

man pages section 3: Extended Library Functions

Sun Microsystems, Inc. 901 San Antonio Road Palo Alto, CA 94303-4900 U.S.A.

Part No: 816-0217-06 December 2001 Copyright 2001 Sun Microsystems, Inc. 901 San Antonio Road Palo Alto, CA 94303-4900 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, docs.sun.com, AnswerBook, AnswerBook2, and Solaris are trademarks, registered trademarks, or service marks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems. Inc.

The OPEN LOOK and Sun^{TM} Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

Federal Acquisitions: Commercial Software-Government Users Subject to Standard License Terms and Conditions.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 2001 Sun Microsystems, Inc. 901 San Antonio Road Palo Alto, CA 94303-4900 U.S.A. Tous droits réservés

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, docs.sun.com, AnswerBook, AnswerBook2, et Solaris sont des marques de fabrique ou des marques déposées, ou marques de service, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux États-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et SunTM a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REPONDRE A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

Index 613

Preface

Both novice users and those familar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question "What does it do?" The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

NAME

This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS

This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

- [] Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
- . . . Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . ."
- Separator. Only one of the arguments separated by this character can be specified at a time.
- { } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL

This section occurs only in subsection 3R to indicate the protocol description file.

DESCRIPTION

This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are

described under USAGE.

IOCTL

This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device). ioctl calls are used for a particular class of devices all of which have an io ending, such as mtio(7I).

OPTIONS

This secton lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS

This section lists the command operands and describes how they affect the actions of the command.

OUTPUT

This section describes the output - standard output, standard error, or output files - generated by the

RETURN VALUES

If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or –1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS

On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph

under the error code.

USAGE This section lists special rules, features, and

commands that require in-depth explanations. The subsections listed here are used to explain built-in

functionality:

Commands Modifiers Variables Expressions Input Grammar

EXAMPLES This section provides examples of usage or of how

to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as example%, or if the user must be superuser, example#. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.

ENVIRONMENT VARIABLES This section lists any environment variables that

the command or function affects, followed by a

brief description of the effect.

EXIT STATUS This section lists the values the command returns to

the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.

FILES This section lists all file names referred to by the

man page, files of interest, and files created or required by commands. Each is followed by a

descriptive summary or explanation.

ATTRIBUTES This section lists characteristics of commands,

utilities, and device drivers by defining the attribute type and its corresponding value. See

attributes(5) for more information.

SEE ALSO This section lists references to other man pages,

in-house documentation, and outside publications.

DIAGNOSTICS This section lists diagnostic messages with a brief

explanation of the condition causing the error.

WARNINGS This section lists warnings about special conditions

which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES This section lists additional information that does

not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never

covered here.

BUGS This section describes known bugs and, wherever

possible, suggests workarounds.

Extended Library Functions

aclcheck(3SEC)

NAME

aclcheck – check the validity of an ACL

SYNOPSIS

```
cc [ flag ... ] file ... -lsec [ library ... ]
#include <sys/acl.h>
```

int aclcheck(aclent t *aclbufp, int nentries, int *which);

DESCRIPTION

The aclcheck() function checks the validity of an ACL pointed to by *aclbufp*. The *nentries* argument is the number of entries contained in the buffer. The *which* parameter returns the index of the first entry that is invalid.

The function verifies that an ACL pointed to by *aclbufp* is valid according to the following rules:

- There must be exactly one GROUP OBJ ACL entry.
- There must be exactly one USER OBJ ACL entry.
- There must be exactly one OTHER OBJ ACL entry.
- If there are any GROUP ACL entries, then the group ID in each group ACL entry must be unique.
- If there are any USER ACL entries, then the user ID in each user ACL entry must be unique.
- If there are any GROUP or USER ACL entries, then there must be exactly one CLASS OBJ (ACL mask) entry.
- If there are any default ACL entries, then the following apply:
 - There must be exactly one default GROUP OBJ ACL entry.
 - There must be exactly one default OTHER OBJ ACL entry.
 - There must be exactly one default USER OBJ ACL entry.
 - If there are any DEF_GROUP entries, then the group ID in each DEF_GROUP ACL entry must be unique.
 - If there are any DEF_USER entries, then the user ID in each DEF_USER ACL entry must be unique.
 - If there are any DEF_GROUP or DEF_USER entries, then there must be exactly one DEF_CLASS_OBJ (default ACL mask) entry.
- If any of the above rules are violated, then the function fails with errno set to EINVAL.

RETURN VALUES

If the ACL is valid, alcheck() will return 0. Otherwise errno is set to EINVAL and return code is set to one of the following:

 ${\tt GRP_ERROR} \qquad \qquad {\tt There is more than one GROUP_OBJ or}$

DEF GROUP OBJ ACL entry.

USER_ERROR There is more than one USER_OBJ or DEF_USER_OBJ

ACL entry.

aclcheck(3SEC)

CLASS ERROR There is more than one CLASS OBJ (ACL mask) or

DEF_CLASS_OBJ (default ACL mask) entry.

There is more than one $\ensuremath{\mathtt{OTHER}}\xspace_\mathtt{OBJ}$ or OTHER ERROR

DEF_OTHER_OBJ ACL entry.

Duplicate entries of USER, GROUP, DEF USER, or DUPLICATE ERROR

DEF GROUP.

The entry type is invalid. ENTRY ERROR

MISS_ERROR Missing an entry. The *which* parameter returns −1 in

this case.

MEM_ERROR The system cannot allocate any memory. The which

parameter returns -1 in this case.

acl(2), aclsort(3SEC)

aclsort(3SEC)

NAME | aclsort – sort an ACL

SYNOPSIS

```
cc [ flag ... ] file ... -lsec [ library ... ]
#include <sys/acl.h>
```

int aclsort(int nentries, int calclass, aclent t *aclbufp);

DESCRIPTION

The aclbufp argument points to a buffer containing ACL entries. The nentries argument specifies the number of ACL entries in the buffer. The calclass argument, if non-zero, indicates that the CLASS OBJ (ACL mask) permissions should be recalculated. The union of the permission bits associated with all ACL entries in the buffer other than CLASS OBJ, OTHER OBJ, and USER OBJ is calculated. The result is copied to the permission bits associated with the CLASS OBJ entry.

The aclsort () function sorts the contents of the ACL buffer as follows:

- Entries will be in the order USER OBJ, USER, GROUP OBJ, GROUP, CLASS OBJ (ACL mask), OTHER OBJ, DEF USER OBJ, DEF USER, DEF GROUP OBJ, DEF GROUP, DEF CLASS OBJ (default ACL mask), and DEF OTHER OBJ.
- Entries of type USER, GROUP, DEF_USER, and DEF GROUP will be sorted in increasing order by ID.

The aclsort () function will succeed if all of the following are true:

- There is exactly one entry each of type USER OBJ, GROUP OBJ, CLASS OBJ (ACL mask), and OTHER OBJ.
- There is exactly one entry each of type DEF USER OBJ, DEF GROUP OBJ, DEF CLASS OBJ (default ACL mask), and DEF OTHER OBJ if there are any default entries.
- Entries of type USER, GROUP, DEF USER, or DEF GROUP may not contain duplicate entries. A duplicate entry is one of the same type containing the same numeric ID.

RETURN VALUES

Upon successful completion, the the function returns 0. Otherwise, it returns −1.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving

SEE ALSO | acl(2), aclcheck(3SEC)

NAME | acltomode, aclfrommode – convert an ACL to or from permission bits

SYNOPSIS

```
cc [ flag ... ] file ... -lsec [ library ... ]
#include <sys/types.h>
#include <sys/acl.h>
int acltomode(aclent t *aclbufp, int nentries, mode t *modep);
int aclfrommode(aclent t *aclbufp, int nentries, mode t *modep);
```

DESCRIPTION

The acltomode () function converts an ACL pointed to by *aclbufp* into the permission bits buffer pointed to by modep. If the USER OBJ ACL entry, GROUP OBJ ACL entry, or the OTHER OBJ ACL entry cannot be found in the ACL buffer, then the function fails with errno set to EINVAL.

The USER OBJ ACL entry permission bits are copied to the file owner permission bits in the permission bits buffer. The OTHER OBJ ACL entry permission bits are copied to the file other permission bits in the permission bits buffer. If there is a CLASS OBJ (ACL mask) entry, then the CLASS OBJ ACL entry permission bits are intersected (bitwise AND) with the ${\tt GROUP_OBJ}$ ACL entry permission bits and the result is copied to the file group permission bits in the permission bits buffer. Otherwise, the GROUP OWNER ACL entry permission bits are copied to the file group permission bits in the permission bits buffer.

The aclfrommode () function converts the permission bits pointed to by *modep* into an ACL pointed to by aclbufp. If the USER OBJ ACL entry, GROUP OBJ ACL entry, or the OTHER OBJ ACL entry cannot be found in the ACL buffer, then the function fails with errno set to EINVAL.

The file owner permission bits from the permission bits buffer are copied to the USER OBJ ACL entry. The file other permission bits from the permission bits buffer are copied to the OTHER OBJ ACL entry. The file group permissions bits from the permission bits buffer are copied to the CLASS OBJ (ACL mask) entry, if available, and to the GROUP OBJ ACL entry.

The *nentries* argument represents the number of ACL entries in the buffer pointed to by aclbufp.

RETURN VALUES

Upon successful completion, the function returns 0. Otherwise, it returns −1 and sets errno to indicate the error.

acltotext(3SEC)

NAME

acltotext, aclfromtext – convert internal representation to or from external representation

SYNOPSIS

```
cc [ flag ... ] file ... -lsec [ library ... ]
#include <sys/acl.h>
char *acltotext(aclent t *aclbufp, int aclcnt);
aclent t *aclfromtext(char *acltextp, int *aclcnt);
```

DESCRIPTION

The acltotext () function converts an internal ACL representation pointed to by aclbufp into an external ACL representation. The space for the external text string is obtained using malloc(3C). The caller is responsible for freeing the space upon completion..

The aclfromtext () function converts an external ACL representation pointed to by acltextp into an internal ACL representation. The space for the list of ACL entries is obtained using malloc(3C). The caller is responsible for freeing the space upon completion. The aclent argument indicates the number of ACL entries found.

An external ACL representation is defined as follows:

```
<acl_entry>[,<acl_entry>]...
```

Each <acl_entry> contains one ACL entry. The external representation of an ACL entry contains two or three colon-separated fields. The first field contains the ACL entry tag type. The entry type keywords are defined as:

user	This ACL entry with no UID specified in the ACL entry ID field specifies the access granted to the owner of the object. Otherwise, this ACL entry specifies the access granted to a specific user-name or user-id number.
group	This ACL entry with no GID specified in the ACL entry ID field specifies the access granted to the owning group of the object. Otherwise, this ACL entry specifies the access granted to a specific

group-name or group-id number.

This ACL entry specifies the access granted to any user or group

that does not match any other ACL entry.

This ACL entry specifies the maximum access granted to user or mask

group entries.

This ACL entry with no uid specified in the ACL entry ID field default:user

specifies the default access granted to the owner of the object. Otherwise, this ACL entry specifies the default access granted to a

specific user-name or user-ID number.

This ACL entry with no gid specified in the ACL entry ID field default:group

specifies the default access granted to the owning group of the

other

object. Otherwise, this ACL entry specifies the default access

granted to a specific group-name or group-ID number.

default:other This ACL entry specifies the default access for other entry.
default:mask This ACL entry specifies the default access for mask entry.

The second field contains the ACL entry ID, as follows:

uid This field specifies a user-name, or user-ID if there is no user-name

associated with the user-ID number.

gid This field specifies a group-name, or group-ID if there is no

group-name associated with the group-ID number.

empty This field is used by the user and group ACL entry types.

The third field contains the following symbolic discretionary access permissions:

r read permission
w write permission

x execute/search permission

no access

RETURN VALUES

Upon successful completion, the acltotext() function returns a pointer to a text string. Otherwise, it returns NULL.

