialing, shows the current number of lines transferred during a file transfer operations, and more. If the <code>nv</code> capability is present, <code>verbose</code> is initially set to <code>off</code> ; otherwise, <code>verbose</code> is initially set to <code>on</code> .                                                                                                                                                                                                                                                                                                                        |
| <code>SHELL</code>     | (str) The name of the shell to use for the <code>~!</code> command; default value is <code>/bin/sh</code> , or taken from the environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>HOME</code>      | (str) The home directory to use for the <code>~c</code> command; default value is taken from the environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**EXAMPLES****EXAMPLE 1** An example of `tip`.

An example of the dialogue used to transfer files is given below.

```

arpa% tip monet
[connected]
... (assume we are talking to a UNIX system)...
ucbmonet login: sam
Password:
monet% cat sylvester.c
~> Filename: sylvester.c
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~< Filename: reply.c
List command for remote host: cat reply.c
65 lines transferred in 2 minutes
monet%
... (or, equivalently)...
monet% ~p sylvester.c
... (actually echoes as ~[put] sylvester.c)...
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~t reply.c
... (actually echoes as ~[take] reply.c)...
65 lines transferred in 2 minutes
monet%
... (to print a file locally)...
monet% ~|Local command: pr h sylvester.c | lpr
List command for remote host: cat sylvester.c
monet% ~^D
[EOT]
... (back on the local system)...

```

**ENVIRONMENT  
VARIABLES**The following environment variables are read by `tip`.**REMOTE** The location of the remote file.**PHONES** The location of the file containing private phone numbers.**HOST** A default host to connect to.**HOME** One's log-in directory (for `chdirs`).**SHELL** The shell to fork on a '~!' escape.**FILES**`/etc/phones``/etc/remote``/var/spool/locks/LCK.*`lock file to avoid conflicts with  
UUCP`/var/adm/aculog`file in which outgoing calls  
are logged`~/ .tiprc`

initialization file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`cu(1C)`, `mail(1)`, `uucp(1C)`, `vi(1)`, `ioctl(2)`, `attributes(5)`

**BUGS**

There are two additional variables `chardelay` and `linedelay` that are currently not implemented.

**NAME** tnfdump - convert binary TNF file to ASCII

**SYNOPSIS** **tnfdump** [-r] *tnf\_file...*

**DESCRIPTION** The `tnfdump` utility converts the specified binary TNF trace files to ASCII. The ASCII output can be used to do performance analysis. The default mode (without the `-r` option) prints all the event records (that were generated by `TNF_PROBE(3TNF)`) and the event descriptor records only. It also orders the events by time.

**OPTIONS** The following option is supported:

`-r` Does a raw conversion of TNF to ASCII. The output is a literal translation of the binary TNF file and includes all the records in the file. This output is useful only if you have a good understanding of TNF. A sample output is listed in **EXAMPLES** below.

**RETURN VALUES** `tnfdump` returns 0 on successful exit.

**EXAMPLES** **EXAMPLE 1** Examples of the `tnfdump` command

To convert the file `/tmp/trace-2130` into ASCII, use the `tnfdump` command and the name of the binary trace file. Be aware that the `tnfdump` output goes to `stdout` by default.

```
example% tnfdump /tmp/trace-2130
```

```
probe tnf_name: "inloop" tnf_string: "keys cookie main loop;\
 file cookie2.c;line 50;sunw%debug in the loop"
probe tnf_name: "end" tnf_string: "keys cookie main end;\
 file cookie2.c;line 41;sunw%debug exiting program"
```

```

All probes that are encountered during execution have a description of it printed out. The description is one per line prefixed by the keyword 'probe'. The name of the probe is in double quotes after the keyword 'tnf\_name'. The description of this probe is in double quotes after the keyword 'tnf\_string'.

A heading is printed after all the description of the probes are printed. The first column gives the elapsed time in milli-seconds since the first event. The second column gives the elapsed time in milli-seconds since the previous event. The next four columns are the process id, lwp id, thread id, and cpu number. The next column is the name of the probe that generated this event. This can be matched to the probe description explained above. The last column is the data that the event contains formatted as `arg_name_n` (see `TNF_PROBE(3TNF)`) followed by a colon and the value of that argument. The format of the value depends on its type: `tnf_opaque` arguments are printed in hex; all other integers are printed in decimal; strings are printed in double quotes; and user-defined records are enclosed in braces '{}'. The first field of a user defined record indicates its TNF type (see `TNF_DECLARE_RECORD(3TNF)`) and the rest of the fields are the members of the record.

A '-' in any column indicates that there is no data for that particular column.

To do a raw conversion of the file `/tmp/trace-4000` into ASCII use:

```
example% tnfdump -r /tmp/trace-4000
```

The output will look like the following:

```

0x10e00 : {
 tnf_tag 0x109c0 tnf_block_header

 }

```

The first number is the file offset of the record. The record is enclosed in braces '{ }'. The first column in a record is the slot name (for records whose fields do not have names, it is the type name). The second column in the record is the value of that slot if it is a scalar (only scalars that are of type `tnf_opaque` are printed in hex), or the offset of the record if it is a reference to another record.

The third column in a record is optional. It does not exist for scalar slots of records. If it exists, the third column is a type name with or without angle brackets, or a string in double quotes. Unadorned names indicate a reference to the named metatag record (that is, a reference to a record with that name in the `tnf_name` field). Type names in angled brackets indicate a reference to a record that is an instance of that type (that is, a reference to a record with that name in the `tnf_tag` field). The content of strings are printed out in double quotes at the reference site.

Records that are arrays have their array elements follow the header slots, and are numbered 0, 1, 2, and so on, except strings where the string is written as the 'chars' (pseudo-name) slot.

Records that are events (generated by `TNF_PROBE(3TNF)`) will have a slot name of `tnf_tag_arg` as their second field which is a reference to the schedule record. Schedule records describe more information about the event like the thread-id, process-id, and the `time_base`. The `time_delta` of an event can be added to the `time_base` of the schedule record that the event references, to give an absolute time. This time is expressed as nanoseconds since some arbitrary time in the past (see `gethrtime(3C)`).

| <b>NAME</b>        | tnfextract – extract kernel probes output into a trace file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <b>tnfextract</b> [-d <i>dumpfile</i> -n <i>namelist</i> ] <i>tnf_file</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>tnfextract</code> utility collects kernel trace output from an in-core buffer in the Solaris kernel, or from the memory image of a crashed system, and generates a binary TNF trace file like those produced directly by user programs being traced.</p> <p>Either both or neither of the <code>-d</code> and <code>-n</code> options must be specified. If neither is specified, trace output is extracted from the running kernel. If both are specified, the <code>-d</code> argument names the file containing the (crashed) system memory image, and the <code>-n</code> argument names the file containing the symbol table for the system memory image.</p> <p>The TNF trace file <i>tnf_file</i> produced is exactly the same size as the in-core buffer; it is essentially a snapshot of that buffer. It is legal to run <code>tnfextract</code> while kernel tracing is active, i.e., while the in-core buffer is being written. <code>tnfextract</code> insures that the output file it generates is low-level consistent, i.e., that only whole probes are written out, and that internal data structures in the buffer are not corrupted because the buffer is being concurrently written.</p> <p>The TNF trace file generated is suitable as input to <code>tnfdump(1)</code>, which will generate an ASCII file.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-d <i>dumpfile</i></code>      Use <i>dumpfile</i> as the system memory image, instead of the running kernel. The <i>dumpfile</i> is normally the path name of a file generated by the <code>savecore</code> utility.</p> <p><code>-n <i>namelist</i></code>      Use <i>namelist</i> as the file containing the symbol table information for the given <i>dumpfile</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>tnf_file</i>            output file generated by <code>tnfextract</code> based on kernel trace output from an in-core buffer in the Solaris kernel.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>DESCRIPTION</b> | <p>The <code>touch</code> utility sets the access and modification times of each file. The <i>file</i> operand is created if it does not already exist.</p> <p>The time used can be specified by <code>-t <i>time</i></code>, by the corresponding time fields of the file referenced by <code>-r <i>ref_file</i></code>, or by the <i>date_time</i> operand. If none of these are specified, <code>touch</code> uses the current time (the value returned by the <code>time(2)</code> function).</p> <p>If neither the <code>-a</code> nor <code>-m</code> options are specified, <code>touch</code> updates both the modification and access times.</p> <p>The <code>settime</code> utility is equivalent to <code>touch -c</code>.</p>                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>touch</b>       | <p>The following options are supported for the <code>touch</code> utility:</p> <p><code>-a</code> Change the access time of <i>file</i>. Do not change the modification time unless <code>-m</code> is also specified.</p> <p><code>-c</code> Do not create a specified <i>file</i> if it does not exist. Do not write any diagnostic messages concerning this condition.</p> <p><code>-m</code> Change the modification time of <i>file</i>. Do not change the access time unless <code>-a</code> is also specified.</p> <p><code>-r</code><br/><i>ref_file</i> Use the corresponding times of the file named by <i>ref_file</i> instead of the current time.</p> <p><code>-t</code><br/><i>time</i> Use the specified <i>time</i> instead of the current time. <i>time</i> will be a decimal number of the form:</p> <p style="padding-left: 40px;">[[CC]YY]MMDDhhmm [.SS]</p> <p>where each two digits represents the following:</p> <p><i>MM</i> The month of the year [01-12].</p> <p><i>DD</i> The day of the month [01-31].</p> <p><i>hh</i> The hour of the day [00-23].</p> |

*mm* The minute of the hour [00-59].

*CC* The first two digits of the year.

*YY* The second two digits of the year.

*SS* The second of the minute [00-61].

Both *CC* and *YY* are optional. If neither is given, the current year will be assumed. If *YY* is specified, but *CC* is not, *CC* will be derived as follows:

| If <i>YY</i> is: | <i>CC</i> becomes: |
|------------------|--------------------|
| 69-99            | 19                 |
| 00-38            | 20                 |
| 39-68            | ERROR              |

The resulting time will be affected by the value of the `TZ` environment variable. If the resulting time value precedes the Epoch, `touch` will exit immediately with an error status. The range of valid times is the Epoch to January 18, 2038.

The range for *SS* is [00-61] rather than [00-59] because of leap seconds. If *SS* is 60 or 61, and the resulting time, as affected by the `TZ` environment variable, does not refer to a leap second, the resulting time will be one or two seconds after a time where *SS* is 59. If *SS* is not given, it is assumed to be 0.

#### **settime**

The following option is supported for the `settime` utility:

`-f` Use the corresponding times of the file named by *ref\_file* instead of the current time.

*ref\_file*

#### **OPERANDS**

The following operand is supported for the `touch` and `settime` utilities:

*file* A path name of a file whose times are to be modified.

#### **touch**

The following operand is supported for the `touch` utility:

*date\_time* Use the specified *date\_time* instead of the current time. This operand is a decimal number of the form:

*MMDDhhmm[YY]*

where each two digits represent the following:

*MM* The month of the year [01-12].

*DD* The day of the month [01-31].

*hh* The hour of the day [00-23].

*mm* The minute of the hour [00-59].

*YY* The second two digits of the year.

*YY* is optional. If it is omitted, the current year will be assumed. If *YY* is specified, the year will be derived as follows:

| <i>YY</i> | Corresponding Year |
|-----------|--------------------|
| 69-99     | 1969-1999          |
| 00-38     | 2000-2038          |
| 39-68     | ERROR              |

If no *-r* option is specified, no *-t* option is specified, at least two operands are specified, and the first operand is an eight- or ten-digit decimal integer, the first operand will be assumed to be a *date\_time* operand; otherwise, the first operand will be assumed to be a *file* operand.

#### USAGE

See `largefile(5)` for the description of the behavior of `touch` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

#### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `touch`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**TZ** Determine the timezone to be used for interpreting the *time* option-argument or the *date\_time* operand.

#### EXIT STATUS

The following exit values are returned:

0 The `touch` utility executed successfully and all requested changes were made.

>0 An error occurred. The `touch` utility returned the number of files for which the times could not be successfully modified.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO**

`time(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`

**NOTES**

Users familiar with the BSD environment will find that for the `touch` utility the `-f` option is accepted but ignored. The `-f` option is unnecessary because `touch` will succeed for all files owned by the user regardless of the permissions on the files.

| <b>NAME</b>        | touch – change file access and modification times                                                                                                                                                                                                                                                                                                             |                |                 |              |          |

**NAME** tplot, t300, t300s, t4014, t450, tek, ver – graphics filters for various plotters

**SYNOPSIS** /usr/bin/tplot [-T *terminal*]

**DESCRIPTION** tplot reads plotting instructions from the standard input and produces plotting instructions suitable for a particular *terminal* on the standard output.

If no *terminal* is specified, the environment variable TERM is used. The default *terminal* is tek.

**ENVIRONMENT VARIABLES** Except for ver, the following terminal-types can be used with 'lpr -g' (see lpr) to produce plotted output:

300 DASI 300 or GSI terminal (Diablo\256 mechanism).

300s | 300S DASI 300s terminal (Diablo mechanism).

450 DASI Hyterm 450 terminal (Diablo mechanism).

4014 | tek Tektronix 4014 and 4015 storage scope with Enhanced Graphics Module. (Use 4013 for Tektronix 4014 or 4015 without the Enhanced Graphics Module).

ver Versatec\256 D1200A printer-plotter. The output is scan-converted and suitable input to 'lpr -v'.

**FILES** /usr/lib/t300  
/usr/lib/t300s  
/usr/lib/t4014  
/usr/lib/t450  
/usr/lib/tek  
/usr/lib/vplot

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>        | tput - initialize a terminal or query terminfo database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>tput</b> [-T <i>type</i> ] <i>capname</i> [ <i>parm...</i> ]<br><b>tput</b> -S <<                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | tput uses the terminfo database to make the values of terminal-dependent capabilities and information available to the shell (see sh(1)); to clear, initialize or reset the terminal; or to return the long name of the requested terminal type. tput outputs a string if the capability attribute ( <i>capname</i> ) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, tput simply sets the exit status (0 for TRUE if the terminal has the capability, 1 for FALSE if it does not), and produces no output. Before using a value returned on standard output, the user should test the exit status (\$?, see sh(1)) to be sure it is 0. See the EXIT STATUS section. |
| <b>OPTIONS</b>     | The following options are supported:<br>-T <i>type</i> Indicates the <i>type</i> of terminal. Normally this option is unnecessary, because the default is taken from the environment variable TERM. If -T is specified, then the shell variables LINES and COLUMNS and the layer size will not be referenced.<br>-S              Allows more than one capability per invocation of tput. The capabilities must be passed to tput from the standard input instead of from the command line (see the example in the EXAMPLES section). Only one <i>capname</i> is allowed per line. The -S option changes the meaning of the 0 and 1 boolean and string exit statuses (see the EXIT STATUS section).                              |
| <b>OPERANDS</b>    | The following operands are supported:<br><i>capname</i> Indicates the capability attribute from the terminfo database. See terminfo(4) for a complete list of capabilities and the <i>capname</i> associated with each.<br>The following strings will be supported as operands by the implementation in the "C" locale:<br>clear            Display the clear-screen sequence.<br>init             If the terminfo database is present and an entry for the user's terminal exists (see -T <i>type</i> , above), the following will occur:<br>1. if present, the terminal's initialization strings will be output ( <i>is1</i> , <i>is2</i> , <i>is3</i> , <i>if</i> , <i>iprogram</i> ),                                       |

2. any delays (for instance, newline) specified in the entry will be set in the tty driver,
3. tabs expansion will be turned on or off according to the specification in the entry, and
4. if tabs are not expanded, standard tabs will be set (every 8 spaces). If an entry does not contain the information needed for any of the four above activities, that activity will silently be skipped.

`reset`

Instead of putting out initialization strings, the terminal's reset strings will be output if present (`rs1`, `rs2`, `rs3`, `rf`). If the reset strings are not present, but initialization strings are, the initialization strings will be output. Otherwise, `reset` acts identically to `init`.

`longname`

If the `terminfo` database is present and an entry for the user's terminal exists (see `-Ttype` above), then the long name of the terminal will be put out. The long name is the last name in the first line of the terminal's description in the `terminfo` database (see `term(5)`).

*parm*

If the attribute is a string that takes parameters, the argument *parm* will be instantiated into the string. An all numeric argument will be passed to the attribute as a number.

## EXAMPLES

**EXAMPLE 1** Using the `tput` command.

This example initializes the terminal according to the type of terminal in the environment variable `TERM`. This command should be included in everyone's `.profile` after the environment variable `TERM` has been exported, as illustrated on the `profile(4)` manual page.

```
example% tput init
```

The next example resets an AT&T 5620 terminal, overriding the type of terminal in the environment variable `TERM`:

```
example% tput -T5620 reset
```

The following example sends the sequence to move the cursor to row 0, column 0 (the upper left corner of the screen, usually known as the "home" cursor position).

```
example% tput cup 0 0
```

The next example echos the clear-screen sequence for the current terminal.

```
example% tput clear
```

The next command prints the number of columns for the current terminal.

```
example% tput cols
```

The following command prints the number of columns for the 450 terminal.

```
example% tput -T450 cols
```

The next example sets the shell variables `bold`, to begin stand-out mode sequence, and `offbold`, to end standout mode sequence, for the current terminal. This might be followed by a prompt:

```
echo "${bold}Please type in your name: ${offbold}\c"
```

```
example% bold='tput smso'
```

```
example% offbold='tput rmso'
```

This example sets the exit status to indicate if the current terminal is a hardcopy terminal.

```
example% tput hc
```

This next example sends the sequence to move the cursor to row 23, column 4.

```
example% tput cup 23 4
```

The next command prints the long name from the `terminfo` database for the type of terminal specified in the environment variable `TERM`.

```
example% tput longname
```

This last example shows `tput` processing several capabilities in one invocation. This example clears the screen, moves the cursor to position 10, 10 and turns on bold (extra bright) mode. The list is terminated by an exclamation mark (!) on a line by itself.

```
example% tput -S <<!
```

```
> clear
```

```
> cup 10 10
```

```
> bold
```

```
> !
```

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tput`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**TERM** Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, an unspecified default terminal type will be used.

## EXIT STATUS

The following exit values are returned:

- 0
  - If *capname* is of type boolean and `-S` is not specified, indicates TRUE.
  - If *capname* is of type string and `-S` is not specified, indicates *capname* is defined for this terminal type.
  - If *capname* is of type boolean or string and `-S` is specified, indicates that all lines were successful.

- *capname* is of type integer.
  - The requested string was written successfully.
- 1 ■ If *capname* is of type boolean and `-S` is not specified, indicates FALSE.
- If *capname* is of type string and `-S` is not specified, indicates that *capname* is not defined for this terminal type.
- 2 Usage error.
- 3 No information is available about the specified terminal type.
- 4 The specified operand is invalid.
- >4 An error occurred.
- 1 *capname* is a numeric variable that is not specified in the terminfo database; for instance, `tput -T450 lines` and `tput -T2621 xmc`.

**FILES**

`/usr/include/curses.h` curses(3CURSES) header

`/usr/include/term.h` terminfo header

`/usr/lib/tabset/*` tab settings for some terminals, in a format appropriate to be output to the terminal (escape sequences that set margins and tabs); for more information, see the "Tabs and Initialization" section of terminfo(4)

`/usr/share/lib/terminfo/?/*` compiled terminal description database

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>        | tr - translate characters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre> /usr/bin/tr [-cs] string1 string2 /usr/bin/tr -s   -d [-c] string1 /usr/bin/tr -ds [-c] string1 string2 /usr/xpg4/bin/tr [-cs] string1 string2 /usr/xpg4/bin/tr -s   -d [-c] string1 /usr/bin/xpg4/tr -ds [-c] string1 string2 </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>tr</code> utility copies the standard input to the standard output with substitution or deletion of selected characters. The options specified and the <i>string1</i> and <i>string2</i> operands control translations that occur while copying characters and single-character collating elements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c      Complement the set of characters specified by <i>string1</i>.</li> <li>-d      Delete all occurrences of input characters that are specified by <i>string1</i>.</li> <li>-s      Replace instances of repeated characters with a single character.</li> </ul> <p>When the <code>-d</code> option is not specified:</p> <ul style="list-style-type: none"> <li>■ Each input character found in the array specified by <i>string1</i> is replaced by the character in the same relative position in the array specified by <i>string2</i>. When the array specified by <i>string2</i> is shorter than the one specified by <i>string1</i>, the results are unspecified.</li> <li>■ If the <code>-c</code> option is specified, the complements of the characters specified by <i>string1</i> (the set of all characters in the current character set, as defined by the current setting of <code>LC_CTYPE</code>, except for those actually specified in the <i>string1</i> operand) are placed in the array in ascending collation sequence, as defined by the current setting of <code>LC_COLLATE</code>.</li> <li>■ Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.</li> </ul> <p>When the <code>-d</code> option is specified:</p> <ul style="list-style-type: none"> <li>■ Input characters found in the array specified by <i>string1</i> will be deleted.</li> <li>■ When the <code>-c</code> option is specified with <code>-d</code>, all characters except those specified by <i>string1</i> will be deleted. The contents of <i>string2</i> will be ignored, unless the <code>-s</code> option is also specified.</li> </ul> |

- The same string cannot be used for both the `-d` and the `-s` option; when both options are specified, both *string1* (used for deletion) and *string2* (used for squeezing) are required.

When the `-s` option is specified, after any deletions or translations have taken place, repeated sequences of the same character will be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

```
tr -s '[:space:]'
```

the last operand's array will contain all of the characters in that character class. However, in a case conversion, as described previously, such as

```
tr -s '[:upper:]' '[:lower:]'
```

the last operand's array will contain only those characters defined as the second characters in each of the `toupper` or `tolower` character pairs, as appropriate. (See `toupper(3C)` and `tolower(3C)`).

An empty string used for *string1* or *string2* produces undefined results.

## OPERANDS

The following operands are supported:

*string1*

*string2* Translation control strings. Each string represents a set of characters to be converted into an array of characters used for the translation.

The operands *string1* and *string2* (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, `tr` will exclude, without a diagnostic, those multi-character elements from the resulting array.

*character* Any character not described by one of the conventions below represents itself.

`\octal` Octal sequences can be used to represent characters with specific coded values. An octal sequence consists of a backslash followed by the longest sequence of one-, two-, or three-octal-digit characters (01234567). The sequence causes the character whose encoding is represented by the one-, two- or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `\` for each byte.

|                                 |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| /usr/xpg4/bin/tr<br>/usr/bin/tr | \ <i>character</i>   | The backslash-escape sequences \a, \b, \f, \n, \r, \t, and \v are supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                 | C-C                  | Represents the range of collating elements between the range endpoints, inclusive, as defined by the current setting of the LC_COLLATE locale category. The starting endpoint must precede the second endpoint in the current collation order. The characters or collating elements in the range are placed in the array in ascending collation sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                 | [ <i>c-c</i> ]       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                 | [ : <i>class</i> : ] | Represents all characters belonging to the defined character class, as defined by the current setting of the LC_CTYPE locale category. The following character class names will be accepted when specified in <i>string1</i> :<br><br><pre data-bbox="789 709 1271 753"> alnum blank digit lower punct upper alpha cntrl graph print space xdigit</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                 |                      | In addition, character class expressions of the form [ : <i>name</i> : ] are recognized in those locales where the <i>name</i> keyword has been given a charclass definition in the LC_CTYPE category.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                 |                      | When both the -d and -s options are specified, any of the character class names will be accepted in <i>string2</i> . Otherwise, only character class names lower or upper are valid in <i>string2</i> and then only if the corresponding character class upper and lower, respectively, is specified in the same relative position in <i>string1</i> . Such a specification is interpreted as a request for case conversion. When [ :lower: ] appears in <i>string1</i> and [ :upper: ] appears in <i>string2</i> , the arrays will contain the characters from the toupper mapping in the LC_CTYPE category of the current locale. When [ :upper: ] appears in <i>string1</i> and [ :lower: ] appears in <i>string2</i> , the arrays will contain the characters from the tolower mapping in the LC_CTYPE category of the current locale. The first character from each mapping pair will be in the array for <i>string1</i> and the second character from each mapping pair will be in the array for <i>string2</i> in the same relative position. |
|                                 |                      | Except for case conversion, the characters specified by a character class expression are placed in the array in an unspecified order.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

If the name specified for *class* does not define a valid character class in the current locale, the behavior is undefined.

[*=equiv=*] Represents all characters or collating elements belonging to the same equivalence class as *equiv*, as defined by the current setting of the LC\_COLLATE locale category. An equivalence class expression is allowed only in *string1*, or in *string2* when it is being used by the combined *-d* and *-s* options. The characters belonging to the equivalence class are placed in the array in an unspecified order.

[*x\*n*] Represents *n* repeated occurrences of the character *x*. Because this expression is used to map multiple characters to one, it is only valid when it occurs in *string2*. If *n* is omitted or is 0, it is interpreted as large enough to extend the *string2*-based sequence to the length of the *string1*-based sequence. If *n* has a leading 0, it is interpreted as an octal value. Otherwise, it is interpreted as a decimal value.

## USAGE

See `largefile(5)` for the description of the behavior of `tr` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

## EXAMPLES

**EXAMPLE 1** Creating a list of words

The following example creates a list of all words in *file1*, one per line in *file2*, where a word is taken to be a maximal string of letters.

```
tr -cs "[:alpha:]" "[\n*]" <file1 >file2
```

**EXAMPLE 2** Translating characters

This example translates all lower-case characters in *file1* to upper-case and writes the results to standard output.

```
tr "[:lower:]" "[:upper:]" <file1
```

Note that the caveat expressed in the corresponding example in XPG3 is no longer in effect. This case conversion is now a special case that employs the `tolower` and `toupper` classifications, ensuring that proper mapping is accomplished (when the locale is correctly defined).

**EXAMPLE 3** Identifying equivalent characters

This example uses an equivalence class to identify accented variants of the base character *e* in *file1*, which are stripped of diacritical marks and written to *file2*.

```
tr "[=e]" e <file1 >file2
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tr`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 All input was processed successfully.
- >0 An error occurred.

**ATTRIBUTES**

`/usr/bin/tr`

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

`/usr/xpg4/bin/tr`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |
| CSI            | Enabled         |

**SEE ALSO**

`ed(1)`, `sed(1)`, `sh(1)`, `tolower(3C)`, `toupper(3C)`, `ascii(5)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

**NOTES**

Unlike some previous versions, `/usr/xpg4/bin/tr` correctly processes NUL characters in its input stream. NUL characters can be stripped by using `tr -d '\000'`.

| <b>NAME</b>        | tr – translate characters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |          |

| <b>SYNOPSIS</b>    | <code>/usr/ucb/tr [-cds] [string1 [string2] ]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |          |
| <b>DESCRIPTION</b> | <p>The <code>tr</code> utility copies the standard input to the standard output with substitution or deletion of selected characters. The arguments <i>string1</i> and <i>string2</i> are considered sets of characters. Any input character found in <i>string1</i> is mapped into the character in the corresponding position within <i>string2</i>. When <i>string2</i> is short, it is padded to the length of <i>string1</i> by duplicating its last character.</p> <p>In either string the notation:</p> <p><i>a-b</i></p> <p>denotes a range of characters from <i>a</i> to <i>b</i> in increasing ASCII order. The character <code>\</code>, followed by 1, 2 or 3 octal digits stands for the character whose ASCII code is given by those digits. As with the shell, the escape character <code>\</code>, followed by any other character, escapes any special meaning for that character.</p> |                |                 |              |          |
| <b>OPTIONS</b>     | <p>Any combination of the options <code>-c</code>, <code>-d</code>, or <code>-s</code> may be used:</p> <p><code>-c</code>     Complement the set of characters in <i>string1</i> with respect to the universe of characters whose ASCII codes are 01 through 0377 octal.</p> <p><code>-d</code>     Delete all input characters in <i>string1</i>.</p> <p><code>-s</code>     Squeeze all strings of repeated output characters that are in <i>string2</i> to single characters.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |          |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b>    Creating a list of all the words in a filename</p> <p>The following example creates a list of all the words in <i>filename1</i>, one per line, in <i>filename2</i>, where a word is taken to be a maximal string of alphabetic characters. The second string is quoted to protect <code>\</code> from the shell. 012 is the ASCII code for NEWLINE.</p> <pre>example% tr -cs A-Za-z '\012' &lt;filename1&gt; filename2</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |          |

| <b>DESCRIPTION</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>sh</b>          | The <code>trap</code> command <i>argument</i> is to be read and executed when the shell receives numeric or symbolic signal(s) ( <i>n</i> ). (Note: <i>argument</i> is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If <i>argument</i> is absent all trap(s) <i>n</i> are reset to their original values. If <i>argument</i> is the null string this signal is ignored by the shell and by the commands it invokes. If <i>n</i> is 0 the command <i>argument</i> is executed on exit from the shell. The <code>trap</code> command with no arguments prints a list of commands associated with each signal number.                                                                                                                                                                                                                                                                                                  |
| <b>cs</b>          | <code>onintr</code> controls the action of the shell on interrupts. With no arguments, <code>onintr</code> restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the <code>-</code> argument, the shell ignores all interrupts. With a <i>label</i> argument, the shell executes a <code>goto label</code> when an interrupt is received or a child process terminates because it was interrupted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ksh</b>         | <code>trap</code> uses <i>arg</i> as a command to be read and executed when the shell receives signal(s) <i>sig</i> . (Note that <i>arg</i> is scanned once when the trap is set and once when the trap is taken.) Each <i>sig</i> can be given as a number or as the name of the signal. <code>trap</code> commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If <i>arg</i> is omitted or is <code>-</code> , then the trap(s) for each <i>sig</i> are reset to their original values. If <i>arg</i> is the null (the empty string, e.g., "" ) string then this signal is ignored by the shell and by the commands it invokes. If <i>sig</i> is <code>ERR</code> then <i>arg</i> will be executed whenever a command has a non-zero exit status. If <i>sig</i> is <code>DEBUG</code> then <i>arg</i> will be executed after each command. If <i>sig</i> is 0 or <code>EXIT</code> for a trap set outside any function then the command <i>arg</i> is executed on exit from the shell. The <code>trap</code> command with no arguments prints a list of commands associated with each signal number. |
|                    | On this man page, <code>ksh(1)</code> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

| <b>NAME</b>        | troff - typeset or format documents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>troff</b> [-a] [-f] [-Fdir] [-i] [-mname] [-nN] [-olist] [-raN] [-sN] [-Tdest] [-uN] [-z] [filename...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>troff formats text in the <i>filenames</i> for typesetting or laser printing. Input to troff is expected to consist of text interspersed with formatting requests and macros. If no <i>filename</i> argument is present, troff reads standard input. A minus sign (-) as a <i>filename</i> indicates that standard input should be read at that point in the list of input files.</p> <p>The output of troff is usually piped through dpost(1) to create a printable postscript file (see EXAMPLES).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported. They may appear in any order, but all must appear before the first <i>filename</i>.</p> <p>-a           Send an ASCII approximation of formatted output to standard output. (Note: a rough ASCII version can also be printed out on ordinary terminals with an old and rarely used command, /usr/bin/ta.)</p> <p>-f           Do not print a trailer after the final page of output or cause the postprocessor to relinquish control of the device.</p> <p>-Fdir       Search directory <i>dir</i> for font width or terminal tables instead of the system default directory.</p> <p>-i           Read standard input after all input files are exhausted.</p> <p>-mname      Prepend the macro file /usr/share/lib/tmac/<i>name</i> to the input <i>filenames</i>. Note: most references to macro packages include the leading <i>m</i> as part of the name; for example, the man(5) macros reside in /usr/share/lib/tmac/an. The macro directory can be changed by setting the TROFFMACS environment variable to a specific path. Be certain to include the trailing '/' (slash) at the end of the path.</p> <p>-nN         Number the first generated page <i>N</i>.</p> <p>-olist      Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; and a final <i>N-</i> means from <i>N</i> to the end.</p> <p>-q           Quiet mode in nroff; ignored in troff.</p> <p>-raN        Set register <i>a</i> (one-character names only) to <i>N</i>.</p> |

- `-sN` Stop the phototypesetter every *N* pages. On some devices, `troff` produces a trailer so you can change cassettes; resume by pressing the typesetter's start button.
- `-Tdest` Prepare output for typesetter *dest*. The following values can be supplied for *dest*:
- `post` A PostScript printer; this is the default value. The output of the `-T` option must go through `dpost(1)` before it is sent to a PostScript printer to obtain the proper output.
  - `aps` Autologic APS-5.
- `-uN` Set the emboldening factor for the font mounted in position 3 to *N*. If *N* is missing, then set the emboldening factor to 0.
- `-z` Suppress formatted output. Only diagnostic messages and messages output using the `.tm` request are output.