Upon successful completion, the aclfromtext() function returns a pointer to a list of ACL entries. Otherwise, it returns NULL.

acl(2), malloc(3C)

acos(3M)

NAME | acos – arc cosine function

SYNOPSIS

cc [flag ...] file ... -lm [library ...] #include <math.h>

double **acos** (double x);

DESCRIPTION

The acos () function computes the principal value of the arc cosine of x. The value of *x* should be in the range [-1,1].

RETURN VALUES

Upon successful completion, acos () returns the arc cosine of x, in the range [0,pi]radians. If the value of x is not in the range [-1,1], and is not $\pm Inf$ or NaN, either 0.0 or NaN is returned and errno is set to EDOM.

If x is NaN, NaN is returned. If x is \pm Inf, either 0.0 is returned and errno is set to EDOM, or NaN is returned and errno may be set to EDOM.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The acos() function will fail if:

The value x is not \pm Inf or NaN and is not in the range [-1,1]. EDOM

The acos () function may fail if:

EDOM The value x is $\pm Inf$.

USAGE

An application wishing to check for error situations should set errno to 0 before calling acos (). If errno is non-zero on return, or the value NaN is returned, an error has occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

cos(3M), isnan(3M), matherr(3M), attributes(5), standards(5)

NAME | acosh, asinh, atanh – inverse hyperbolic functions

SYNOPSIS

```
\texttt{cc} [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
double acosh(double x);
double asinh(double x);
double atanh(double x);
```

DESCRIPTION

The acosh(), asinh() and atanh() functions compute the inverse hyperbolic cosine, sine, and tangent of their argument, respectively.

RETURN VALUES

The acosh(), asinh() and atanh() functions return the inverse hyperbolic cosine, sine, and tangent of their argument, respectively.

The acosh () function returns NaN and sets errno to EDOM when its argument is less than 1.0.

The atanh() function returns NaN and sets errno to EDOM when its argument has absolute value greater than 1.0.

The atanh() function returns ±Inf and sets errno to ERANGE when its argument is $\pm 1.0.$

If x is NaN, the asinh(), acosh() and atanh() functions return NaN.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The acosh() function will fail if:

EDOM The *x* argument is less than 1.0.

The atanh() function will fail if:

EDOM The *x* argument has an absolute value greater than 1.0.

ERANGE The *x* argument has an absolute value equal to 1.0

ATTRIBUTES

asin(3M)

NAME | asin – arc sine function

SYNOPSIS

cc [flag ...] file ... -lm [library ...]

#include <math.h>

double asin(double x);

DESCRIPTION

The asin() function computes the principal value of the arc sine of x. The value of xshould be in the range [-1,1].

RETURN VALUES

Upon successful completion, as in () returns the arc sine of x, in the range [-pi/2,pi/2] radians. If the value of x is not in the range [-1,1] and is not \pm Inf or NaN, either 0.0 or NaN is returned and errno is set to EDOM.

If *x* is NaN, NaN is returned.

If x is $\pm Inf$, either 0.0 is returned and errno is set to EDOM or NaN is returned and errno may be set to EDOM.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The asin() function will fail if:

EDOM The value x is not \pm Inf or NaN and is not in the range [-1,1].

The asin() function may fail if:

EDOM

The value of x is $\pm Inf$.

USAGE

An application wishing to check for error situations should set errno to 0, then call asin(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

NAME | atan2 – arc tangent function

SYNOPSIS

```
\texttt{cc} [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
double atan2 (double y, double x);
```

DESCRIPTION

The atan2 () function computes the principal value of the arc tangent of y/x, using the signs of both arguments to determine the quadrant of the return value.

RETURN VALUES

Upon successful completion, at an 2 () returns the arc tangent of y/x in the range [-pi,pi] radians. If both arguments are 0.0, 0.0 is returned and errno may be set to EDOM.

If *x* or *y* is NaN, NaN is returned.

In IEEE 754 mode atan2 () handles the following exceptional arguments in the spirit of ANSI/IEEE Std 754-1985.

```
atan2 (\pm 0, x) returns \pm 0 for x > 0 or x = +0;
atan2 (\pm 0, x) returns \pm pi for x < 0 or x = -0;
atan2 (y, \pm 0) returns pi/2 for y > 0;
atan2 (y, \pm 0) returns -pi/2 for y < 0;
atan2 (\pm y, Inf) returns \pm 0 for finite y > 0;
atan2 (\pmInf, x) returns \pmpi/2 for finite x;
atan2 (\pm y, –Inf) returns \pm pi for finite y > 0;
atan2 (±Inf, Inf) returns ±pi/4;
atan2 (\pmInf, -Inf) returns \pm3pi/4.
```

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The atan2() function may fail if:

EDOM Both arguments are 0.0.

USAGE

An application wishing to check for error situations should set errno to 0 before calling atan2 (). If errno is non-zero on return, or the return value is NaN, an error has occurred.

ATTRIBUTES

NAME |

au open, au close, au write - construct and write audit records

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket
                                       -lnsl
                                                -lintl [ library ... ]
#include <bsm/libbsm.h>
int au_close(int d, int keep, short event);
int au open(void);
int au write (int d, token t *m);
```

DESCRIPTION

au open () returns an audit record descriptor to which audit tokens can be written using au write(). The audit record descriptor is an integer value that identifies a storage area where audit records are accumulated.

au close () terminates the life of an audit record *d* of type *event* started by au open(). If the keep parameter is zero, the data contained therein is discarded and the memory used is given up by calling free(3C). Otherwise, the additional parameters are used to create a header token. Depending on the audit policy information obtained by auditon(2), additional tokens such as sequence and trailer tokens may be added to the record. au close () finally writes the record to the audit trail by calling audit(2).

au write() adds the audit token pointed to by *m* to the audit record identified by the descriptor *d*. After this call is made the audit token is no longer available to the caller.

RETURN VALUES

A successful invocation of au write() and au close() will return a 0.

A successful invocation of au open () returns an audit record descriptor. au open () returns -1 if a descriptor could not be allocated. au write() returns -1 if d is not a valid descriptor or if audit(2) experienced an error. errno is set to indicate the error. au write() will return -1 if d is an invalid descriptor or if m is an invalid token.

ATTRIBUTES

See attributes (5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO

bsmconv(1M), audit(2), auditon(2), au preselect(3BSM), au to(3BSM), free(3C), attributes(5)

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

au preselect(3BSM)

NAME |

au_preselect – preselect an audit event

SYNOPSIS

```
cc [ flag ... ] file... -lbsm -lsocket -lnsl -lintl [ library ... ]
#include <bsm/libbsm.h>
```

int au_preselect(au_event_t event, au_mask_t *mask_p, int sorf, int
 flag);

DESCRIPTION

au_preselect() determines whether or not the audit event *event* is preselected against the binary preselection mask pointed to by *mask_p* (usually obtained by a call to getaudit(2)). au_preselect() looks up the classes associated with *event* in audit_event(4) and compares them with the classes in *mask_p*. If the classes associated with *event* match the classes in the specified portions of the binary preselection mask pointed to by *mask_p*, the event is said to be preselected.

sorf indicates whether the comparison is made with the success portion, the failure portion or both portions of the mask pointed to by *mask_p*.

The following are the valid values of *sorf*:

AU PRS SUCCESS Compare the event class with the success portion of the

preselection mask.

AU_PRS_FAILURE Compare the event class with the failure portion of the

preselection mask.

AU PRS BOTH Compare the event class with both the success and

failure portions of the preselection mask.

flag tells au_preselect() how to read the audit_event(4) database. Upon initial
invocation, au_preselect() reads the audit_event(4) database and allocates
space in an internal cache for each entry with malloc(3C). In subsequent invocations,
the value of flag determines where au_preselect() obtains audit event information.
The following are the valid values of flag:

AU_PRS_REREAD Get audit event information by searching the

audit event(4) database.

AU PRS USECACHE Get audit event information from internal cache created

upon the initial invocation. This option is much faster.

RETURN VALUES

au_preselect() returns:

0 *event* is not preselected.

1 *event* is preselected.

An error occurred. au_preselect() couldn't allocate memory or

couldn't find event in the audit event(4) database.

FILES

/etc/security/audit_class maps audit class number to audit class

names and descriptions

/etc/security/audit event

maps audit even number to audit event names and associates

ATTRIBUTES

See attributes(5) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

    uid t ruid, gid t rgid, pid t pid, au asid t sid, au tid addr t
    *tid);
```

```
token t *au to text(char *text);
```

DESCRIPTION

The au to arg() function formats the data in v into an "argument token." The nargument indicates the argument number. The text argument is a null terminated string describing the argument.

The au to attr() function formats the data pointed to by *attr* into a "vnode attribute token."

The au to data () function formats the data pointed to by p into an "arbitrary data token." The unit print parameter determines the preferred display base of the data and is one of AUP BINARY, AUP OCTAL, AUP DECIMAL, AUP HEX, or AUP STRING. The unit_type parameter defines the basic unit of data and is one of AUR BYTE, AUR CHAR, AUR SHORT, AUR INT, or AUR LONG. The unit count parameter specifies the number of basic data units to be used and must be positive.

The au to groups () function formats the array of 16 integers pointed to by groups into a "groups token."

The au to in addr () function formats the data pointed to by *internet addr* into an "internet address token."

The au to new in addr() function formats the data pointed to by <code>internet_addr</code> into an "internet address token." The internet_addr is one containing an IPv6 IP address.

The au to ipc() function formats the data in the *id* parameter into an "interprocess communications ID token."

The au to ipc perm() function formats the data pointed to by perm into an "interprocess communications permission token."

The au to iport () function formats the data pointed to by *iport* into an "ip port address token."

The au to me () function collects audit information from the current process and creates a "subject token" by calling au to subject().

The au to newgroups () function formats the array of *n* integers pointed to by groups into a "newgroups token."

The au to subject () function formats an auid (audit user ID), an euid (effective user ID), an egid (effective group ID), a ruid (real user ID), an rgid (real group ID), a pid (process ID), an sid (audit session ID), an tid (audit terminal ID), into a "subject token." au to(3BSM)

The au_to_new_subject() function formats an *auid* (audit user ID), an *euid* (effective user ID), an *egid* (effective group ID), a *ruid* (real user ID), an *rgid* (real group ID), a *pid* (process ID), an *sid* (audit session ID), an *tid* (audit terminal ID), into a "subject token." The audit terminal ID is one that contains an IPv6 IP address.

The au_to_opaque() function formats the *bytes* bytes pointed to by *data* into an "opaque token." The value of *size* must be positive.

The $au_to_path()$ function formats the path name pointed to by path into a "path token."

The au_to_process () function formats an *auid* (audit user ID), an *euid* (effective user ID), an *egid* (effective group ID), a *ruid* (real user ID), a *rgid* (real group ID), a *pid* (process ID), an *sid* (audit session ID), and a *tid* (audit terminal ID), into a "process token." A process token should be used when the process is the object of an action (ie. when the process is the receiver of a signal).

The au_to_new_process() function formats an *auid* (audit user ID), an *euid* (effective user ID), an *egid* (effective group ID), a *ruid* (real user ID), a *rgid* (real group ID), a *pid* (process ID), an *sid* (audit session ID), and a *tid* (audit terminal ID), into a "process token." A process token should be used when the process is the object of an action (ie. when the process is the receiver of a signal). The audit terminal ID is one that contains an IPv6 IP address.

The au_to_return() function formats an error number *number* and a return value *value* into a "return value token."

The au_to_socket() function format the data pointed to by so into a "socket token."

The au_to_new_socket() function format the data pointed to by *so* into a "socket token." The socket contains IPv6 IP addresses.

The au_to_text() function formats the null-terminated string pointed to by *text* into a "text token."