**OPERANDS**

The following operand is supported:

*filename* The file containing text to be processed by `troff`.

**EXAMPLES**

**EXAMPLE 1** Using `troff`

The following example shows how to print an input text file `mytext`, coded with formatting requests and macros. The input file contains equations and tables and must go through the `tbl(1)` and `eqn(1)` preprocessors before it is formatted by `troff` with `ms` macros, processed by `dpost(1)`, and printed by `lp(1)`:

```
tbl mytext | eqn | troff -ms | dpost | lp
```

**FILES**

|                                     |                                                                  |
|-------------------------------------|------------------------------------------------------------------|
| <code>/tmp/trtmp</code>             | temporary file                                                   |
| <code>/usr/share/lib/tmac/*</code>  | standard macro files                                             |
| <code>/usr/lib/font/*</code>        | font width tables for alternate mounted <code>troff</code> fonts |
| <code>/usr/share/lib/nterm/*</code> | terminal driving tables for <code>nroff</code>                   |

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**SEE ALSO**

**NOTES**

troff is not 8-bit clean because it is by design based on 7-bit ASCII.

Previous documentation incorrectly described the numeric register `yr` as being the "Last two digits of current year". `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in a document and subsequently used to display a two-digit year. Note that any other available one- or two-character register name may be substituted for `yy`.

```
.\" definition of new string register yy--last two digits of year
.\" use yr (# of years since 1900) if it is < 100
.ie \n(yr<100 .ds yy \n(yr
.el \{
 .\" else, subtract 100 from yr, store in ny
.nr ny \n(yr-100
.ie \n(ny>9 \{
 .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\" if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

**NAME** true, false – provide truth values

**SYNOPSIS** true  
false

**DESCRIPTION** true does nothing, successfully. false does nothing, unsuccessfully. They are typically used in a shell script sh as:

```
while truedo
 commanddone
```

which executes command forever.

**EXIT STATUS** true has exit status 0 .

false always will exit with a non-zero value.

| <b>NAME</b>        | truss - trace system calls and signals                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>truss</b> [-fcaeilD] [- [tTvX] [!] <i>syscall</i> , ... ] [- [sS] [!] <i>signal</i> , ... ] [- [mM] [!] <i>fault</i> , ... ] [- [rw] [!] <i>fd</i> , ... ] [- [uU] [!] <i>lib</i> , ... : [:] [!] <i>func</i> , ... ] [-o <i>outfile</i> ] <i>command</i>   -p <i>pid</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>truss</code> utility executes the specified command and produces a trace of the system calls it performs, the signals it receives, and the machine faults it incurs. Each line of the trace output reports either the fault or signal name or the system call name with its arguments and return value(s). System call arguments are displayed symbolically when possible using defines from relevant system headers; for any path name pointer argument, the pointed-to string is displayed. Error returns are reported using the error code names described in <code>intro(3)</code>.</p> <p>Optionally (see the <code>-u</code> option), <code>truss</code> will also produce an entry/exit trace of user-level function calls executed by the traced process, indented to indicate nesting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are recognized. For those options that take a list argument, the name <code>all</code> can be used as a shorthand to specify all possible members of the list. If the list begins with a <code>!</code>, the meaning of the option is negated (for example, exclude rather than trace). Multiple occurrences of the same option may be specified. For the same name in a list, subsequent options (those to the right) override previous ones (those to the left).</p> <p><code>-p</code><br/>Interprets the <i>command</i> arguments to <code>truss</code> as a list of process-ids for existing processes (see <code>ps(1)</code>) rather than as a command to be executed. <code>truss</code> takes control of each process and begins tracing it provided that the <code>userid</code> and <code>groupid</code> of the process match those of the user or that the user is a privileged user. Processes may also be specified by their names in the <code>/proc</code> directory, for example, <code>/proc/12345</code>.</p> <p><code>-f</code><br/>Follows all children created by <code>fork()</code> or <code>vfork()</code> and includes their signals, faults, and system calls in the trace output. Normally, only the first-level command or process is traced. When <code>-f</code> is specified, the process-id is included with each line of trace output to indicate which process executed the system call or received the signal.</p> <p><code>-c</code><br/>Counts traced system calls, faults, and signals rather than displaying the trace line-by-line. A summary report is produced after the traced command terminates or when <code>truss</code> is interrupted. If <code>-f</code> is also specified, the counts include all traced system calls, faults, and signals for child processes.</p> <p><code>-a</code></p> |

- Shows the argument strings that are passed in each `exec( )` system call.
- `-e`  
Shows the environment strings that are passed in each `exec( )` system call.
- `-i`  
Do not display interruptible sleeping system calls. Certain system calls, such as `open( )` and `read( )` on terminal devices or pipes, can sleep for indefinite periods and are interruptible. Normally, `truss` reports such sleeping system calls if they remain asleep for more than one second. The system call is reported again a second time when it completes. The `-i` option causes such system calls to be reported only once, when they complete.
- `-l`  
Includes the id of the responsible lightweight process (*LWP*) with each line of trace output. If `-f` is also specified, both the process-id and the LWP-id are included.
- `-d`  
Includes a time stamp on each line of trace output. The time stamp appears as a field containing *seconds.fraction* at the start of the line. This represents a time in seconds relative to the beginning of the trace. The first line of the trace output will show the base time from which the individual time stamps are measured, both as seconds since the epoch (see `time(2)`) and as a date string (see `ctime(3C)` and `date(1)`). The times that are reported are the times that the event in question occurred. For all system calls, the event is the completion of the system call, not the start of the system call.
- `-D`  
Includes a time delta on each line of trace output. The value appears as a field containing *seconds.fraction* and represents the elapsed time for the LWP that incurred the event since the last reported event incurred by that LWP. Specifically, for system calls, this is not the time spent within the system call.
- `-t [!]syscall,...`  
System calls to trace or exclude. Those system calls specified in the comma-separated list are traced. If the list begins with a `!`, the specified system calls are excluded from the trace output. Default is `-tall`.
- `-T [!]syscall,...`  
System calls that stop the process. The specified system calls are added to the set specified by `-t`. If one of the specified system calls is encountered, `truss` leaves the process stopped and abandoned. That is, `truss` releases the process and exits but leaves the process in the stopped state at completion of the system call in question. A debugger or other process inspection tool (see `proc(1)`) can then be applied to the stopped process.

`truss` can be reapplied to the stopped process with the same or different options to continue tracing. Default is `-T!all`.

A process left stopped in this manner cannot be restarted by the application of `kill -CONT` because it is stopped on an event of interest via `/proc`, not by the default action of a stopping signal (see `signal(3HEAD)`). The `prun(1)` command described in `proc(1)` can be used to set the stopped process running again.

`-v [!]syscall,...`

Verbose. Displays the contents of any structures passed by address to the specified system calls (if traced by `-t`). Input values as well as values returned by the operating system are shown. For any field used as both input and output, only the output value is shown. Default is `-v!all`.

`-x [!]syscall,...`

Displays the arguments to the specified system calls (if traced by `-t`) in raw form, usually hexadecimal, rather than symbolically. This is for unredeemed hackers who must see the raw bits to be happy. Default is `-x!all`.

`-s [!]signal,...`

Signals to trace or exclude. Those signals specified in the comma-separated list are traced. The trace output reports the receipt of each specified signal, even if the signal is being ignored (not blocked). (Blocked signals are not received until they are unblocked.) Signals may be specified by name or number (see `<sys/signal.h>`). If the list begins with a `!`, the specified signals are excluded from the trace output. Default is `-s!all`.

`-S [!]signal,...`

Signals that stop the process. The specified signals are added to the set specified by `-s`. If one of the specified signals is received, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-S!all`.

`-m [!]fault,...`

Machine faults to trace or exclude. Those faults specified in the comma-separated list are traced. Faults may be specified by name or number (see `<sys/fault.h>`). If the list begins with a `!`, the specified faults are excluded from the trace output. Default is `-m!all -m!fltpage`.

`-M [!]fault,...`

Machine faults that stop the process. The specified faults are added to the set specified by `-m`. If one of the specified faults is incurred, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-M!all`.

`-r [!]fd,...`

Shows the full contents of the I/O buffer for each `read()` on any of the specified file descriptors. The output is formatted 32 bytes per line and

shows each byte as an ASCII character (preceded by one blank) or as a 2-character C language escape sequence for control characters such as horizontal tab (`\t`) and newline (`\n`). If ASCII interpretation is not possible, the byte is shown in 2-character hexadecimal representation. (The first 12 bytes of the I/O buffer for each traced `read()` are shown even in the absence of `-r`.) Default is `-r!all`.

`-w [!]fd,...`

Shows the contents of the I/O buffer for each `write()` on any of the specified file descriptors (see the `-r` option). Default is `-w!all`.

`-u [!]lib,...[:][!]func,...`

User-level function call tracing. `lib,...` is a comma-separated list of dynamic library names, excluding the `.so.n` suffix. `func,...` is a comma-separated list of function names. In both cases the names can include name-matching metacharacters `*,?,[ ]` with the same meanings as those of `sh(1)` but as applied to the library/function name spaces, not to files. An empty library or function list defaults to `*`, trace all libraries or functions in a library. A leading `!` on either list specifies an exclusion list, names of libraries or functions not to be traced. Excluding a library excludes all functions in that library; any function list following a library exclusion list is ignored.

A single `:` separating the library list from the function list means to trace calls into the libraries from outside the libraries, but omit calls made to functions in a library from other functions in the same library. A double `::` means to trace all calls, regardless of origin.

Library patterns do not match either the executable file or the dynamic linker unless there is an exact match (`l*` will not match `ld.so.1`). To trace functions in either of these objects, the names must be specified exactly, as in: `truss -u a.out -u ld ... a.out` is the literal name to be used for this purpose; it does not stand for the name of the executable file. Tracing `a.out` function calls implies all calls (default is `::`).

Multiple `-u` options may be specified and they are honored left-to-right. If the process is linked with `-lthread`, the id of the thread that performed the function call is included in the trace output for the call. `truss` searches the dynamic symbol table in each library to find function names and will also search the standard symbol table if it has not been stripped.

`-U [!]lib,...[:][!]func,...`

User-level function calls that stop the process. The specified functions are added to the set specified by `-u`. If one of the specified functions is called, `truss` leaves the process stopped and abandoned (see the `-T` option).

`-o outfile`

File to be used for the trace output. By default, the output goes to standard error.

See *man pages section 2: System Calls* for system call names accepted by the `-t`, `-T`, `-v`, and `-x` options. System call numbers are also accepted.

If `truss` is used to initiate and trace a specified command and if the `-o` option is used or if standard error is redirected to a non-terminal file, then `truss` runs with hangup, interrupt, and quit signals ignored. This facilitates tracing of interactive programs that catch interrupt and quit signals from the terminal.

If the trace output remains directed to the terminal, or if existing processes are traced (the `-p` option), then `truss` responds to hangup, interrupt, and quit signals by releasing all traced processes and exiting. This enables the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.

## EXAMPLES

### EXAMPLE 1 Tracing a command

This example produces a trace of the `find(1)` command on the terminal:

```
example$ truss find . -print >find.out
```

### EXAMPLE 2 Tracing common system calls

To see only a trace of the `open`, `close`, `read`, and `write` system calls:

```
example$ truss -t open,close,read,write find . -print >find.out
```

### EXAMPLE 3 Tracing a shell script

This produces a trace of the `spell(1)` command on the file `truss.out`:

```
example$ truss -f -o truss.out spell document
```

`spell` is a shell script, so the `-f` flag is needed to trace not only the shell but also the processes created by the shell. (The `spell` script runs a pipeline of eight processes.)

### EXAMPLE 4 Abbreviating output

A particularly boring example is:

```
example$ truss nroff -mm document >nroff.out
```

because 97% of the output reports `lseek()`, `read()`, and `write()` system calls. To abbreviate it:

```
example$ truss -t !lseek,read,write nroff -mm document >nroff.out
```

### EXAMPLE 5 Tracing library calls from outside the C library

This example traces all user-level calls made to any function in the C library from outside the C library:

```
example$ truss -u libc ...
```

**EXAMPLE 6** Tracing library calls from within the C library

This example includes calls made to functions in the C library from within the C library itself:

```
example$ truss -u libc:: ...
```

**EXAMPLE 7** Tracing library calls other than the C library

This example traces all user-level calls made to any library other than the C library:

```
example$ truss -u '*' -u !libc ...
```

**EXAMPLE 8** Tracing printf and scanf function calls

This example traces all user-level calls to functions in the printf and scanf family contained in the C library:

```
example$ truss -u 'libc:*printf,*scanf' ...
```

**EXAMPLE 9** Tracing any user-level function call

This example traces every user-level function call from anywhere to anywhere:

```
example$ truss -u a.out -u ld:: -u :: ...
```

**EXAMPLE 10** Tracing a system call verbosely

This example verbosely traces the system call activity of process #1, init(1M) (if you are a privileged user):

```
example# truss -p -v all 1
```

Interrupting truss returns init to normal operation.

**FILES**

/proc/\* process files

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | SUNWtoo (32-bit)  |
|                | SUNWtoox (64-bit) |

## NOTES

*man pages section 2: System Calls*

Some of the system calls described in *man pages section 2: System Calls* differ from the actual operating system interfaces. Do not be surprised by minor deviations of the trace output from the descriptions in that document.

Every machine fault (except a page fault) results in the posting of a signal to the LWP that incurred the fault. A report of a received signal will immediately follow each report of a machine fault (except a page fault) unless that signal is being blocked.

The operating system enforces certain security restrictions on the tracing of processes. In particular, any command whose object file (`a.out`) cannot be read by a user cannot be traced by that user; `set-uid` and `set-gid` commands can be traced only by a privileged user. Unless it is run by a privileged user, `truss` loses control of any process that performs an `exec()` of a set-id or unreadable object file; such processes continue normally, though independently of `truss`, from the point of the `exec()`.

To avoid collisions with other controlling processes, `truss` will not trace a process that it detects is being controlled by another process via the `/proc` interface. This allows `truss` to be applied to `proc(4)`-based debuggers as well as to another instance of itself.

The trace output contains tab characters under the assumption that standard tab stops are set (every eight positions).

The trace output for multiple processes or for a multithreaded process (one that contains more than one LWP) is not produced in strict time order. For example, a `read()` on a pipe may be reported before the corresponding `write()`. For any one LWP (a traditional process contains only one), the output is strictly time-ordered.

When tracing more than one process, `truss` runs as one controlling process for each process being traced. For the example of the `spell` command shown above, `spell` itself uses 9 process slots, one for the shell and 8 for the 8-member pipeline, while `truss` adds another 9 processes, for a total of 18.

Not all possible structures passed in all possible system calls are displayed under the `-v` option.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | tset, reset – establish or restore terminal characteristics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>tset [-InQrs] [-e c] [-k c] [-m [port-ID [baudrate]: type ...] ] [type] reset [-] [-e c] [-I] [-k c] [-n] [-Q] [-r] [-s] [-m [indent] [test baudrate]: type       ...] [type]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>tset</code> utility sets up your terminal, typically when you first log in. It does terminal dependent processing such as setting erase and kill characters, setting or resetting delays, sending any sequences needed to properly initialize the terminal, and the like. <code>tset</code> first determines the <code>type</code> of terminal involved, and then does necessary initializations and mode settings. If a port is not wired permanently to a specific terminal (not hardwired) it is given an appropriate generic identifier such as <code>dialup</code>.</p> <p><code>reset</code> clears the terminal settings by turning off CBREAK and RAW modes, output delays and parity checking, turns on NEWLINE translation, echo and TAB expansion, and restores undefined special characters to their default state. It then sets the modes as usual, based on the terminal type (which will probably override some of the above). See <code>stty(1)</code> for more information. All arguments to <code>tset</code> may be used with <code>reset</code>. <code>reset</code> also uses <code>rs=</code> and <code>rf=</code> to reset the initialization string and file. This is useful after a program dies and leaves the terminal in a funny state. Often in this situation, characters will not echo as you type them. You may have to type <code>LINEFEED reset LINEFEED</code> since <code>RETURN</code> may not work.</p> <p>When no arguments are specified, <code>tset</code> reads the terminal type from the <code>TERM</code> environment variable and re-initializes the terminal, and performs initialization of mode, environment and other options at login time to determine the terminal type and set up terminal modes.</p> <p>When used in a startup script (<code>.profile</code> for <code>sh(1)</code> users or <code>.login</code> for <code>csh(1)</code> users) it is desirable to give information about the type of terminal you will usually use on ports that are not hardwired. Any of the alternate generic names given in the file <code>/etc/termcap</code> are possible identifiers. Refer to the <code>-m</code> option below for more information. If no mapping applies and a final <code>type</code> option, not preceded by a <code>-m</code>, is given on the command line then that type is used.</p> <p>It is usually desirable to return the terminal type, as finally determined by <code>tset</code>, and information about the terminal's capabilities, to a shell's environment. This can be done using the <code>-</code>, <code>-s</code>, or <code>-S</code> options.</p> <p>For the Bourne shell, put this command in your <code>.profile</code> file:</p> <pre>eval `tset -s options...`</pre> <p>or using the C shell, put these commands in your <code>.login</code> file:</p> |

```
set noglob
eval `tset -s options...`unset noglob
```

With the C shell, it is also convenient to make an alias in your `.cshrc` file:

```
alias ts 'eval `tset -s \\!*`'
```

This also allows the command:

```
ts 2621
```

to be invoked at any time to set the terminal and environment. It is not possible to get this aliasing effect with a Bourne shell script, because shell scripts cannot set the environment of their parent. If a process could set its parent's environment, none of this nonsense would be necessary in the first place.

Once the terminal type is known, `tset` sets the terminal driver mode. This normally involves sending an initialization sequence to the terminal, setting the single character erase (and optionally the line-kill (full line erase)) characters, and setting special character delays. TAB and NEWLINE expansion are turned off during transmission of the terminal initialization sequence.

On terminals that can backspace but not overstrike (such as a CRT), and when the erase character is '#', the erase character is changed as if `-e` had been used.

## OPTIONS

- The name of the terminal finally decided upon is output on the standard output. This is intended to be captured by the shell and placed in the `TERM` environment variable.
- e Set the erase character to be the named character `c` on all terminals. Default is the BACKSPACE key on the keyboard, usually `^H` (CTRL-H). The character `c` can either be typed directly, or entered using the circumflex-character notation used here.
- `c`
- i Set the interrupt character to be the named character `c` on all terminals. Default is `^C` (CTRL-C). The character `c` can either be typed directly, or entered using the circumflex-character notation used here.
- `c`
- I Suppress transmitting terminal-initialization strings.
- k Set the line kill character to be the named character `c` on all terminals. Default is `^U` (CTRL-U). The kill character is left alone if `-k` is not specified. Control characters can be specified by prefixing the alphabetical character with a circumflex (as in CTRL-U) instead of entering the actual control key itself. This allows you to specify control keys that are currently assigned.
- `c`

- n Specify that the new tty driver modes should be initialized for this terminal. Probably useless since `stty new` is the default.
- Q Suppress printing the 'Erase set to ' and 'Kill set to ' messages.
- r In addition to other actions, reports the terminal type.
- s Output commands to set and export `TERM`. This can be used with
 

```
set noglob
eval `tset -s ...`
unset noglob
```

 to bring the terminal information into the environment. Doing so makes programs such as `vi(1)` start up faster. If the `SHELL` environment variable ends with `csh`, C shell commands are output, otherwise Bourne shell commands are output.
- m [ *port-ID* [ *baudrate* ] : *type* ] ...
 

Specify (map) a terminal type when connected to a generic port (such as *dialup* or *plugboard*) identified by *port-ID*. The *baudrate* argument can be used to check the baudrate of the port and set the terminal type accordingly. The target rate is prefixed by any combination of the following operators to specify the conditions under which the mapping is made:

  - > Greater than
  - @ Equals or "at"
  - < Less than
  - ! It is not the case that (negates the above operators)
  - ? Prompt for the terminal type. If no response is given, then `type` is selected by default.

In the following example, the terminal type is set to `adm3a` if the port is a dialup with a speed of greater than 300 or to `dw2` if the port is a dialup at 300 baud or less. In the third case, the question mark preceding the terminal type indicates that the user is to verify the type desired. A `NULL` response indicates that the named type is correct. Otherwise, the user's response is taken to be the type desired.

```
tset -m 'dialup>300:adm3a' -m 'dialup:dw2' -m 'plugboard:?adm3a'
```

To prevent interpretation as metacharacters, the entire argument to `-m` should be enclosed in single quotes. When using the C shell, exclamation points should be preceded by a backslash (`\`).

## EXAMPLES

These examples all use the `-` option. A typical use of `tset` in a `.profile` or `.login` will also use the `-e` and `-k` options, and often the `-n` or `-Q` options as well. These options have been omitted here to keep the examples short.

### EXAMPLE 1 Selecting a terminal

To select a 2621, you might put the following sequence of commands in your `.login` file (or `.profile` for Bourne shell users).

```
set noglob
eval `tset -s 2621`
unset noglob
```

If you want to make the selection based only on the baud rate, you might use the following:

```
set noglob
eval `tset -s -m '>1200:wy' 2621`
unset noglob
```

### EXAMPLE 2 Selecting terminals according to speed or baud rate

If you have a switch which connects to various ports (making it impractical to identify which port you may be connected to), and use various terminals from time to time, you can select from among those terminals according to the *speed* or baud rate. In the example below, `tset` will prompt you for a terminal type if the baud rate is greater than 1200 (say, 9600 for a terminal connected by an RS-232 line), and use a Wyse `\256 50` by default. If the baud rate is less than or equal to 1200, it will select a 2621. Note the placement of the question mark, and the quotes to protect the `>` and `?` from interpretation by the shell.

```
set noglob
eval `tset -s -m 'switch>1200:?wy' -m 'switch<=1200:2621'`
unset noglob
```

### EXAMPLE 3 Selecting the terminal used most often

The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals, and the terminal you use most often is an `adm3a`.

```
set noglob
eval `tset -s ?adm3a`
unset noglob
```

**EXAMPLE 4** Selecting a terminal with specific settings

The following example quietly sets the erase character to BACKSPACE, and kill to CTRL-U. If the port is switched, it selects a Concept(TM) 100 for speeds less than or equal to 1200, and asks for the terminal type otherwise (the default in this case is a Wyse 50). If the port is a direct dialup, it selects Concept 100 as the terminal type. If logging in over the ARPANET, the terminal type selected is a Datamedia\\256 2500 terminal or emulator. Note the backslash escaping the NEWLINE at the end of the first line in the example.

```
set noglob
eval `tset -e -k^U -Q -s -m 'switch<=1200:concept100' -m\\
'switch:?wy' -m dialup:concept100 -m arpanet:dm2500`
unset noglob
```

**NOTES**

The `tset` command is one of the first commands a user must master when getting started on a UNIX system. Unfortunately, it is one of the most complex, largely because of the extra effort the user must go through to get the environment of the login shell set. Something needs to be done to make all this simpler, either the `login` program should do this stuff, or a default shell alias should be made, or a way to set the environment of the parent should exist.

This program cannot intuit personal choices for erase, interrupt and line kill characters, so it leaves these set to the local system standards.

It could well be argued that the shell should be responsible for ensuring that the terminal remains in a sane state; this would eliminate the need for the `reset` program.

| <b>NAME</b>                  | tsort – topological sort                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|-----------|
| <b>SYNOPSIS</b>              | <code>/usr/ccs/bin/tsort [file]</code>                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |           |
| <b>DESCRIPTION</b>           | <p>The <code>tsort</code> command produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input <code>file</code>.</p> <p>The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.</p> |                |                 |              |           |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><code>file</code> A path name of a text file to order. If no <code>file</code> operand is given, the standard input is used.</p>                                                                                                                                                                                                            |                |                 |              |           |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> An example of the <code>tsort</code> command.</p> <p>The command:</p> <pre>tsort &lt;&lt;EOF a b c c d e g g f g e f EOF</pre> <p>produces the output:</p> <pre>a b c d e f g</pre>                                                                                                                                                                                   |                |                 |              |           |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>tsort</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                       |                |                 |              |           |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>&gt;0 An error occurred.</p>                                                                                                                                                                                                                                                                            |                |                 |              |           |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                              |                |                 |              |           |

**DIAGNOSTICS**

Odd data: there are an odd number of fields in the input file.

| <b>NAME</b>                  | tty - return user's terminal name                                                                                                                                                                                                                              |                |                 |              |         |     |         |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|-----|---------|
| <b>SYNOPSIS</b>              | tty [-l] [-s]                                                                                                                                                                                                                                                  |                |                 |              |         |     |         |
| <b>DESCRIPTION</b>           | The tty utility writes to the standard output the name of the terminal that is open as standard input. The name that is used is equivalent to the string that would be returned by the ttyname(3C) function.                                                   |                |                 |              |         |     |         |
| <b>OPTIONS</b>               | The following options are supported:<br>-l Prints the synchronous line number to which the user's terminal is connected, if it is on an active synchronous line.<br>-s Inhibits printing of the terminal path name, allowing one to test just the exit status. |                |                 |              |         |     |         |
| <b>ENVIRONMENT VARIABLES</b> | See environ(5) for descriptions of the following environment variables that affect the execution of tty: LC_CTYPE, LC_MESSAGES, and NLSPATH.                                                                                                                   |                |                 |              |         |     |         |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br>0 Standard input is a terminal.<br>1 Standard input is not a terminal.<br>>1 An error occurred.                                                                                                                     |                |                 |              |         |     |         |
| <b>ATTRIBUTES</b>            | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                |                |                 |              |         |     |         |

| <b>SYNOPSIS</b>              | <b>type</b> <i>name</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
| <b>DESCRIPTION</b>           | <p>The <code>type</code> utility indicates how each <i>name</i> operand would be interpreted if used as a command. <code>type</code> displays information about each operand identifying the operand as a shell built-in, function, alias, hashed command, or keyword, and where applicable, may display the operand's path name.</p> <p>There is also a shell built-in version of <code>type</code> that is similar to the <code>type</code> utility.</p> |                |                 |              |         |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><i>name</i>    A name to be interpreted.</p>                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>ENVIRONMENT VARIABLES</b> | <p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>type</code>: <code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, and <code>NLSPATH</code>.</p> <p><code>PATH</code>    Determine the location of <i>name</i>.</p>                                                                                                                                                                   |                |                 |              |         |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <p>0        Successful completion.</p> <p>&gt;0      An error occurred.</p>                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>typeset sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables <i>name</i> is created. The variables <i>value</i> and <code>type</code> are restored when the function completes. The following list of attributes may be specified:</p> <ul style="list-style-type: none"> <li><code>-H</code> This flag provides UNIX to host-name file mapping on non-UNIX machines.</li> <li><code>-L</code> Left justify and remove leading blanks from <i>value</i> . If <i>n</i> is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the <code>-Z</code> flag is also set. The <code>-R</code> flag is turned off.</li> <li><code>-R</code> Right justify and fill with leading blanks. If <i>n</i> is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The <code>-L</code> flag is turned off.</li> <li><code>-Z</code> Right justify and fill with leading zeros if the first non-blank character is a digit and the <code>-L</code> flag has not been set. If <i>n</i> is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.</li> <li><code>-f</code> The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are <code>-t</code> , <code>-u</code> and <code>-x</code> . The flag <code>-t</code> turns on execution tracing for this function. The flag <code>-u</code> causes this function to be marked undefined. The <code>FPATH</code> variable will be searched to find the function definition when the function is referenced. The flag <code>-x</code> allows the function definition to remain in effect across shell procedures invoked by name.</li> <li><code>-i</code> Parameter is an integer. This makes arithmetic faster. If <i>n</i> is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.</li> <li><code>-l</code> All upper-case characters are converted to lower-case. The upper-case flag, <code>-u</code> is turned off.</li> <li><code>-r</code> The given <i>name</i> s are marked <code>readonly</code> and these names cannot be changed by subsequent assignment.</li> </ul> |

- t Tags the variables. Tags are user definable and have no special meaning to the shell.
- u All lower-case characters are converted to upper-case characters. The lower-case flag, -l is turned off.
- x The given *name* s are marked for automatic export to the environment of subsequently-executed commands.

The -i attribute can not be specified along with -R , -L , -Z , or -f .

Using + rather than - causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values* ) of the *variables* which have these flags set is printed. (Using + rather than - keeps the values from being printed.) If no *name* s and flags are given, the *names* and *attributes* of all *variables* are printed.

For each *name* , whence indicates how it would be interpreted if used as a command name.

The -v flag produces a more verbose report.

The -p flag does a path search for *name* even if name is an alias, a function, or a reserved word.

On this man page, ksh(1) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**NAME** ucblinks – adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices

**SYNOPSIS** /usr/ucb/ucblinks [-e *rulebase*] [-r *rootdir*]

**DESCRIPTION** ucblinks creates symbolic links under the /dev directory for devices whose SunOS 5.x names differ from their SunOS 4.x names. Where possible, these symbolic links point to the device's SunOS 5.x name rather than to the actual /devices entry.

ucblinks does not remove unneeded compatibility links; these must be removed by hand.

ucblinks should be called each time the system is reconfiguration-booted, after any new SunOS 5.x links that are needed have been created, since the reconfiguration may have resulted in more compatibility names being needed.

In releases prior to SunOS 5.4, ucblinks used a *nawk* rule-base to construct the SunOS 4.x compatible names. ucblinks no longer uses *nawk* for the default operation, although *nawk* rule-bases can still be specified with the *-e* option. The *nawk* rule-base equivalent to the SunOS 5.4 default operation can be found in /usr/ucblib/ucblinks.awk.

**OPTIONS**

*-e rulebase* Specify *rulebase* as the file containing *nawk*(1) pattern-action statements.

*-r rootdir* Specify *rootdir* as the directory under which *dev* and *devices* will be found, rather than the standard root directory /.

**FILES** /usr/ucblib/ucblinks.awk sample rule-base for compatibility links

| <b>SYNOPSIS</b>      | <b>ul</b> [-i] [-t <i>terminal</i> ] [ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>DESCRIPTION</b>   | ul reads the named <i>filenames</i> (or the standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable TERM. ul uses the /usr/share/lib/terminfo entry to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to cat(1). If the terminal cannot underline, underlining is ignored. |                |                 |              |         |
| <b>OPTIONS</b>       | <p>-t <i>terminal</i>      Override the terminal kind specified in the environment. If the terminal cannot underline, underlining is ignored. If the terminal name is not found, no underlining is attempted.</p> <p>-i                    Indicate underlining by a separate line containing appropriate dashes '-'; this is useful when you want to look at the underlining which is present in an nroff(1) output stream on a CRT-terminal.</p>                                                                                                                                                                |                |                 |              |         |
| <b>RETURN VALUES</b> | ul returns exit code 1 if the file specified is not found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>FILES</b>         | /usr/share/lib/terminfo/*                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>The <code>umask</code> utility sets the file mode creation mask of the current shell execution environment to the value specified by the <code>mask</code> operand. This mask affects the initial value of the file permission bits of subsequently created files. If <code>umask</code> is called in a subshell or separate utility execution environment, such as one of the following:</p> <pre>(umask 002) nohup umask ... find . -exec umask ...</pre> <p>it does not affect the file mode creation mask of the caller's environment. For this reason, the <code>/usr/bin/umask</code> utility cannot be used to change the umask in an ongoing session. Its usefulness is limited to checking the caller's umask. To change the umask of an ongoing session you must use one of the shell builtins.</p> <p>If the <code>mask</code> operand is not specified, the <code>umask</code> utility writes the value of the invoking process's file mode creation mask to standard output.</p> <p><b>sh</b> The user file-creation mode mask is set to <code>000</code>. The three octal digits refer to read/write/execute permissions for owner, group, and other, respectively (see <code>chmod(1)</code>, <code>chmod(2)</code>, and <code>umask(2)</code>). The value of each specified digit is subtracted from the corresponding "digit" specified by the system for the creation of a file (see <code>creat(2)</code>). For example, <code>umask 022</code> removes write permission for group and other (files normally created with mode <code>777</code> become mode <code>755</code>; files created with mode <code>666</code> become mode <code>644</code>).</p> <ul style="list-style-type: none"> <li>■ If <code>000</code> is omitted, the current value of the mask is printed.</li> <li>■ <code>umask</code> is recognized and executed by the shell.</li> <li>■ <code>umask</code> can be included in the user's <code>.profile</code> (see <code>profile(4)</code>) and invoked at login to automatically set the user's permissions on files or directories created.</li> </ul> <p><b>cs</b> See the description above for the Bourne shell (<code>sh</code>)<code>umask</code> built-in.</p> <p><b>ksh</b> The user file-creation mask is set to <code>mask</code>. <code>mask</code> can either be an octal number or a symbolic value as described in <code>chmod(1)</code>. If a symbolic value is given, the new <code>umask</code> value is the complement of the result of applying <code>mask</code> to the</p> |

complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed.

## OPTIONS

The following option is supported:

`-S` Produce symbolic output.

The default output style is unspecified, but will be recognized on a subsequent invocation of `umask` on the same system as a *mask* operand to restore the previous file mode creation mask.

## OPERANDS

The following operand is supported:

*mask* A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the `chmod(1)` manual page.

For a *symbolic\_mode* value, the new value of the file mode creation mask is the logical complement of the file permission bits portion of the file mode specified by the *symbolic\_mode* string.

In a *symbolic\_mode* value, the permissions *op* characters `+` and `-` are interpreted relative to the current file mode creation mask. `+` causes the bits for the indicated permissions to be cleared in the mask. `-` causes the bits of the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

The file mode creation mask is set to the resulting numeric value.

The default output of a prior invocation of `umask` on the same system with no operand will also be recognized as a *mask* operand. The use of an operand obtained in this way is not obsolescent, even if it is an octal number.

## OUTPUT

When the *mask* operand is not specified, the `umask` utility will write a message to standard output that can later be used as a `umask mask` operand.

If `-S` is specified, the message will be in the following format:

```
"u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>, <other permissions>
```

where the three values will be combinations of letters from the set `{r, w, x}`; the presence of a letter will indicate that the corresponding bit is clear in the file mode creation mask.

If a *mask* operand is specified, there will be no output written to standard output.

**EXAMPLES**

**EXAMPLE 1** Using The umask Command

Either of the commands:

```
umask a=rx,ug+w
umask 002
```

sets the mode mask so that subsequently created files have their S\_IWOTH bit cleared.

After setting the mode mask with either of the above commands, the umask command can be used to write the current value of the mode mask:

```
$ umask
0002
```

(The output format is unspecified, but historical implementations use the obsolescent octal integer mode format.)