RETURN VALUES

These functions return NULL if memory cannot be allocated to put the resultant token into, or if an error in the input is detected.

au user mask(3BSM)

NAME |

au_user_mask - get user's binary preselection mask

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket -lnsl -lintl [ library ... ]
#include <bsm/libbsm.h>
```

int au user mask(char *username, au mask t *mask_p);

DESCRIPTION

au_user_mask() reads the default, system wide audit classes from audit_control(4), combines them with the per-user audit classes from the audit_user(4) database, and updates the binary preselection mask pointed to by mask p with the combined value.

The audit flags in the *flags* field of the audit_control(4) database and the *always-audit-flags* and *never-audit-flags* from the audit_user(4) database represent binary audit classes. These fields are combined by au preselect(3BSM) as follows:

mask = (flags + always-audit-flags) - never-audit-flags

au_user_mask() only fails if both the both the audit_control(4) and the audit_user(4) database entries could not be retrieved. This allows for flexible configurations.

RETURN VALUES

au user mask() returns:

0 Success.

-1 Failure. Both the audit_control(4) and the audit_user(4) database entries could not be retrieved.

FILES

/etc/security/audit_control contains default parameters read by the audit daemon, auditd(1M)

/etc/security/audit user stores per-user audit event mask

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
N	MT-Level	MT-Safe

SEE ALSO

$$\label{eq:login} \begin{split} &\log \text{in}(1), \text{bsmconv}(1M), \text{getaudit}(2), \text{setaudit}(2), \text{au_preselect}(3BSM), \\ &\text{getacinfo}(3BSM), \text{getauusernam}(3BSM), \text{audit_control}(4), \text{audit_user}(4), \\ &\text{attributes}(5) \end{split}$$

NOTES

au_user_mask() should be called by programs like login(1) which set a process's
preselection mask with setaudit(2). getaudit(2) should be used to obtain audit
characteristics for the current process.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

NAME | bgets – read stream up to next delimiter

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
char *bgets(char *buffer, size t count, FILE *stream, const char
     *breakstring);
```

DESCRIPTION

The bgets () function reads characters from *stream* into *buffer* until either *count* is exhausted or one of the characters in breakstring is encountered in the stream. The read data is terminated with a null byte $(' \setminus 0')$ and a pointer to the trailing null is returned. If a breakstring character is encountered, the last non-null is the delimiter character that terminated the scan.

Note that, except for the fact that the returned value points to the end of the read string rather than to the beginning, the call

```
bgets(buffer, sizeof buffer, stream, "\n");
is identical to
fgets (buffer, sizeof buffer, stream);
```

There is always enough room reserved in the buffer for the trailing null character.

If breakstring is a null pointer, the value of breakstring from the previous call is used. If breakstring is null at the first call, no characters will be used to delimit the string.

RETURN VALUES

NULL is returned on error or end-of-file. Reporting the condition is delayed to the next call if any characters were read but not yet returned.

EXAMPLES

EXAMPLE 1 Example of the bgets() function.

The following example prints the name of the first user encountered in /etc/passswd, including a trailing ":"

```
#include <stdio.h>
#include<libgen.h>
int main()
{
    char buffer[8];
    FILE *fp;
    if ((fp = fopen("/etc/passwd","r")) == NULL) {
       perror("/etc/passwd");
        return 1;
    if (bgets(buffer, 8, fp, ":") == NULL) {
        perror("bgets");
        return 1;
    (void) puts(buffer);
    return 0;
}
```

bgets(3GEN)

ATTRIBUTES

NOTES

When compiling multithread applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications.

NAME | bufsplit – split buffer into fields

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
size t bufsplit(char *buf, size t n, char **a);
```

DESCRIPTION

bufsplit() examines the buffer, buf, and assigns values to the pointer array, a, so that the pointers point to the first *n* fields in *buf* that are delimited by TABs or NEWLINEs.

To change the characters used to separate fields, call bufsplit() with *buf* pointing to the string of characters, and *n* and *a* set to zero. For example, to use colon (:), period (.), and comma (,), as separators along with TAB and NEWLINE:

```
bufsplit (":.,\t\n", 0, (char**)0 );
```

RETURN VALUES

The number of fields assigned in the array a. If buf is zero, the return value is zero and the array is unchanged. Otherwise the value is at least one. The remainder of the elements in the array are assigned the address of the null byte at the end of the buffer.

EXAMPLES

EXAMPLE 1 Example of bufsplit () function.

```
* set a[0] = "This", a[1] = "is", a[2] = "a",
* a[3] = "test"
bufsplit("This\tis\ta\test\n", 4, a);
```

NOTES

bufsplit () changes the delimiters to null bytes in buf.

When compiling multithreaded applications, the REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications.

NAME | ceil – ceiling value function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double **ceil** (double x);

DESCRIPTION

The ceil() function computes the smallest integral value not less than x.

RETURN VALUES

Upon successful completion, ceil() returns the smallest integral value not less than *x*, expressed as a type double.

If *x* is NaN, NaN is returned.

If x is $\pm Inf$ or ± 0 , x is returned.

ERRORS

No errors will occur.

USAGE

The integral value returned by ceil() as a double may not be expressible as an int or long int. The return value should be tested before assigning it to an integer type to avoid the undefined results of an integer overflow.

Deprecated Interfaces

The following interfaces have been deprecated and their use is strongly discouraged:

HARDWARE DEPENDENT LIBRARY SYNOPSIS

The config_admin library is a generic interface that is used for dynamic configuration, (DR). Each piece of hardware that supports DR must supply a hardware-specific *plugin* library that contains the entry points listed in this subsection. The generic library will locate and link to the appropriate library to effect DR operations. The interfaces specified in this subsection are really "hidden" from users of the generic libraries. It is, however, necessary that writers of the hardware-specific plug in libraries know what these interfaces are.

cfga_err_t cfga_change_state(cfga_cmd_t state_change_cmd, const char

 cfga_msg *msgp, char **errstring, cfga_flags_t flags);

- cfqa err t cfqa private func (const char *function, const char *ap id, const char *options, struct cfga confirm *confp, struct cfga msg *msgp, char **errstring, cfqa flags t flags);
- cfga_err_t cfga_test(const char *ap_id, const char *options, struct cfga msg *msgp, char **errstring, cfga flags t flags);
- cfga err t cfga list ext(const char *ap_id, struct cfga list data **ap id_list, int *nlist, const char *options, const char *listopts, char **errstring, cfqa flags t flags);
- cfga_err_t cfga_help(struct cfga_msg *msgp, const char *options, cfqa flaqs t flags);
- int **cfga** ap id **cmp**(const cfga ap id t ap_id1, const cfga ap id t $ap_id2)$;

Deprecated Interfaces

The following interfaces have been deprecated and their use is strongly discouraged:

- cfga err t cfga stat (const char *ap_id, struct cfga stat data *buf, const char *options, char **errstring);
- cfga err t cfga list(const char *ap_id, struct cfga stat data **ap_id_list, int *nlist, const char *options, char **errstring);

DESCRIPTION

The config *() functions provide a hardware independent interface to hardware-specific system configuration administration functions. The cfga *() functions are provided by hardware-specific libraries that are dynamically loaded to handle configuration administration functions in a hardware-specific manner.

The libcfgadm library is used to provide the services of the cfgadm(1M) command. The hardware-specific libraries are located in

/usr/platform/\${machine}/lib/cfgadm,

/usr/platform/ $\{arch\}/lib/cfgadm$, and /usr/lib/cfgadm. The hardware-specific library names are derived from the driver name or from class names in device tree nodes that identify attachment points.

The config change state() function performs operations that change the state of the system configuration. The *state_change_cmd* argument can be one of the following: CFGA CMD INSERT, CFGA CMD REMOVE, CFGA CMD DISCONNECT, CFGA CMD CONNECT, CFGA CMD CONFIGURE, or CFGA CMD UNCONFIGURE. The state change cmd CFGA CMD INSERT is used to prepare for manual insertion or to activate automatic hardware insertion of an occupant. The state_change_cmd CFGA CMD REMOVE is used to prepare for manual removal or activate automatic hardware removal of an occupant. The state change cmd CFGA CMD DISCONNECT is used to disable normal communication to or from an occupant in a receptacle. The state_change_cmd CFGA CMD CONNECT is used to enable communication to or from an occupant in a receptacle. The state change cmd CFGA CMD CONFIGURE is used to bring the hardware resources contained on, or attached to, an occupant into the realm of Solaris, allowing use of the occupant's hardware resources by the system. The state_change_cmd CFGA CMD UNCONFIGURE is used to remove the hardware resources

config_admin(3CFGADM)

contained on, or attached to, an occupant from the realm of Solaris, disallowing further use of the occupant's hardware resources by the system.

The flags argument may contain one or both of the defined flags, CFGA_FLAG_FORCE and CFGA_FLAG_VERBOSE. If the CFGA_FLAG_FORCE flag is asserted certain safety checks will be overridden. For example, this may not allow an occupant in the failed condition to be configured, but might allow an occupant in the failing condition to be configured. Acceptance of a force is hardware dependent. If the CFGA_FLAG_VERBOSE flag is asserted hardware-specific details relating to the operation are output utilizing the cfga_msg mechanism.

The config private func() function invokes private hardware-specific functions.

The config_test() function is used to initiate testing of the specified attachment point.

The num_ap_ids argument specifies the number of ap_ids in the ap_ids array. The ap_ids argument points to an array of ap_ids .

The *ap_id* argument points to a single *ap_id*.

The *function* and *options* strings conform to the <code>getsubopt(3C)</code> syntax convention and are used to supply hardware-specific function or option information. No generic hardware-independent functions or options are defined.

The cfga_confirm structure referenced by *confp* provides a call-back interface to get permission to proceed should the requested operation require, for example, a noticeable service interruption. The cfga_confirm structure includes the following members:

```
int (*confirm)(void *appdata_ptr, const char *message);
void *appdata ptr;
```

The confirm() function is called with two arguments: the generic pointer <code>appdata_ptr</code> and the message detailing what requires confirmation. The generic pointer <code>appdata_ptr</code> is set to the value passed in in the <code>cfga_confirm</code> structure member <code>appdata_ptr</code> and can be used in a graphical user interface to relate the <code>confirm</code> function call to the <code>config_*</code> call. The <code>confirm</code> function should return 1 to allow the operation to proceed and 0 otherwise.

The cfga_msg structure referenced by *msgp* provides a call-back interface to output messages from a hardware-specific library. In the presence of the CFGA_FLAG_VERBOSE flag, these messages can be informational; otherwise they are restricted to error messages. The cfga msg structure includes the following members:

```
void (*message_routine)(void *appdata_ptr, const char *message);
void *appdata ptr;
```

The message_routine() function is called with two arguments: the generic pointer <code>appdata_ptr</code> and the message. The generic pointer <code>appdata_ptr</code> is set to the value passed

in in the cfga_confirm structure member appdata_ptr and can be used in a graphical user interface to relate the message_routine() function call to the config_*() call. The messages must be in the native language specified by the LC MESSAGES locale category; see setlocale(3C).

For some generic errors a hardware-specific error message can be returned. The storage for the error message string, including the terminating null character, is allocated by the config_* functions using malloc(3C) and a pointer to this storage returned through *errstring*. If *errstring* is NULL no error message will be generated or returned. If *errstring* is not NULL and no error message is generated, the pointer referenced by *errstring* will be set to NULL. It is the responsibility of the function calling config_*() to deallocate the returned storage using free(3C). The error messages must be in the native language specified by the LC_MESSAGES locale category; see setlocale(3C).

The config_list_ext() function provides the listing interface. When supplied with a list of ap_ids through the first two arguments, it returns an array of cfga_list_data_t structures for each attachment point specified. If the first two arguments are 0 and NULL respectively, then all attachment points in the device tree will be listed. Additionally, dynamic expansion of an attachment point to list dynamic attachment points may also be requested by passing the CFGA_FLAG_LIST_ALL flag through the <code>flags</code> argument. Storage for the returned array of stat structures is allocated by the config_list_ext() function using malloc(3C). This storage must be freed by the caller of config_list_ext() by using <code>free(3C)</code>.

The cfga list data structure includes the following members:

```
cfga_log_ext_t ap_log_id; /* Attachment point logical id */
cfga_phys_ext_t ap_phys_id; /* Attachment point physical id */
cfga_class_t ap_class; /* Attachment point class */
cfga_stat_t ap_r_state; /* Receptacle state */
cfga_stat_t ap_o_state; /* Occupant state */
cfga_cond_t ap_cond; /* Attachment point condition */
cfga_busy_t ap_busy; /* Busy indicator */
time_t ap_status_time; /* Attachment point last change*/
cfga_info_t ap_info; /* Miscellaneous information */
cfga_type_t ap_type; /* Occupant type */
```

The types are defined as follows:

```
typedef char cfga_log_ext_t[CFGA_LOG_EXT_LEN];
typedef char cfga_phys_ext_t[CFGA_PHYS_EXT_LEN];
typedef char cfga_class_t[CFGA_CLASS_LEN];
typedef char cfga_info_t[CFGA_INFO_LEN];
typedef char cfga_type_t[CFGA_TYPE_LEN];
typedef enum cfga_cond_t;
typedef enum cfga_stat_t;
typedef enum cfga_busy_t;
typedef int cfga flags t;
```

The *listopts* argument to config_list_ext() conforms to the getsubopt (3C) syntax and is used to pass listing sub-options. Currently, only the sub-option

config_admin(3CFGADM)

class=class_name is supported. This list option restricts the listing to attachment
points of class class name.

The *listopts* argument to cfga_list_ext() is reserved for future use. Hardware-specific libraries should ignore this argument if it is NULL. If *listopts* is not NULL and is not supported by the hardware-specific library, an appropriate error code should be returned.

The ap_log_id and the ap_phys_id members give the hardware-specific logical and physical names of the attachment point. The ap_busy memberd indicates activity is present that may result in changes to state or condition. The ap_status_time member provides the time at which either the ap_r_state, ap_o_state, or ap_cond field of the attachment point last changed. The ap_info member is available for the hardware-specific code to provide additional information about the attachment point. The ap_class member contains the attachment point class (if any) for an attachment point. The ap_class member is filled in by the generic library. If the ap_log_id and ap_phys_id members are not filled in by the hardware-specific library, the generic library will fill in these members using a generic format. The remaining members are the responsibility of the corresponding hardware-tospecific library.

The ap_log_id, ap_phys_id, ap_info, ap_class, and ap_type members are fixed-length strings. If the actual string is shorter than the size of the member, it will be null-terminated. Because of this, programs should not rely on there being a terminating null character. When printing these fields, the following format is suggested:

```
printf("%.*s", sizeof(p->ap log id), p->ap log id);
```

The config_stat(), config_list(), cfga_stat(), and cfga_list() functions and the cfga_stat_data data structure are deprecated interfaces and are provided solely for backward compatibility. Use of these interfaces is strongly discouraged.

The config_ap_id_cmp function performs a hardware dependent comparison on two ap_ids, returning an equal to, less than or greater than indication in the manner of strcmp(3C). Each argument is either a cfga_ap_id_t or can be a null-terminated string. This function can be used when sorting lists of ap_ids, for example with qsort(3C), or when selecting entries from the result of a config_list function call.

The config_unload_libs function unlinks all previously loaded hardware-specific libraries.

The config_strerror function can be used to map an error return value to an error message string. See RETURN VALUES. The returned string should not be overwritten. config_strerror returns NULL if *cfgerrnum* is out-of-range.

The cfga_help function can be used request that a hardware-specific library output it's localized help message.

RETURN VALUES

The config_*() and cfga_*() functions return the following values. Additional error information may be returned through *errstring* if the return code is not CFGA_OK. See DESCRIPTION for details.

CFGA BUSY	The command was not completed due to an

element of the system configuration administration system being busy.

CFGA ATTR INVAL No attachment points with the specified

attributes exists

CFGA ERROR An error occurred during the processing of

the requested operation. This error code includes validation of the command arguments by the hardware-specific code.

CFGA_INSUFFICIENT_CONDITION Operation failed due to attachment point

condition.

CFGA_INVAL The system configuration administration

operation requested is not supported on the

specified attachment point.

CFGA LIB ERROR A procedural error occurred in the library,

including failure to obtain process resources

such as memory and file descriptors.

CFGA_NACK The command was not completed due to a

negative acknowledgement from the

confp->confirm function.

CFGA NO LIB A hardware-specific library could not be

located using the supplied *ap_id*.

CFGA NOTSUPP System configuration administration is not

supported on the specified attachment

point.

CFGA OK The command completed as requested.

CFGA OPNOTSUPP System configuration administration

operation is not supported on this

attachment point.

CFGA_PRIV The caller does not have the required

process privileges. For example, if

configuration administration is performed through a device driver, the permissions on the device node would be used to control

access.

config_admin(3CFGADM)

CFGA SYSTEM BUSY

The command required a service interruption and was not completed due to a part of the system that could not be quiesced.

ERRORS

Many of the errors returned by the system configuration administration functions are hardware-specific. The strings returned in *errstring* may include the following:

attachment point ap_id not known

The attachment point detailed in the error message does not exist.

unknown hardware option option for operation

An unknown option was encountered in the options string.

hardware option option requires a value

An option in the *options* string should have been of the form *option=value*.

listing option list_option requires a value

An option in the listopts string should have been of the form *option*=value.

hardware option option does not require a value

An option in the *options* string should have been a simple option.

attachment point ap_id is not configured

A *config_change_state* command to CFGA_CMD_UNCONFIGURE an occupant was made to an attachment point whose occupant was not in the CFGA_STAT_CONFIGURED state.

attachment point ap_id is not unconfigured

A *config_change_state* command requiring an unconfigured occupant was made to an attachment point whose occupant was not in the CFGA_STAT_UNCONFIGURED state.

attachment point ap_id condition not satisfactory

A *config_change_state* command was made to an attachment point whose condition prevented the operation.

attachment point ap_id in condition condition cannot be used

A *config_change_state* operation with force indicated was directed to an attachment point whose condition fails the hardware dependent test.

NOTES

Applications using this library should be aware that the underlying implementation may use system services which alter the contents of the external variable errno and may use file descriptor resources.

The following code shows the intended error processing when config *() returns a value other than CFGA OK:

```
void
emit_error(int cfgerrnum, char *estrp)
   const char *ep;
    ep = config strerror(cfgerrnum);
   if (ep == NULL)
       ep = gettext("configuration administration unknown error");
    if (estrp != NULL && *estrp != '\0') {
       (void) fprintf(stderr, "%s: %s\n", ep, estrp);
        (void) fprintf(stderr, "%s\n", ep);
    if (estrp != NULL)
        free((void *)estrp);
}
```

Reference should be made to the Hardware Specific Guide for details of System Configuration Administration support.

ConnectToServer(3DMI)

NAME |

ConnectToServer – connect to a DMI service provider

SYNOPSIS

```
cc [ flag ... ] file ... -ldmici -ldmimi [ library ... ]
#include <dmi/api.hh>
```

bool t ConnectToServer(ConnectI *argp, DmiRpcHandle *dmi_rpc_handle);

DESCRIPTION

The ConnectToServer() function enables a management application or a component instrumentation to connect to a DMI service provider.

The *argp* parameter is an input parameter that uses the following data structure:

The host member indicates the host on which the service provider is running. The default is *localhost*.

The nettype member specifies the type of transport RPC uses. The default is *netpath*.

The servertype member indicates whether the connecting process is a management application or a component instrumentation.

The rpctype member specifies the type of RPC, either ONC or DCE. Only ONC is supported in the Solaris 7 release.

The *dmi_rpc_handle* parameter is the output parameter that returns DMI RPC handle.

RETURN VALUES

The ConnectToServer() function returns TRUE if successful, otherwise FALSE.

ATTRIBUTES

NAME | copylist – copy a file into memory

SYNOPSIS

```
cc [ \mathit{flag} ... ] \mathit{file} ... -lgen [ \mathit{library} ... ]
#include <libgen.h>
char *copylist(const char *filenm, off t *szptr);
```

DESCRIPTION

The copylist () function copies a list of items from a file into freshly allocated memory, replacing new-lines with null characters. It expects two arguments: a pointer filenm to the name of the file to be copied, and a pointer szptr to a variable where the size of the file will be stored.

Upon success, copylist() returns a pointer to the memory allocated. Otherwise it returns NULL if it has trouble finding the file, calling malloc(), or reading the file.

USAGE

The copylist () function has a transitional interface for 64-bit file offsets. See 1f64(5).

EXAMPLES

EXAMPLE 1 Example of copylist () function.

```
/* read "file" into buf */
off_t size;
char *buf;
buf = copylist("file", &size);
if (buf) {
    for (i=0; i<size; i++)
        if (buf[i])
           putchar(buf[i]);
            putchar('\n');
    }
} else {
    fprintf(stderr, "%s: Copy failed for "file".\n", argv[0]);
    exit (1);
```

ATTRIBUTES

NOTES

When compiling multithreaded applications, the REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications.

copysign(3M)

NAME | copysign – return magnitude of first argument and sign of second argument

SYNOPSIS

```
\texttt{cc} [ flag ... ] file ... -lm [ library ... ]
```

#include <math.h>

double copysign(double x, double y);

DESCRIPTION

The copysign () function returns a value with the magnitude of x and the sign of y. It produces a NaN with the sign of *y* if *x* is a NaN.

RETURN VALUES

The copysign () function returns a value with the magnitude of x and the sign of y.

NAME | cos – cosine function

SYNOPSIS

cc [flag ...] file ... -lm [library ...]#include <math.h>

double cos(double x);

DESCRIPTION

The cos() function computes the cosine of x, measured in radians.

RETURN VALUES

Upon successful completion, cos() returns the cosine of x.

If x is NaN or \pm Inf, NaN is returned.

ERRORS

No errors will occur.

ATTRIBUTES

cosh(3M)

NAME | cosh – hyperbolic cosine function

SYNOPSIS

```
cc [ flag \dots ] file \dots -lm [ library \dots ]
```

#include <math.h>

double cosh(double x);

DESCRIPTION

The cosh() function computes the hyperbolic cosine of x.

RETURN VALUES

Upon successful completion, cosh() returns the hyperbolic cosine of x.

If the result would cause an overflow, <code>HUGE_VAL</code> is returned and <code>errno</code> is set to ERANGE.

If *x* is NaN, NaN is returned.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The cosh() function will fail if:

ERANGE The result would cause an overflow.

USAGE

An application wishing to check for error situations should set errno to 0 before calling cosh(). If errno is non-zero on return, or the returned value is NaN, an error has occurred.

NAME

cpc – hardware performance counters

DESCRIPTION

The UltraSPARC and Pentium microprocessor families contain hardware performance counters that allow the measurement of many different hardware events related to CPU behavior, including instruction and data cache misses as well as various internal states of the processor. More recent processors allow a variety of events to be captured. The counters can be configured to count user events or system events, or both. The two processor families currently share the restriction that only two event types can be measured simultaneously.

UltraSPARC III and Pentium II processors are able to generate an interrupt on counter overflow, allowing the counters to be used for various forms of profiling.

This manual page describes a set of APIs that allow Solaris applications to use these counters. Applications can measure their own behavior, the behavior of other applications, or the behavior of the whole system.

Shared counters or private counters?

There are two principal models for using these performance counters. Some users of these statistics wish to observe system-wide behavior; others wish to view the performance counters as part of the register set exported by each LWP. On a machine performing more than one activity, these two models are in conflict because the counters represent a critical hardware resource that cannot simultaneously be both shared and private.

To fully support the two-level threads model in Solaris, it would be necessary to virtualize the performance counters to each thread. This version of the library does not allow per-thread data to be captured unless bound threads are used. Even without bound threads, however, the counters can still be used to assess aggregate program behavior.

Generic or specific events?

Although some events are common to all processors, it is apparent that the counters expose a great deal of the specific implementation details of the processor architecture. For this reason, events are specified by name using a string-based hardware event specification language. The values of the tokens in the language vary from processor model to processor model, and can only be interpreted with reference to the relevant hardware documentation. The functions provided to specify the strings use environment variables or arguments so that the names do not have to be compiled in applications, thus extending their longevity and portability across platforms and processor generations.

Configuration Interfaces

The following configuration interfaces are provided:

cpc_version(3CPC)	check the version the application was compiled with against the version of the library
cpc_getcpuver(3CPC)	determine the performance counter version of the current CPU
cpc_getcciname(3CPC)	return the corresponding printable string to describe that interface

cpc(3CPC)

cpc getnpic(3CPC) return the number of valid counter registers in the

cpc_event(3CPC) data structure

cpc getcpuref(3CPC) return a reference to the corresponding processor

documentation

Performance Counter Access

Performance counters can be present in hardware but not accessible because either some of the necessary system software components are not available or not installed, or the counters may be in use by other processes. The <code>cpc_access(3CPC)</code> function determines the accessibility of the counters and should be invoked before any attempt to program the counters.

Programming events

Events are specified using a getsubopt(3C)-style language for both the events and the additional control bits that determine what causes the counters to increment. The cpc_strtoevent() function translates a string to an event specification which can then be used to program the counters. The cpc_eventtostr() function returns the canonical form of the string that corresponds to a particular event. The cpc_getusage(3CPC) function returns a string that specifies the syntax of the string, while cpc_walk_names(3CPC) allows the caller to apply a function to each possible event supported on the relevant processor.

Performance counter context

Each processor on the system possesses its own set of performance counter registers. For a single process, it is often desirable to maintain the illusion that the counters are an intrinsic part of that process (whichever processors it runs on), since this allows the events to be directly attributed to the process without having to make passive all other activity on the system.

To achieve this behavior, the library associates *performance counter context* with each LWP in the process; the context consists of a small amount of kernel memory to hold the counter values when the LWP is not running, and some simple kernel functions to save and restore those counter values from and to the hardware registers when the LWP performs a normal context switch. A process can only observe and manipulate its own copy of the performance counter control and data registers.

Performance Counters In Other Processes

Though applications can be modified to instrument themselves as demonstrated above, it is frequently useful to be able to examine the behavior of an existing application without changing the source code. A separate library, libpctx, provides a simple set of interfaces that use the facilities of proc(4) to control a target process, and together with functions in libcpc, allow truss-like tools to be constructed to measure the performance counters in other applications. An example of one such application is cputrack(1).

The functions in libpetx are independent of those in libepe. These functions manage a process using an event-loop paradigm — that is, the execution of certain system calls by the controlled process cause the library to stop the controlled process and execute callback functions in the context of the controlling process. These handlers can perform various operations on the target process using APIs in libpetx and libepe that consume petx_t handles.

cpc_access(3CPC)

NAME |

cpc_access – test access CPU performance counters

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
```