```
$ umask -S
u=rwx,g=rwx,o=rx
```

Either of these outputs can be used as the mask operand to a subsequent invocation of the umask utility.

Assuming the mode mask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their S\_IWGRP, and S\_IWOTH bits cleared.

The command:

```
umask - -w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Note that *mask* operands *r*, *w*, *x*, or anything beginning with a hyphen (-), must be preceded by - (two hyphens) to keep it from being interpreted as an option.

**ENVIRONMENT VARIABLES**

See *environ(5)* for descriptions of the following environment variables that affect the execution of *umask*: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

- 0 The file mode creation mask was successfully changed, or no *mask* operand was supplied.
- >0 An error occurred.

**ATTRIBUTES**

See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

**NAME** | `uname` – print name of current system

**SYNOPSIS** | `uname [-aimnprsvX]`  
`uname [-S system_name]`

**DESCRIPTION** | The `uname` utility prints information about the current system on the standard output. When options are specified, symbols representing one or more system characteristics will be written to the standard output. If no options are specified, `uname` prints the current operating system's name. The options print selected information returned by `uname(2)`, `sysinfo(2)`, or both.

**OPTIONS** | The following options are supported:

- `-a` | Print basic information currently available from the system.
- `-i` | Print the name of the hardware implementation (platform).
- `-m` | Print the machine hardware name (class). Use of this option is discouraged; use `uname -p` instead. See NOTES section below.
- `-n` | Print the nodename (the nodename is the name by which the system is known to a communications network).
- `-p` | Print the current host's ISA or processor type.
- `-r` | Print the operating system release level.
- `-s` | Print the name of the operating system. This is the default.
- `-v` | Print the operating system version.
- `-X` | Print expanded system information, one information element per line, as expected by SCO UNIX. The displayed information includes:
  - system name, node, release, version, machine, and number of CPUs.
  - BusType, Serial, and Users (set to "unknown" in Solaris)
  - OEM# and Origin# (set to 0 and 1, respectively)
- `-S system_name` | The nodename may be changed by specifying a system name argument. The system name argument is restricted to `SYS_NMLN` characters. `SYS_NMLN` is an implementation specific value defined in `<sys/utsname.h>`. Only the super-user is allowed this capability.

**EXAMPLES** | **EXAMPLE 1** Using The `uname` Command

The following command:

**ENVIRONMENT  
VARIABLES**

`example% uname -sr`  
 prints the operating system name and release level, separated by one SPACE character.

`SYSV3` This variable is used to override the default behavior of `uname`. This is necessary to make it possible for some INTERACTIVE UNIX Systems and SCO UNIX programs and scripts to work properly. Many scripts use `uname` to determine the OS type or the version of the OS to ensure software is compatible with that OS. Setting `SYSV3` to an empty string will make `uname` print the following default values:

```
nodename nodename 3.2 2 i386
```

The individual elements that `uname` displays can also be modified by setting `SYSV3` in the following format:

```
os,sysname,node,rel,ver,mach
```

|                |                                                            |
|----------------|------------------------------------------------------------|
| <i>os</i>      | Operating system (IUS or SCO).                             |
| <i>sysname</i> | System name.                                               |
| <i>node</i>    | Nodename as displayed by the <code>-n</code> option.       |
| <i>rel</i>     | Release level as displayed by the <code>-r</code> option.  |
| <i>ver</i>     | Version number as displayed by the <code>-v</code> option. |
| <i>mach</i>    | Machine name as displayed by <code>-m</code> option.       |

Do not put spaces between the elements. If an element is omitted, the current system value will be used.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uname`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.  
 >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

arch(1), isalist(1), sysinfo(2), uname(2), attributes(5), environ (5)

**NOTES**

Independent software vendors (ISVs) and others who need to determine detailed characteristics of the platform on which their software is either being installed or executed should use the `uname` command.

To determine the operating system name and release level, use `uname -sr`. To determine only the operating system release level, use `uname -r`. Note that operating system release levels are not guaranteed to be in *x.y* format (such as 5.3, 5.4, 5.5, and so forth); future releases could be in the *x.y.z* format (such as 5.3.1, 5.3.2, 5.4.1, and so forth).

In SunOS 4.x releases, the `arch(1)` command was often used to obtain information similar to that obtained by using the `uname` command. The `arch(1)` command output "sun4" was often incorrectly interpreted to signify a SunOS SPARC system. If hardware platform information is desired, use `uname -sp`.

The `arch -k` and `uname -m` commands return equivalent values; however, the use of either of these commands by third party programs is discouraged, as is the use of the `arch` command in general. To determine the machine's Instruction Set Architecture (ISA or processor type), use `uname` with the `-p` option.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>NAME</b>        | unifdef – resolve and remove ifdef'ed lines from C program source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>unifdef</b> [-c] [-Dname] [-Uname] [-iDname] [-iUname] ... [filename]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>unifdef removes <i>ifdef</i>ed lines from a file while otherwise leaving the file alone. It is smart enough to deal with the nested <i>ifdef</i>s, comments, single and double quotes of C syntax, but it does not do any including or interpretation of macros. Neither does it strip out comments, though it recognizes and ignores them. You specify which symbols you want defined with <i>-D</i> options, and which you want undefined with <i>-U</i> options. Lines within those <i>ifdef</i>s will be copied to the output, or removed, as appropriate. Any <i>ifdef</i>, <i>ifndef</i>, <i>else</i>, and <i>endif</i> lines associated with <i>filename</i> will also be removed.</p> <p><i>ifdef</i>s involving symbols you do not specify are untouched and copied out along with their associated <i>ifdef</i>, <i>else</i>, and <i>endif</i> lines.</p> <p>If an <i>ifdefX</i> occurs nested inside another <i>ifdefX</i>, then the inside <i>ifdef</i> is treated as if it were an unrecognized symbol. If the same symbol appears in more than one argument, only the first occurrence is significant.</p> <p>unifdef copies its output to the standard output and will take its input from the standard input if no <i>filename</i> argument is given.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c      Complement the normal operation. Lines that would have been removed or blanked are retained, and vice versa.</li> <li>-l      Replace “lines removed” lines with blank lines.</li> <li>-t      Plain text option. <i>unifdef</i> refrains from attempting to recognize comments and single and double quotes.</li> <li>-Dname Lines associated with the defined symbol <i>name</i>.</li> <li>-Uname Lines associated with the undefined symbol <i>name</i>.</li> <li>-iDname Ignore, but print out, lines associated with the defined symbol <i>name</i>.<br/>If you use <i>ifdef</i>s to delimit non-C lines, such as comments or code which is under construction, then you must tell <i>unifdef</i> which symbols are used for that purpose so that it will not try to parse for quotes and comments within them.</li> <li>-iUname Ignore, but print out, lines associated with the undefined symbol <i>name</i>.</li> </ul>                                                                                                                                                                                                                                                   |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0      Successful operation.</li> <li>1      Operation failed.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>NAME</b>        | uniq – report or filter out repeated lines in a file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>uniq</b> [-c   -d   -u ][-f <i>fields</i> ] [-s <i>char</i> ] [ <i>input_file</i> [ <i>output_file</i> ] ]<br><b>uniq</b> [-c   -d   -u ][-n] [+ <i>m</i> ] [ <i>input_file</i> [ <i>output_file</i> ] ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | The <code>uniq</code> utility will read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines will not be written.<br><br>Repeated lines in the input will not be detected if they are not adjacent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | The following options are supported:<br>-c           Precede each output line with a count of the number of times the line occurred in the input.<br>-d           Suppress the writing of lines that are not repeated in the input.<br>-f <i>fields</i> Ignore the first <i>fields</i> fields on each input line when doing comparisons, where <i>fields</i> is a positive decimal integer. A field is the maximal string matched by the basic regular expression:<br>[[ :blank: ]]*[^[ :blank: ]]*<br>If <i>fields</i> specifies more fields than appear on an input line, a null string will be used for comparison.<br>-s <i>chars</i> Ignore the first <i>chars</i> characters when doing comparisons, where <i>chars</i> is a positive decimal integer. If specified in conjunction with the -f option, the first <i>chars</i> characters after the first <i>fields</i> fields will be ignored. If <i>chars</i> specifies more characters than remain on an input line, a null string will be used for comparison.<br>-u           Suppress the writing of lines that are repeated in the input.<br>-n           Equivalent to -f <i>fields</i> with <i>fields</i> set to <i>n</i> .<br>+m           Equivalent to -s <i>chars</i> with <i>chars</i> set to <i>m</i> . |
| <b>OPERANDS</b>    | The following operands are supported:<br><i>input_file</i> A path name of the input file. If <i>input_file</i> is not specified, or if the <i>input_file</i> is -, the standard input will be used.<br><i>output_file</i> A path name of the output file. If <i>output_file</i> is not specified, the standard output will be used. The results are unspecified if the file named by <i>output_file</i> is the file named by <i>input_file</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**EXAMPLES****EXAMPLE 1** Using The `uniq` Command

The following example lists the contents of the `uniq.test` file and outputs a copy of the repeated lines.

```
example% cat uniq.test
This is a test.
This is a test.
TEST.
Computer.
TEST.
TEST.
Software.

example% uniq -d uniq.test
This is a test.
TEST.
example%
```

The next example outputs just those lines that are not repeated in the `uniq.test` file.

```
example% uniq -u uniq.test
TEST.
Computer.
Software.
example%
```

The last example outputs a report with each line preceded by a count of the number of times each line occurred in the file:

```
example% uniq -c uniq.test
 2 This is a test.
 1 TEST.
 1 Computer.
 2 TEST.
 1 Software.
example%
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uniq`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

```
0 Successful completion.
>0 An error occurred.
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |
| CSI            | Enabled         |

**NAME** | units – converts quantities expressed in standard scales to other scales

**SYNOPSIS** | **units**

**DESCRIPTION** | `units` converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:

```
You have:~~inch
You want:~~cm
 * 2.540000e+00
 / 3.937008e-01
```

A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, division by the usual sign:

```
You have:~~15 lbs force/in2
You want:~~atm
 * 1.020689e+00
 / 9.797299e-01
```

`units` only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:

`pi`     ratio of circumference to diameter,  
`c`       speed of light,  
`e`       charge on an electron,  
`g`       acceleration of gravity,  
`force`   same as `g`,  
`mole`    Avogadro's number,  
`water`   pressure head per unit height of water,  
`au`      astronomical unit.

Pound is not recognized as a unit of mass; `lb` is. Compound names are run together, (for example, `lightyear`). British units that differ from their U.S. counterparts are prefixed thus: `brgallon`. For a complete list of units, type:

```
cat /usr/share/lib/unittab
/usr/share/lib/unittab
```

| <b>NAME</b>        | unix2dos - convert text file from ISO format to DOS format                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>unix2dos</b> [-ascii] [-iso] [-7] <i>originalfile convertedfile</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>unix2dos converts ISO standard characters to the corresponding characters in the DOS extended character set.</p> <p>This command may be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.</p> <p>If the original file and the converted file are the same, unix2dos will rewrite the original file after converting it.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p>-ascii Adds carriage returns and converts end of file characters in SunOS format text files to conform to DOS requirements.</p> <p>-iso This is the default. Converts ISO standard characters to the corresponding character in the DOS extended character set.</p> <p>-7 Convert 8 bit SunOS characters to 7 bit DOS characters.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DIAGNOSTICS</b> | <p>File <i>filename</i> not found, or no read permission<br/>The input file you specified does not exist, or you do not have read permission (check with the SunOS command <code>ls -l</code>).</p> <p>Bad output filename <i>filename</i>, or no write permission<br/>The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.</p> <p>Error while writing to temporary file<br/>An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the DIR command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Note that when this error occurs, the original file remains intact.</p> <p>Could not rename tmpfile to <i>filename</i>.<br/>Translated tmpfile name = <i>filename</i>.<br/>The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message.</p> |

dos2unix(1), attributes(5)

**NAME** uptime – show how long the system has been up

**SYNOPSIS** **uptime**

**DESCRIPTION** The `uptime` command prints the current time, the length of time the system has been up, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. It is, essentially, the first line of a `w(1)` command.

**EXAMPLES** Below is an example of the output `uptime` provides:

```
example% uptime
10:47am up 27 day(s), 50 mins, 1 user, load average: 0.18, 0.26, 0.20
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `w(1)`, `who(1)`, `whodo(1M)`, `attributes(5)`

**NOTES** `who -b` gives the time the system was last booted.

**NAME** users – display a compact list of users logged in

**SYNOPSIS** /usr/ucb/users [*filename*]

**DESCRIPTION** The `users` utility lists the login names of the users currently on the system in a compact, one-line format.

Specifying *filename* tells `users` where to find its information; by default it checks `/var/adm/utmp`.

Typing `users` is equivalent to typing `who -q`.

**EXAMPLES**

**EXAMPLE 1** Listing current users

```
example% users
paul george ringo
example%
```

**FILES** /var/adm/utmp

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>uucp</b>        | uucp copies files named by the <i>source-file</i> arguments to the <i>destination-file</i> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>uulog</b>       | uulog queries a log file of uucp or uuxqt transactions in file /var/uucp/.Log/uucico/ <i>system</i> or /var/uucp/.Log/uuxqt/ <i>system</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>uuname</b>      | uuname lists the names of systems known to uucp .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>uucp</b>        | <p>The following options are supported by uucp :</p> <p>-c Do not copy local file to the spool directory for transfer to the remote machine (default).</p> <p>-C Force the copy of local files to the spool directory for transfer.</p> <p>-d Make all necessary directories for the file copy (default).</p> <p>-f Do not make intermediate directories for the file copy.</p> <p>-g <i>grade</i> <i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The uuglist command can determine whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the uuglist command will be a list of service grades that are available, or a message that says to use a single letter or number as a grade of service.</p> <p>-j Print the uucp job identification string on standard output. This job identification can be used by uustat to obtain the status of a uucp job or to terminate a uucp job. The uucp job is valid as long as the job remains queued on the local system.</p> |

|                 | where <i>system-name</i> is taken from a list of system names that uucp knows about. <i>source_file</i> is restricted to no more than one <i>system-name</i> . The destination <i>system-name</i> may also include a list of system names such as |                                                                                                                                                                                                                   |
|                 | <i>system-name ! system-name ! . . . ! system-name ! pathname</i>                                                                                                                                                                                 |                                                                                                                                                                                                                   |

In this case, an attempt is made to send the file, using the specified route, to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information (see NOTES below for restrictions).

For C-Shell users, the "!" character must be surrounded by single quotes ('), or preceded by a backslash (\).

The shell metacharacters ?, \* and [...] appearing in *pathname* will be expanded on the appropriate system.

Pathnames may be one of the following:

- (1) An absolute pathname.
- (2) A pathname preceded by ~ *user* where *user* is a login name on the specified system and is replaced by that user's login directory.
- (3) A pathname preceded by ~ /*destination* where *destination* is appended to /var/spool/uucppublic. (Note: This destination will be treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that the destination is a directory, follow it with a '/'. For example ~/dan/ as the destination will make the directory /var/spool/uucppublic/dan if it does not exist and put the requested file(s) in that directory).

Anything else is prefixed by the current directory.

If the result is an erroneous path name for the remote system, the copy will fail. If the *destination-file* is a directory, the last part of the *source-file* name is used.

Invoking uucp with shell wildcard characters as the remote *source-file* invokes the uux(1C) command to execute the uucp command on the remote machine. The remote uucp command spools the files on the remote machine. After the first session terminates, if the remote machine is configured to transfer the spooled files to the local machine, the remote machine will initiate a call and send the files; otherwise, the user must "call" the remote machine to transfer the files from the spool directory to the local machine. This call can be done manually using Uutry(1M), or as a side effect of another uux(1C) or uucp call.

Note that the local machine must have permission to execute the uucp command on the remote machine in order for the remote machine to send the spooled files.

uucp removes execute permissions across the transmission and gives 0666 read and write permissions (see chmod(2)).

## ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of uucp: LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, LC\_TIME, TZ, and NLSPATH.

## EXIT STATUS

The following exit values are returned:

0 Successful completion.  
 >0 An error occurred.

**NOTES**

For security reasons, the domain of remotely accessible files may be severely restricted. You will probably not be able to access files by path name; ask a responsible person on the remote system to send them to you. For the same reasons you will probably not be able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin /var/spool/uucppublic (equivalent to ~/).

All files received by uucp will be owned by uucp .

The -m option will only work when sending files or receiving a single file. Receiving multiple files specified by special shell characters ? , & , and [ . . . ] will not activate the -m option.

The forwarding of files through other systems may not be compatible with the previous version of uucp . If forwarding is used, all systems in the route must have compatible versions of uucp .

Protected files and files that are in protected directories that are owned by the requester can be sent by uucp . However, if the requester is root, and the directory is not searchable by "other" or the file is not readable by "other", the request will fail.

Strings that are passed to remote systems may not be evaluated in the same locale as the one in use by the process that invoked uucp on the local system.

Configuration files must be treated as C (or POSIX) locale text files.

| <b>NAME</b>                  | uuencode, uudecode – encode a binary file, or decode its encoded representation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>              | <b>uuencode</b> [ <i>source-file</i> ] <i>decode_pathname</i><br><b>uudecode</b> [-p] [ <i>encoded-file</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b>           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>uuencode</b>              | uuencode converts a binary file into an encoded representation that can be sent using mail(1). It encodes the contents of <i>source-file</i> , or the standard input if no <i>source-file</i> argument is given. The <i>decode_pathname</i> argument is required. The <i>decode_pathname</i> is included in the encoded file's header as the name of the file into which uudecode is to place the binary (decoded) data. uuencode also includes the permission modes of <i>source-file</i> , (except setuid, setgid, and sticky-bits), so that <i>decode_pathname</i> is recreated with those same permission modes. |
| <b>uudecode</b>              | uudecode reads an <i>encoded-file</i> , strips off any leading and trailing lines added by mailer programs, and recreates the original binary data with the filename and the mode specified in the header.<br><br>The encoded file is an ordinary portable character set text file; it can be edited by any text editor. It is best only to change the mode or <i>decode_pathname</i> in the header to avoid corrupting the decoded binary.                                                                                                                                                                          |
| <b>OPTIONS</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>uudecode</b>              | -p      decode <i>encoded-file</i> and send it to standard output. This allows uudecode to be used in a pipeline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPERANDS</b>              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>uuencode</b>              | The following operands are supported by uuencode :<br><i>decode_pathname</i> The pathname of the file into which the uudecode utility will place the decoded file. If there are characters in <i>decode_pathname</i> that are not in the portable filename character set the results are unspecified.<br><br><i>source-file</i> A pathname of the file to be encoded.                                                                                                                                                                                                                                                |
| <b>uudecode</b>              | The following operand is supported by uudecode :<br><i>encoded-file</i> The pathname of a file containing the output of uuencode .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>USAGE</b>                 | See largefile(5) for the description of the behavior of uuencode and uudecode when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ENVIRONMENT VARIABLES</b> | See environ(5) for descriptions of the following environment variables that affect the execution of uuencode and uudecode : LC_CTYPE , LC_MESSAGES , and NLSPATH .                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**OUTPUT**  
**stdout**

The standard output is a text file (encoded in the character set of the current locale) that begins with the line:

```
"begin%s%s\ ", <mode >, decode_pathname
```

and ends with the line:

```
end\
```

In both cases, the lines have no preceding or trailing blank characters.

The algorithm that is used for lines in between `begin` and `end` takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets are converted to characters by adding a value of `0x20` to each octet, so that each octet is in the range `0x20-0x5f`, and then it is assumed to represent a printable character. It then will be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet `0x41`, representing `A`, would be translated to `A` in the current codeset, such as `0xc1` if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet are shifted left and combined with the most significant bits of the second octet shifted right. Thus the three octets `A`, `B`, `C` are converted into the four octets:

```
0x20 + ((A >> 2) & 0x3F)
0x20 + (((A << 4) ((B >> 4) & 0xF)) & 0x3F)
0x20 + (((B << 2) ((C >> 6) & 0x3)) & 0x3F)
0x20 + ((C) & 0x3F)
```

These octets are then translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus `0x20` translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line is 45.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**SEE ALSO**

`mail(1)`, `mailx(1)`, `uucp(1C)`, `uux(1C)`, `attributes(5)`, `largefile(5)`

**NOTES**

The encoded file's size is expanded by 35% (3 bytes become 4, plus control information), causing it to take longer to transmit than the equivalent binary.

The user on the remote system who is invoking `uudecode` (typically `uucp`) must have write permission on the file specified in the `decode_pathname`.

If you `uuencode` then `uudecode` a file in the same directory, you will overwrite the original file.

**NAME** uuglist - print the list of service grades that are available on this UNIX system

**SYNOPSIS** **uuglist** [-u]

**DESCRIPTION** uuglist prints the list of service grades that are available on the system to use with the -g option of uucp(1C) and uux(1C).

**OPTIONS** -u List the names of the service grades that the user is allowed to use with the -g option of the uucp and uux commands.

**FILES** /etc/uucp/Grades contains the list of service grades

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbnuu        |

| <b>NAME</b>           | <b>uustat</b> – uucp status inquiry and job control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>       | <b>uustat</b> [[-m]   [-p]   [-q]   [-k <i>jobid</i> [-n] ] [-r <i>jobid</i> [-n] ] ]<br><b>uustat</b> [-a] [-s <i>system</i> [-j] ] [-u <i>user</i> ] [-S <i>qric</i> ]<br><b>uustat</b> -t <i>system</i> [-c] [-d <i>number</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>    | <b>uustat</b> functions in the following three areas:<br>1.) Displays the general status of, or cancels, previously specified <b>uucp</b> commands.<br>2.) Provides remote system performance information, in terms of average transfer rates or average queue times.<br>3.) Provides general remote system-specific and user-specific status of <b>uucp</b> connections to other systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>General Status</b> | These options obtain general status of, or cancel, previously specified <b>uucp</b> commands:<br>-a List all jobs in queue.<br>-j List the total number of jobs displayed. The -j option can be used in conjunction with the -a or the -s option.<br>-k <i>jobid</i> Kill the <b>uucp</b> request whose job identification is <i>jobid</i> . The killed <b>uucp</b> request must belong to the user issuing the <b>uustat</b> command unless the user is the super-user or <b>uucp</b> administrator. If the job is killed by the super-user or <b>uucp</b> administrator, electronic mail is sent to the user.<br>-m Report the status of accessibility of all machines.<br>-n Suppress all standard output, but not standard error. The -n option is used in conjunction with the -k and -r options.<br>-p Execute the command <code>ps -flp</code> for all the process-ids that are in the lock files.<br>-q List the jobs queued for each machine. If a status file exists for the machine, its date, time and status information are reported. In addition, if a number appears in parentheses next to the number of C or X files, it is the age in days of the oldest C./X. file for that system. The <code>Retry</code> field represents the number of hours until the next possible call. The <code>Count</code> is the number of failure attempts. Note: For systems with a moderate number of outstanding jobs, this could take 30 seconds or more of real-time to execute. An example of the output produced by the -q option is: |

```
eagle 3C 04/07-11:07 NO DEVICES AVAILABLE
mh3bs3 2C 07/07-10:42 SUCCESSFUL
```

This indicates the number of command files that are waiting for each system. Each command file may have zero or more files to be sent (zero means to call the system and see if work is to be done). The date and time refer to the previous interaction with the system followed by the status of the interaction.

*-rjobid* Rejuvenate *jobid*. The files associated with *jobid* are touched so that their modification time is set to the current time. This prevents the cleanup daemon from deleting the job until the jobs' modification time reaches the limit imposed by the daemon.

**Remote System Status**

These options provide remote system performance information, in terms of average transfer rates or average queue times; the *-c* and *-d* options can only be used in conjunction with the *-t* option:

*-t**system* Report the average transfer rate or average queue time for the past 60 minutes for the remote *system*. The following parameters can only be used with this option:

*-c* Average queue time is calculated when the *-c* parameter is specified and average transfer rate when *-c* is not specified. For example, the command:

```
example% uustat -teagle -d50 -c
```

produces output in the following format:

```
average queue time to eagle for last 50
minutes: 5 seconds
```

The same command without the *-c* parameter produces output in the following format:

```
average transfer rate with eagle for last 50
minutes: 2000.88 bytes/sec
```

*-d**number* *number* is specified in minutes. Used to override the 60 minute default used for calculations. These calculations are based on information contained in the optional performance log and therefore may not be available. Calculations can only be made from the time that the performance log was last cleaned up.

**User- or  
System-Specific  
Status**

These options provide general remote system-specific and user-specific status of uucp connections to other systems. Either or both of the following options can be specified with `uustat`. The `-j` option can be used in conjunction with the `-s` option to list the total number of jobs displayed:

`-ssystem` Report the status of all uucp requests for remote system *system*.

`-uuser` Report the status of all uucp requests issued by *user*.

Output for both the `-s` and `-u` options has the following format:

```
eagleN1bd7 4/07-11:07 S eagle dan 522 /home/dan/A
eagleC1bd8 4/07-11:07 S eagle dan 59 D.3b2a12ce4924
 4/07-11:07 S eagle dan rmail mike
```

With the above two options, the first field is the *jobid* of the job. This is followed by the date/time. The next field is an `S` if the job is sending a file or an `R` if the job is requesting a file. The next field is the machine where the file is to be transferred. This is followed by the user-id of the user who queued the job. The next field contains the size of the file, or in the case of a remote execution (`rmail` is the command used for remote mail), the name of the command. When the size appears in this field, the file name is also given. This can either be the name given by the user or an internal name (for example, `D.3b2a12ce4924`) that is created for data files associated with remote executions (`rmail` in this example).

`-Sqric` Report the job state:

```
q for queued jobs
r for running jobs
i for interrupted jobs
c for completed jobs
```

A job is queued if the transfer has not started. A job is running when the transfer has begun. A job is interrupted if the transfer began but was terminated before the file was completely transferred. A completed job is a job that successfully transferred. The completed state information is maintained in the accounting log, which is optional and therefore may be unavailable. The parameters can be used in any combination, but at least one parameter must be specified. The `-S` option can also be used with `-s` and `-u` options. The output for this option is exactly like the output for `-s` and `-u` except that the job states are appended as the last output word. Output for a completed job has the following format:

```
eagleC1bd3 completed
```

When no options are given, `uustat` writes to standard output the status of all uucp requests issued by the current user.

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uustat`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

0        Successful completion.  
 >0      An error occurred.

**FILES**

|                                       |                   |
|---------------------------------------|-------------------|
| <code>/var/spool/uucp/*</code>        | spool directories |
| <code>/var/uucp/.Admin/account</code> | accounting log    |
| <code>/var/uucp/.Admin/perflog</code> | performance log   |

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbnuu        |

**SEE ALSO**

`uucp(1C)`, `attributes(5)`

**DIAGNOSTICS**

The `-t` option produces no message when the data needed for the calculations is not being recorded.

**NOTES**

After the user has issued the `uucp` request, if the file to be transferred is moved, deleted or was not copied to the spool directory (`-C` option) when the `uucp` request was made, `uustat` reports a file size of `-99999`. This job will eventually fail because the file(s) to be transferred can not be found.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |            |                   |   |                   |   |                                                                                                                                                                                                                                                                      |              |  |   |  |   |                                                                          |              |  |   |  |   |                                |

| <b>NAME</b>        | uuto, uupick – public UNIX-to-UNIX system file copy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                   |   |                   |   |                                                                                                                                                                                                                                                                      |              |  |   |  |   |                                                                          |              |  |   |  |   |                                |
| <b>SYNOPSIS</b>    | <b>uuto</b> [-mp] <i>source-file...</i> <i>destination</i><br><b>uupick</b> [-s <i>system</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |            |                   |   |                   |   |                                                                                                                                                                                                                                                                      |              |  |   |  |   |                                                                          |              |  |   |  |   |                                |
| <b>DESCRIPTION</b> | <p><b>uuto</b> sends <i>source-file</i> to <i>destination</i>. <b>uuto</b> uses the uucp(1C) facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the form:</p> <pre>system [!<i>system</i>] ... !<i>user</i></pre> <p>where <i>system</i> is taken from a list of system names that uucp knows about. <i>User</i> is the login name of someone on the specified system.</p> <p>The files (or sub-trees if directories are specified) are sent to PUBDIR on <i>system</i>, where PUBDIR is a public directory defined in the uucp source. By default, this directory is /var/spool/uucppublic. Specifically the files are sent to</p> <pre>PUBDIR/receive/ <i>user</i> /<i>mssystem</i> /files.</pre> <p>The recipient is notified by mail(1) of the arrival of files.</p> <p><b>uupick</b> accepts or rejects the files transmitted to the user. Specifically, <b>uupick</b> searches PUBDIR for files destined for the user. For each entry (file or directory) found, the following message is printed on standard output:</p> <pre>from system <i>sysname</i> : [file <i>file-name</i>] [dir <i>dirname</i>] ?</pre> <p><b>uupick</b> then reads a line from standard input to determine the disposition of the file:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">&lt;new-line&gt;</td> <td>Go to next entry.</td> </tr> <tr> <td style="padding-right: 20px;">d</td> <td>Delete the entry.</td> </tr> <tr> <td style="padding-right: 20px;">m</td> <td>Move the entry to named directory <i>dir</i>. If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.</td> </tr> <tr> <td style="padding-right: 20px;">[ <i>dir</i></td> <td></td> </tr> <tr> <td style="padding-right: 20px;">]</td> <td></td> </tr> <tr> <td style="padding-right: 20px;">a</td> <td>Same as m above, except it moves all the files sent from <i>system</i>.</td> </tr> <tr> <td style="padding-right: 20px;">[ <i>dir</i></td> <td></td> </tr> <tr> <td style="padding-right: 20px;">]</td> <td></td> </tr> <tr> <td style="padding-right: 20px;">p</td> <td>Print the content of the file.</td> </tr> </table> | <new-line> | Go to next entry. | d | Delete the entry. | m | Move the entry to named directory <i>dir</i> . If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory. | [ <i>dir</i> |  | ] |  | a | Same as m above, except it moves all the files sent from <i>system</i> . | [ <i>dir</i> |  | ] |  | p | Print the content of the file. |
| <new-line>         | Go to next entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |            |                   |   |                   |   |                                                                                                                                                                                                                                                                      |              |  |   |  |   |                                                                          |              |  |   |  |   |                                |

|                 |                                            |
|-----------------|--------------------------------------------|
| q               | Stop.                                      |
| EOT (control-d) | Same as q .                                |
| !               | Escape to the shell to do <i>command</i> . |
| <i>command</i>  |                                            |
| *               | Print a command summary.                   |

**OPTIONS****uuto**

The following options are supported by *uuto* :

|    |                                                                    |
|----|--------------------------------------------------------------------|
| -m | Send mail to the sender when the copy is complete.                 |
| -p | Copy the source file into the spool directory before transmission. |

**uupick**

The following option is supported by *uupick* :

|               |                                                                   |
|---------------|-------------------------------------------------------------------|
| -s            | Search only the <i>PUBDIR</i> for files sent from <i>system</i> . |
| <i>system</i> |                                                                   |

**OPERANDS**

The following operands are supported for *uuto* :

|                    |                       |
|--------------------|-----------------------|
| <i>destination</i> | A string of the form: |
|--------------------|-----------------------|

*system-name ! user*

where *system-name* is taken from a list of system names that *uucp* knows about; see *uname* . The argument *user* is the login name of someone on the specified system. The *destination system-name* can also be a list of names such as

*system-name ! system-name ! ... ! system-name ! user*

in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <i>source-file</i> | A pathname of a file on the local system to be copied to <i>destination</i> . |
|--------------------|-------------------------------------------------------------------------------|

**ENVIRONMENT VARIABLES**

See *environ(5)* for descriptions of the following environment variables that affect the execution of *uuto* and *uupick* : *LC\_TYPE* , *LC\_MESSAGES* , and *NLS\_PATH* .

**EXIT STATUS**

The following exit values are returned:

|    |                        |
|----|------------------------|
| 0  | Successful completion. |
| >0 | An error occurred.     |

**FILES**

PUBDIR /var/spool/uucppublic public directory

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbnuu        |

**SEE ALSO**

mail(1), uucp(1C), uustat(1C), uux(1C), uucleanup(1M), attributes(5)

**NOTES**

In order to send files that begin with a dot (for instance, .profile), the files must be qualified with a dot. For example, the following files are correct:

```
.profile .prof* .profil?
```

The following files are incorrect:

```
prof ?profile
```

| <b>NAME</b>        | <code>uux</code> – UNIX-to-UNIX system command execution                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <code>uux [-] [-bcCjnprz] [-a<code>name</code>] [-g<code>grade</code>] [-s<code>filename</code>] [-x<code>debug_level</code>]<br/><code>command-string</code></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p><code>uux</code> will gather zero or more files from various systems, execute a command on a specified system and then send standard output to a file on a specified system.</p> <p>Note: For security reasons, most installations limit the list of commands executable on behalf of an incoming request from <code>uux</code>, permitting only the receipt of mail (see <code>mail(1)</code>). (Remote execution permissions are defined in <code>/etc/uucp/Permissions</code>.)</p> <p>The <code>command-string</code> is made up of one or more arguments that look like a shell command line, except that the command and file names may be prefixed by <code>system-name!</code>. A null <code>system-name</code> is interpreted as the local system.</p> <p>File names may be one of the following:</p> <ul style="list-style-type: none"> <li>■ An absolute path name.</li> <li>■ A path name preceded by <code>~xxx</code>, where <code>xxx</code> is a login name on the specified system and is replaced by that user's login directory.</li> </ul> <p>Anything else is prefixed by the current directory.</p> <p>As an example, the command:</p> <pre>example% uux "!diff sys1!/home/dan/filename1 sys2!/a4/dan/filename2 &gt; !~/dan/filename.diff"</pre> <p>will get the <code>filename1</code> and <code>filename2</code> files from the "sys1" and "sys2" machines, execute a <code>diff(1)</code> command and put the results in <code>filename.diff</code> in the local <code>PUBDIR/dan/</code> directory. <code>PUBDIR</code> is a public directory defined in the <code>uucp</code> source. By default, this directory is <code>/var/spool/uucppublic</code>.</p> <p>Any special shell characters such as <code>&lt;</code>, <code>&gt;</code>, <code>;</code>, <code> </code> should be quoted either by quoting the entire <code>command-string</code>, or quoting the special characters as individual arguments. The redirection operators <code>&gt;&gt;</code>, <code>&lt;&lt;</code>, <code>&gt; </code> and <code>&gt;&amp;</code> cannot be used.</p> <p><code>uux</code> will attempt to get all appropriate files to the specified system where they will be processed. For files that are output files, the file name must be escaped using parentheses. For example, the command:</p> <pre>example% uux "a!cut -f1 b!/usr/filename &gt; c!/usr/filename"</pre> |

gets `"/usr/filename"` from system "b" and sends it to system "a", performs a `cut` command on that file and sends the result of the `cut` command to system "c".

`uux` will notify you if the requested command on the remote system was disallowed. This notification can be turned off by the `-n` option. The response comes by remote mail from the remote machine.

## OPTIONS

- `-` The standard input to `uux` is made the standard input to the *command-string*.
- `-aname` Use *name* as the user job identification replacing the initiator user-id. (Notification will be returned to user-id *name*.)
- `-b` Return whatever standard input was provided to the `uux` command if the exit status is non-zero.
- `-c` Do not copy local file to the spool directory for transfer to the remote machine (default).
- `-C` Force the copy of local files to the spool directory for transfer.
- `-g grade` *grade* can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The `uuglist(1C)` command determines whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the `uuglist` command will be a list of service grades that are available or a message that says to use a single letter or number as a grade of service.
- `-j` Output the jobid string on the standard output which is the job identification. This job identification can be used by `uustat(1C)` to obtain the status or terminate a job.
- `-n` Do not notify the user if the command fails.
- `-p` Same as `-`: The standard input to `uux` is made the standard input to the *command-string*.
- `-r` Do not start the file transfer, just queue the job.
- `-s filename` Report status of the transfer in *filename*. This option is accepted for compatibility, but it is ignored because it is insecure.

-x *debug\_level* Produce debugging output on the standard output. *debug\_level* is a number between 0 and 9; as it increases to 9, more detailed debugging information is given.

-z Send success notification to the user.

**ENVIRONMENT VARIABLES**

See *environ(5)* for descriptions of the following environment variables that affect the execution of *uux*: *LC\_CTYPE*, *LC\_MESSAGES*, and *NLSPATH*.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES**

- /etc/uucp/\** other data and programs
- /etc/uucp/Permissions* remote execution permissions
- /usr/lib/uucp/\** other programs
- /var/spool/uucp* spool directories

**ATTRIBUTES**

See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbnuu        |

**SEE ALSO**

*cut(1)*, *mail(1)*, *uucp(1C)*, *uuglist(1C)*, *uustat(1C)*, *attributes(5)*

**NOTES**

The execution of commands on remote systems takes place in an execution directory known to the *uucp* system.

All files required for the execution will be put into this directory unless they already reside on that machine. Therefore, the simple file name (without path or machine reference) must be unique within the *uux* request. The following command will NOT work:

```
example% uux "a!diff b!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

But the command:

```
example% uux "a!diff a!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

will work. (If *diff* is a permitted command.)

Protected files and files that are in protected directories that are owned by the requester can be sent in commands using `uux`. However, if the requester is root, and the directory is not searchable by "other", the request will fail.

The following restrictions apply to the shell pipeline processed by `uux`:

- In gathering files from different systems, pathname expansion is not performed by `uux`. Thus, a request such as

```
uux "c89 remsys!~/*.c"
```

would attempt to copy the file named literally `*.c` to the local system.

- Only the first command of a shell pipeline may have a *system-name*!. All other commands are executed on the system of the first command.
- The use of the shell metacharacter `*` will probably not do what you want it to do.
- The shell tokens `<<` and `>>` are not implemented.
- The redirection operators `>>`, `<<`, `>|` and `>&` cannot be used.
- The reserved word `!` cannot be used at the head of the pipeline to modify the exit status.
- Alias substitution is not performed.

| <b>SYNOPSIS</b>                    | <p><b>vacation</b> [-I]</p> <p><b>vacation</b> [-a <i>alias</i>] [-f <i>database_file</i>] [-j] [-m <i>message_file</i>] [-s <i>sender</i>] [-tN]</p> <p style="padding-left: 40px;"><i>username</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>                 | <p>The <code>vacation</code> utility automatically replies to incoming mail.</p> <p><b>Installation</b><br/>The installation consists of an interactive program which sets up <code>vacation</code>'s basic configuration.</p> <p>To install <code>vacation</code>, type it with no arguments on the command line. The program creates a <code>.vacation.msg</code> file, which contains the message that is automatically sent to all senders when <code>vacation</code> is enabled, and starts an editor for you to modify the message. (See <b>USAGE</b> section.) Which editor is invoked is determined by the <code>VISUAL</code> or <code>EDITOR</code> environment variable, or <code>vi(1)</code> if neither of those environment variables are set.</p> <p>A <code>.forward</code> file is also created if one does not exist in your home directory. Once created, the <code>.forward</code> file will contain a line of the form:</p> <pre style="padding-left: 40px;">\username, " /usr/bin/vacation username"</pre> <p>One copy of an incoming message is sent to the <code>username</code> and another copy is piped into <code>vacation</code>.</p> <p>If a <code>.forward</code> file is present in your home directory, it will ask whether you want to remove it, which disables <code>vacation</code> and ends the installation.</p> <p>The program automatically creates <code>.vacation.pag</code> and <code>.vacation.dir</code>, which contain a list of senders when <code>vacation</code> is enabled.</p> |
| <b>Activation and Deactivation</b> | The presence of the <code>.forward</code> file determines whether or not <code>vacation</code> is disabled or enabled. To disable <code>vacation</code> , remove the <code>.forward</code> file, or move it to a new name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Initialization</b>              | The <code>-I</code> option clears the <code>vacation</code> log files, <code>.vacation.pag</code> and <code>.vacation.dir</code> , erasing the list of senders from a previous <code>vacation</code> session. (See <b>OPTIONS</b> section.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Additional Configuration</b>    | <code>vacation</code> provides configuration options that are not part of the installation, these being <code>-a</code> , <code>-f</code> , <code>-j</code> , <code>-m</code> , <code>-s</code> , and <code>-t</code> . (See <b>OPTIONS</b> section.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>                     | <p>The following options are supported:</p> <p><code>-I</code>                Initializes the <code>.vacation.pag</code> and <code>.vacation.dir</code> files and enables <code>vacation</code>. If the <code>-I</code> flag is not specified, and a <code>user</code> argument is given, <code>vacation</code> reads the first line from</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

the standard input (for a `From:` line, no colon). If absent, it produces an error message.

Options `-a`, `-f`, `-j`, `-m`, `-t`, and `-s` are configuration options to be used in conjunction with `vacation` in the `.forward` file, not on the command line. For example,

```
\username, "|/usr/bin/vacation -t1m username"
```

repeats replies to the sender every minute.

- `-a alias` Indicates that *alias* is one of the valid aliases for the user running `vacation`, so that mail addressed to that alias generates a reply.
- `-f file` Uses *file* instead of `.vacation` as the base name for the database file.
- `-j` Does not check whether the recipient appears in the `To:` or the `Cc:` line. Warning: use of this option can result in vacation replies being sent to mailing lists and other inappropriate places; its use is therefore strongly discouraged.
- `-m file` Uses *file* instead of `.vacation.msg` as the message to send for the reply.
- `-s sender` Replies to *sender* instead of the value read from the UNIX `From` line of the incoming message.
- `-tN` Changes the interval between repeat replies to the same sender. The default is 1 week. A trailing *s*, *m*, *h*, *d*, or *w* scales *N* to seconds, minutes, hours, days, or weeks, respectively.

## USAGE

### Files

`.vacation.msg` should include a header with at least a `Subject:` line (it should not include a `From:` or a `To:` line). For example:

```
Subject: I am on vacation
I am on vacation until July 22. If you have something urgent,
please contact Joe Jones (jones@fB0).
--John
```

If the string `$SUBJECT` appears in the `.vacation.msg` file, it is replaced with the subject of the original message when the reply is sent; thus, a `.vacation.msg` file such as

```

Subject: I am on vacation
I am on vacation until July 22.
Your mail regarding "$SUBJECT" will be read when I return.
If you have something urgent, please contact
Joe Jones (jones@fb0).
--John

```

will include the subject of the message in the reply.

No message is sent if the `To:` or the `Cc:` line does not list the user to whom the original message was sent or one of a number of aliases for them, if the initial `From` line includes the string `-REQUEST@`, or if a `Precedence: bulk` or `Precedence: junk` line is included in the header.

vacation will also not respond to mail from either `postmaster` or `Mailer-Daemon`.

#### FILES

```

~/ .forward
~/ .vacation.msg

```

A list of senders is kept in the `dbm` format files `.vacation.pag` and `.vacation.dir` in your home directory. These files are `dbm` files and cannot be viewed directly with text editors.

#### ATTRIBUTES

| <b>NAME</b>        | vc – version control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | vc [-a] [-t] [-c <i>char</i> ] [-s] [ <i>keyword=value... keyword=value</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This command is obsolete and will be removed in the next release.</p> <p>The <code>vc</code> command copies lines from the standard input to the standard output under control of its arguments and of “control statements” encountered in the standard input. In the process of performing the copy operation, user-declared <i>keywords</i> may be replaced by their string <i>value</i> when they appear in plain text and/or control statements.</p> <p>The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as <code>vc</code> command arguments.</p> <p>A control statement is a single line beginning with a control character, except as modified by the <code>-t</code> keyletter (see below). The default control character is colon (:), except as modified by the <code>-c</code> keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety.</p> <p>A keyword is composed of 9 or less alphanumeric; the first must be alphabetic. A value is any ASCII string that can be created with <code>ed</code>; a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.</p> <p>Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The <code>-a</code> keyletter (see below) forces replacement of keywords in all lines of text. An uninterpreted control character may be included in a value by preceding it with <code>\</code>. If a literal <code>\</code> is desired, then it too must be preceded by <code>\</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-a</code> Forces replacement of keywords surrounded by control characters with their assigned value in all text lines and not just in <code>vc</code> statements.</li> <li><code>-t</code> All characters from the beginning of a line up to and including the first tab character are ignored for the purpose of detecting a control statement. If a control statement is found, all characters up to and including the tab are discarded.</li> <li><code>-cchar</code> Specifies a control character to be used in place of the “:” default.</li> <li><code>-s</code> Silences warning messages (not error) that are normally printed on the diagnostic output.</li> </ul> <p><code>vc</code> recognizes the following version control statements:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

```
:dc1 keyword[, ..., keyword]
```

Declare keywords. All keywords must be declared.

```
:asg keyword=value
```

Assign values to keywords. An `asg` statement overrides the assignment for the corresponding keyword on the `vc` command line and all previous `asg` statements for that keyword. Keywords that are declared but are not assigned values have null values.

```
:if condition
```

```
...
```

```
:end
```

Skip lines of the standard input. If the condition is true, all lines between the `if` statement and the matching `end` statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note: Intervening `if` statements and matching `end` statements are recognized solely for the purpose of maintaining the proper `if-end` matching.

The syntax of a condition is:

```
<cond> ::= ["not"] <or>
```

```
<or> ::=
<and> | <and> " | "
<or>
```

```
<and> ::=
<exp> | <exp> "&"
<and>
```

```
<exp> ::= "(" <or> ")"
| <value> <op> <value>
```

```
<op> ::= "=" | "!="
| "<" | ">"
```

```
<value> ::=
<arbitrary ASCII string> | <numeric string>
```

The available operators and their meanings are:

|     |                                                                                                                    |
|-----|--------------------------------------------------------------------------------------------------------------------|
| =   | equal                                                                                                              |
| !=  | not equal                                                                                                          |
| &   | and                                                                                                                |
|     | or                                                                                                                 |
| >   | greater than                                                                                                       |
| <   | less than                                                                                                          |
| ( ) | used for logical groupings                                                                                         |
| not | may only occur immediately after the <code>if</code> , and when present, inverts the value of the entire condition |

The `>` and `<` operate only on unsigned integer values (for example, `: 012 > 12` is false). All other operators take strings as arguments (for example, `: 012 != 12` is true).

The precedence of the operators (from highest to lowest) is:

|          |                         |
|----------|-------------------------|
| = != > < | all of equal precedence |
|----------|-------------------------|

|   |
|---|
| & |
|   |

Parentheses may be used to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

Replace keywords on lines that are copied to the standard output. The two leading control characters are removed, and keywords surrounded

`: : text`

by control characters in text are replaced by their value before the line is copied to the output file. This action is independent of the `-a` keyletter.

`:on`

`:off`

Turn on or off keyword replacement on all lines.

`:ctl char`

Change the control character to *char*.

`:msg message`

Print *message* on the diagnostic output.

`:err message`

Print *message* followed by:

```
ERROR: err statement on line
... (915)
```

on the diagnostic output. `vc` halts execution, and returns an exit code of 1.

| <b>NAME</b>        | vgrind – grind nice program listings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <b>vgrind</b> [-2fntwWx] [-d <i>defs-file</i> ] [-h <i>header</i> ] [-l <i>language</i> ] [-s <i>n</i> ] [-o <i>pagelist</i> ]<br>[-P <i>printer</i> ] [-T <i>output-device</i> ] <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>vgrind</code> utility formats the program sources named by the <i>filename</i> arguments in a nice style using <code>troff(1)</code>. Comments are placed in italics, keywords in bold face, and as each function is encountered its name is listed on the page margin.</p> <p><code>vgrind</code> runs in two basic modes, filter mode or regular mode. In filter mode, <code>vgrind</code> acts as a filter in a manner similar to <code>tbl(1)</code>. The standard input is passed directly to the standard output except for lines bracketed by the <code>troff</code>-like macros:</p> <pre>.vS    starts processing .vE    ends processing</pre> <p>These lines are formatted as described above. The output from this filter can be passed to <code>troff</code> for output. There need be no particular ordering with <code>eqn(1)</code> or <code>tbl(1)</code>.</p> <p>In regular mode, <code>vgrind</code> accepts input <i>filenames</i>, processes them, and passes them to <code>troff</code> for output. Use a hyphen ('-') to specify standard input; otherwise, <code>vgrind</code> will exit without attempting to read from the standard input. Filenames must be specified after all other option arguments.</p> <p>In both modes, <code>vgrind</code> passes any lines beginning with a decimal point without conversion.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported.</p> <p>Note: The syntax of options with arguments is important. Some require a SPACE between the option name and the argument, while those that do not have a SPACE below will not tolerate one.</p> <pre>-2          Produces two column output. Specifying this option             changes the default point size to 8 (as if the -s8 option             were supplied). It also arranges for output to appear in             landscape mode, by supplying the -L flag to the formatter             and changing the page height and width accordingly.  -f          Forces filter mode.  -n          Does not make keywords boldface.  -w          Considers TAB characters to be spaced four columns apart             instead of the usual eight.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

- `-x` Outputs the index file in a “pretty” format. The index file itself is produced whenever `vgrind` is run with a file called `index` present in the current directory. The index of function definitions can then be run off by giving `vgrind` the `-x` option and the file `index` as argument.
- `-d defs-file` Specify an alternate language definitions file (default is `/usr/lib/vgrindefs`).
- `-h header` Specify a header to appear in the center of every output page.
- `-l language` Specify the language to use. Among the languages currently known are: Bourne shell (`-lsh`), C (`-lc`, the default), C++ (`-lc++`), C shell (`-lcs`), emacs MLisp (`-lm1`), FORTRAN (`-lf`), Icon (`-lI`), ISP (`-i`), LDL (`-lLDL`), Model (`-lm`), Pascal (`-lp`), and RATFOR (`-lr`).
- `-sn` Specify a point size to use on output (exactly the same as the argument of a `troff .ps` point size request).

`vgrind` passes the following options to the formatter specified by the `TROFF` environment variable. See `ENVIRONMENT`.

- `-t` Similar to the same option in `troff`; that is, formatted text goes to the standard output.
- `-W` Forces output to the (wide) Versatec printer rather than the (narrow) Varian.
- `-o pagelist` Prints only those pages whose page numbers appear in the comma-separated *pagelist* of numbers and ranges. A range *N-M* means pages *N* through *M*; an initial *-N* means from the beginning to page *N*; and a final *N-* means from *N* to the end.
- `-P printer` Sends output to the named *printer*.
- `-T output-device` Formats output for the specified *output-device*.

## OPERANDS

The following operand is supported:

- filename* Name of the program source to be processed by `vgrind`. Use `-` to specify the standard input.

## ENVIRONMENT VARIABLES

In regular mode, `vgrind` feeds its intermediate output to the text formatter given by the value of the `TROFF` environment variable, or to `troff` if this variable is not defined in the environment. This mechanism allows for local variations in `troff`'s name.

|              |                                 |                                        |
|--------------|---------------------------------|----------------------------------------|
| <b>FILES</b> | index                           | file where source for index is created |
|              | /usr/lib/vgrindefs              | language descriptions                  |
|              | /usr/lib/vfontedpr              | preprocessor                           |

**BUGS**

vgrind assumes that a certain programming style is followed:

|         |                                                                                                                                         |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------|
| C       | Function names can be preceded on a line only by SPACE, TAB, or an asterisk. The parenthesized arguments must also be on the same line. |
| FORTRAN | Function names need to appear on the same line as the keywords <i>function</i> or <i>subroutine</i> .                                   |
| MLisp   | Function names should not appear on the same line as the preceding <i>defun</i> .                                                       |
| Model   | Function names need to appear on the same line as the keywords <i>is beginproc</i> .                                                    |
| Pascal  | Function names need to appear on the same line as the keywords <i>function</i> or <i>procedure</i> .                                    |

If these conventions are not followed, the indexing and marginal function name comment mechanisms will fail.

More generally, arbitrary formatting styles for programs usually give unsightly results. To prepare a program for vgrind output, use TAB rather than SPACE characters to align source code properly, since vgrind use variable width fonts.

The mechanism of ctags(1) in recognizing functions should be used here.

The -w option is annoying, but there is no other way to achieve the desired effect.

The macros defined in tmac.vgrind do not coexist gracefully with those of other macro packages, making filter mode difficult to use effectively.

vgrind does not process certain special characters in csh(1) scripts correctly.

The `tmac.vgrind` formatting macros wire in the page height and width used in two-column mode, effectively making two column output useless for paper sizes other than the standard American size of 8.5 inches by 11 inches. For other paper sizes, it is necessary to edit the size values given in `tmac.vgrind`. A better solution would be to create a `troff` output device specification intended specifically for landscape output and record size information there.

| <b>DESCRIPTION</b>        | <p>vi (visual) is a display-oriented text editor based on an underlying line editor ex . It is possible to use the command mode of ex from within vi and to use the command mode of vi from within ex . The visual commands are described on this manual page; how to set options (like automatically numbering lines and automatically starting a new output line when you type carriage return) and all ex line editor commands are described on the ex(1) manual page.</p> <p>When using vi , changes you make to the file are reflected in what you see on your terminal screen. The position of the cursor on the screen indicates the position within the file.</p> <p>The view invocation is the same as vi except that the readonly flag is set.</p> <p>The vedit invocation is intended for beginners. It is the same as vi except that the report flag is set to 1 , the showmode and novice flags are set, and magic is turned off. These defaults make it easier to learn how to use vi .</p> |   |                                                                                        |    |  |    |                                                                                                                                             |
| <b>OPTIONS</b>            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |                                                                                        |    |  |    |                                                                                                                                             |
| <b>Invocation Options</b> | <p>The following invocation options are interpreted by vi (previously documented options are discussed in the NOTES section of this manual page):</p> <table border="0"> <tr> <td style="vertical-align: top;">-</td> <td>Suppress all interactive user feedback. This is useful when processing editor scripts.</td> </tr> <tr> <td style="vertical-align: top;">  -s</td> <td></td> </tr> <tr> <td style="vertical-align: top;">-C</td> <td>Encryption option; same as the -x option, except that vi simulates the C command of ex . The C command is like the X command of ex , except</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                             | - | Suppress all interactive user feedback. This is useful when processing editor scripts. | -s |  | -C | Encryption option; same as the -x option, except that vi simulates the C command of ex . The C command is like the X command of ex , except |
| -                         | Suppress all interactive user feedback. This is useful when processing editor scripts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                        |    |  |    |                                                                                                                                             |
| -s                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |                                                                                        |    |  |    |                                                                                                                                             |
| -C                        | Encryption option; same as the -x option, except that vi simulates the C command of ex . The C command is like the X command of ex , except                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |                                                                                        |    |  |    |                                                                                                                                             |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | that all text read in is assumed to have been encrypted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -l                    | Set up for editing LISP programs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -L                    | List the name of all files saved as the result of an editor or system crash.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -r<br><i>filename</i> | Edit <i>filename</i> after an editor or system crash. (Recovers the version of <i>filename</i> that was in the buffer when the crash occurred.)                                                                                                                                                                                                                                                                                                                                                                                                          |
| -R                    | Readonly mode; the <code>readonly</code> flag is set, preventing accidental overwriting of the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -S                    | This option is used in conjunction with the <code>-t tag</code> option to tell <code>vi</code> that the tags file may not be sorted and that, if the binary search (which relies on a sorted tags file) for <i>tag</i> fails to find it, the much slower linear search should also be done. Since the linear search is slow, users of large tags files should ensure that the tags files are sorted rather than use this flag. Creation of tags files normally produces sorted tags files. See <code>ctags(1)</code> for more information on tags files. |
| -t<br><i>tag</i>      | Edit the file containing the tag, <i>tag</i> , and position the editor at its definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -v                    | Start up in display editing state using <code>vi</code> . You can achieve the same effect by simply typing the <code>vi</code> command itself.                                                                                                                                                                                                                                                                                                                                                                                                           |
| -V                    | Verbose. When <code>ex</code> commands are read by means of standard input, the input will be echoed to standard error. This may be useful when                                                                                                                                                                                                                                                                                                                                                                                                          |

processing `ex` commands within shell scripts.

`-w`  
*n*  
Set the default window size to *n*. This is useful when using the editor over a slow speed line.

`-x`  
Encryption option; when used, `vi` simulates the `x` command of `ex` and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the `crypt` command. The `x` command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the `-x` option. If an empty encryption key is entered (that is, if the return key is pressed right after the prompt), the file will not be encrypted. This is a good way to decrypt a file erroneously encrypted with a mistyped encryption key, such as a backspace or undo key.

`+`  
*command*  
`| -c`  
*command*  
Begin editing by executing the specified editor *command* (usually a search or positioning command).

`/usr/xpg4/bin/vi`

If both the `-t tag` and the `-c command` options are given, the `-t tag` option will be processed first. That is, the file containing *tag* is selected by `-t` and then the command is executed.

**OPERANDS**

The following operands are supported:  
*filename*            A file to be edited.

**COMMAND SUMMARY**

**vi Modes**

Command            Normal and initial mode. Other modes return to command mode upon completion. `ESC` (escape) is used to cancel a partial command.

Input                Entered by setting any of the following options:

|                                  |                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
|                                  | a A i I o O c C s S R                                                                                                            |
|                                  | Arbitrary text may then be entered. Input mode is normally terminated with the ESC character, or, abnormally, with an interrupt. |
| Last line                        | Reading input for : / ? or ! . Terminate by typing a carriage return. An interrupt cancels termination.                          |
| <b>Sample commands</b>           | In the descriptions, CR stands for carriage return and ESC stands for the escape key.                                            |
|                                  | <-                                                                                                                               |
|                                  | ->                                                                                                                               |
|                                  | down-arrow                                                                                                                       |
|                                  | up-arrow                                                                                                                         |
|                                  | arrow keys move the cursor                                                                                                       |
|                                  | h j k l                                                                                                                          |
|                                  | same as arrow keys                                                                                                               |
|                                  | i text                                                                                                                           |
|                                  | insert text                                                                                                                      |
|                                  | ESC                                                                                                                              |
|                                  | cw new                                                                                                                           |
|                                  | change word to new                                                                                                               |
|                                  | ESC                                                                                                                              |
|                                  | eas                                                                                                                              |

|                                 | R <i>text</i><br>ESC | replace characters                                                                                                                                                                                                                                                     |
| <b>Operators</b>                |                      | Operators are followed by a cursor motion and affect all text that would have been moved over. For example, since <i>w</i> moves over a word, <i>dw</i> deletes the word that would be moved over. Double the operator, for example <i>dd</i> , to affect whole lines. |

*OpenWindows Advanced User's Guide*

**AUTHOR**

vi and ex were developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

**NOTES**

Two options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see intro(1)). An -r option that is not followed with an option-argument has been replaced by -L and + command has been replaced by -c command.

The message file too large to recover with -r option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the -r option will not be possible.

The editing environment defaults to certain configuration options. When an editing session is initiated, vi attempts to read the EXINIT environment variable. If it exists, the editor uses the values defined in EXINIT; otherwise the values set in \$HOME/.exrc are used. If \$HOME/.exrc does not exist, the default values are used.

To use a copy of .exrc located in the current directory other than \$HOME, set the exrc option in EXINIT or \$HOME/.exrc. Options set in EXINIT can be turned off in a local .exrc only if exrc is set in EXINIT or \$HOME/.exrc.

Tampering with entries in /usr/share/lib/terminfo/\*/\* or /usr/share/lib/terminfo/\*/\* (for example, changing or removing an entry) can affect programs such as vi that expect the entry to be present and

correct. In particular, removing the "dumb" terminal may cause unexpected problems.

Software tabs using `^T` work only immediately after the *autoindent*.

Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.

The standard Solaris version of `vi` will be replaced by the POSIX.2-conforming version (see `standards(5)`) in the future. Scripts which use the `ex` family of addressing and features should use the `/usr/xpg4/bin` version of these utilities.

**NAME** vipw – edit the password file

**SYNOPSIS** /usr/ucb/vipw

**DESCRIPTION** vipw edits the password file while setting the appropriate locks, and does any necessary processing after the password file is unlocked. If the password file is already being edited, then you will be told to try again later. The vi(1) editor will be used unless the environment variable VISUAL or EDITOR indicates an alternate editor.

vipw performs a number of consistency checks on the password entry for root, and will not allow a password file with a “mangled” root entry to be installed. It also checks the /etc/shells file to verify the login shell for root.

**FILES** /etc/ptmp  
/etc/shells

**NAME** volcancel – cancel user’s request for removable media that is not currently in drive

**SYNOPSIS** /usr/lib/vold/volcancel [-n] [*volume*]

**DESCRIPTION** volcancel cancels a user’s request to access a particular floppy or CD-ROM file system. This command is useful when the removable media containing the file system is not currently in the drive.

Use the path /vol/rdisk/*name\_of\_volume* to specify the volume. If called without a volume name to cancel, volcancel checks for Volume Management running.

**OPTIONS** -n Display the nickname to the device name translation table.

**EXAMPLES** **EXAMPLE 1** A sample of the volcancel command.

To cancel a request to access an unnamed CD-ROM, use

```
example% /usr/lib/vold/volcancel vol/rdisk/unnamed_cdrom
```

To check if volume management is running, use:

```
example% /usr/lib/vold/volcancel || echo volmgmt not running
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

**SEE ALSO** rmmount(1M), volcheck(1), vold(1M), volmissing(1), rmmount.conf(4), vold.conf(4), attributes(5), volfs(7FS)

**NAME** volcheck – checks for media in a drive and by default checks all floppy media

**SYNOPSIS** **volcheck** [-v] [-i *secs*] [-t *secs*] *pathname*

**DESCRIPTION** The `volcheck` utility tells Volume Management to look at each *dev/pathname* in sequence and determine if new media has been inserted in the drive.

The default action is to `volcheck` all checkable media managed by volume management.

**OPTIONS** The following options are supported:

-i *secs* Set the frequency of device checking to *secs* seconds. The default is 2 seconds. The minimum frequency is 1 second.

-t *secs* Check the named device(s) for the next *secs* seconds. The maximum number of seconds allowed is 28800, which is 8 hours. The frequency of checking is specified by -i. There is no default total time.

-v Verbose.

**OPERANDS** The following operands are supported:

*pathname* The path name of a media device.

**EXAMPLES** **EXAMPLE 1** A sample of the `volcheck` command.

The following example

```
example% volcheck -v /dev/diskette
/dev/diskette has media
```

asks Volume Management to examine the floppy drive for new media.

The following example

```
example% volcheck -i 2 -t 600 /dev/diskette1 &
```

asks Volume Management if there is a floppy in the floppy drive every 2 seconds for 600 seconds (10 minutes).

**FILES** /dev/volctl Volume Management control port

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWvolu        |

**SEE ALSO** `eject(1)`, `volcancel(1)`, `volmissing(1)`, `rmmount(1M)`, `vold(1M)`, `rmmount.conf(4)`, `vold.conf(4)`, `attributes(5)`, `volfs(7FS)`

**WARNINGS**

Due to a hardware limitation in many floppy drives, the act of checking for media causes mechanical action in the floppy drive. Continuous polling of the floppy drive will cause the drive to wear out. It is recommended that polling the drive only be performed during periods of high use.

| <b>NAME</b>        | volmissing - notify user that volume requested is not in the CD-ROM or floppy drive                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/usr/lib/vold/volmissing [-c] [-p] [-s] [-m <i>alias</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>volmissing informs a user when a requested volume is not available. Depending on the option selected, users are notified through their console window, syslogd(1M), or a mail message.</p> <p>volmissing -p is the default action taken by vold(1M), the Volume Management daemon, when it needs to notify a user that the requested volume is not available. If you want to change this default event, modify the <code>/etc/vold.conf</code> file. See vold.conf(4).</p> <p>You can change the notification method for your system by editing the vold.conf configuration file and providing a new option for volmissing in the notify entry under the Events category.</p> |                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | -c                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Send a message to the user's console requesting the volume be inserted. To end the notification without inserting the requested volume, use volcancel(1).                                                     |
|                    | -p                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | All volmissing events will be handled through a GUI, provided a window system is running on the console. If this option is specified, and no window system is running, all messages go to the system console. |
|                    | -s                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Send one message to the syslogd(1M).                                                                                                                                                                          |

rmmount.conf(4), vold.conf(4), attributes(5), volfs(7FS)

**NAME** volrmmount – call rmmount to mount or unmount media

**SYNOPSIS** **volrmmount** [-i | -e ][*name* | *nickname* ]

**volrmmount** [-d]

**DESCRIPTION** **volrmmount** calls **rmmount(1M)** to, in effect, simulate an insertion (-i) or an ejection (-e). Simulating an insertion often means that **rmmount** will mount the media. Conversely, simulating an ejection often means that **rmmount** will unmount the media. However, these actions can vary depending on the **rmmount** configuration and media type (see **rmmount.conf(4)**).

For example, if you use the default `/etc/rmmount.conf` and insert a music CD, it won't be mounted. However, you can configure **rmmount** so that it calls **workman** whenever a music CD is inserted.

This command allows you to override Volume Management's usual handling of media (see **EXAMPLES** below).

**OPTIONS**

- i Simulate an insertion of the specified media by calling **rmmount**.
- e Simulate an ejection of the specified media by calling **rmmount**.
- d Display the name of the default device for **volrmmount** to handle. This device is used if no *name* or *nickname* is supplied.

**OPERANDS**

*name* The name that Volume Management recognizes as the device's name, see **volfs(7FS)**.

*nickname* A shortened version of the device's name. Following is the list of recognized nicknames:

| Nickname   | Path            |
|------------|-----------------|
| fd         | /dev/rdiskette  |
| fd0        | /dev/rdiskette  |
| fd1        | /dev/rdiskette1 |
| diskette   | /dev/rdiskette  |
| diskette0  | /dev/rdiskette0 |
| diskette1  | /dev/rdiskette1 |
| rdiskette  | /dev/rdiskette  |
| rdiskette0 | /dev/rdiskette0 |
| rdiskette1 | /dev/rdiskette1 |
| floppy     | /dev/rdiskette  |

| Nickname | Path            |
|----------|-----------------|
| floppy0  | /dev/rdiskette0 |
| floppy1  | /dev/rdiskette1 |

**EXAMPLES**

**EXAMPLE 1** A sample case of `volrmmount` command.

When Volume Management finds a floppy that contains a filesystem, it calls `rmmount` to mount it. If you wish to run `tar(1)` or `cpio(1)` on that floppy, it must first be unmounted. To unmount the floppy use:

```
example% volrmmount -e floppy0
```

After `volrmmount` unmounts the floppy, if you wish to re-mount it (rather than ejecting it and reinserting it) use:

```
example% volrmmount -i floppy0
```

Note that if you are using a named floppy you can use its name in place of `floppy0`.

**FILES**

`/dev/volctl` Volume Management control port

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWvolu        |

**SEE ALSO**

`cpio(1)`, `eject(1)`, `tar(1)`, `rmmount(1M)`, `vold(1M)`, `rmmount.conf(4)`, `attributes(5)`, `volfs(7FS)`

**NOTES**

Volume Management (`vold`) must be running to use this command.

**NAME** vsig – synchronize a co-process with the controlling FMLI application

**SYNOPSIS** vsig

**DESCRIPTION** The vsig executable sends a SIGUSR2 signal to the controlling FMLI process. This signal/alarm causes FMLI to execute the FMLI built-in command `checkworld` which causes all posted objects with a `reread` descriptor evaluating to TRUE to be reread. vsig takes no arguments.

**EXAMPLES** **EXAMPLE 1** A sample output of vsig command.

The following is a segment of a shell program:

```
echo "Sending this string to an FMLI process"
vsig
```

The vsig executable will flush the output buffer *before* it sends the SIGUSR2 signal to make sure the string is actually in the pipe created by the `cocreate` function.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**SEE ALSO** `coproc(1F)`, `kill(1)`, `kill(2)`, `signal(3C)`, `attributes(5)`

**NOTES** Because vsig synchronize with FMLI, it should be used rather than `kill` to send a SIGUSR2 signal to FMLI.

| <b>SYNOPSIS</b>              | w [-hlsuw] [ <i>user</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>           | <p>The <code>w</code> command displays a summary of the current activity on the system, including what each user is doing. The heading line shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.</p> <p>The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged on (in <i>hours:minutes</i>), the idle time—that is, the number of minutes since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), and the name and arguments of the current process.</p> |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-h     Suppress the heading.</li> <li>-l     Produce a long form of output, which is the default.</li> <li>-s     Produce a short form of output. In the short form, the tty is abbreviated, the login time and CPU times are left off, as are the arguments to commands.</li> <li>-u     Produces the heading line which shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.</li> <li>-w     Produces a long form of output, which is also the same as the default.</li> </ul>                                                                                                                                               |
| <b>OPERANDS</b>              | <i>user</i> Name of a particular user for whom login information is displayed. If specified, output is restricted to that user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**NOTES**

The notion of the “current process” is unclear. The current algorithm is ‘the highest numbered process on the terminal that is not ignoring interrupts, or, if there is none, the highest numbered process on the terminal’. This fails, for example, in critical sections of programs like the shell and editor, or when faulty programs running in the background fork and fail to ignore interrupts. In cases where no process can be found, w prints –.

The CPU time is only an estimate, in particular, if someone leaves a background process running after logging out, the person currently on that terminal is “charged” with the time.

Background processes are not shown, even though they account for much of the load on the system.

Sometimes processes, typically those in the background, are printed with null or garbaged arguments. In these cases, the name of the command is printed in parentheses.

w does not know about the conventions for detecting background jobs. It will sometimes find a background job instead of the right one.

| <b>DESCRIPTION</b> | <p>The shell itself executes <code>wait</code>, without creating a new process. If you get the error message <code>cannot fork, too many processes</code>, try using the <code>wait</code> command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. (There is a limit to the number of process IDs associated with your login, and to the number the system can keep track of.)</p> <p>Not all the processes of a pipeline with three or more stages are children of the shell, and thus cannot be waited for.</p> <p>Wait for your background process whose process ID is <i>pid</i> and report its termination status. If <i>pid</i> is omitted, all your shell's currently active background processes are waited for and the return code will be 0. The <code>wait</code> utility accepts a job identifier, when Job Control is enabled (<code>jsh</code>), and the argument, <i>jobid</i>, is preceded by a percent sign (%).</p> <p>If <i>pid</i> is not an active process ID, the <code>wait</code> utility will return immediately and the return code will be 0.</p> <p><b>csh</b> Wait for your background processes.</p> <p><b>ksh</b> When an asynchronous list is started by the shell, the process ID of the last command in each element of the asynchronous list becomes known in the current shell execution environment.</p> <p>If the <code>wait</code> utility is invoked with no operands, it will wait until all process IDs known to the invoking shell have terminated and exit with an exit status of 0.</p> <p>If one or more <i>pid</i> or <i>jobid</i> operands are specified that represent known process IDs (or jobids), the <code>wait</code> utility will wait until all of them have terminated. If one or more <i>pid</i> or <i>jobid</i> operands are specified that represent unknown process IDs (or jobids), <code>wait</code> will treat them as if they were known process IDs (or jobids) that exited with exit status 127. The exit status returned by the <code>wait</code> utility will be the exit status of the process requested by the last <i>pid</i> or <i>jobid</i> operand.</p> <p>The known process IDs are applicable only for invocations of <code>wait</code> in the current shell execution environment.</p> |
| <b>OPERANDS</b>    | The following operands are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

One of the following:

- pid* The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.
- jobid* A job control job ID that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of `wait` in the current shell execution environment, and only on systems supporting the job control option.

## USAGE

On most implementations, `wait` is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following,

```
(wait)
nohup wait ...
find . -exec wait ... \;
```

it will return immediately because there will be no known process IDs to wait for in those environments.

## EXAMPLES

### EXAMPLE 1 Using A Script To Identify The Termination Signal

For Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal is using `kill`, as shown by the following (`/bin/ksh` and `/usr/xpg4/bin/sh`):

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l ${ $?-128}) signal.
```

### EXAMPLE 2 Returning The Exit Status Of A Process

If the following sequence of commands is run in less than 31 seconds (`/bin/ksh` and `/usr/xpg4/bin/sh`):

```
sleep 257 | sleep 31 &
```

```
jobs -l %%
```

then either of the following commands will return the exit status of the second sleep in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `wait`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>                  | wc – display a count of lines, words and characters in a file                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>              | wc [-c   -m   -C ][-lw] [file...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>           | <p>The wc utility reads one or more input files and, by default, writes the number of newline characters, words and bytes contained in each input file to the standard output.</p> <p>The utility also writes a total count for all named files, if more than one input file is specified.</p> <p>wc considers a <i>word</i> to be a non-zero-length string of characters delimited by white space (for example, SPACE, TAB). See <code>iswspace(3C)</code> or <code>isspace(3C)</code>.</p>                                |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c     Count bytes.</li> <li>-m     Count characters.</li> <li>-C     Same as -m.</li> <li>-l     Count lines.</li> <li>-w     Count words delimited by white space characters or new line characters. Delimiting characters are Extended Unix Code (EUC) characters from any code set defined by <code>iswspace()</code>.</li> </ul> <p>If no option is specified the default is <code>-lwc</code> (count lines, words, and bytes.)</p> |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <ul style="list-style-type: none"> <li><i>file</i>    A path name of an input file. If no <i>file</i> operands are specified, the standard input will be used.</li> </ul>                                                                                                                                                                                                                                                                                                        |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of wc when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of wc: LC_CTYPE, LC_MESSAGES, and NLSPATH.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0       Successful completion.</li> <li>&gt;0     An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                       |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>SYNOPSIS</b>    | <b>what</b> [-s] <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |
| <b>DESCRIPTION</b> | what searches each <i>filename</i> for occurrences of the pattern <code>@(#)</code> that the SCCS <code>get</code> command (see <code>sccs-get(1)</code> ) substitutes for the <code>@(#)</code> ID keyword, and prints what follows up to a <code>"</code> , <code>&gt;</code> , <code>NEWLINE</code> , <code>\</code> , or null character.                                                                                                                                                                 |                |                 |              |          |
| <b>OPTIONS</b>     | The following option is supported:<br><b>-s</b> Stop after the first occurrence of the pattern.                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |          |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Extracting SCCS version information</p> <p>If a C program in file <code>program.c</code> contains</p> <pre>char sccsid[] = "@(#)identification information";</pre> <p>and <code>program.c</code> is compiled to yield <code>program.o</code> and <code>a.out</code>, the command:</p> <pre>example% what program.c program.o a.out</pre> <p>produces:</p> <pre>program.c:  identification information program.o:  identification information a.out:     identification information</pre> |                |                 |              |          |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |

| ATTRIBUTE TYPE     | ATTRIBUTE VALUE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |          |
| Availability       | SUNWspot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |          |
| <b>SEE ALSO</b>    | <code>sccs(1)</code> , <code>sccs-admin(1)</code> , <code>sccs-cdc(1)</code> , <code>sccs-comb(1)</code> , <code>sccs-delta(1)</code> , <code>sccs-get(1)</code> , <code>sccs-help(1)</code> , <code>sccs-prs(1)</code> , <code>sccs-prt(1)</code> , <code>sccs-rmdel(1)</code> , <code>sccs-sact(1)</code> , <code>sccs-sccsdiff(1)</code> , <code>sccs-unget(1)</code> , <code>sccs-val(1)</code> , <code>sccsfile(4)</code> , <code>attributes(5)</code>                                                  |                |                 |              |          |
| <b>DIAGNOSTICS</b> | Use the SCCS <code>help</code> command for explanations (see <code>sccs-help(1)</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |          |
| <b>BUGS</b>        | There is a remote possibility that a spurious occurrence of the <code>'@(#)'</code> pattern could be found by <code>what</code> .                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |          |

**NAME** | `whatis` – display a one-line summary about a keyword

**SYNOPSIS** | `whatis` *command*...

**DESCRIPTION** | `whatis` looks up a given *command* and displays the header line from the manual section. You can then run the `man(1)` command to get more information. If the line starts '*name(section) ...*' you can do '`man -s section name`' to get the documentation for it. Try '`whatis ed`' and then you should do '`man -s 1 ed`' to get the manual page for `ed(1)`.

`whatis` is actually just the `-f` option to the `man(1)` command.

`whatis` uses the `/usr/share/man/windex` database. This database is created by `catman(1M)`. If this database does not exist, `whatis` will fail.

**FILES** | `/usr/share/man/windex` | Table of contents and keyword database

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |
| CSI            | enabled         |

**SEE ALSO** | `apropos(1)`, `man(1)`, `catman(1M)`, `attributes(5)`

| <b>NAME</b>        | whereis - locate the binary, source, and manual page files for a command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/whereis [-bmsu] [-BMS directory... -f ] filename...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>whereis</code> utility locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form <code>.ext</code>, for example, <code>.c</code>. Prefixes of <code>s.</code> resulting from use of source code control are also dealt with. <code>whereis</code> then attempts to locate the desired program in a list of standard places:</p> <pre> /usr/bin /usr/bin /usr/5bin /usr/games /usr/hosts /usr/include /usr/local /usr/etc /usr/lib /usr/share/man /usr/src /usr/ucb </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-b</code> Search only for binaries.</li> <li><code>-m</code> Search only for manual sections.</li> <li><code>-s</code> Search only for sources.</li> <li><code>-u</code> Search for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus <code>'whereis -m -u *'</code> asks for those files in the current directory which have no documentation.</li> <li><code>-B</code> Change or otherwise limit the places where <code>whereis</code> searches for binaries.</li> <li><code>-M</code> Change or otherwise limit the places where <code>whereis</code> searches for manual sections.</li> <li><code>-S</code> Change or otherwise limit the places where <code>whereis</code> searches for sources.</li> <li><code>-f</code> Terminate the last directory list and signals the start of file names, and <i>must</i> be used when any of the <code>-B</code>, <code>-M</code>, or <code>-S</code> options are used.</li> </ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Finding files with the <code>whereis</code> command</p> <p>Find all files in <code>/usr/bin</code> which are not documented in <code>/usr/share/man/man1</code> with source in <code>/usr/src/cmd</code>:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

```
example% cd /usr/ucb
example% whereis -u -M /usr/share/man/man1 -S /usr/src/cmd -f *
```

**FILES**

```
/usr/src/*
/usr/{doc,man}/*
/etc, /usr/{lib,bin,ucb,old,new,local}
```

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO**

chdir(2), attributes(5)

**BUGS**

Since whereis uses chdir(2) to run faster, pathnames given with the -M, -S, or -B must be full; that is, they must begin with a '/.

**NAME** | which – locate a command; display its pathname or alias

**SYNOPSIS** | **which** [*filename...*]

**DESCRIPTION** | **which** takes a list of names and looks for the files which would be executed had these names been given as commands. Each argument is expanded if it is aliased, and searched for along the user's path. Both aliases and path are taken from the user's `.cshrc` file.

**FILES** | `~/ .cshrc` source of aliases and path values  
`/usr/bin/which`

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `csh(1)`, `attributes(5)`

**DIAGNOSTICS** | A diagnostic is given for names which are aliased to more than a single word, or if an executable file with the argument name was not found in the path.

**NOTES** | **which** is not a shell built-in command; it is the UNIX command,  
`/usr/bin/which`

**BUGS** | Only aliases and paths from `~/ .cshrc` are used; importing from the current environment is not attempted. Must be executed by `csh(1)`, since only `csh` knows about aliases.

To compensate for `~/ .cshrc` files in which aliases depend upon the `prompt` variable being set, **which** sets this variable to `NULL`. If the `~/ .cshrc` produces output or prompts for input when `prompt` is set, **which** may produce some strange results.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>            | while, until – shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>        |                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>sh</b>              | <b>while</b> [ <i>conditions</i> ] ; do <i>actions</i> ; done<br><b>until</b> [ <i>conditions</i> ] ; do <i>actions</i> ; done                                                                                                                                                                                                                                                                    |
| <b>cs</b>              | <b>while</b> ( <i>conditions</i> )<br>[...] # do actions<br><b>end</b>                                                                                                                                                                                                                                                                                                                            |
| <b>ksh</b>             | <b>while</b> [ <i>conditions</i> ] ; do <i>actions</i> ; done<br><b>until</b> [ <i>conditions</i> ] ; do <i>actions</i> ; done                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b>     |                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>sh</b>              | A while command repeatedly executes the while <i>conditions</i> and, if the exit status of the last command in the <i>conditions</i> list is 0 , executes the <i>do actions</i> ; otherwise the loop terminates. If no commands in the <i>do actions</i> are executed, then the while command returns a 0 exit status; until may be used in place of while to negate the loop termination test.   |
| <b>cs</b>              | While <i>conditions</i> is TRUE (evaluates to nonzero), repeat commands between the while and the matching end statement. The while and end must appear alone on their input lines. If the shell's input is a terminal, it prompts for commands with a question-mark until the end command is entered and then performs the commands in the loop.                                                 |
| <b>ksh</b>             | A while command repeatedly executes the while <i>conditions</i> and, if the exit status of the last command in the <i>conditions</i> list is zero, executes the <i>do actions</i> ; otherwise the loop terminates. If no commands in the <i>do actions</i> are executed, then the while command returns a 0 exit status; until may be used in place of while to negate the loop termination test. |
| <b>loop interrupts</b> | The built-in command continue may be used to terminate the execution of the current iteration of a while or until loop, and the built-in command break may be used to terminate execution of a while or until command.                                                                                                                                                                            |
| <b>EXAMPLES</b>        | <b>EXAMPLE 1</b> Using The while Command With sh and ksh<br><br>In these examples, the user is repeated prompted for a name of a file to be located, until the user chooses to finish the execution by entering an empty line.<br><pre>filename=anything while [ \$filename ] do   echo "file?"   read filename # read from terminal   find . -name \$filename -print</pre>                       |

```
done
```

The brackets surrounding `$filename` are necessary for evaluation. (See the `test` built-in command in the `if(1)` man page). Additionally, there must be a blank space separating each bracket from any characters within.

**EXAMPLE 2** Using The `while` Command With `csh`

```
set filename = anything
while ("$filename" != " ")
 echo "file?"
 set filename = $< # read from terminal
 find . -name $filename -print
end
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`break(1)`, `csh(1)`, `if(1)`, `ksh(1)`, `sh(1)`, `attributes(5)`

**NOTES**

Both the Bourne shell, `sh`, and the Korn shell, `ksh`, can use the semicolon and the carriage return interchangeably in their syntax of the `if`, `for`, and `while` built-in commands.

| <b>DESCRIPTION</b> | <p>The <code>who</code> utility can list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current UNIX system user. It examines the <code>/var/adm/utmp</code> file to obtain its information. If <i>file</i> is given, that file (which must be in <code>utmp(4)</code> format) is examined. Usually, <i>file</i> will be <code>/var/adm/wtmp</code>, which contains a history of all the logins since the file was last created.</p> <p>The general format for output is:</p> <pre> name [state] line time [idle] [pid] [comment] [exit] </pre> <p>where:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>name</i></td> <td>user's login name.</td> </tr> <tr> <td><i>state</i></td> <td>capability of writing to the terminal.</td> </tr> <tr> <td><i>line</i></td> <td>name of the line found in <code>/dev</code>.</td> </tr> <tr> <td><i>time</i></td> <td>time since user's login.</td> </tr> <tr> <td><i>idle</i></td> <td>time elapsed since the user's last activity.</td> </tr> <tr> <td><i>pid</i></td> <td>user's process id.</td> </tr> <tr> <td><i>comment</i></td> <td>comment line in <code>inittab(4)</code>.</td> </tr> <tr> <td><i>exit</i></td> <td>exit status for dead processes.</td> </tr> </table> | <i>name</i> | user's login name. | <i>state</i> | capability of writing to the terminal. | <i>line</i> | name of the line found in <code>/dev</code> . | <i>time</i> | time since user's login. | <i>idle</i> | time elapsed since the user's last activity. | <i>pid</i> | user's process id. | <i>comment</i> | comment line in <code>inittab(4)</code> . | <i>exit</i> | exit status for dead processes. |
| <i>name</i>        | user's login name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                    |              |                                        |             |                                               |             |                          |             |                                              |            |                    |                |                                           |             |                                 |

- d Display all processes that have expired and not been respawned by `init`. The `exit` field appears for dead processes and contains the termination and exit values (as returned by `wait(3UCB)`), of the dead process. This can be useful in determining why a process terminated.
  - H Output column headings above the regular output.
  - l List only those lines on which the system is waiting for someone to login. The `name` field is `LOGIN` in such cases. Other fields are the same as for user entries except that the `state` field does not exist.
  - m Output only information about the current terminal.
  - n *x* Take a numeric argument, *x*, which specifies the number of users to display per line. *x* must be at least 1. The `-n` option may only be used with `-q`.
  - p List any other process which is currently active and has been previously spawned by `init`. The `name` field is the name of the program executed by `init` as found in `/sbin/inittab`. The `state`, `line`, and `idle` fields have no meaning. The `comment` field shows the `id` field of the line from `/sbin/inittab` that spawned this process. See `inittab(4)`.
  - q (quick who) display only the names and the number of users currently logged on. When this option is used, all other options are ignored.
  - r Indicate the current *run-level* of the `init` process.
  - s (default) List only the `name`, `line`, and `time` fields.
  - T Same as the `-s` option, except that the `state`, `idle`, `pid`, and `comment` fields are also written. `state` is one of the following characters:
    - + The terminal allows write access to other users.
    - The terminal denies write access to other users.
    - ? The terminal write-access state cannot be determined.
- /usr/bin/who**
- T Same as the `-s` option, except that the `state` field is also written. `state` is one of the characters listed under the `/usr/bin/who` version of this option. If the `-u` option is used with `-T`, the idle time is added to the end of the previous format.
  - t Indicate the last change to the system clock (using the `date` utility) by `root`. See `su(1M)` and `date(1)`.
- /usr/xpg4/bin/who**

-u List only those users who are currently logged in. The *name* is the user's login name. The *line* is the name of the line as found in the directory */dev*. The *time* is the time that the user logged in. The *idle* column contains the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is therefore "current". If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked *old*. This field is useful when trying to determine whether a person is working at the terminal or not. The *pid* is the process-ID of the user's shell. The *comment* is the comment field associated with this line as found in */sbin/inittab* (see *inittab(4)*). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, and so forth.

**OPERANDS**

The following operands are supported:

- am i*
- am I* In the "C" locale, limit the output to describing the invoking user, equivalent to the *-m* option. The *am* and *i* or *I* must be separate arguments.
- file* Specify a path name of a file to substitute for the database of logged-on users that *who* uses by default.

**ENVIRONMENT VARIABLES**

See *environ(5)* for descriptions of the following environment variables that affect the execution of *who*: *LC\_CTYPE*, *LC\_MESSAGES*, *LC\_TIME*, and *NLSPATH*.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES**

- /sbin/inittab* script for *init*.
- /var/adm/utmp* current user and accounting information
- /var/adm/wtmp* historic user and accounting information

**ATTRIBUTES**

See *attributes(5)* for descriptions of the following attributes:

*/usr/bin/who*

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

`/usr/xpg4/bin/who`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

**SEE ALSO**

date(1), login(1), mesg(1), init(1M), su(1M), wait(3UCB), inittab(4), utmp(4), attributes(5), environ(5), XPG4(5)

**NOTES**

Super user: After a shutdown to the single-user state, `who` returns a prompt; since `/var/adm/utmp` is updated at login time and there is no login in single-user state, `who` cannot report accurately on this state. `who am i`, however, returns the correct information.

**NAME** | whoami - display the effective current username

**SYNOPSIS** | **/usr/ucb/whoami**

**DESCRIPTION** | whoami displays the login name corresponding to the current effective user ID. If you have used `su` to temporarily adopt another user, whoami will report the login name associated with that user ID. whoami gets its information from the `geteuid` and `getpwuid` library routines (see `getuid` and `getpwnam(3C)`, respectively).

**FILES** | `/etc/passwd` | username data base

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** | `su(1M)`, `who(1)`, `getuid(2)`, `getpwnam(3C)`, `attributes(5)`

**NAME** whocalls – report on the calls to a specific procedure.

**SYNOPSIS** `/usr/ccs/bin/whocalls whocalls [-l wholib] funcname executable [executable arguments... ]`

**DESCRIPTION** `whocalls` is a simple example of a utility based on the *Link-Auditing* library, which permits the tracking of a given function call. See *Linker and Libraries Guide* The *executable* is run as normal. Each time the procedure *funcname* is called, both the arguments to that procedure and a stack trace are displayed on standard output.