int cpc access (void);

DESCRIPTION

Access to CPU performance counters is possible only on systems where the appropriate hardware exists and is correctly configured. The cpc_access() function *must* be used to determine if the hardware exists and is accessible on the platform before any of the interfaces that use the counters are invoked.

When the hardware is available, access to the per-process counters is always allowed to the process itself, and allowed to other processes mediated using the existing security mechanisms of /proc.

RETURN VALUES

Upon successful completion, cpc_access() returns 0. Otherwise, it returns -1 and sets errno to indicate the error.

By default, two common errno values are decoded and cause the library to print an error message using its reporting mechanism. See cpc_seterrfn(3CPC) for a description of how this behavior can be modified.

ERRORS

The cpc access () function will fail if:

EAGAIN Another process may be sampling system-wide CPU statistics.

ENOSYS CPU performance counters are inaccessible on this machine. This

error can occur when the machine supports CPU performance counters, but some software components are missing. Check to see that all CPU Performance Counter packages have been correctly

installed.

NAME | cpc_bind_event, cpc_take_sample, cpc_rele – use CPU performance counters on lwps

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
int cpc bind event (cpc event t *event, int flags);
int cpc take sample(cpc event t *event);
int cpc rele(void);
```

DESCRIPTION

Once the events to be sampled have been selected using, for example, cpc strtoevent(3CPC), the event selections can be bound to the calling LWP using cpc_bind_event(). If cpc_bind_event() returns successfully, the system has associated performance counter context with the calling LWP. The context allows the system to virtualize the hardware counters to that specific LWP, and the counters are enabled.

Two flags are defined that can be passed into the routine to allow the behavior of the interface to be modified, as described below.

Counter values can be sampled at any time by calling cpc take sample(), and dereferencing the fields of the ce pic[] array returned. The ce hrt field contains the timestamp at which the kernel last sampled the counters.

To immediately remove the performance counter context on an LWP, the cpc rele() interface should be used. Otherwise, the context will be destroyed after the LWP or process exits.

The caller should take steps to ensure that the counters are sampled often enough to avoid the 32-bit counters wrapping. The events most prone to wrap are those that count processor clock cycles. If such an event is of interest, sampling should occur frequently so that less than 4 billion clock cycles can occur between samples. Practically speaking, this is only likely to be a problem for otherwise idle systems, or when processes are bound to processors, since normal context switching behavior will otherwise hide this problem.

RETURN VALUES

Upon successful completion, cpc bind event() and cpc take sample() return 0. Otherwise, these functions return −1, and set errno to indicate the error.

ERRORS

The cpc bind event() and cpc take sample() functions will fail if:

EFAULT	The <i>event</i> argument specifies a bad address.
ENOTSUP	The caller has attempted an operation that is illegal or not supported on the current platform, such as attempting to specify signal delivery on counter overflow on a CPU that doesn't generate an interrupt on counter overflow.
EAGAIN	Another process may be sampling system-wide CPU statistics. For cpc_bind_event(), this implies that no new contexts can be created. For cpc_take_sample(), this implies that the

cpc_bind_event(3CPC)

performance counter context has been invalidated and must be released with cpc_rele(). Robust programs should be coded to expect this behavior and recover from it by releasing the now invalid context by calling cpc_rele() sleeping for a while, then attempting to bind and sample the event once more.

EINVAL The cpc_take_sample() function has been invoked before the context is bound.

USAGE

Prior to calling cpc_bind_event(), applications should call cpc_access(3CPC) to determine if the counters are accessible on the system.

EXAMPLES

EXAMPLE 1 Use hardware performance counters to measure events in a process.

The example below shows how a standalone program can be instrumented with the libcpc routines to use hardware performance counters to measure events in a process. The program performs 20 iterations of a computation, measuring the counter values for each iteration. By default, the example makes the counters measure external cache references and external cache hits; these options are only appropriate for UltraSPARC processors. By setting the PERFEVENTS environment variable to other strings (a list of which can be gleaned from the -h flag of the cpustat or cputrack utilities), other events can be counted. The error() routine below is assumed to be a user-provided routine analogous to the familiar printf(3C) routine from the C library but which also performs an exit(2) after printing the message.

```
#include <inttypes.h>
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <libcpc.h>
int
main(int argc, char *argv[])
int couver, iter:
char *setting = NULL;
cpc_event_t event;
if (cpc_version(CPC_VER_CURRENT) != CPC_VER_CURRENT)
    error("application:library cpc version mismatch!");
if ((cpuver = cpc_getcpuver()) == -1)
    error("no performance counter hardware!");
if ((setting = getenv("PERFEVENTS")) == NULL)
    setting = "pic0=EC ref,pic1=EC hit";
if (cpc strtoevent(cpuver, setting, &event) != 0)
    error("can't measure '%s' on this processor", setting);
setting = cpc eventtostr(&event);
if (cpc_access() == -1)
    error("can't access perf counters: %s", strerror(errno));
```

EXAMPLE 1 Use hardware performance counters to measure events in a process. (Continued)

```
if (cpc_bind_event(&event, 0) == -1)
    error("can't bind lwp%d: %s", _lwp_self(), strerror(errno));
for (iter = 1; iter <= 20; iter++) {
    cpc event t before, after;
   if (cpc take sample(&before) == -1)
       break:
   /* ==> Computation to be measured goes here <== */
   if (cpc_take_sample(&after) == -1)
       break:
    (void) printf("%3d: %" PRId64 " %" PRId64 "\n", iter,
       after.ce_pic[0] - before.ce_pic[0],
        after.ce pic[1] - before.ce pic[1]);
}
if (iter != 20)
   error("can't sample '%s': %s", setting, strerror(errno));
free(setting);
return (0);
}
```

EXAMPLE 2 Write a signal handler to catch overflow signals.

This example builds on Example 1, but demonstrates how to write the signal handler to catch overflow signals. The counters are preset so that counter zero is 1000 counts short of overflowing, while counter one is set to zero. After 1000 counts on counter zero, the signal handler will be invoked.

First the signal handler:

```
#definePRESET0
                      (UINT64 MAX - 999ull)
#definePRESET1
                      0
void
emt_handler(int sig, siginfo_t *sip, void *arg)
ucontext t *uap = arg;
cpc_event_t sample;
if (sig != SIGEMT || sip->si code != EMT CPCOVF) {
   psignal(sig, "example");
   psiginfo(sip, "example");
    return;
(void) printf("lwp%d - si_addr %p ucontext: %%pc %p %%sp %p\n",
    _lwp_self(), (void *)sip->si_addr,
    (void *)uap->uc mcontext.gregs[PC],
    (void *)uap->uc_mcontext.gregs[USP]);
```

EXAMPLE 2 Write a signal handler to catch overflow signals. (*Continued*)

```
if (cpc_take_sample(&sample) == -1)
    error("can't sample: %s", strerror(errno));

(void) printf("0x%" PRIx64 " 0x%" PRIx64 "\n",
    sample.ce_pic[0], sample.ce_pic[1]);

(void) fflush(stdout);

sample.ce_pic[0] = PRESETO;
sample.ce_pic[1] = PRESET1;
if (cpc_bind_event(&sample, CPC_BIND_EMT_OVF) == -1)
    error("cannot bind lwp%d: %s", _lwp_self(), strerror(errno));
}
```

and second the setup code (this can be placed after the code that selects the event to be measured):

```
struct sigaction act;
cpc_event_t event;
...
act.sa_sigaction = emt_handler;
bzero(&act.sa_mask, sizeof (act.sa_mask));
act.sa_flags = SA_RESTART|SA_SIGINFO;
if (sigaction(SIGEMT, &act, NULL) == -1)
    error("sigaction: %s", strerror(errno));
event.ce_pic[0] = PRESETO;
event.ce_pic[1] = PRESET1;
if (cpc_bind_event(&event, CPC_BIND_EMT_OVF) == -1)
    error("cannot bind lwp%d: %s", _lwp_self(), strerror(errno));

for (iter = 1; iter <= 20; iter++) {
    /* ==> Computation to be measured goes here <== */
}
cpc bind event(NULL, 0); /* done */</pre>
```

Note that a more general version of the signal handler would use write(2) directly instead of depending on the signal-unsafe semantics of stderr and stdout. Most real signal handlers will probably do more with the samples than just print them out.

NOTES

Sometimes, even the overhead of performing a system call will be too disruptive to the events being measured. Once a call to cpc_bind_event() has been issued, it is possible to directly access the performance hardware registers from within the application. If the performance counter context is active, then the counters will count on behalf of the current LWP.

SPARC

IA