**OPTIONS** `-l wholib` Specify an alternate `who.so` *Link-Auditing* library to use.

**EXAMPLES** **EXAMPLE 1** A sample of the `whocalls` command.

This examples tracks the calls to `printf()` made by a simple `hello_world` program

```
% whocalls printf hello
printf(0x106e4, 0xef625310, 0xef621ba8)
 hello:main+0x10
 hello:_start+0x5c
hello
%
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

**SEE ALSO** `ld.so.1(1)`, `sotruss(1)`, `attributes(5)`

| <b>SYNOPSIS</b>    | <b>whois</b> [-h <i>host</i> ] <i>identifier</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><b>whois</b> searches for an Internet directory entry for an <i>identifier</i> which is either a name (such as "Smith") or a handle (such as "SRI-NIC"). To force a name-only search, precede the name with a period; to force a handle-only search, precede the handle with an exclamation point.</p> <p>To search for a group or organization entry, precede the argument with * (an asterisk). The entire membership list of the group will be displayed with the record.</p> <p>You may of course use an exclamation point and asterisk, or a period and asterisk together.</p> |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using The <b>whois</b> Command</p> <p>The command:<br/> <pre>example% whois Smith</pre> looks for the name or handle SMITH.</p> <p>The command:<br/> <pre>example% whois !SRI-NIC</pre> looks for the handle SRI-NIC only.</p> <p>The command:<br/> <pre>example% whois .Smith, John</pre> looks for the name JOHN SMITH only.</p> <p>Adding . . . to the name or handle argument will match anything from that point; that is, ZU . . . will match ZUL, ZUM, and so on.</p>                                                                                       |                |                 |              |         |

**NAME** write – write to another user

**SYNOPSIS** `write user [terminal]`

**DESCRIPTION** The `write` utility reads lines from the user's standard input and writes them to the terminal of another user. When first invoked, it writes the message:

```
Message from sender-login-id (sending-terminal) [date]...
```

to *user*. When it has successfully completed the connection, the sender's terminal will be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.

If the recipient wants to reply, this can be accomplished by typing

```
write sender-login-id [sending-terminal]
```

upon receipt of the initial message. Whenever a line of input as delimited by a NL, EOF, or EOL special character is accumulated while in canonical input mode, the accumulated data will be written on the other user's terminal.

Characters are processed as follows:

- Typing the alert character will write the alert character to the recipient's terminal.
- Typing the erase and kill characters will affect the sender's terminal in the manner described by the `termios(3C)` interface.
- Typing the interrupt or end-of-file characters will cause `write` to write an appropriate message (EOT\n in the "C" locale) to the recipient's terminal and exit.
- Typing characters from `LC_CTYPE` classifications `print` or `space` will cause those characters to be sent to the recipient's terminal.
- When and only when the `stty iexten` local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.
- Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a '^' followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.

To write to a user who is logged in more than once, the *terminal* argument can be used to indicate which terminal to write to; otherwise, the recipient's terminal is the first writable instance of the user found in `/usr/adm/utmp`, and the following informational message will be written to the sender's standard output, indicating which terminal was chosen:

```
user is logged on more than one place.
You are connected to terminal.
Other locations are:terminal
```

Permission to be a recipient of a `write` message can be denied or granted by use of the `mesg` utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The `write` utility will fail when the user lacks the appropriate privileges to perform the requested action.

If the character `!` is found at the beginning of a line, `write` calls the shell to execute the rest of the line as a command.

`write` runs `setgid()` (see `setuid(2)`) to the group ID `tty`, in order to have write permissions on other user's terminals.

The following protocol is suggested for using `write`: when you first write to another user, wait for them to write back before starting to send. Each person should end a message with a distinctive signal (that is, `(o)` for "over") so that the other person knows when to reply. The signal `(oo)` (for "over and out") is suggested when conversation is to be terminated.

## OPERANDS

The following operands are supported:

*user*            User (login) name of the person to whom the message will be written. This operand must be of the form returned by the `who(1)` utility.

*terminal*        Terminal identification in the same format provided by the `who` utility.

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `write`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

## EXIT STATUS

The following exit values are returned:

0            Successful completion.

>0          The addressed user is not logged on or the addressed user denies permission.

## FILES

`/var/adm/utmp`        user and accounting information for `write`

`/usr/bin/sh`         Bourne shell executable file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO**

`mail(1)`, `mesg(1)`, `pr(1)`, `sh(1)`, `talk(1)`, `who(1)`, `setuid (2)`, `termios(3C)`, `attributes(5)`, `environ(5)`

**DIAGNOSTICS**

user is not logged on

The person you are trying to write to is not logged on.

Permission denied

The person you are trying to write to denies that permission (with `mesg`).

Warning: cannot respond, set `mesg -y`

Your terminal is set to `mesg n` and the recipient cannot respond to you.

Can no longer write to user

The recipient has denied permission (`mesg n`) after you had started writing.

| <b>NAME</b>        | xargs - construct argument lists and invoke utility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>xargs</b> [-t] [-p] [-e <i>eofstr</i> ] [-E <i>eofstr</i> ] [-I <i>replstr</i> ] [-i [ <i>replstr</i> ]] [-L <i>number</i> ] [-l [ <i>number</i> ]] [-n <i>number</i> ] [-x] [-s <i>size</i> ] [ <i>utility</i> [ <i>argument</i> ... ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <i>xargs</i> utility constructs a command line consisting of the <i>utility</i> and <i>argument</i> operands specified followed by as many arguments read in sequence from standard input as will fit in length and number constraints specified by the options. The <i>xargs</i> utility then invokes the constructed command line and waits for its completion. This sequence is repeated until an end-of-file condition is detected on standard input or an invocation of a constructed command line returns an exit status of 255.</p> <p>Arguments in the standard input must be separated by unquoted blank characters, or unescaped blank characters or newline characters. A string of zero or more non-double-quote (") and non-newline characters can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (') and non-newline characters can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash (\). The <i>utility</i> will be executed one or more times until the end-of-file is reached. The results are unspecified if the utility named by <i>utility</i> attempts to read from its standard input.</p> <p>The generated command line length will be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The <i>xargs</i> utility will limit the command line length such that when the command line is invoked, the combined argument and environment lists will not exceed {ARG_MAX}-2048 bytes. Within this constraint, if neither the -n nor the -s option is specified, the default command line length will be at least {LINE_MAX}.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-e [<i>eofstr</i>]      Use <i>eofstr</i> as the logical end-of-file string. Underscore ( _ ) is assumed for the logical EOF string if neither -e nor -E is used. When the -eofstr option-argument is omitted, the logical EOF string capability is disabled and underscores are taken literally. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered.</p> <p>-E <i>eofstr</i>        Specify a logical end-of-file string to replace the default underscore. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered.</p> <p>-I <i>replstr</i>        Insert mode. <i>utility</i> will be executed for each line from standard input, taking the entire line as a single argument, inserting it in <i>argument s</i> for each occurrence of <i>replstr</i>. A</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | <p>maximum of five arguments in <i>arguments</i> can each contain one or more instances of <i>replstr</i>. Any blank characters at the beginning of each line are ignored. Constructed arguments cannot grow larger than 255 bytes. Option <i>-x</i> is forced on. The <i>-I</i> and <i>-i</i> options are mutually exclusive; the last one specified takes effect.</p>                                                                                                                                                                                          |
| <i>-i [replstr]</i> | <p>This option is equivalent to <i>-I replstr</i>. The string { } is assumed for <i>replstr</i> if the option-argument is omitted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>-L number</i>    | <p>The <i>utility</i> will be executed for each non-empty <i>number</i> lines of arguments from standard input. The last invocation of <i>utility</i> will be with fewer lines of arguments if fewer than <i>number</i> remain. A line is considered to end with the first newline character unless the last character of the line is a blank character; a trailing blank character signals continuation to the next non-empty line, inclusive. The <i>-L</i>, <i>-l</i>, and <i>-n</i> options are mutually exclusive; the last one specified takes effect.</p> |
| <i>-l [number]</i>  | <p>(The letter ell.) This option is equivalent to <i>-L number</i>. If <i>number</i> is omitted, 1 is assumed. Option <i>-x</i> is forced on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>-n number</i>    | <p>Invoke <i>utility</i> using as many standard input arguments as possible, up to <i>number</i> (a positive decimal integer) arguments maximum. Fewer arguments will be used if:</p> <ul style="list-style-type: none"> <li>■ The command line length accumulated exceeds the size specified by the <i>-s</i> option (or {<i>LINE_MAX</i>} if there is no <i>-s</i> option), or</li> <li>■ The last iteration has fewer than <i>number</i>, but not zero, operands remaining.</li> </ul>                                                                        |
| <i>-p</i>           | <p>Prompt mode. The user is asked whether to execute <i>utility</i> at each invocation. Trace mode (<i>-t</i>) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response (specific to the user's locale) read from <i>/dev/tty</i> will execute the command; otherwise, that particular invocation of <i>utility</i> is skipped.</p>                                                                                                                                                            |
| <i>-s size</i>      | <p>Invoke <i>utility</i> using as many standard input arguments as possible yielding a command line length less than <i>size</i> (a positive decimal integer) bytes. Fewer arguments will be used if:</p> <ul style="list-style-type: none"> <li>■ The total number of arguments exceeds that specified by the <i>-n</i> option, or</li> </ul>                                                                                                                                                                                                                   |

- The total number of lines exceeds that specified by the `-L` option, or
- End of file is encountered on standard input before *size* bytes are accumulated.

Values of *size* up to at least `{LINE_MAX}` bytes are supported, provided that the constraints specified in `DESCRIPTION` are met. It is not considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in `DESCRIPTION` is given; `xargs` will use the largest value it supports within the constraints.

- `-t` Enable trace mode. Each generated command line will be written to standard error just prior to invocation.
- `-x` Terminate if a command line containing *number* arguments (see the `-n` option above) or *number* lines (see the `-L` option above) will not fit in the implied or specified size (see the `-s` option above).

## OPERANDS

The following operands are supported:

*utility* The name of the utility to be invoked, found by search path using the `PATH` environment variable; see `environ(5)`. If *utility* is omitted, the default is the `echo(1)` utility. If the *utility* operand names any of the special built-in utilities in `shell_builtins(1)`, the results are undefined.

*argument* An initial option or operand for the invocation of *utility*.

## USAGE

The 255 exit status allows a utility being used by `xargs` to tell `xargs` to terminate if it knows no further invocations using the current data stream will succeed. Thus, *utility* should explicitly `exit` with an appropriate value to avoid accidentally returning with 255.

Note that input is parsed as lines; blank characters separate arguments. If `xargs` is used to bundle output of commands like `find dir -print` or `ls` into commands to be executed, unexpected results are likely if any filenames contain any blank characters or newline characters. This can be fixed by using `find` to call a script that converts each file found into a quoted string that is then piped to `xargs`. Note that the quoting rules used by `xargs` are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules and the shell syntax is not fully compatible with it. An easy rule that can be used to transform any string into a quoted form that `xargs` will interpret correctly is to precede each character in the string with a backslash (`\`).

On implementations with a large value for `{ARG_MAX}`, `xargs` may produce command lines longer than `{LINE_MAX}`. For invocation of utilities, this is not a problem. If `xargs` is being used to create a text file, users should explicitly set the maximum command line length with the `-s` option.

The `xargs` utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.

## EXAMPLES

### EXAMPLE 1 Using The `xargs` Command

The following will move all files from directory `$1` to directory `$2`, and echo each move command just before doing it:

```
ls $1 | xargs -I {} -t mv $1/{ } $2/{ }
```

The following command will combine the output of the parenthesised commands onto one line, which is then written to the end of file `log`:

```
(logname; date; printf "%s\n" "$0 $*") | xargs >>log
```

The following command will invoke `diff` with successive pairs of arguments originally typed as command line arguments (assuming there are no embedded blank characters in the elements of the original argument list):

```
printf "%s\n" "$*" | xargs -n 2 -x diff
```

The user is asked which files in the current directory are to be archived. The files are archived into `arch`; `a`, one at a time, or `b`, many at a time:

```
ls | xargs -p -L 1 ar -r arch
ls | xargs -p -L 1 | xargs ar -r arch
```

The following will execute with successive pairs of arguments originally typed as command line arguments:

```
echo $* | xargs -n 2 diff
```

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `xargs`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`, and `PATH`.

## EXIT STATUS

The following exit values are returned:

0 All invocations of *utility* returned exit status 0.

1-125 A command line meeting the specified requirements could not be assembled, one or more of the invocations of *utility* returned a non-zero exit status, or some other error occurred.

126 The utility specified by *utility* was found but could not be invoked.

127 The utility specified by *utility* could not be found.

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the `xargs` utility will write a diagnostic message and exit without processing any remaining input.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

## SEE ALSO

| <b>NAME</b>        | xgettext – extract gettext call strings from C programs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>xgettext</b> [-ns] [-a [-x <i>exclude-file</i> ] ] [-c <i>comment-tag</i> ] [-d <i>default-domain</i> ] [-j]<br>[-m <i>prefix</i> ] [-M <i>suffix</i> ] [-p <i>pathname</i> ] -  <i>filename</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p><b>xgettext -h</b></p> <p>The <code>xgettext</code> utility is used to automate the creation of portable message files (<code>.po</code>). A <code>.po</code> file contains copies of “C” strings that are found in ANSI C source code in <i>filename</i> or the standard input if ‘-’ is specified on the command line. The <code>.po</code> file can be used as input to the <code>msgfmt(1)</code> utility, which produces a binary form of the message file that can be used by application during run-time.</p> <p><code>xgettext</code> writes <i>msgid</i> strings from <code>gettext(3C)</code> calls in <i>filename</i> to the default output file <code>messages.po</code>. The default output file name can be changed by <code>-d</code> option. <i>msgid</i> strings in <code>dgettext( )</code> calls are written to the output file <code>domainname.po</code> where <i>domainname</i> is the first parameter to the <code>dgettext( )</code> call.</p> <p>By default, <code>xgettext</code> creates a <code>.po</code> file in the current working directory, and each entry is in the same order that the strings are extracted from <i>filenames</i>. When the <code>-p</code> option is specified, the <code>.po</code> file is created in the <i>pathname</i> directory. An existing <code>.po</code> file is overwritten.</p> <p>Duplicate <i>msgids</i> are written to the <code>.po</code> file as comment lines. When the <code>-s</code> option is specified, the <code>.po</code> is sorted by the <i>msgid</i> string, and all duplicated <i>msgids</i> are removed. All <i>msgstr</i> directives in the <code>.po</code> file are empty unless the <code>-m</code> option is used.</p> <p><b>OPTIONS</b></p> <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-n</code> Add comment lines to the output file indicating file name and line number in the source file where each extracted string is encountered. These lines appear before each <i>msgid</i> in the following format: <pre style="margin-left: 40px;"># # File: <i>filename</i>, line: <i>line-number</i></pre> </li> <li><code>-s</code> Generate output sorted by <i>msgids</i> with all duplicate <i>msgids</i> removed.</li> <li><code>-a</code> Extract all strings, not just those found in <code>gettext(3C)</code>, and <code>dgettext( ) ( )</code> calls. Only one <code>.po</code> file is created.</li> <li><code>-c <i>comment-tag</i></code> The comment block beginning with <i>comment-tag</i> as the first token of the comment block is added to the output <code>.po</code> file as # delimited comments.</li> </ul> |

- For multiple domains, `xgettext` directs comments and messages to the prevailing text domain.
- `-d default-domain` Rename default output file from `messages.po` to `default-domain.po`.
- `-j` Join messages with existing message files. If a `.po` file does not exist, it is created. If a `.po` file does exist, new messages are appended. Any duplicate `msgid`s are commented out in the resulting `.po` file. Domain directives in the existing `.po` file are ignored. Results not guaranteed if the existing message file has been edited.
- `-m prefix` Fill in the `msgstr` with `prefix`. This is useful for debugging purposes. To make `msgstr` identical to `msgid`, use an empty string (" ") for `prefix`.
- `-M suffix` Fill in the `msgstr` with `suffix`. This is useful for debugging purposes.
- `-p pathname` Specify the directory where the output files will be placed. This option overrides the current working directory.
- `-x exclude-file` Specify a `.po` file that contains a list of `msgid`s that are not to be extracted from the input files. The format of `exclude-file` is identical to the `.po` file. However, only the `msgid` directive line in `exclude-file` is used. All other lines are simply ignored. The `-x` option can only be used with the `-a` option.
- `-h` Print a help message on the standard output.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

**SEE ALSO**

**NOTES**

`xgettext` is not able to extract cast strings, for example ANSI C casts of literal strings to `(const char *)`. This is unnecessary anyway, since the prototypes in `<libintl.h>` already specify this type.

In messages and translation notes, lines greater than 2048 characters are truncated to 2048 characters and a warning message is printed to stderr.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>NAME</b>        | xstr - extract strings from C programs to implement shared strings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>xstr -c filename [-v] [-l array] xstr [-l array] xstr filename [-v] [-l array]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>xstr maintains a file called <code>strings</code> into which strings in component parts of a large program are hashed. These strings are replaced with references to this common area. This serves to implement shared constant strings, which are most useful if they are also read-only.</p> <p>The command:</p> <pre>example% xstr -c filename</pre> <p>extracts the strings from the C source in <code>name</code>, replacing string references by expressions of the form <code>&amp;xstr[ number]</code> for some number. An appropriate declaration of <code>xstr</code> is prepended to the file. The resulting C text is placed in the file <code>x.c</code>, to then be compiled. The strings from this file are placed in the <code>strings</code> data base if they are not there already. Repeated strings and strings which are suffixes of existing strings do not cause changes to the data base.</p> <p>After all components of a large program have been compiled, a file declaring the common <code>xstr</code> space called <code>xs.c</code> can be created by a command of the form:</p> <pre>example% xstr</pre> <p>This <code>xs.c</code> file should then be compiled and loaded with the rest of the program. If possible, the array can be made read-only (shared) saving space and swap overhead.</p> <p><code>xstr</code> can also be used on a single file. A command:</p> <pre>example% xstr filename</pre> <p>creates files <code>x.c</code> and <code>xs.c</code> as before, without using or affecting any <code>strings</code> file in the same directory.</p> <p>It may be useful to run <code>xstr</code> after the C preprocessor if any macro definitions yield strings or if there is conditional code which contains strings which may not, in fact, be needed. <code>xstr</code> reads from the standard input when the argument <code>'-'</code> is given. An appropriate command sequence for running <code>xstr</code> after the C preprocessor is:</p> |

```
example% cc -E name.c | xstr -c -
example% cc -c x.c
example% mv x.o name.o
```

`xstr` does not touch the file `strings` unless new items are added; thus `make(1S)` can avoid remaking `xs.o` unless truly necessary.

**OPTIONS**

`-c filename` Take C source text from *filename*.

`-v` Verbose: display a progress report indicating where new or duplicate strings were found.

`-l array` Specify the named *array* in program references to abstracted strings. The default array name is `xstr`.

**FILES**

`strings` data base of strings

`x.c` massaged C source

`xs.c` C source for definition of array “`xstr*(rq`

`/tmp/xs*` temp file when `xstr filename` doesn't touch `strings`

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`make(1S)`, `attributes(5)`

**BUGS**

If a string is a suffix of another string in the data base, but the shorter string is seen first by `xstr` both strings will be placed in the data base, when just placing the longer one there would do.

**NOTES**

Be aware that `xstr` indiscriminately replaces all strings with expressions of the form `&xstr[number]` regardless of the way the original C code might have used the string. For example, you will encounter a problem with code that uses `sizeof()` to determine the length of a literal string because `xstr` will replace the literal string with a pointer that most likely will have a different size than the string's. To circumvent this problem:

- use `strlen()` instead of `sizeof()`; note that `sizeof()` returns the size of the array (including the null byte at the end), whereas `strlen()` doesn't count the null byte. The equivalent of `sizeof("XXX")` really is `(strlen("XXX")+1)`.

- use `#define` for operands of `sizeof()` and use the define'd version. `xstr` ignores `#define` statements. Make sure you run `xstr` on *filename* before you run it on the preprocessor.

You will also encounter a problem when declaring an initialized character array of the form

```
char x[] = "xxx";
```

`xstr` will replace `xxx` with an expression of the form `&xstr[number]` which will not compile. To circumvent this problem, use `static char *x = "xxx"` instead of `static char x[] = "xxx"`.

| <b>DESCRIPTION</b> | <p>The <code>yacc</code> command converts a context-free grammar into a set of tables for a simple automaton that executes an LALR(1) parsing algorithm. The grammar may be ambiguous; specified precedence rules are used to break ambiguities.</p> <p>The output file, <code>y.tab.c</code>, must be compiled by the C compiler to produce a function <code>yyparse()</code>. This program must be loaded with the lexical analyzer program, <code>yylex()</code>, as well as <code>main()</code> and <code>yyerror()</code>, an error handling routine. These routines must be supplied by the user; the <code>lex(1)</code> command is useful for creating lexical analyzers usable by <code>yacc</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-b <i>file_prefix</i></code>     Use <i>file_prefix</i> instead of <code>y</code> as the prefix for all output files. The code file <code>y.tab.c</code>, the header file <code>y.tab.h</code> (created when <code>-d</code> is specified), and the description file <code>y.output</code> (created when <code>-v</code> is specified), will be changed to <code>file_prefix.tab.c</code>, <code>file_prefix.tab.h</code>, and <code>file_prefix.output</code>, respectively.</p> <p><code>-d</code>                     Generates the file <code>y.tab.h</code> with the <code>#define</code> statements that associate the <code>yacc</code> user-assigned “token codes” with the user-declared “token names.” This association allows source files other than <code>y.tab.c</code> to access the token codes.</p> <p><code>-l</code>                     Specifies that the code produced in <code>y.tab.c</code> will not contain any <code>#line</code> constructs. This option should only be used after the grammar and the associated actions are fully debugged.</p> <p><code>-P <i>parser</i></code>             Allows you to specify the parser of your choice instead of <code>/usr/ccs/bin/yaccpar</code>. For example, you can specify:</p> <pre style="margin-left: 40px;">example% yacc -P ~/myparser parser.y</pre> <p><code>-p <i>sym_prefix</i></code>        Use <i>sym_prefix</i> instead of <code>yy</code> as the prefix for all external names produced by <code>yacc</code>. The names affected include the functions <code>yyparse()</code>, <code>yylex()</code> and <code>yyerror()</code>, and the variables <code>yyval</code>, <code>yychar</code> and <code>yydebug</code>. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the <code>-p</code> option; however, the <code>-p</code> option does not affect <code>#define</code> symbols generated by <code>yacc</code>.</p> |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-Q[y n]</code> | The <code>-Qy</code> option puts the version stamping information in <code>y.tab.c</code> . This allows you to know what version of <code>yacc</code> built the file. The <code>-Qn</code> option (the default) writes no version information.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-t</code>      | Compiles runtime debugging code by default. Runtime debugging code is always generated in <code>y.tab.c</code> under conditional compilation control. By default, this code is not included when <code>y.tab.c</code> is compiled. Whether or not the <code>-t</code> option is used, the runtime debugging code is under the control of <code>YYDEBUG</code> , a preprocessor symbol. If <code>YYDEBUG</code> has a non-zero value, then the debugging code is included. If its value is 0, then the code will not be included. The size and execution time of a program produced without the runtime debugging code will be smaller and slightly faster. |
| <code>-V</code>      | Prints on the standard error output the version information for <code>yacc</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-v</code>      | Prepares the file <code>y.output</code> , which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**OPERANDS**

The following operand is required:

*file* A path name of a file containing instructions for which a parser is to be created.

**EXAMPLES****EXAMPLE 1** Using The `yacc` Command

Access to the `yacc` library is obtained with library search operands to `cc`. To use the `yacc` library `main`,

```
example% cc y.tab.c -ly
```

Both the `lex` library and the `yacc` library contain `main`. To access the `yacc` `main`,

```
example% cc y.tab.c lex.yy.c -ly -ll
```

This ensures that the `yacc` library is searched first, so that its `main` is used.

The historical `yacc` libraries have contained two simple functions that are normally coded by the application programmer. These library functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
 extern int yyparse();

 setlocale(LC_ALL, "");
```

```

 /* If the following parser is one created by lex, the
 application must be careful to ensure that LC_CTYPE
 and LC_COLLATE are set to the POSIX locale. */
 (void) yyparse();
 return (0);
 }

#include <stdio.h>

int yyerror(const char *msg)
{
 (void) fprintf(stderr, "%s\n", msg);
 return (0);
}

```

## ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `yacc`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`yacc` can handle characters from EUC primary and supplementary codesets as one-token symbols. EUC codes may only be single character quoted terminal symbols. `yacc` expects `yylex()` to return a wide character (`wchar_t`) value for these one-token symbols.

## EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**DIAGNOSTICS**

The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output; a more detailed report is found in the `y.output` file. Similarly, if some rules are not reachable from the start symbol, this instance is also reported.

**NOTES**

Because file names are fixed, at most one `yacc` process can be active in a given directory at a given time.

**NAME** ypcat – print values in a NIS database

**SYNOPSIS** **ypcat** [-kx] [-d *ypdomain*] *mname*

**DESCRIPTION** The *ypcat* command prints out values in the NIS name service map specified by *mname*, which may be either a map name or a map nickname. Since *ypcat* uses the NIS network services, no NIS server is specified.

Refer to *ypfiles*(4) for an overview of the NIS name service.

**OPTIONS** **-k** Display the keys for those maps in which the values are null or the key is not part of the value. None of the maps derived from files that have an ASCII version in */etc* fall into this class.

**-d *ypdomain*** Specify a domain other than the default domain.

**-x** Display map nicknames.

**ATTRIBUTES** See *attributes*(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** *ypmatch*(1), *ypfiles*(4), *attributes*(5)

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|
| <b>SYNOPSIS</b>    | <b>ypmatch</b> [-k] [-t] [-d <i>domain</i> ] <i>key</i> [ <i>key...</i> ] <i>mname</i><br><b>ypmatch</b> -x                                                                                                                                                                                                                                                                                                                           |                |                 |              |          |
| <b>DESCRIPTION</b> | <i>ypmatch</i> prints the values associated with one or more keys from the NIS's name services map specified by <i>mname</i> , which may be either a map name or a map nickname.<br><br>Multiple keys can be specified; all keys will be searched for in the same map. The keys must be the same case and length. No pattern matching is available. If a key is not matched, a diagnostic message is produced.                        |                |                 |              |          |
| <b>OPTIONS</b>     | The following options are supported:<br>-k                Before printing the value of a key, print the key itself, followed by a colon (:).<br>-t                Inhibit map nickname translation.<br>-d <i>domain</i> Specify a domain other than the default domain.<br>-x                Display the map nickname table. This lists the nicknames the command knows of, and indicates the map name associated with each nickname. |                |                 |              |          |
| <b>OPERANDS</b>    | The following operand is supported:<br><i>mname</i> The NIS's name services map                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |          |
| <b>EXIT STATUS</b> | The following exit values are returned:<br>0                Successful operation.<br>1                An error occurred.                                                                                                                                                                                                                                                                                                              |                |                 |              |          |
| <b>ATTRIBUTES</b>  | See <i>attributes(5)</i> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |          |

| Availability       | SUNWnisu                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |          |
| <b>SEE ALSO</b>    | <i>ypcat(1)</i> , <i>ypfiles(4)</i> , <i>attributes(5)</i>                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |          |
| <b>NOTES</b>       | <i>ypmatch</i> will fail with an RPC error message on <i>yp</i> operation if enough file descriptors are not available. The number of file descriptors should be increased if this occurs.                                                                                                                                                                                                                                            |                |                 |              |          |

**NAME** yppasswd – change your network password in the NIS database

**SYNOPSIS** **yppasswd** [*username*]

**DESCRIPTION** *yppasswd* changes the network password associated with the user *username* in the Network Information Service (NIS+) database. If the user has done a *keylogin(1)*, and a *publickey/secretkey* pair exists for the user in the NIS *publickey.byname* map, *yppasswd* also re-encrypts the *secretkey* with the new password. The NIS password may be different from the local one on your own machine. Use *passwd(1)* to change the password information on the local machine, and *nispasswd(1)* to change the password information stored in Network Information Service Plus, Version 3 (NIS+).

*yppasswd* prompts for the old NIS password, and then for the new one. You must type in the old password correctly for the change to take effect. The new password must be typed twice, to forestall mistakes.

New passwords must be at least four characters long, if they use a sufficiently rich alphabet, and at least six characters long if monospace. These rules are relaxed if you are insistent enough. Only the owner of the name or the super-user may change a password; superuser on the root master will not be prompted for the old password, and does not need to follow password construction requirements.

The NIS password daemon, *rpc.yppasswdd* must be running on your NIS server in order for the new password to take effect.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** *keylogin(1)*, *login(1)*, *nispasswd(1)*, *passwd(1)*, *getpwnam(3C)*, *getspnam(3C)*, *secure\_rpc(3NSL)*, *nsswitch.conf(4)*, *attributes(5)*

**WARNINGS** Even after the user has successfully changed his or her password using this command, the subsequent *login(1)* using the new password will be successful only if the user's password and shadow information is obtained from NIS, (see *getpwnam(3C)*, *getspnam(3C)*, and *nsswitch.conf(4)*).

**NOTES** The use of *yppasswd* is discouraged, as it is now only a link to the *passwd(1)* command, which should be used instead. Using *passwd(1)* with the *-r nis* option will achieve the same results, and will be consistent across all the different name services available.

**BUGS** The update protocol passes all the information to the server in one RPC call, without ever looking at it. Thus if you type your old password incorrectly, you will not be notified until after you have entered your new password.

**NAME** ypwhich – return name of NIS server or map master

**SYNOPSIS** **ypwhich** [-d *domain*] [[-t] -m [*mname*] | [-v*n*] *hostname* ]  
**ypwhich** -x

**DESCRIPTION** ypwhich returns the name of the NIS server that supplies the NIS name services to a NIS client, or which is the master for a map. If invoked without arguments, it gives the NIS server for the local machine. If *hostname* is specified, that machine is queried to find out which NIS master it is using.

Refer to *ypfiles(4)* for an overview of the NIS name services.