```
rd %pic, %rN ! All UltraSPARC wr %rN, %pic ! (ditto, but see text) rdpmc ! Pentium II only
```

If the counter context is not active or has been invalidated, the *pic register (SPARC), and the rdpmc instruction (Pentium) will become unavailable.

Note that the two 32-bit UltraSPARC performance counters are kept in the single 64-bit <code>%pic</code> register so a couple of additional instructions are required to separate the values. Also note that when the <code>%pcr</code> register bit has been set that configures the <code>%pic</code> register as readable by an application, it is also writable. Any values written will be preserved by the context switching mechanism.

Pentium II processors support the non-privileged rdpmc instruction which requires [5] that the counter of interest be specified in %ecx, and returns a 40-bit value in the %edx: %eax register pair. There is no non-privileged access mechanism for Pentium I processors.

Handling counter overflow

As described above, when counting events, some processors allow their counter registers to silently overflow. More recent CPUs such as UltraSPARC III and Pentium II, however, are capable of generating an interrupt when the hardware counter overflows. Some processors offer more control over when interrupts will actually be generated. For example, they might allow the interrupt to be programmed to occur when only one of the counters overflows. See cpc_strtoevent(3CPC) for the syntax.

The most obvious use for this facility is to ensure that the full 64-bit counter values are maintained without repeated sampling. However, current hardware does not record which counter overflowed. A more subtle use for this facility is to preset the counter to a value to a little less than the maximum value, then use the resulting interrupt to catch the counter overflow associated with that event. The overflow can then be used as an indication of the frequency of the occurrence of that event.

Note that the interrupt generated by the processor may not be particularly precise. That is, the particular instruction that caused the counter overflow may be earlier in the instruction stream than is indicated by the program counter value in the ucontext.

When cpc_bind_event() is called with the CPC_BIND_EMT_OVF flag set, then as before, the control registers and counters are preset from the 64-bit values contained in event. However, when the flag is set, the kernel arranges to send the calling process a SIGEMT signal when the overflow occurs, with the si_code field of the corresponding siginfo structure set to EMT_CPCOVF, and the si_addr field is the program counter value at the time the overflow interrupt was delivered. Counting, and thus the subsequent delivery of the signal on overflow is disabled until the next call to cpc_bind_event(). Even in a multithreaded process, during execution of the signal handler, the thread behaves as if it is temporarily bound to the running LWP.

Different processors have different counter ranges available, though all processors supported by Solaris allow at least 31 bits to be specified as a counter preset value; thus portable preset values lie in the range UINT64_MAX to UINT64 MAX-INT32 MAX.

cpc_bind_event(3CPC)

The appropriate preset value will often need to be determined experimentally. Typically, it will depend on the event being measured, as well as the desire to minimize the impact of the act of measurement on the event being measured; less frequent interrupts and samples lead to less perturbation of the system.

If the processor cannot detect counter overflow, this call will fail (ENOTSUP). Specifying a null event unbinds the context from the underlying LWP and disables signal delivery. Currently, only user events can be measured using this technique. See Example 2, above.

Inheriting events onto multiple LWPs

By default, the library binds the performance counter context to the current LWP only. If the CPC_BIND_LWP_INHERIT flag is set, then any subsequent LWPs created by that LWP will automatically inherit the same performance counter context. The counters will be initialized to 0 as if a cpc_bind_event() had just been issued. This automatic inheritance behavior can be useful when dealing with multithreaded programs to determine aggregate statistics for the program as a whole.

If the CPC_BIND_EMT_OVF flag is also set, the process will immediately dispatch a SIGEMT signal to the freshly created LWP so that it can preset its counters appropriately on the new LWP. This initialization condition can be detected using cpc_take_sample() to check that both ce_pic[] values are set to UINT64_MAX.

NAME

cpc_count_usr_events, cpc_count_sys_events – enable and disable performance counters

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
int cpc_count_usr_events(int enable);
int cpc count sys events(int enable);
```

DESCRIPTION

In certain applications, it can be useful to explicitly enable and disable performance counters at different times so that the performance of a critical algorithm can be examined. The <code>cpc_count_usr_events()</code> function can be used to control whether events are counted on behalf of the application running in user mode, while <code>cpc_count_sys_events()</code> can be used to control whether events are counted on behalf of the application while it is running in the kernel, without otherwise disturbing the binding of events to the invoking LWP. If the <code>enable</code> argument is non-zero, counting of events is enabled, otherwise they are disabled.

RETURN VALUES

Upon successful completion, cpc_count_usr_events() and cpc_count_sys_events() return 0. Otherwise, the functions return -1 and set errno to indicate the error.

ERRORS

The cpc_count_usr_events() and cpc_count_sys_events() functions will fail if:

EAGAIN The associated performance counter context has been invalidated

by another process.

EINVAL No performance counter context has been created, or an attempt

was made to enable system events while delivering counter

overflow signals.

EXAMPLES

EXAMPLE 1 Use cpc_count_usr_events() to minimize code needed by application.

In this example, the routine <code>cpc_count_usr_events()</code> is used to minimize the amount of code that needs to be added to the application. The <code>cputrack(1)</code> command can be used in conjunction with these interfaces to provide event programming, sampling, and reporting facilities.

If the application is instrumented in this way and then started by cputrack with the nouser flag set in the event specification, counting of user events will only be enabled around the critical code section of interest. If the program is run normally, no harm will ensue.

```
int have_counters = 0;
int
main(int argc, char *argv[])
{
    if (cpc_version(CPC_VER_CURRENT) == CPC_VER_CURRENT &&
        cpc_getcpuver() != -1 && cpc_access() == 0)
        have counters = 1;
```

cpc_count_usr_events(3CPC)

NAME |

cpc_event – data structure to describe CPU performance counters

SYNOPSIS

```
#include <libcpc.h>
```

DESCRIPTION

The libcpc interfaces manipulate CPU performance counters using the cpc_event_t data structure. This structure contains several fields that are common to all processors, and some that are processor-dependent. These structures can be declared by a consumer of the API, thus the size and offsets of the fields and the entire data structure are fixed per processor for any particular version of the library. See cpc_version(3CPC) for details of library versioning.

SPARC

For UltraSPARC, the structure contains the following members:

```
typedef struct {
    int ce_cpuver;
    hrtime_t ce_hrt;
    uint64_t ce_tick;
    uint64_t ce_pic[2];
    uint64_t ce_pcr;
} cpc event t;
```

IA

For Pentium, the structure contains the following members:

```
typedef struct {
    int ce_cpuver;
    hrtime_t ce_hrt;
    uint64_t ce_tsc;
    uint64_t ce_pic[2];
    uint32_t ce_pes[2];
#define ce_cesr ce_pes[0]
} cpc event t;
```

The APIs are used to manipulate the highly processor-dependent control registers (the ce_pcr, ce_cesr, and ce_pes fields); the programmer is strongly advised not to reference those fields directly in portable code. The ce_pic array elements contain 64-bit accumulated counter values. The hardware registers are virtualized to 64-bit quantities even though the underlying hardware only supports 32-bits (UltraSPARC) or 40-bits (Pentium) before overflow.

The ce_hrt field is a high resolution timestamp taken at the time the counters were sampled by the kernel. This uses the same timebase as gethrtime(3C).

On SPARC V9 machines, the number of cycles spent running on the processor is computed from samples of the processor-dependent %tick register, and placed in the ce_tick field. On Pentium processors, the processor-dependent time-stamp counter register is similarly sampled and placed in the ce_tsc field.

NAME | cpc_event_diff, cpc_event_accum - simple difference and accumulate operations

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
```

```
void cpc event accum(cpc event t *accum, cpc event t *event);
void cpc event diff(cpc event t *diff, cpc event t *after,
    cpc event t *before);
```

DESCRIPTION

The cpc event accum() and cpc event diff() functions perform common accumulate and difference operations on cpc event (3CPC) data structures. Use of these functions increases program portability, since structure members are not referenced directly.

cpc event accum() The cpc event accum() function adds the ce pic fields of event into the corresponding fields of accum. The ce hrt field of accum is set to the later of the times in event and accum.

SPARC:

The function adds the contents of the ce tick field of *event* into the corresponding field of accum.

IA:

The function adds the contents of the ce tsc field of event into the corresponding field of accum.

cpc event diff()

The cpc event diff() function places the difference between the ce pic fields of after and before and places them in the corresponding field of diff. The ce hrt field of diff is set to the ce hrt field of after.

SPARC:

Additionally, the function computes the difference between the ce tick fields of after and *before*, and places it in the corresponding field of diff.

IA:

Additionally, the function computes the difference between the ce tsc fields of after and before, and places it in the corresponding field of diff.

NAME |

cpc getcpuver, cpc getcciname, cpc getcpuref, cpc getusage, cpc getnpic, cpc_walk_names - determine CPU performance counter configuration

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
int cpc getcpuver(void);
const char *cpc getcciname(int cpuver);
const char *cpc getcpuref(int cpuver);
const char *cpc getusage(int cpuver);
uint t cpc getnpic (int cpuver);
void cpc walk names (int cpuver, int regno, void *arg, void
     (*action) (void *arg, int regno, const char *name, uint8 t bits));
```

DESCRIPTION

The cpc getcpuver () function returns an abstract integer that corresponds to the distinguished version of the underlying processor. The library distinguishes between processors solely on the basis of their support for performance counters, so the version returned should not be interpreted in any other way. The set of values returned by the library is unique across all processor implementations.

The cpc getcpuver () function returns -1 if the library cannot support CPU performance counters on the current architecture. This may be because the processor has no such counter hardware, or because the library is unable to recognize it. Either way, such a return value indicates that the configuration functions described on this manual page cannot be used.

The cpc getcciname() function returns a printable description of the processor performance counter interfaces for example, the string UltraSPARC I&II. Note that this name should not be assumed to be the same as the name the manufacturer might otherwise ascribe to the processor. It simply names the performance counter interfaces as understood by the library, and thus names the set of performance counter events that can be described by that interface. If the cpuver argument is unrecognized, the function returns NULL.

The cpc getcpuref () function returns a string that describes a reference work that should be consulted to (allow a human to) understand the semantics of the performance counter events that are known to the library. If the *cpuver* argument is unrecognized, the function returns NULL.

The cpc getusage () function returns a compact description of the getsubopt () -oriented syntax that is consumed by cpc strtoevent(3CPC). It is returned as a space-separated set of tokens to allow the caller to wrap lines at convenient boundaries. If the *cpuver* argument is unrecognized, the function returns NULL.

The cpc getnpic() function returns the number of valid fields in the ce pic[] array of a cpc event t data structure.

cpc_getcpuver(3CPC)

The library maintains a list of events that it believes the processor capable of measuring, along with the bit patterns that must be set in the corresponding control register, and which counter the result will appear in. The <code>cpc_walk_names()</code> function calls the <code>action()</code> function on each element of the list so that an application can print appropriate help on the set of events known to the library. The <code>arg</code> parameter is passed uninterpreted from the caller on each invocation of the <code>action()</code> function.

If the parameters specify an invalid or unknown CPU or register number, the function silently returns without invoking the action function.

USAGE

Prior to calling any of these functions, applications should call <code>cpc_access(3CPC)</code> to determine if the counters are accessible on the system.

NAME | cpc pctx bind event, cpc pctx take sample, cpc pctx rele, cpc pctx invalidate access CPU performance counters in other processes

SYNOPSIS

```
cc [ flag... ] file... -lcpc -lpctx [ library... ]
#include <libpctx.h>
#include <libcpc.h>
int cpc pctx bind event(pctx t *pctx, id t lwpid, cpc event t *event,
     int flags);
int cpc pctx take sample (pctx t *pctx, id t lwpid, cpc event t
     *event);
int cpc pctx rele(pctx t *pctx, id t lwpid);
int cpc pctx invalidate(pctx t *pctx, id t lwpid);
```

DESCRIPTION

These functions are designed to be run in the context of an event handler created using the libpctx(3LIB) family of functions that allow the caller, also known as the controlling process, to manipulate the performance counters in the context of a controlled process. The controlled process is described by the pctx argument, which must be obtained from an invocation of pctx capture(3CPC) or pctx create(3CPC) and passed to the functions described on this page in the context of an event handler.

The semantics of the functions cpc pctx bind event(), cpc pctx take sample(), and cpc pctx rele() are directly analogous to those of cpc bind event(), cpc take sample(), and cpc rele() described on the cpc bind event(3CPC) manual page.

The cpc pctx invalidate() function allows the performance context to be invalidated in an LWP in the controlled process.

RETURN VALUES

These functions return 0 on success. On failure, they return -1 and set errno to indicate the error.

ERRORS

The cpc pctx bind event(), cpc pctx take sample(), and cpc pctx rele() functions return the same errno values the analogous functions described on the cpc bind event(3CPC) manual page. In addition, these function may fail if:

ESRCH

The value of the *lwpid* argument is invalid in the context of the controlled process.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE	
MT-Level	Unsafe	
Availability	SUNWcpcu (32-bit)

NOTES

The capability to create and analyze overflow events in other processes is not available, though it may be made available in a future version of this API. In the current implementation, the *flags* field must be specified as 0.