**OPTIONS**

- d *domain* Use *domain* instead of the default domain.
- t This option inhibits map nickname translation.
- m *mname* Find the master NIS server for a map. No *hostname* can be specified with -m. *mname* can be a mapname, or a nickname for a map. When *mname* is omitted, produce a list of available maps.
- x Display the map nickname translation table.
- v*n* Version of *ypbind*, V3 is default.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** *ypfiles(4)*, *attributes(5)*

## A

a new version of the network information name  
    service - NIS+ 1036

accounting  
    search and print files — acctcom 38

acctcom — search and print process accounting  
    files 38

adb — debugger 41

  ? and / Modifiers 45

  \$ Modifier 46

  : Modifier 45

  ?, /, and = Modifiers 43

  Binary Operators 42

  Commands 43

  Expressions 42

  Unary Operators 42

  Variables 43

  Verbs 43

addbib — create or extend bibliography 51

adds /dev entries to give SunOS 4.x compatible  
    names to SunOS 5.x devices —  
    ucblinks 1612

alias - shell built-in functions to create your  
    own pseudonym or shorthand  
    for a command or series of  
    commands 53

aliases  
    collected by sendmail — praliases 1219

answerbook2 — online documentation  
    system 56

apply changes to files — patch 1144

appttrace — trace application function calls to  
    Solaris shared libraries 57

apropos — locate commands by keyword 62

ar — maintain portable archive or library 63

arch — display architecture of current host 67

archive  
    maintain a portable one across all machines  
    — ar 63

archives  
    create tape archives, and add or extract files  
    — tar 1516

as — assembler 68

asa — convert FORTRAN carriage-control  
    output to printable form 73

assembler  
    — as 68

at - execute commands at a later time 75, 264

atq — display the jobs queued to run at  
    specified times 82

atrm — remove jobs spooled by at or batch 83

audio file formats  
    convert — audioconvert 84

audio files  
    play — audioplay 89

    record — audiorecord 93

audioconvert — convert audio file formats 84

audioplay — play audio files 89

audiorecord — record an audio file 93

authentication and authorization for network  
    environment  
    — kerberos 614

auths — print authorizations granted to a user 97  
awk — pattern scanning and processing language 98

## B

banner — make posters 104  
basename — strips affixes from path names 105, 107  
batch — execute commands at a later time 75, 264  
bc — arbitrary precision arithmetic language 108  
bdiff — display line-by-line differences between pairs of large text files 112  
bfs — big file scanner 113  
  bfs Commands 113  
bg — shell built-in functions to control process execution 599  
bibliography  
  create an inverted index to a bibliographic database — indexbib 587  
  create or extend — addbib 51  
  expand and insert references from a bibliographic database — refer 1289  
  find references in a bibliographic database — lookbib 803  
  format and print a bibliographic database — roffbib 1308  
  sort a bibliographic database — sortbib 1457  
biff — mail notifier 117  
big file scanner — bfs 113  
binary file transmission  
  decode binary file — uudecode 1635  
  encode binary file — uuencode 1635  
binary files  
  find printable strings — strings 1473  
  locate — whereis 1691  
block count  
  for a file — sum 1494  
blocks, count a in file — sum 1495  
Bourne shell  
  — sh 1413  
Bourne shell commands

login command 1426  
Bourne shell variables 1417  
  — CDPATH 1417  
  — HOME 1417  
  — IFS 1418  
  — MAIL 1417  
  — MAILCHECK 1417  
  — MAILPATH 1417  
  — PATH 1417  
  — PS1 1418  
  — PS2 1418  
  — SHACCT 1418  
  — SHELL 1418  
break — shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop 118  
build programs — make 883

## C

C compiler 130  
C language  
  C preprocessor — cpp 212  
C language program  
  resolve and remove ifdef'ed lines from C program source — unifdef 1620  
C program verifier — lint 759  
C programming language  
  create C error messages — mkstr 968  
  extract strings from C code — xstr 1714  
  formats program in nice style using troff — vgrind 1657  
C shell  
  aliases — csh 240  
  built-in commands — csh 247  
  command and filename substitution — csh 243  
  command execution — csh 245  
  command line parsing — csh 237  
  command substitution — csh 243  
  control flow — csh 245  
  environment variables and shell variables — csh 257  
  event designators — csh 238  
  expressions and operators — csh 244

- filename completion — csh 236
- filename substitution — csh 243
- history substitution — csh 237
- I/O redirection — csh 240
- initialization and termination — csh 235
- interactive operation — csh 235
- job control — csh 246
- lexical structure — csh 237
- modifiers — csh 239
- noninteractive operation — csh 235
- quick substitution — csh 240
- signal handling — csh 246
- status reporting — csh 247
- variable substitution — csh 241
- word designators — csh 239

C shell commands

- unalias 255
- unhash 256
- unlimit 256
- unset 256
- unsetenv 256
- wait 256
- while 256

- cal — display a calendar 120
- calculator, desk
  - dc 286
- calendar — reminder service 121
  - display — cal 120
- call rmmount to mount or unmount media —
  - volrmmount 1679
- call-graph, display profile data — gprof 536
- cancel — cancel print requests 123
- cancel user's request for removable media that
  - is not currently in drive —
    - volcancel 1674
- case — shell built-in functions to choose from
  - among a list of actions 125
- cat — concatenate and display files 128
- cc — C compiler 130
- cd — shell built-in functions to change the current
  - working directory 132
- CDPATH variable — sh 1417
- change a user's Kerberos password —
  - kpasswd 630

change file access and modification times —  
    touch 1609  
    - settime 1572  
    - touch 1572

character translation — tr 1582, 1587

chdir - shell built-in functions to change  
    the current working  
    directory 132

check spelling - spell 1461

check for media in a drive — volcheck 1675

check path names — pathchk 1149

checkeq - check eqn constructs 358

checknr — check nroff/troff files 135

chgrp — change the group ownership of a  
    file 137

chmod — change the permissions mode of a  
    file 141

chown — change owner of file 147

chown — change owner of file 149

cksum — write file checksums and sizes 171

clear — clear terminal screen 181

cmp — compare two files 182

cocheck - (FMLI utility) communicate with a  
    process 195

cocreate - (FMLI utility) communicate with a  
    process 195

code formatter  
    formats program in nice style using troff —  
    vgrind 1657

code set  
    conversion utility — iconv 568

codestroy - (FMLI utility) communicate with a  
    process 195

col — filters reverse line-feeds from two-column  
    nroff text 184

comm — select or reject lines common to two  
    files 186

command — execute a simple command 188  
    describe — whatis 1690

command options  
    parse — getopt 521, 523

commands  
    display the last commands executed,  
    in reverse order —  
    lastcomm 697  
    locate a command; display its pathname or  
    alias — which 1693  
    locate by keyword — apropos 62

communications  
    connect to remote system — cu 272, 1556  
    decode binary files - uuencode 1635  
    encode binary files - uuencode 1635  
    system to system command execution —  
    uux 1646  
    talk to another user — talk 1513  
    UNIX-to-UNIX copy - uucp 1631  
    user interface to a remote system using  
    the TELNET protocol —  
    telnet 1530  
    UUCP log - uulog 1631  
    write to another user — write 1703

Compaq Smart-2 EISA/PCI and Smart-2SL PCI  
    Array Controller ioctl utility  
    — smart2cfg 1444

compilers  
    C compiler — cc 130  
    C program verifier — lint 759  
    regular expression compile —  
    regcmp 1291  
    RPC protocol compiler — rpcgen 1312

compress - compress files 191

concatenate  
    files and display them — cat 128

configure LLC2 interface parameters —  
    llc\_config 763

connect to remote system  
    — cu 272

construct argument lists and invoke utility —  
    xargs 1706

continue - shell built-in functions to escape  
    from or advance within a  
    controlling while, for, foreach,  
    or until loop 118

control  
    audio mixer control — mixerctl 962

control line printer — lpc 814

control tracing and manipulate probe points  
    in a process or the kernel —  
    prex 1220

convert binary log file to Common Log File  
    format — ncab2clf 1018

convert binary TNF file to ASCII —  
    tnfdump 1566

convert FORTRAN carriage-control output to  
     printable form — asa 73  
 convert units — units 1625  
 coproc - (FMLI utility) communicate with a  
     process 195  
 copy  
     archives — cpio 204  
     files — cp 200  
 core image  
     of running processes — gcore 481  
 coreceive - (FMLI utility) communicate with a  
     process 195  
 cosend - (FMLI utility) communicate with a  
     process 195  
 count blocks in file — sum 1495  
 count lines, words, characters in file —  
     wc 1687  
 cp — copy files 200  
 cpio — copy archives 204  
 cpp — C preprocessor 212  
 cputrack — monitor process and LWP behavior  
     using CPU performance  
     counters 219  
 create  
     bibliography — addbib 51  
 crontab — user crontab file 230  
 crypt — encrypt 234  
 csh — shell command interpreter with a C-like  
     syntax 235  
 csplit — split files based on context 264  
 ct — spawn login to a remote terminal 267  
 ctags — create a tags file for use with ex and  
     vi 269  
 cu — connect to remote system 272  
 curve, smooth  
     interpolate — spline 1464  
 cut — cut out selected fields of each line of a  
     file 279

## D

date — display date and/or set date 282  
     prompts for a date — ckdate 150  
     provides error message for date —  
         errdate 150  
     validates a date — valdate 150  
 debug tools

debugger — adb 41  
 decode binary file — uudecode 1635  
 decode files  
     — crypt 234  
 decrypt — crypt 234  
 define locale environment — localedef 784  
 dependencies, dynamic  
     of executable files or shared objects —  
         ldd 729  
 deroff — remove nroff, troff, tbl and eqn  
     constructs 290  
 describe command — whatis 1690  
 describe instruction set architectures —  
     isainfo 596  
 desk calculator  
     — dc 286  
 determine which variant instruction set is  
     optimal to use — optisa 1129  
 devices  
     eject media device from drive — eject 348  
 df — display status of disk space on file  
     systems 291  
 dhcpinfo — display value of parameters  
     received through DHCP 293  
 dictionary, system  
     find words — look 802  
 diff — display line-by-line differences between  
     pairs of text files 295  
     3-way — diff3 299  
     big — bdiff 112  
 diff command  
     side-by-side — sdiff 1382  
 diff3 — display line-by-line differences between  
     three text files 299  
 diffmk — mark differences between versions of  
     a troff input file 301  
 digestp - frontends to the mp PostScript pretty  
     printer 852  
 dircmp — compares contents of directories 302  
 directories  
     compare contents — dircmp 302  
     list contents — ls 832  
     list contents of — ls 838  
     make — mkdir 964  
     make link to — ln 777  
     print working directory name —  
         pwd 1273

- remove - rmdir 1304
- dirname - delivers all but last level of path name 105
- dirs - shell built-in functions to change the current working directory 132
- dis - object code disassembler 303
- disable - disable LP printers 354
- disassembler
  - object code - dis 303
- display editor - vi 1661
  - a list of all valid user names - dispuid 306
  - architecture of current host - arch 67
  - call-graph profile data - gprof 536
  - contents of directory - ls 832
  - current news - news 1033
    - date 282
  - disk usage - du 315

  - size of page of memory - pagesize 1133
  - status of disk space on file system -
    - df 291
  - status of local hosts - ruptime 1326
  - status of network hosts - rup 1324
  - users on system - users 1630
  - working directory name - pwd 1273

- display discretionary file information -
  - getfacl 515
- display information about currently logged-in users - w 1682
- display names and references bound in FNS context - fnlist 451
- display package parameter values -
  - pkgparam 1185
- display profile data - prof 1252
- display reference bound to FNS name -
  - fnlookup 453
- display the internal versioning information of dynamic objects - pvs 1270
- display the native instruction sets executable on this platform - isalist 598
- display value of parameters received through DHCP - dhcpinfo 293
- document production
  - check spelling - spell 1461
  - check nroff/troff files - checknr 135
  - create an inverted index to a bibliographic database - indexbib 587
  - create or extend bibliography -
    - addbib 51
  - eliminate .so's from nroff input -
    - soelim 1446
  - expand and insert references from a bibliographic database -
    - refer 1289
  - filters reverse line-feeds from two-column nroff text - col 184
  - find references in a bibliographic database -
    - lookbib 803
  - format and print a bibliographic database -
    - roffbib 1308
  - format documents for display or line-printer - nroff 1117
  - format tables for nroff or troff - tbl 1526
  - mark differences between versions of a troff input file - diffmk 301
  - remove nroff, troff, tbl and eqn constructs -
    - deroff 290
  - simple text formatters - fmt 439
  - sort a bibliographic database -
    - sortbib 1457
  - troff postprocessor for PostScript printers -
    - dpost 311

- typeset mathematics - eqn 358
- typeset or format documents — troff 1590
- DOS
  - convert text file from DOS format to ISO format — dos2unix 307
  - convert text file from ISO format to DOS format — unix2dos 1627
- dos2unix — convert text file from DOS format to ISO format 307
- download — host resident PostScript font downloader 309
- dpost — troff postprocessor for PostScript printers 311
- draw graph — graph 542
- du — display disk usage per directory or file 315
- dump — dump selected parts of an object file 317
- dump selected parts of an object file — dump 317, 352
- dumppcs — show codeset table for the current locale 320
- dumpkeys - dump keyboard translation tables 780

## E

- echo — echo arguments 321, 326
- echo — echo arguments to standard output 325
- ed - text editor 327
- edit — text editor 340
- editing text
  - sed — stream editor 1392
- egrep — search a file for a pattern using full regular expressions 345
- eject — eject media device from drive 348
- elfdump — dump selected parts of an object file 352
- enable - enable LP printers 354
- encode binary file - uuencode 1635
- encode files
  - crypt 234
- encryption key, user
  - change — chkey 139

- env — set environment for command invocation 356
- environment
  - display variables — printenv 1234
  - set terminal characteristics - tset 1601
- environment variables, global
  - FMLI 1405
- eqn - mathematical typesetting 358
  - remove nroff, troff, tbl and eqn constructs — deroff 290
- equations
  - typeset mathematics - eqn 358
- error — analyze error messages 363
- eval - shell built-in functions to execute other commands 378
- ex — text editor 367
- exec - shell built-in functions to execute other commands 378
- execute commands at a later time - at 75, 1171
  - batch 75
- execute a simple command — command 188
- execute commands at a later time — at 264
  - batch 264
- exit - shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps 380
- expand - expand TAB characters to SPACE characters 382
- export - shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents 1399
- exportfs — translates exportfs options to share/unshare commands 385
- expr — evaluate arguments as an expression 386, 390
- expression evaluation — expr 390
- exstr — extract strings from source files 393
- extract kernel probes output into a trace file — tnfextract 1570
- extract strings from C code — xstr 1714

## F

- face — executable for the Framed Access Command Environment Interface 397
- factor — obtain the prime factors of a number 398
- false — provide truth values 1593
- fastboot — reboot system without checking disks 399
- fasthalt — halt system without checking disks 399
- fc — shell built-in functions to re-use previous command-lines from the current shell 556
- fdformat — floppy diskette format format floppy diskette 400
- fg — shell built-in functions to control process execution 599
- fgrep — search file for fixed-character string 405
- file — determine file type 407
  - change ownership — chown 149
  - determine type of — file 409
  - display names — ls 838
  - files perusal filter for CRTs — pg 1172
  - make link to — ln 777
  - print — lpr 820
  - strip affixes — basename 107
  - sum — sum and count blocks in file 1495
  - update last modified date of — touch 1576
- file — get file type 409
- file system
  - display status of disk space — df 291
  - make hard or symbolic links to files — ln 774
  - where am I — pwd 1273
- file transfer program
  - ftp 469
- filep — frontends to the mp PostScript pretty printer 852
- files
  - change owner of file — chown 147
  - change the permissions mode of a file — chmod 141
  - compare two files — cmp 182
  - compress — compress 191, 1130
  - concatenate and display — cat 128
  - copy — cp 200
  - copy archives — cpio 204
  - crypt — encrypt/decrypt 234
  - cut out selected fields of each line of a file
    - cut 279
  - display uncompressed files but leaves compressed files intact — zcat 191
  - display a count of lines, words and characters in a file — wc 1687
  - display first few lines — head 554
  - display last part — tail 1510
  - display line-by-line differences between pairs of large text files — bdiff 112
  - display line-by-line differences between pairs of text files — diff 295
  - display line-by-line differences between three text files — diff3 299
  - expand compressed files — unpack 1130
  - extract SCCS version information from a file — what 1689
  - find 419
  - mark differences between versions of a troff input file — diffmk 301
  - merge same lines of several files or subsequent lines of one file — paste 1141
  - move — mv 989
  - print checksum and block count for a file — sum 1494
  - print differences between two files side-by-side — sdiff 1382
  - remove — rm 1304
  - search a file for a pattern — grep 544
  - search file for fixed-character string — fgrep 405
  - search for a pattern using full regular expressions — egrep 345
  - sort or merge — sort 1450
  - split a file into pieces — split 1465
  - strip affixes from path names — basename 105
  - transfer to and from a remote machine — tftp 1547
  - uncompress — uncompress 191

filesync — synchronize files and directories 411  
 Multiple Nomadic Machines 413  
 Rules File 412

filofaxp — frontends to the mp PostScript pretty printer 852

find — find files 419

find or signal processes by name and other attributes  
 - pgrep 1177  
 - pkill 1177

floppy diskette format — fdformat 400

fmlcut — (FMLI utility) cut out columns from a table or fields from each line of a file 429

fmlexpr — (FMLI utility) evaluate arguments as an expression 431

fmlgrep — (FMLI utility) search afile for a pattern 434

FMLI

- cocheck — communicate with a process 195
- cocreate — communicate with a process 195
- codestroy — communicate with a process 195
- coproc — communicate with a process 195
- coreceive — communicate with a process 195
- cosend — communicate with a process 195
- echo — put string on virtual output 326
- fmlcut — cut out columns from a table or fields from each line of a file 429
- fmlexpr — evaluate arguments as an expression 431
- fmlgrep — search afile for a pattern 434
- fmli — invoke fmli 436
- getfrm — returns the current frameID number 519
- getitems — returns a list of currently marked menu items 520
- indicator — displays application specific alarms or working indicator, or both, on FMLI banner line 585
- message — puts arguments on FMLI message line 959

pathconv — converts an alias to its pathname 1152

readfile, longline — reads file, gets longest line 1287

regex — match patterns against a string 1293

reinit — changes the descriptors in the initialization file 1296

reset — (FMLI utility) changes the entry in a field of a form to its default value 1300

run — runs a program 1322

set, unset — set and unset local or global environment variables 1405

setcolor — redefine or create a color 1407

shell — run a command using shell 1434

test — evaluates the expression  
 expression 1544

vsig — synchronize a co-process with the controlling FMLI application 1681

fmt — simple text formatters 439

fnattr — update and examine attributes associated with FNS named object 446

fnlist — display names and references bound in FNS context 451

fnlookup — display reference bound to FNS name 453

fnrename — rename the binding of an FNS name 455

FNS

- display names and references — fnlist 451
- display reference bound to FNS name — fnlookup 453
- search for FNS objects — fnsearch 456
- update attributes — fnattr 446

fnsearch — search for FNS objects with specified attributes 456

- Displaying Selected Attributes 458
- Extended Operations 460
- Filter Arguments 459
- Grammar of Filter Expressions 461
- Logical Operators 457
- Relational Operators 458
- Simple Filter Expressions 457
- Wildcarded Strings 460

fnunbind — unbind the reference from an FNS name 463

fold — fold long lines 464

fonts  
 prepends host resident PostScript fonts to files — download 309

for — shell built-in functions to repeatedly execute action(s) for a selected number of times 466

foreach — shell built-in functions to repeatedly execute action(s) for a selected number of times 466

formatters, text  
 — fmt 439

Forms and Menu Language InterpreterFMLI

FORTTRAN  
 create a tags file for use with ex and vi — ctags 269

Framed Access Command Environmentface

frameID number (FMLI utility) — getfrm 519

franklinp — frontends to the mp PostScript pretty printer 852

from — sender of mail messages 468

frontends to the mp PostScript pretty printer — filep 852

ftp — file transfer program 469

function — shell built-in command to define a function which is usable within this shell 480

function calls  
 trace application function calls to Solaris shared libraries — appttrace 57

## G

gcore — get core images of running processes 481

gencat — generate a formatted message catalog 482

generate iconv code conversion tables — geniconvtbl 485

generate LLC2 configuration files — llc\_autoconfig 762

generate message source file from source files — genmsg 504

generate programs for lexical tasks — lex 740

geniconvtbl — generate iconv code conversion tables 485

genmsg — generate message source file from source files 504  
 Auto Message Numbering 504  
 Comment Extraction 504  
 Invocation 504  
 Testing 504

get configuration values — getconf 510

get locale-specific information — locale 781

get or set the resource limits of running processes  
 — plimit 1191

getconf — get configuration values 510

getfac — display discretionary file information 515

getfrm — (FMLI utility) returns the current frameID number 519

getitems — (FMLI utility) returns a list of currently marked menu items 520

getopt — parse command options 521, 523

getoptcv — parse command options 523

getoptcv — parse command options 523, 526

gettext — retrieve text string from message database 532–533

glob — shell built-in function to expand a word list 535

goto — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps 380

gprof — call-graph profile 536

graph — draw graph 542

graphics filters for plotters — plot 1193, 1577  
 interpolate smooth curve — spline 1464

grep  
 search a file for a pattern — grep 544  
 search a file for a pattern using full regular expressions — egrep 345  
 search file for fixed-character string — fgrep 405

group IDs  
 change real and effective — newgrp 1031  
 change the group ownership of a file — chgrp 137

display a list of all valid group names —  
    dispgid 305  
prompts for group ID — ckgid 153  
provides error message for group ID —  
    errgid 153  
validates group ID — valgid 153  
groups — print group membership of  
    user 549-550  
grpck — check group database entries 551

## H

halt system without checking disks —  
    fasthalt 399  
hash — shell built-in functions to evaluate the  
    internal hash table of the  
    contents of directories 552  
hashstat — shell built-in functions to evaluate  
    the internal hash table of the  
    contents of directories 552  
head — display first few lines of files 554  
history — shell built-in functions to re-use  
    previous command-lines from  
    the current shell 556  
HOME variable — sh 1417  
host machines, local  
    show status — ruptime 1326  
    who is logged in — rwho 1330  
host machines, remote  
    display status of network hosts (RPC  
    version) — rup 1324  
    who is logged in — rusers 1329  
host resident PostScript font downloader —  
    download 309  
hostid — display host ID 566  
hostname — display host name 567

## I

i386 — get processor type truth value 848  
iAPX286 — get processor type truth value 848  
if — shell built-in functions to evaluate  
    condition(s) or to make  
    execution of actions dependent  
    upon the evaluation of  
    condition(s) 570

IFS variable — sh 1418  
indicator — (FMLI utility) displays application  
    specific alarms or working  
    indicator, or both, on FMLI  
    banner line 585  
indxbib — create an inverted index to a  
    bibliographic database 587  
install — install files 588  
instruction set, determining which variant is  
    optimal to use — optisa 1129  
integer  
    prompts for an integer — ckint 155  
    provides help message for integer —  
        helpint 155  
    validates an integer — valint 155  
integer, range  
    prompts for an integer within a specified  
    range — ckrange 165  
    provides error message for integer within a  
    specified range — errrange 165  
    validate an integer within a specified range  
    — valrange 165  
Internet  
    transfer files to and from a remote machine  
    — tftp 1547  
    transfer of files to and from remote network  
    sites — ftp 469  
    user name directory service — whois 1702  
interprocess communication  
    remove a message queue, semaphore set,  
    or shared memory ID —  
    ipcrm 590  
    report status — ipcs 591  
invoke a command with an altered scheduling  
    priority — nice 1034  
ipcrm — remove a message queue, semaphore  
    set, or shared memory ID 590  
ipcs — report inter-process communication  
    facilities status 591  
isainfo — describe instruction set  
    architectures 596  
isalist — display the native instruction  
    sets executable on this  
    platform 598

## J

jobs – shell built-in functions to control process execution 599  
join — relational database operator 606  
jsh – the job control shell command interpreter 1413

## K

kbd — manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect 609  
Kerberos keytab maintenance utility — ktutil 693  
Kerberos login utility — kinit 624  
Kerberos system introduction — Kerberos 614  
Kerberos ticket-granting-ticket fetch and store using service key — ksrvtgt 692  
Kerberos tickets destroy — kdestroy 613 list currently held — klist 628  
keyboard load and dump keyboard translation tables – loadkeys, dumpkeys 780 manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect — kbd 609  
keylogin — decrypt and store secret key with keyserver 617  
keylogout — delete stored secret key with keyserver 619  
keywords prompts for and validates a keyword — ckkeywd 160  
kill — terminate a process by default 620  
Korn shell commands login command 677  
KornShell aliasing – ksh 634 arithmetic evaluation – ksh 652 blank interpretation – ksh 650 command substitution – ksh 637, 662–663

commands – ksh 631  
comments – ksh 634  
conditional expressions – ksh 653  
definitions – ksh 631  
emacs editing mode – ksh 664  
environment – ksh 658  
file name generation – ksh 650  
functions – ksh 659  
I/O – ksh 657  
in-line editing options – ksh 663  
invocation – ksh 687  
jobs – shell\_builtins 602, 661  
parameter substitution – ksh 640  
process substitution – ksh 640  
prompting – ksh 653  
quoting – ksh 652  
restricted command and programming language – rksh 631  
signals – ksh 662  
special commands – ksh 673  
tilde substitution – ksh 635  
vi editing mode – ksh 668  
kpasswd — change a user's Kerberos password 630  
ksh – KornShell, a standard command and programming language 631  
ktutil — Kerberos keytab maintenance utility 693

## L

languages C compiler — cc 130 C preprocessor — cpp 212 C program verifier — lint 759 create C error messages — mkstr 968 extract strings from C code — xstr 1714  
last — display login and logout information about users and terminals 695  
lastcomm — display the last commands executed, in reverse order 697  
ld — link-editor for object files 699  
ld — link editor 709  
ld.so.1 — runtime linker for dynamic objects 732

- ldap — LDAP as a naming repository 710
- LDAP as a naming repository — ldap 710
- ldap delete entry tool — ldapdelete 713
- ldap entry addition and modification tools
  - ldapadd 718
  - ldapmodify 718
- ldap modify entry RDN tool —
  - ldapmodrdn 722
- ldap search tool — ldapsearch 724
- ldapadd - ldap entry addition and modification tools 718
- ldapdelete — ldap delete entry tool 713
- ldaplist — search and list naming information from a LDAP directory service 715
- ldapmodify - ldap entry addition and modification tools 718
- ldapmodrdn — ldap modify entry RDN tool 722
  - Input Format 723
- ldapsearch — ldap search tool 724
  - Output Format 726
- ldd — list dynamic dependencies of executable files or shared objects 729
- let — shell built-in function to evaluate one or more arithmetic expressions 739
- lex — generate programs for lexical tasks 740
  - Actions in lex 748
  - create a tags file for use with ex and vi — ctags 269
  - Definitions in lex 742
  - Output Files 741
  - Regular Expressions in lex 744
  - Rules in lex 744
  - Stderr 741
  - Stdout 741
  - User Subroutines in lex 744
- library archive
  - find ordering relation for an object or library archive — lorder 804
- limit - set or get limitations on the system resources available to the current shell and its descendents 753
  - csk 753
  - ksh 753
  - sh 753
  - sh/ksh 756
  - /usr/bin/ulimit 753
- line — read one line from standard input and write to standard output 758
- line numbering filter — nl 1105
- line printer control — lpc 814
- link
  - make hard or symbolic links to files — ln 774
- link editor — ld 709
- link-editor — ld 699
- lint — C program verifier 759
- list
  - contents of directory — ls 832
  - file names — ls 838
- list of service grades
  - print — uuglist 1638
- list, sorted
  - find lines — look 802
- listusers — list user login information 761
- llc\_autoconfig — generate LLC2 configuration files 762
- llc\_config — configure LLC2 interface parameters 763
- LLC2 Station, SAP, and Connection Statistics — llc2\_stats 765
- llc2\_stats — LLC2 Station, SAP, and Connection Statistics 765
- ln — make hard or symbolic links to files 774
- loadkeys - load keyboard translation tables 780
- locale — get locale-specific information 781
- localedef — define locale environment 784
- log, system
  - add entries — logger 789
- logger — add entries to the system log 789, 791
- login command 677, 793, 1426
  - change login password and password attributes — passwd 1134
  - display effective user name — whoami 1700
  - display login and logout information about users and terminals — last 695

- get the name of the user running the process — logname 800
- list user login information — listusers 761
- remote — rlogin 1301
- spawn login to a remote terminal — ct 267
- who is logged in, and what are they doing — w 1682
- login environment
  - display variables — printenv 1234
  - set terminal characteristics - tset 1601
- login password
  - change in NIS — yppasswd 1723
- logname — get the name of the user running the process 800
- logout — shell built-in function to exit from a login session 801
  - display login and logout information about users and terminals — last 695
- look — find words in the system dictionary or lines in a sorted list 802
- lookbib — find references in a bibliographic database 803
- lorder — find ordering relation for an object or library archive 804
- lp — send requests to a print service 805
- LP print services
  - cancel requests — cancel 123
  - control line printer — lpc 814
  - display printer queue — lpq 818
  - generate printer test pattern — lptest 831
  - print files — lp 805
  - print files (BSD) — lpr 820
  - remove print jobs — lprm 824
- lpc — line printer control 814
- lpq — display printer queue 818
- lpr — print files 820
- lprm — remove print jobs 824
- lpstat — print information about the status of the print service 826
- lptest — generate printer test pattern 831
- ls — list contents of directory 832, 838

## M

- m4 — macro processor 841

- mach — display processor type of current host 847
- machid — get processor type truth value 848
- machine IDs
  - get processor type truth value - machid 848
- macro processor — m4 841
- magnetic tape
  - backspace files — mt 986
  - backspace records — mt 986
  - copy — tcopy 1528
  - erase — mt 986
  - forward space files — mt 986
  - forward space records — mt 986
  - get unit status — mt 986
  - manipulate — mt 986
  - place unit off-line — mt 986
  - retension — mt 986
  - rewind — mt 986
  - skip backward files — mt 986
  - skip backward records — mt 986
  - skip forward files — mt 986
  - skip forward records — mt 986
  - write EOF mark on — mt 986
- mail — interactive message processing system 850, 1417
  - automatic replies — vacation 1650
- mail aliases
  - aliases— system mail 1219
- mail services
  - mail notifier — biff 117
  - sender of mail messages — from 468
- mail utilities
  - create aliases database — newaliases 1026
  - statistics — mailstats 855
- mailbox
  - storage for incoming mail - mailx 857
- MAILCHECK variable - sh 1417
- mailcompat — provide SunOS compatibility for Solaris mailbox format 851
- mailp - frontends to the mp PostScript pretty printer 852
- MAIL variable - sh 1417
- mailstats — mail delivery statistics 855
- mailx - interactive message processing system 857, 882
- mailx commands

- matrix display program for PostScript printers
  - postmd 1202
- mbox
  - storage file for read mail - mailx 857
- mconnect — open connection to remote mail server 925
- mcs — manipulate the comment section of an object file 926
- mdb — modular debugger 928
- menu item
  - builds a menu and prompts user to choose one item from menu - ckitem 157
  - provides help message for menu item - helpitem 157
- menu items, FMLI
  - returns a list of — getitems 520
- mesg — permit or deny messages via write 958
- message — puts arguments on FMLI message line 959
- messages
  - create message object file — msgfmt 983
  - creating portable object files — msgfmt 983
  - display contents of, or search for a text string in, message data bases — srchtxt 1467
  - display on stderr or system console — fmtmsg 441

- editing messages — msgfmt 983
- extract gettext call strings — xgettext 1711
- generate a formatted message catalog —
  - gencat 482
- permit or deny messages via write —
  - mesg 958
- retrieve text string from message database
  - gettext 532
- setting the domain — msgfmt 983
- setting the message identifier —
  - msgfmt 983
- setting the message string — msgfmt 983
- mixerctl — audio mixer control 962
- mkdir — make directories 964
- mkmsgs — create message files for use by
  - gettext 966
- mkstr — create C error messages 968
- .mo files
  - message object files — msgfmt 983
- modify the Access Control List (ACL) for a file or files — setfacl 1408
- modular debugger — mdb 928
- monitor process and LWP behavior using CPU performance counters —
  - cpustrack 219
- more - browse through a text file 970
- mp — PostScript pretty printer 978
- msgfmt — create message object file 983
- mt — manipulate magnetic tape 986
- mv — move files 989

## N

- nawk — pattern scanning and processing language 992
  - Actions 992
  - Arithmetic Functions 992
  - Expression Patterns 992
  - Expressions in nawk 992
  - Functions 992
  - Input/Output and General Functions 992
  - Output Statements 992
  - Pattern Ranges 992
  - Patterns 992
  - Regular Expressions 992
  - Special Patterns 992
  - String Functions 992

- User-defined Functions 992
- /usr/bin/nawk 992
- /usr/xcu4/bin/awk 992
- /usr/xpg4/bin/awk 992
- Variables and Special Variables 992
- nca – the Network Cache and Accelerator (NCA) 1016
- NCA – the Network Cache and Accelerator (NCA) 1016
- ncab2clf — convert binary log file to Common Log File format 1018
- ncakmod — start or stop the NCA kernel module 1020
- neqn – mathematical typesetting 358
- netscape — start Netscape Communicator for Solaris 1021
- newaliases — make mail aliases database 1026
- newform — change the format of a text file 1028
- newgrp — shell built-in function to allow new group permissions to the user 1031
- news — print news items 1033
- newsp – frontends to the mp PostScript pretty printer 852
- NFS, secure
  - decrypt and store secret key with keysevr — keylogin 617
  - delete stored secret key with keysevr— keylogout 619
- nice — invoke a command with an altered scheduling priority 1034
  - change process nice value — renice 1297
  - csh Builtin 1034
- nis – a new version of the network information name service 1036
- NIS
  - change login password in — yppasswd 1723
  - print the value of one or more keys from a NIS map — ypmatch 1722
  - print values in a NIS database — ypcat 1721
  - return name of NIS server or map master — ypwhich 1724
- nis+ – a new version of the network information name service 1036