NAME | cpc_seterrfn – control libcpc error reporting

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ] #include <libcpc.h>
typedef void(cpc errfn t) (const char *fn, const char *fmt, va list
     ap);
void cpc seterrfn(cpc errfn t *errfn);
```

DESCRIPTION

For the convenience of programmers instrumenting their code, several libcpc functions automatically emit to stderr error messages that attempt to provide a more detailed explanation of their error return values. While this can be useful for simple programs, some applications may wish to report their errors differently—for example, to a window or to a log file.

The cpc seterrfn() function allows the caller to provide an alternate function for reporting errors; the type signature is shown above. The fn argument is passed the library function name that detected the error, the format string fmt and argument pointer ap can be passed directly to vsnprintf(3C) or similar varargs-based routine for formatting.

The default printing routine can be restored by calling the routine with an errfn argument of NULL.

EXAMPLES

EXAMPLE 1 Debugging example.

This example produces error messages only when debugging the program containing it, or when the cpc strtoevent () function is reporting an error when parsing an event specification

```
int debugging;
void
myapp_errfn(const char *fn, const char *fmt, va list ap)
        if (strcmp(fn, "strtoevent") != 0 && !debugging)
           return;
        (void) fprintf(stderr, "myapp: cpc_%s(): ", fn);
        (void) vfprintf(stderr, fmt, ap);
}
```

NAME |

cpc shared open, cpc shared bind event, cpc shared take sample, cpc shared rele, cpc_shared_close – use CPU performance counters on processors

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
int cpc shared open (void);
int cpc shared bind event (int fd, cpc event t *event, int flags);
int cpc shared take sample(int fd, cpc event t *event);
int cpc shared rele(int fd);
void cpc shared close(int fd);
```

DESCRIPTION

The cpc shared open () function allows the caller to access the hardware counters in such a way that the performance of the currently bound CPU can be measured. The function returns a file descriptor if successful. Only one such open can be active at a time on any CPU.

The cpc shared bind event(), cpc shared take sample(), and cpc shared rele() functions are directly analogous to the corresponding cpc bind event(), cpc take sample(), and cpc rele() functions described on the cpc bind event(3CPC)manual page, except that they operate on the counters of a particular processor.

USAGE

If a thread wishes to access the counters using this interface, it must do so using a thread bound to an lwp, (see the THR BOUND flag to thr create(3THR)), that has in turn bound itself to a processor using processor bind(2).

Unlike the cpc bind event(3CPC) family of functions, no counter context is attached to those lwps, so the performance counter samples from the processors reflects the system-wide usage, instead of per-lwp usage.

The first successful invocation of cpc_shared_open() will immediately invalidate *all* existing performance counter context on the system, and prevent *all* subsequent attempts to bind counter context to lwps from succeeding anywhere on the system until the last caller invokes cpc shared close().

This is because it is impossible to simultaneously use the counters to accurately measure per-lwp and system-wide events, so there is an exclusive interlock between these uses.

Access to the shared counters is mediated by file permissions on a cpc pseudo device. As shipped, only the superuser is allowed to access the shared device; this is because doing so prevents use of the counters on a per-lwp basis to any other users.

The CPC BIND LWP INHERIT and CPC BIND EMT OVF flags are invalid for the shared interface.

cpc_shared_open(3CPC)

RETU	IRN	VΔ	TI	FS
NEIL		v /	டப	Liv.

On success, the functions (apart from cpc_shared_close()) return 0. On failure, the functions return -1 and set errno, to indicate the reason.

ERRORS

ı	runctions return –1	and set errno, to indicate the reason.
	ENXIO	The current machine either has no performance counters, or has been configured to disallow access to them system-wide.
	EACCES	The caller does not have appropriate privilege to access the CPU performance counters system-wide.
	EAGAIN	For cpc_shared_open(), this value implies that the counters on the bound cpu are busy because they are already being used to measure system-wide events by some other caller.
	EAGAIN	Otherwise, this return value implies that the counters are not available because the thread has been unbound from the processor it was bound to at open time. Robust programs should be coded to expect this behavior, and should invoke <code>cpc_shared_close()</code> , before retrying the operation.
	EINVAL	The counters cannot be accessed on the current CPU because the calling thread is not bound to that CPU using processor_bind(2).
	EFAULT	The <i>event</i> argument specifies a bad address.

NAME | cpc_strtoevent, cpc_eventtostr – translate strings to and from events

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
```

int cpc strtoevent (int cpuver, const char *spec, cpc event t *event); char *cpc eventtostr(cpc event t *event);

DESCRIPTION

The cpc strtoevent () function translates an event specification to the appropriate collection of control bits in a cpc event t structure pointed to by the event argument. The event specification is a get subopt (3C)-style string that describes the event and any attributes that the processor can apply to the event or events. If successful, the funciton returns 0, the ce cpuver field and the ISA-dependent control registers of event are initialized appropriately, and the rest of the cpc event t structure is initialized to 0.

The cpc eventtostr() function takes an event and constructs a compact canonical string representation for that event.

RETURN VALUES

Upon successful completion, cpc strtoevent () returns 0. If the string cannot be decoded, a non-zero value is returned and a message is printed using the library's error-reporting mechanism (see cpc seterrfn(3CPC)).

Upon successful completion, cpc eventtostr() returns a pointer to a string. The string returned must be freed by the caller using free(3C). If cpc eventtostr() a null pointer is returned.

USAGE

The event selection syntax used is processor architecture-dependent. The supported processor families allow variations on how events are counted as well as what events can be counted. This information is available in compact form from the cpc getusage() function (see cpc getcpuver(3CPC)), but is explained in further detail below.

UltraSPARC

On UltraSPARC processors, the syntax for setting options is as follows:

```
pic0=<eventspec>,pic1=<eventspec> [,sys] [,nouser]
```

This syntax, which reflects the simplicity of the options available using the %pcr register, forces both counter events to be selected. By default only user events are counted; however, the sys keyword allows system (kernel) events to be counted as well. User event counting can be disabled by specifying the nouser keyword.

The keywords pic0 and pic1 may be omitted; they can be used to resolve ambiguities if they exist.

Pentium I

On Pentium processors, the syntax for setting counter options is as follows:

```
pic0=<eventspec>,pic1=<eventspec> [,sys[[0|1]]] [,nouser[[0|1]]]
[,noedge[[0|1]]] [,pc[[0|1]]]
```

cpc_strtoevent(3CPC)

The syntax and semantics are the same as UltraSPARC, except that is possible to specify whether a particular counter counts user or system events. If unspecified, the specification is presumed to apply to both counters.

There are some additional keywords. The noedge keyword specifies that the counter should count clocks (duration) instead of events. The pc keyword allows the external pin control pins to be set high (defaults to low). When the pin control register is set high, the external pin will be asserted when the associated register overflows. When the pin control register is set low, the external pin will be asserted when the counter has been incremented. The electrical effect of driving the pin is dependent uptoon how the motherboard manufacturer has chosen to connect it, if it is connected at all.

Pentium II

For Pentium II processors, the syntax is substantially more complex, reflecting the complex configuration options available:

```
pic0=<eventspec>,pic1=<eventspec> [,sys[[0|1]]]
[,nouser[[0|1]]] [,noedge[[0|1]]] [,pc[[0|1]]] [,inv[[0|1]]] [,int[[0|1]]]
[,cmask[0|1]=<maskspec>] [,umask[0|1]=<maskspec>]
```

This syntax is a straightforward extension of the earlier syntax. The additional inv, int, cmask0, cmask1, umask0, and umask1 keywords allow extended counting semantics. The mask specification is a number between 0 and 255, expressed in hexadecimal, octal or decimal notation.

SPARC

EXAMPLE 1 SPARC Example.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe
Availability	SUNWcpcu (32-bit)
	SUNWcpcux (64-bit)
Interface Stability	Evolving

SEE ALSO

```
cpc(3CPC), cpc_getcpuver(3CPC), cpc_seterrfn(3CPC), free(3C),
getsubopt(3C), attributes(5)
```

NOTES

These functions are provided as a convenience only. As new processors are usually released asynchronously with software, the library allows the pic0 and pic1 keywords to interpret numeric values specified directly in hexadecimal, octal, or decimal.

cpc_version(3CPC)

NAME

cpc_version – coordinate CPC library and application versions

SYNOPSIS

```
cc [ flag... ] file... -lcpc [ library... ]
#include <libcpc.h>
uint_t cpc_version(uint_t version);
```

DESCRIPTION

The cpc_version() function takes an interface version as an argument and returns an interface version as a result. Usually, the argument will be the value of CPC_VER_CURRENT bound to the application when it was compiled.

RETURN VALUES

If the version requested is still supported by the implementation, <code>cpc_version()</code> returns the requested version number and the application can use the facilities of the library on that platform. If the implementation cannot support the version needed by the application, <code>cpc_version()</code> returns <code>CPC_VER_NONE</code>, indicating that the application will at least need to be recompiled to operate correctly on the new platform, and may require further changes.

If version is CPC_VER_NONE, cpc_version() returns the most current version of the library.

EXAMPLES

EXAMPLE 1 Protect an application from using an incompatible library.

The following lines of code protect an application from using an incompatible library:

```
if (cpc_version(CPC_VER_CURRENT) == CPC_VER_NONE) {
    /* version mismatch - library cannot translate */
    exit(1);
}
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe
Availability	SUNWcpcu (32-bit)
	SUNWcpcux (64-bit)
Interface Stability	Evolving

SEE ALSO

cpc(3CPC), attributes(5)

NOTES

The version number is used only to express incompatible semantic changes in the performance counter interfaces on the given platform within a single instruction set architecture, for example, when a new set of performance counter registers are added to an existing processor family that cannot be specified in the existing <code>cpc_event_t</code> data structure.

NAME

demangle, cplus_demangle – decode a C++ encoded symbol name

SYNOPSIS

```
cc [ flag ... ] file [ library ... ] -ldemangle
```

#include <demangle.h>

int **cplus demangle**(const char *symbol, char *prototype, size t size);

DESCRIPTION

The cplus demanqle() function decodes (demangles) a C++ linker symbol name (mangled name) into a (partial) C++ prototype, if possible. C++ mangled names may not have enough information to form a complete prototype.

The *symbol* string argument points to the input mangled name.

The *prototype* argument points to a user-specified output string buffer, of size bytes.

The cplus demangle () function operates on mangled names generated by SPARCompilers C++ 3.0.1, 4.0.1, 4.1 and 4.2.

The cplus demangle() function improves and replaces the demangle() function.

Refer to the CC.1, dem.1, and c++filt.1 manual pages in the /opt/SUNWspro/man/man1 directory. These pages are only available with the SPROcc package.

RETURN VALUES

The cplus demangle () function returns the following values:

The symbol argument is a valid mangled name and

prototype contains a (partial) prototype for the symbol.

The symbol argument is not a valid mangled name and DEMANGLE ENAME

the content of *prototype* is a copy of the symbol.

DEMANGLE ESPACE The *prototype* output buffer is too small to contain the

prototype (or the symbol), and the content of prototype

is undefined.

devid_get(3DEVID)

NAME

devid_get, devid_compare, devid_deviceid_to_nmlist, devid_free, devid_free_nmlist, devid_get_minor_name, devid_sizeof, devid_str_decode, devid_str_free, devid_str_encode, devid_valid – device ID interfaces for user applications

SYNOPSIS

```
cc [ flag ... ] file ... -ldevid [ library ... ]
#include <devid.h>
int devid_get(int fd, ddi_devid_t *retdevid);
void devid_free(ddi_devid_t devid);
int devid_get_minor_name(int fd, char **retminor_name);
int devid_deviceid_to_nmlist(char *search_path, ddi_devid_t devid, char *minor_name, devid_nmlist_t **retlist);
void devid_free_nmlist(devid_nmlist_t *list);
int devid_compare(ddi_devid_t devid1, ddi_devid_t devid2);
size_t devid_sizeof(ddi_devid_t devid);
int devid_valid(ddi_devid_t devid);
char *devid_str_encode(ddi_devid_t devid, char *minor_name);
int devid_str_decode(char *devidstr, ddi_devid_t *retdevid, char **retminor_name);
void devid str free(char *str);
```

DESCRIPTION

These functions provide unique identifiers (device IDs) for devices. Applications and device drivers use these functions to identify and locate devices, independent of the device's physical connection or its logical device name or number.