- NIS+ – a new version of the network information name service 1036
  - Authentication – nis+ 1043
  - Authorization – nis+ 1044
  - change access rights on a NIS+ object — nischmod 1059
  - change password information — nispasswd 1088
  - change the group owner of a NIS+ object — nischgrp 1057
  - change the owner of a NIS+ object — nischown 1062
  - change the time to live of a NIS+ object — nischttl 1064
  - Concatenation Path – nis+ 1040
  - create NIS+ directories — nismkdir 1082
  - Directories and Domains – nis+ 1043
  - Directory Authorization – nis+ 1045
  - display NIS+ defaults — nisdefaults 1066
  - display NIS+ error messages — niserror 1069
  - display tables — niscat 1054
  - Grammar – nis+ 1038
  - Group Names – nis+ 1042
  - group administration — nisgrpadm 1070
  - Indexed Names – nis+ 1038
  - list the contents of a NIS+ directory — nisl 1077
  - Name Expansion – nis+ 1039
  - Namespaces – nis+ 1040
  - NIS+ Table Object – nis+ 1036–1037, 1047–1049, 1053
  - Principal Names – nis+ 1040
  - remove directories — nisrmdir 1094
  - remove objects — nisrm 1092
  - return the state of the NIS+ namespace using a conditional expression — nistest 1102
  - Simple Names – nis+ 1037
  - symbolically link NIS+ objects — nisln 1074
  - Table Authorization – nis+ 1046
  - table administration tool — nistbladm 1096
  - utilities for searching NIS+ tables – nismatch, nisgrep 1079
- niscat — display NIS+ tables 1054

nischgrp — change the group owner of a NIS+ object 1057  
 nischmod — change access rights on a NIS+ object 1059  
 nischown — change the owner of a NIS+ object 1062  
 nischttl — change the time to live of a NIS+ object 1064  
 nisdefaults — display NIS+ defaults 1066  
 niserror — display NIS+ error messages 1069  
 nisgrep — utility for searching NIS+ tables 1079  
 nisgrpadm — NIS+ group administration command 1070  
 nisl — symbolically link NIS+ objects 1074  
 nisl — list the contents of a NIS+ directory 1077  
 nismatch — utility for searching NIS+ tables 1079  
 nismkdir — create a NIS+ directory 1082  
 nisrm — remove NIS+ objects 1092  
 nisrmdir — remove a NIS+ directory 1094  
 nistbladm — administer NIS+ tables 1096  
 nistest — return the state of the NIS+ namespace using a conditional expression 1102  
 nl — number lines 1105  
 nm — print name list of an object file 1109  
 nohup — run a command immune to hangups 1114  
 notify — shell built-in functions to control process execution 599  
 notify user that volume requested is not in the CD-ROM or floppy drive — volmissing 1677  
 nroff — format documents for display or line-printer 1117  
 nroff utilities  
   check nroff and troff files — checknr 135  
   eliminate .so's from nroff input — soelim 1446  
   filters reverse line-feeds from two-column nroff text — col 184  
   format tables — tbl 1526  
   remove nroff, troff, tbl and eqn constructs — deroff 290

## O

object archive  
   find ordering relation for an object or library archive — lorder 804  
 object files  
   find printable strings — strings 1473  
   manipulate the comment section — mcs 926  
   print section sizes in bytes — size 1441  
   strip symbol table, debugging and line number information — strip 1475  
 octal dump  
   — od 1120  
 od — octal dump 1120  
 on — execute a command on a remote system, but with the local environment 1127  
 onintr — shell built-in functions to respond to (hardware) signals 1588  
 online documentation system  
   — answerbook2 56  
 online reference pages — man 919  
 optisa — determine which variant instruction set is optimal to use 1129

## P

pack — compress files 1130  
 page — page through a text file 970  
 pagesize — display size of a page of memory 1133  
 Pascal  
   create a tags file for use with ex and vi — ctags 269  
 passwd — change login password and password attributes 1134  
 password  
   change in NIS — yppasswd 1723  
 password file  
   edit — vipw 1673  
 passwords  
   change login password and password attributes — passwd 1134  
 paste — merge same lines of several files or subsequent lines of one file 1141

patch — apply changes to files 1144  
     Filename Determination 1147  
     Patch Application 1147  
     Patchfile Format 1146  
 PATH variable – sh 1417  
 pathchk — check path names 1149  
 pathconv — search FMLI criteria for  
     filename 1152  
 pathname  
     prompts for a pathname – ckpath 162  
     provides error message for pathname –  
         errpath 162  
     validates pathname – valpath 162  
 pattern scanning and processing language —  
     nawk 992  
 pax — portable archive interchange 1154  
     Modes of Operations 1154  
     Standard Error 1160  
     Standard Output 1160  
 pcat – compress files 1130  
 pcred – proc tools 1249  
 pdp11 – get processor type truth value 848  
 performance monitoring  
     display call-graph profile data —  
         gprof 536  
     resource usage for a command —  
         rusage 1327  
     time a command; report process data and  
         system activity — timex 1554  
 perl — Practical Extraction and Report  
     Language 1163  
 pfcsh – execute a command in a profile 1171  
 pfexec – execute a command in a profile 1171  
 pfiles – proc tools 1249  
 pfksh – execute a command in a profile 1171  
 pflags – proc tools 1249  
 pfsh – execute a command in a profile 1171  
 pg — files perusal filter for CRTs 1172  
 pgrep – find processes by name and other  
     attributes 1177  
 pkginfo — display software package  
     information 1181  
 pkgmk — produce an installable package 1183  
 pkgparam — display package parameter  
     values 1185  
 pkgproto — generate prototype file entries  
     for input to pkgmk  
         command 1187  
 pkgtrans — translate package format 1189  
 pkill – signal processes by name and other  
     attributes 1177  
 pldd – proc tools 1249  
 plimit — get or set the resource limits of running  
     processes 1191  
 plot – graphics filters for plotters 1193  
 plotters  
     graphics filters – plot 1193  
     graphics filters 1577  
 pmap – proc tools 1249  
 .po files  
     portable object files — msgfmt 983  
 popd – shell built-in functions to change  
     the current working  
     directory 132  
 portable archive interchange — pax 1154  
 postplot — PostScript translator for plot(4B)  
     graphics files 1206  
 postdaisy — PostScript translator for Diablo 630  
     daisy-wheel files 1195  
 postdmd — PostScript translator for DMD  
     bitmap files 1197  
 postio — serial interface for PostScript  
     printers 1199  
 postmd — matrix display program for  
     PostScript printers 1202  
 postprint — PostScript translator for text  
     files 1208  
 postprocessors  
     troff for PostScript printers — dpost 311  
 postreverse — reverse the page order in a  
     PostScript file 1210  
 PostScript  
     matrix display program — postmd 1202  
     prepends host resident PostScript fonts to  
         files — download 309  
     reverse the page order in a PostScript file —  
         postreverse 1210  
     serial interface — postio 1199  
     translator for Diablo 630 daisy-wheel files  
         — postdaisy 1195  
     translator for DMD bitmap files —  
         postdmd 1197

**Index-1743**

- translator for plot(4B) graphics files —
  - postplot 1206
- translator for Tektronix 4014 files —
  - posttek 1212
- translator for text files — postprint 1208
- troff postprocessor for PostScript printers
  - dpost 311
- PostScript pretty printer — mp 978
- PostScript translator for Diablo 630 daisy-wheel
  - files — postdaisy 1195
- PostScript translator for MD bitmap files —
  - postdmd 1197
- PostScript translator for Tektronix 4014 files —
  - posttek 1212
- PostScript translator for text files —
  - postprint 1208
- posttek — PostScript translator for Tektronix
  - 4014 files 1212
- pr — print files 1214
- Practical Extraction and Report Language —
  - perl 1163
- praliases — display system mail aliases 1219
- prex — control tracing and manipulate probe
  - points in a process or the kernel 1220
- prime factors
  - obtain for a number — factor 398
- print — shell built-in function to output
  - characters to the screen or window 1233
  - formatted output — printf 1235
  - print files — pr 1214
- print authorizations granted to a user —
  - auths 97
- print execution profiles for a user —
  - profiles 1256
- print files — lpr 820
  - prepends host resident PostScript fonts to
    - files — download 309
- print roles granted to a user — roles 1310
- print services
  - print information about the status —
    - lpstat 826
- printenv — display environment
  - variables 1234
- printers
  - cancel requests — cancel 123
- control — lpc 814
- display queue — lpq 818
- print information about the status —
  - lpstat 826
- remove jobs from queue — lprm 824
- send requests — lp 805
- test — lptest 831
- printers, LP
  - disable 354
  - enable 354
- printf — print formatted output 1235
- proc tools
  - pcred 1249
  - pfiles 1249
  - pflags 1249
  - pldd 1249
  - pmap 1249
  - prun 1249
  - psig 1249
  - pstack 1249
  - pstop 1249
  - ptime 1249
  - ptree 1249
  - pwait 1249
  - pwdx 1249
- process accounting
  - search and print files — acctcom 38
  - time a command; report process data and
    - system activity — timex 1554
- process scheduler
  - display or set scheduling parameters
    - of specified process(es) —
      - priocntl 1240
- process status
  - report — ps 1258
- process, running
  - change priority — renice 1297
- processes
  - display status — ps 1267
  - get core images of running processes —
    - gcore 481
  - terminate a process by default — kill 620
- processors
  - display type — mach 847
- prof — display profile data 1252
- profile
  - display call-graph — gprof 536

profiles — print execution profiles for a user 1256

programming languages

- analyze and disperse compiler error messages — error 363
- C compiler — cc 130
- C preprocessor — cpp 212
- C program verifier — lint 759
- extract strings from C code — xstr 1714
- formats program in nice style using troff — vgrind 1657

programming tools

- arbitrary precision arithmetic language — bc 108
- assembler — as 68
- create a tags file for use with ex and vi — ctags 269
- create C error messages — mkstr 968
- debugger — adb 41
- display call-graph profile data — gprof 536
- dump selected parts of an object file — dump 317
- find printable strings in an object or binary file — strings 1473
- install 588
- link editor — ld 709
- link-editor for object files — ld 699
- macro processor — m4 841
- make — build programs 883
- object code disassembler — dis 303
- print name list of an object file — nm 1109
- print section sizes in bytes of object files — size 1441
- regular expression compile — regcmp 1291
- resolve and remove ifdef'ed lines from C program source — undef 1620
- resource usage for a command — rusage 1327
- RPC protocol compiler — rpcgen 1312
- Source Code Control System — sccs 1339
- strip symbol table, debugging and line number information from an object file — strip 1475

- touch — update last modified date of file 1576
- prun — proc tools 1249
- ps — display process status 1267
- PS1 variable — sh 1418
- PS2 variable — sh 1418
- psig — proc tools 1249
- pstack — proc tools 1249
- pstop — proc tools 1249
- ptime — proc tools 1249
- ptree — proc tools 1249
- pushd — shell built-in functions to change the current working directory 132
- pvs — display the internal versioning information of dynamic objects 1270
- pwait — proc tools 1249
- pwd — print working directory name 1273
- pwdx — proc tools 1249

## Q

- queue, printer
  - display — lpq 818
- queues
  - display the jobs queued to run at specified times — atq 82
  - remove jobs spooled by at or batch — atrm 83

## R

- true — convert archives to random libraries 1274
- rcp — remote file copy 1275
- rdist — remote file distribution 1277
- read — shell built-in function to receive from standard input (keyboard) 1284
- readfile, longline — (FMLI utility) reads file, gets longest line 1287
- readonly — shell built-in function to protect the value of the given variable from reassignment 1288
- reboot system without checking disks — fastboot 399
- red — text editor 327

refer — expand and insert references from a bibliographic database 1289

regcmp — regular expression compile 1291

regenerate groups of programs — sysV-make 1498

regenerate programs — make 883

regex — (FMLI utility) match patterns against a string 1293

registration 1447

rehash — shell built-in functions to evaluate the internal hash table of the contents of directories 552

reinit — (FMLI utility) changes the descriptors in the initialization file 1296

relational database — join 606

reminder services — calendar 121  
mail notifier — biff 117

remote shell — rsh 1318

remote system  
connect — tip 1556  
connect to — cu 272  
execute a command on a remote system, but with the local environment — on 1127  
file copy — rcp 1275  
file distribution — rdist 1277  
remote login — rlogin 1301  
shell — rsh 1318  
show status — rup 1324–1325  
spawn login — ct 267  
system to system command execution — uux 1646  
transfer files to and from — tftp 1547  
who is logged in on remote machines — rusers 1329

rename the binding of an FNS name — fnrename 455

renice — alter priority of running processes 1297

repeat — shell built-in function to execute a command more than once 466

report on the calls to a specific procedure. — whocalls 1701

report or filter out repeated lines in a file — uniq 1622

reset — (FMLI utility) changes the entry in a field of a form to its default value 1300, 1601

return — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps 380

reverse page order  
PostScript file — postreverse 1210

reverse the page order in a PostScript file — postreverse 1210

rksh — KornShell, restricted command and programming language 631

rlogin — remote login 1301

rm — remove files 1304

rmdir — remove directories 1304

roffbib — format and print bibliographic database 1308

roles — print roles granted to a user 1310

RPC  
display host status of remote machines — rup 1325  
display status of network hosts — rup 1324  
protocol compiler — rpcgen 1312

RPC Language  
RPC protocol compiler — rpcgen 1312

RPC, secure  
decrypt and store secret key with keysevr — keylogin 617  
delete stored secret key with keysevr — keylogout 619

rpcgen — RPC protocol compiler 1312

rsh — remote shell 1318

run — (FMLI utility) runs a program 1322

run a command immune to hangups — nohup 1114

runtime linker for dynamic objects — ld.so.1 732

rup — display status of network hosts (RPC version) 1324–1325

ruptime — display status of local hosts 1326

rusage — resource usage for a command 1327

rusers — who is logged in on remote machines 1329

rwwho — who is logged in on local machines 1330

## S

sag — system activity graph 1331

sar — system activity reporter 1333

### SCCS

extract SCCS version information from a file — what 1689

sccs — Source Code Control System 1339

### SCCS commands

admin — create and administer SCCS history files 1349

cdc — change the delta commentary of an SCCS delta 1353

comb — combine deltas 1355

delta — change the delta commentary of an SCCS delta 1357

get — retrieve a version of an SCCS file 1360

help — help regarding SCCS error or warning messages 1367

prt — display delta table information from an SCCS file 1372

rmDEL — remove a delta from an SCCS file 1375

sact — show editing activity status of an SCCS file 1376

sccs-prs — display selected portions of an SCCS history 1368

sccsdiff — compare versions of SCCS file 1377

unget — unget SCCS file 1378

val — validate SCCS file 1379

### SCCS delta

change commentary — sccs-cdc 1353

combine — sccs-comb 1355

create — delta 1357

remove — rmDEL 1375

### SCCS delta table

print from an SCCS file — sccs-prt 1372

### SCCS files

compare versions — sccs-sccsdiff 1377

retrieve a version of a file — sccs-get 1360

show editing activity status — sccs-sact 1376

undo a previous get of an SCCS file — sccs-unget 1378

validate — sccs-val 1379

### SCCS help

regarding SCCS error or warning messages — sccs-help 1367

### SCCS history

display selected portions — sccs-prs 1368

### SCCS history files

create and administer — sccs-admin 1349

sccs-admin — create and administer SCCS history files 1349

sccs-cdc — change the delta commentary of an SCCS delta 1353

sccs-comb — combine deltas 1355

sccs-delta — change the delta commentary of an SCCS delta 1357

sccs-get — retrieve a version of an SCCS file 1360

sccs-help — help regarding SCCS error or warning messages 1367

sccs-prs — display selected portions of an SCCS history 1368

sccs-prt — display delta table information from an SCCS file 1372

sccs-rmDEL — remove delta from SCCS file 1375

sccs-sact — show editing activity status of an SCCS file 1376

sccs-sccsdiff — compare versions of SCCS file 1377

sccs-unget — unget SCCS file 1378

sccs-val — validate SCCS file 1379

screen-oriented editor — vi 1661

script — make script of terminal session 1381

sdiff — print differences between two files side-by-side 1382

search and list naming information from a LDAP directory service — ldaplist 715

search for FNS objects with specified attributes — fnsearch 456

sed — stream editor 1384, 1392

Functions 1393

sed Addresses 1385

sed Editing Commands 1385

sed Regular Expressions 1385

sed Scripts 1392

select – shell built-in functions to choose from  
among a list of actions 125

select or reject lines common to two files —  
comm 186

serial interface for PostScript printers —  
postio 1199

set – shell built-in functions to determine  
the characteristics for  
environmental variables  
of the current shell and its  
descendents 1399

set environment for command invocation —  
env 356

set or get limitations on the system resources  
available to the current shell  
and its descendents

- limit 753
- ulimit 753
- unlimited 753

set, unset – (FLMI utility) set and unset  
local or global environment  
variables 1405

setcolor — (FMLI utility) redefine or create a  
color 1407

setenv – shell built-in functions to determine  
the characteristics for  
environmental variables  
of the current shell and its  
descendents 1399

setfacl — modify the Access Control List (ACL)  
for a file or files 1408

- acl\_entries Syntax 1408

settime – change file access and modification  
times 1572

sh – the standard shell command  
interpreter 1413

SHACCT variable – sh 1418

SHELL variable – sh 1418, 1434

- Korn shell – ksh 631
- restricted Korn shell – rksh 631

shell command interpreter built-in functions —  
shell\_builtins 1435

shell command interpreter builtin-functions

- alias 53
- bg 599
- break 118
- case 125
- cd 132
- chdir 132
- continue 118
- dirs 132
- eval 378
- exit 380
- fc 556
- fg 599
- for 466
- foreach 466
- function 480
- getopt 526
- glob 535
- hash 552
- hashstat 552

- let 739
- logout 801
- newgrp 1031
- notify 599
- onintr 1588
- popd 132
- print 1233
- pushd 132
- read 1284
- readonly 1288
- rehash 552
- repeat 466
- return 380
- select 125
- set 1399
- setenv 1399
- shift 1439
- source 378
- stop 599
- suspend 1496
- switch 125
- test 570
- times 1553
- trap 1588
- typeset 1610
- umask 1614
- unalias 53
- unhash 552

- unset 1399
- unsetenv 1399
- until 1694
- wait 1684
- whence 1610
- while 1694

shell programming

- echo arguments — echo 321
- read one line from standard input and write to standard output — line 758

shell scripts

- display size of page memory — pagesize 1133
- provide truth values - true, false 1593

shell variables, in Bourne shell 1417

shell\_builtins — shell command interpreter built-in functions 1435

shells

- C shell — csh 235
- remote - rsh 1318
- the standard shell command interpreter - sh 1413

shift — shell built-in function to traverse either a shell's argument list or a list of field-separated words 1439

show codeset table for the current locale — dumpps 320

shutdown — shut down multiuser operation 1440

sign on to the system — login 793

Simple Mail Transfer Protocol

- connection to remote mailserver — mconnect 925

size — print section sizes in bytes of object files 1441

sleep — suspend execution for an interval 1443

smart2cfg — Compaq Smart-2 EISA/PCI and Smart-2SL PCI Array Controller ioctl utility 1444

SMTPSimple Mail Transfer Protocol

soelim — eliminate .so's from nroff input 1446

software package

- display information — pkginfo 1181
- display parameter values — pkgparam 1185
- generate prototype file entries for input to pkgmk command — pkgproto 1187
- produce an installable package — pkgmk 1183
- translate package format — pkgtrans 1189

Solaris user registration — solregis 1447

solregis — Solaris user registration 1447

sort — sort and/or merge files 1450

sort, topological

- items mentioned in input — tsort 1606

sortbib — sort bibliographic database 1457

sotruss — trace shared library procedure calls 1459

source - shell built-in functions to execute other commands 378

Source Code Control SystemSCCS

source files

- locate — whereis 1691

sparc - get processor type truth value 848

spell - check spelling 1461

spline — interpolate smooth curve 1464

split — split a file into pieces 1465

split files based on context — csplit 264

srchtxt — display contents of, or search for a text string in, message data bases 1467

standard output

- replicate — tee 1529

start Netscape Communicator for Solaris — netscape 1021

start or stop the NCA kernel module — ncakmod 1020

statistics

- collected by sendmail — mailstats 855

stop - shell built-in functions to control process execution 599

strchg - change stream configuration 1470

strconf - query stream configuration 1470

stream editor — sed 1384, 1392

STREAMS

- change or query stream configuration - strchg, strconf 1470

string

- prompt for defined string answer - ckstr 168

provide an help message for defined string  
     answer - helpstr 168  
 validate a defined string answer -  
     valstr 168  
 strings — find printable strings in object or  
     binary file 1473  
 strip — strip symbol table, debugging and line  
     number information from an  
     object file 1475  
 stty — set the options for a terminal 1477, 1486  
 sum — print checksum and block count for a  
     file 1494-1495  
 sun - get processor type truth value 848  
 provide SunOS compatibility for Solaris mailbox  
     format — mailcompat 851  
 SunOS/BSD Source Compatibility Package  
     — stty 1486  
 SunOS/BSD Source Compatibility Package  
     commands  
     — arch 67  
     — basename 107  
     — biff 117  
     — cc 130  
     — chown 149  
     — df 291  
     — du 315  
     — echo 325  
     — expr 390  
     - fastboot 399  
     — file 409  
     — from 468  
     — groups 550  
     — grpck 551  
     — hostid 566  
     — hostname 567  
     — install 588  
     — ld 709  
     — lint 759  
     — ln 777  
     — logger 791  
     — lpc 814  
     — lpq 818  
     — lpr 820  
     — lprm 824  
     — lptest 831  
     — ls 838  
     — mach 847  
     — mkstr 968  
     — pagesize 1133  
     - plot 1193  
     — printenv 1234  
     — ps 1267  
     — rusage 1327  
     — shutdown 1440  
     — sum 1495  
     — test 1542  
     — tr 1587  
     - tset 1601  
     — users 1630  
     — vipw 1673  
     — whereis 1691  
     — whoami 1700  
 suspend — shell built-in function to halt the  
     current shell 1496  
 suspend execution of command  
     — sleep 1443  
 switch - shell built-in functions to choose from  
     among a list of actions 125  
 symorder — update symbol table  
     ordering 1497  
 synchronize files and directories —  
     filesync 411  
 system to system copy - uucp 1631  
 system activity  
     graphical representation — sag 1331  
     reporter — sar 1333  
     time a command; report process data and  
     system activity — timex 1554  
 system administration  
     — install 588  
 system call and signals  
     trace — truss 1594  
 system log  
     add entries — logger 789  
 system name  
     print — uname 1617  
 system to system command execution —  
     uux 1646  
 system uptime  
     display — uptime 1629  
 sysV-make — maintain, update, and regenerate  
     groups of programs 1498

## T

### TAB characters

- expand to SPACE characters, and vice versa
  - expand, unexpand 382

### tables

- format for nroff or troff — tbl 1526

tabs — set tabs on a terminal 1506

tail — display last part of file 1510

talk — talk to another user 1513

### tape

- backspace files — mt 986
- backspace records — mt 986
- erase — mt 986
- forward space files — mt 986
- forward space records — mt 986
- get unit status — mt 986
- place unit off-line — mt 986
- retension — mt 986
- rewind — mt 986
- skip backward files — mt 986
- skip backward records — mt 986
- skip forward files — mt 986
- skip forward records — mt 986
- write EOF mark on — mt 986

### tape archives

- create — tar 1516

### tape, magnetic

- copy, blocking preserved — tcopy 1528
- manipulate — mt 986
- scan — tcopy 1528

tar — create tape archives, and add or extract files 1516

tbl — format tables for nroff or troff 1526

- remove nroff, troff, tbl and eqn constructs
  - deroff 290

tcopy — copy a magnetic tape 1528

tee — replicate the standard output 1529

telnet — user interface to a remote system using the TELNET protocol 1530

### TELNET protocol

- user interface to a remote system using the TELNET protocol — telnet 1530

### terminal

- set options — stty 1477
- set tabs — tabs 1506

### terminal screen

- clear 181

### terminal session

- make script— script 1381

### terminals

- get name — tty 1608
- initialize a terminal or query terminfo database — tput 1578
- reset bits — reset 1601
- set characteristics — tset 1601
- set characteristics — stty 1486

terminate a process by default — kill 620

### terminfo database

- initialize a terminal or query terminfo database — tput 1578

test - shell built-in functions to evaluate condition(s) or to make execution of actions dependent upon the evaluation of condition(s) 570, 1544

test — condition evaluation 1542

### text editing

- screen-oriented (visual) display editor based on ex - vi 1661
- sed — stream editor 1392
- stream editor — sed 1384

### text editor

- ed 327
- edit 340
- ex 367

### text files

- browse or page through a text file - more, page 970
- change format — newform 1028

### text formatter

- format documents for display or line-printer — nroff 1117

### text processing utilities

- check spelling - spell 1461
- concatenate and display files — cat 128
- display last part of file — tail 1510
- pattern scanning and processing language — awk 98

search a file for a pattern — grep 544

search a file for a pattern using full regular expressions — egrep 345

search file for fixed-character string — fgrep 405

sort and/or merge files — sort 1450  
 split a file into pieces — split 1465  
 translate characters — tr 1582, 1587  
 underline text — ul 1613  
 text retrieval tools  
   create message files for use by gettxt —  
     mkmsgs 966  
   retrieve text string from message database  
     — gettxt 533  
 tftp — trivial file transfer program 1547  
 the Network Cache and Accelerator (NCA) —  
   NCA 1016  
 tilde escape commands for mail  
   — mailx 870  
 time — time a simple command 1550  
   prompts for time — cktime 173  
   provides error message for time —  
     errtime 173  
   validates time — valtime 173  
 time a simple command — time 1550  
 timed event services  
   display the jobs queued to run at specified  
     times — atq 82  
   reminder service — calendar 121  
   remove jobs spooled by at or batch —  
     atrm 83  
   user crontab file — crontab 230  
 timemanp — frontends to the mp PostScript  
   pretty printer 852  
 times — shell built-in function to report  
   time usages of the current  
   shell 1553  
 timesysp — frontends to the mp PostScript pretty  
   printer 852  
 timex — time a command; report process data  
   and system activity 1554  
 tip — connect to remote system 1556  
 tnfdump — convert binary TNF file to  
   ASCII 1566  
 tnfxtract — extract kernel probes output into a  
   trace file 1570  
 touch — change file access and modification  
   times 1572, 1609  
   settime 1573  
   touch 1572  
 touch — update last modified date of file 1576  
 tplot — graphics filters for plotters 1577

tput — initialize a terminal or query terminfo  
   database 1578  
 tr — translate characters 1582, 1587  
 trace function calls  
   trace application function calls to  
     Solaris shared libraries —  
       apptrace 57  
 trace shared library procedure calls —  
   sotruss 1459  
 translate characters — tr 1582, 1587  
 translates exportfs options to share/unshare  
   commands — exportfs 385  
 trap — shell built-in functions to respond to  
   (hardware) signals 1588  
 Trivial File Transfer Protocol/TFTP  
 troff — typeset or format documents 1590  
 troff utilities  
   check nroff and troff files — checknr 135  
   eliminate .so's from nroff input —  
     soelim 1446  
   filters reverse line-feeds from two-column  
     nroff text — col 184  
   format tables — tbl 1526  
   formats program code — vgrind 1657  
   postprocessor for PostScript printers —  
     dpost 311  
   remove nroff, troff, tbl and eqn constructs  
     — deroff 290  
 true — provide truth values 1593  
 truss — trace system calls and signals 1594  
 tset — set terminal characteristics 1601  
 tsort — topological sort of items mentioned in  
   input 1606  
 ttl — time to live value, nischtll 1064  
 tty, set characteristics — stty 1486, 1601  
   set options — stty 1477  
 tty — get the name of the terminal 1608  
 typeset — shell built-in functions to set/get  
   attributes and values for shell  
   variables and functions 1610  
 typeset documents — troff 1590

## U

u370 — get processor type truth value 848  
 u3b — get processor type truth value 848  
 u3b15 — get processor type truth value 848

u3b2 – get processor type truth value 848  
u3b5 – get processor type truth value 848  
ucblinks — adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices 1612  
ul — underline text 1613  
ulimit – set or get limitations on the system resources available to the current shell and its descendents 753  
umask — shell built-in function to restrict read/write/execute permissions 1614  
unalias – shell built-in functions to create your own pseudonym or shorthand for a command or series of commands 53  
uname — print name of current system 1617  
unbind the reference from an FNS name — fnunbind 463  
uncompress – uncompress files 191  
underline text — ul 1613  
unexpand – unexpand SPACE characters to TAB characters 382  
unhash – shell built-in functions to evaluate the internal hash table of the contents of directories 552  
unifdef — resolve and remove ifdef'ed lines from C program source 1620  
uniq — report or filter out repeated lines in a file 1622  
units — converts quantities expressed in standard scales to other scales 1625  
UNIX  
convert text file from DOS format to ISO format — dos2unix 307  
UNIX-to-UNIX commands  
uucp – uucp 1631  
uulog – uucp 1631  
uuname – uucp 1631  
unix2dos — convert text file from ISO format to DOS format 1627  
unlimit – set or get limitations on the system resources available to the current shell and its descendents 753  
unpack – expand compressed files 1130  
unset – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents 1399  
unsetenv – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents 1399  
until – shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE 1694  
update and examine attributes associated with FNS named object — fnattr 446  
update groups of programs — sysV-make 1498  
update last modified date of file — touch 1576  
update programs — make 883  
uptime — show how long the system has been up 1629  
user ID  
change user IDs of files — chown 149  
user IDs  
display a list of all valid user names — dispuid 306  
prompts for user ID – ckuid 176  
provides help message for user ID – helpuid 176  
validates user ID – valuid 176  
users  
display effective name — whoami 1700  
display group membership — groups 549  
display information about local and remote users — finger 426  
get the name of the user running the process — logname 800  
list user login information — listusers 761  
talk to another user — talk 1513  
who is logged in on local machines — rwho 1330  
who is logged in on remote machines — rusers 1329  
who is logged in, and what are they doing — w 1682

**Index-1753**

who is on the system — who 1696  
write to another user — write 1703  
users — display users on system 1630  
users, network  
    Internet user name directory service —  
        whois 1702  
uucp - UNIX-to-UNIX copy 1631  
    log - uulog 1631  
    uucp status inquiry — uustat 1639  
uudecode - decode binary file 1635  
uuencode - encode binary file 1635  
uuglist — print list of service grades  
    available 1638  
uulog - UUCP log 1631  
uuname - UUCP list of names 1631  
uustat — uucp status inquiry 1639  
uux — system to system command  
    execution 1646

## V

vacation — automatic mail replies 1650  
vax - get processor type truth value 848  
version control  
    — vc 1653  
vgrind — formats program in nice style using  
    troff 1657  
vi - screen-oriented (visual) display editor  
    based on ex 1661  
vipw — edit password file 1673  
volcancel — cancel user's request for removable  
    media that is not currently in  
    drive 1674  
volcheck — check for media in a drive 1675  
volmissing — notify user that volume requested  
    is not in the CD-ROM or  
    floppy drive 1677  
volrmmount — call rmmount to mount or  
    unmount media 1679

### Volume Management

    cancel user's request for removable media  
    that is not currently in drive  
    — volcancel 1674  
    check for media in a drive —  
    volcheck 1675  
    missing volume notification —  
    volmissing 1677

vsig — synchronize a co-process with  
    the controlling FMLI  
    application 1681

## W

w — display information about currently  
    logged-in users 1682  
w — who is logged in, and what are they  
    doing 1682  
wait — shell built-in function to wait for other  
    jobs or processes 1684  
wc — display a count of lines, words and  
    characters in a file 1687  
what — extract SCCS version information from  
    a file 1689  
whatis — describe command 1690  
whence - shell built-in functions to set/get  
    attributes and values for shell  
    variables and functions 1610  
whereis — locate the binary, source and  
    manual page files for a  
    command 1691  
which — locate a command; display its  
    pathname or alias 1693  
while - shell built-in functions to repetitively  
    execute a set of actions  
    while/until conditions are  
    evaluated TRUE 1694  
who is logged in — w 1682  
who — who is on the system 1696  
whoami — display effective user name 1700  
whocalls — report on the calls to a specific  
    procedure. 1701  
whois — Internet user name directory  
    service 1702  
write — write to another user 1703  
write file checksums and sizes — cksum 171

## X

xargs — construct argument lists and invoke  
    utility 1706  
xgettext — extract gettext call strings 1711  
xstr — extract strings from C code 1714

## Y

yacc — yet another compiler-compiler 1717  
create a tags file for use with ex and vi —  
ctags 269  
yes/no answer  
prompts for yes/no answer - ckyorn 179  
provides error message for yes/no answer  
- erryorn 179  
validates yes/no answer - valyorn 179  
yet another compiler-compiler — yacc 1717  
ypcat — print values in a NIS database 1721

ypmatch — print the value of one or more keys  
from a NIS map 1722  
yppasswd — change your network password in  
the NIS database 1723  
ypwhich — return name of NIS server or map  
master 1724

## Z

zcat - displays uncompressed files but leaves  
compressed files intact 191