The devid_get() function returns in *retdevid* the device ID for the device associated with the open file descriptor *fd*, which refers to any device. It returns an error if the device does not have an associated device ID. The caller must free the memory allocated for *retdevid* using the devid free() function.

The devid_free() function frees the space that was allocated for the returned *devid* by devid get() and devid str decode().

The devid_get_minor_name() function returns the minor name, in *retminor_name*, for the device associated with the open file descriptor *fd*. This name is specific to the particular minor number, but is "instance number" specific. The caller of this function must free the memory allocated for the returned *retminor_name* string using devid str free().

The devid_deviceid_to_nmlist() function returns an array of devid_nmlist structures, where each entry matches the devid and minor_name passed in. If the minor_name specified is one of the special values (DEVID_MINOR_NAME_ALL, DEVID_MINOR_NAME_ALL_CHR, or DEVID_MINOR_NAME_ALL_BLK), then all minor names associated with devid which also meet the special minor_name filtering

requirements are returned. The <code>devid_nmlist</code> structure contains the device name and device number. The last entry of the array contains a null pointer for the <code>devname</code> and <code>NODEV</code> for the device number. This function traverses the file tree, starting at <code>search_path</code>. For each device with a matching device ID and minor name tuple, a device name and device number are added to the <code>retlist</code>. If no matches are found, an error is returned. The caller of this function must free the memory allocated for the returned array with the <code>devid_free_nmlist()</code> function. This function may take a long time to complete if called with the device ID of an unattached device.

The devid_free_nmlist() function frees the memory allocated by the devid deviceid to nmlist() function.

The devid_compare() function compares two device IDs and determines both equality and sort order. The function returns an integer greater than 0 if the device ID pointed to by *devid1* is greater than the device ID pointed to by *devid2*. It returns 0 if the device ID pointed to by *devid1* is equal to the device ID pointed to by *devid2*. It returns an integer less than 0 if the device ID pointed to by *devid1* is less than the device ID pointed to by *devid2*. This function is the only valid mechanism to determine the equality of two devids. This function may indicate equality for arguments which by simple inspection appear different.

The devid sizeof() function returns the size of devid in bytes.

The devid_valid() function validates the format of a *devid*. It returns 1 if the format is valid, and 0 if invalid. This check may not be as complete as the corresponding kernel function ddi devid valid() (see ddi devid compare(9F)).

The devid_str_encode() function encodes a *devid* and *minor_name* into a null-terminated ASCII string, returning a pointer to that string. If both a *devid* and a *minor_name* are non-null, a '/' is used to separate the *devid* from the *minor_name* in the encoded string. If *minor_name* is null, only the *devid* is encoded. If the *devid* is null then the special string "id0" is returned. Note that you cannot compare the returned string against another string with strcmp(3C) to determine devid equality. The string returned must be freed by calling devid str free().

The devid_str_decode() function takes a string previously produced by the devid_str_encode() or ddi_devid_str_encode() (see ddi_devid_compare(9F)) function and decodes the contained device ID and minor name, allocating and returning pointers to the extracted parts via the *retdevid* and *retminor_name* arguments. If the special *devidstr* "id0" was specified, the returned device ID and minor name will both be null. A non-null returned devid must be freed by the caller by the devid_free() function. A non-null returned minor name must be freed by calling devid str free().

The devid_str_free() function frees the character string returned by devid_str_encode() and the *retminor_name* argument returned by devid str_decode().

devid_get(3DEVID)

RETURN VALUES

Upon successful completion, the $devid_get()$, $devid_get_minor_name()$, $devid_str_decode()$, and $devid_deviceid_to_nmlist()$ functions return 0. Otherwise, they return -1.

The devid compare () function returns the following values:

- -1 The device ID pointed to by devid1 is less than the device ID pointed to by devid2.
- The device ID pointed to by *devid1* is equal to the device ID pointed to by *devid2*.
- 1 The device ID pointed to by *devid1* is greater than the device ID pointed to by *devid2*.

The devid_sizeof() function returns the size of *devid* in bytes. If *devid* is null, the number of bytes that must be allocated and initialized to determine the size of a complete device ID is returned.

The devid_valid() function returns 1 if the *devid* is valid and 0 if the *devid* is invalid.

The devid_str_encode() function returns NULL to indicate failure. Failure may be caused by attempting to encode an invalid string. If the return value is non-null, the caller must free the returned string by using the devid_str_free() function.

EXAMPLES

```
\begin{tabular}{ll} \textbf{EXAMPLE 1} Using \verb|devid_get()|, \verb|devid_get_minor_name()|, and \\ devid_str_encode() \end{tabular}
```

The following example shows the proper use of devid_get(), devid_get_minor_name(), and devid_str_encode() to free the space allocated for devid, minor_name and encoded devid.

```
\begin{tabular}{ll} \textbf{EXAMPLE 1} Using \ devid\_get(), devid\_get\_minor\_name(), and \\ devid\_str\_encode() & (Continued) \end{tabular}
EXAMPLE 2 Using devid_deviceid_to_nmlist() and devid_free_nmlist()
The following example shows the proper use of devid_deviceid_to_nmlist()
```

and devid free nmlist(): devid_nmlist_t *list = NULL; int err;

```
if (devid deviceid to nmlist("/dev/rdsk", devid,
   minor_name, &list))
      return (-1);
/* loop through list and process device names and numbers */
devid_free_nmlist(list);
```

di_binding_name(3DEVINFO)

NAME |

di_binding_name, di_bus_addr, di_compatible_names, di_devid, di_driver_name, di_driver_ops, di_instance, di_nodeid, di_node_name – return libdevinfo node information

SYNOPSIS

```
char *di_binding_name(di_node_t node);
char *di_bus_addr(di_node_t node);
int di_compatible_names(di_node_t node, char **names);
ddi_devid_t di_devid(di_node_t node);
char *di_driver_name(di_node_t node);
uint_t di_driver_ops(di_node_t node);
int di_instance(di_node_t node);
int di_nodeid(di_node_t node);
char *di node name(di node t node);
```

DESCRIPTION

These functions extract information associated with a device node.

PARAMETERS

The following parameter descriptions apply to all interfaces:

node A handle to a device node.

The following parameter description applies only to di compatible names ():

names The address of a pointer.

RETURN VALUES

di binding name()

#include <libdevinfo.h>

The di_binding_name() function returns a pointer to the binding name. The binding name is the name used by the system to select a driver for the device.

di bus addr()

The di_bus_addr() function returns a pointer to a null-terminated string containing the assigned bus address for the device. NULL is returned if a bus address has not been assigned to the device. A zero-length string may be returned and is considered a valid bus address.

```
di compatible names()
```

The return value of di_compatible_names() is the number of compatible names. *names* is updated to point to a buffer contained within the snapshot. The buffer contains a concatenation of null-terminated strings, for example:

```
<name1>/0<name2>/0...<namen>/0
```

See the discussion of generic names in *Writing Device Drivers* for a description of how compatible names are used by Solaris to achieve driver binding for the node.

di devid()

The di devid() function returns the device ID for *node*, if it is registered. Otherwise, a null pointer is returned. Interfaces in the libdevid(3LIB) library may be used to manipulate the handle to the device id.

This function is obsolete and may be removed from a future Solaris release. Applications should use the "devid" property instead.

di driver name()

The di driver name () function returns the name of the driver bound to the *node*. A null pointer is returned if *node* is not bound to any driver.

di driver ops()

The di driver ops () function returns a bit array of device driver entry points that are supported by the driver bound to this *node*. Possible bit fields supported by the driver are DI CB OPS, DI BUS OPS, DI STREAM OPS.

di instance()

The di instance () function returns the instance number of the device. A value of -1 indicates an instance number has not been assigned to the device by the system.

di nodeid()

The di nodeid() function returns the type of device, which may be one of the following possible values: DI PSEUDO NODEID, DI PROM NODEID, and DI SID NODEID. Devices of type DI PROM NODEID may have additional properties that are defined by the PROM. See di prom prop data(3DEVINFO) and di prom prop lookup bytes(3DEVINFO).

di node name()

The di node name () function returns a pointer to a null-terminated string containing the node name.

EXAMPLES

See di init(3DEVINFO) for an example showing typical use of these functions.

di child node(3DEVINFO)

NAME |

#include <libdevinfo.h>

di_child_node, di_parent_node, di_sibling_node, di_drv_first_node, di_drv_next_node – libdevinfo node traversal functions

SYNOPSIS

```
di_node_t di_child_node(di_node_t node);
di_node_t di_parent_node(di_node_t node);
di_node_t di_sibling_node(di_node_t node);
di_node_t di_drv_first_node(const char *drv_name, di_node_t root);
```

di node t di drv next node (di node t node);

DESCRIPTION

The kernel device configuration data may be viewed in two ways, either as a tree of device configuration nodes or as a list of nodes associated with each driver. In the tree view, each node may contain references to its parent, the next sibling in a list of siblings, and the first child of a list of children. In the per-driver view, each node contains a reference to the next node associated with the same driver.

Both views are captured in the snapshot, and the interfaces are provided for node access.

- di_child_node() obtains a handle to the first child of node. DI_NODE_NIL is returned and errno is set to ENXIO or ENOTSUP, if no child node exists in the snapshot.
- di_parent_node() obtains a handle to the parent node of *node*. DI_NODE_NIL is returned and errno is set to ENXIO or ENOTSUP, if no parent node exists in the snapshot.
- di_sibling_node() obtains a handle to the next sibling node of *node*. A DI_NODE_NIL is returned and errno is set to ENXIO or ENOTSUP, if no next sibling node exists in the snapshot.
- di_drv_first_node() obtains a handle to the first node associated with the driver specified by drv_name. If there is no such driver, DI_NODE_NIL is returned with errno is set to EINVAL. If the driver exists, but there is no node associated with this driver, DI_NODE_NIL is returned and errno is set to ENXIO or ENOTSUP.
- di_drv_next_node() returns a handle to the next node bound to the same driver.
 DI_NODE_NIL is returned if no more nodes exist.

PARAMETERS

```
The following parameter descriptions apply to di_child_node(), di_drv_next_node(), di_parent_node(), and di_sibling_node():
```

node A handle to any node in the snapshot.

The following parameter descriptions apply to di drv first node():

drv_name The name of the driver of interest.

di_child_node(3DEVINFO)

The handle of the root node for the snapshot returned by root

di init().

RETURN VALUES

Upon successful completion, a handle is returned. Otherwise, DI NODE NIL is returned and errno is set to indicate the error.

ERRORS

These functions set errno as listed for the following conditions:

EINVAL The argument is invalid.

ENXIO The requested node does not exist.

ENOTSUP The node was not found in the snapshot, but it may exist in the

kernel. This error may occur if the snapshot contains a partial

device tree.

di_devfs_path(3DEVINFO)

NAME | di_devfs_path, di_devfs_path_free - generate and free physical path names

SYNOPSIS | #include <libdevinfo.h>

char *di_devfs_path(di_node_t node);

void di devfs path free(char *path_buf);

DESCRIPTION di_devfs_path() generates the physical path of the device *node*. The caller is

responsible for freeing the memory allocated to store the physical path by calling

di_devfs_path_free().

di devfs path free() frees memory that was allocated by di devfs path().

PARAMETERS The parameter descriptions for di devfs path() are as follows:

node Handle to a device node in the snapshot.

The parameter descriptions for di devfs path free() are as follows:

path_buf Pointer returned by di devfs path().

RETURN VALUES di_devfs_path() returns a pointer to the string containing the physical path of

node.

ERRORS EINVAL *node* is not a valid handle.

di devfs path() also return any error code from malloc(3C).

NAME

di_init, di_fini - create and destroy a snapshot of kernel device tree

SYNOPSIS

```
#include <libdevinfo.h>
```

di_node_t di_init(const char *phys_path, uint_t flags);

void di fini(di node t root);

DESCRIPTION

di_init() creates a snapshot of the kernel device tree and returns a handle of the *root* node. The caller specifies the contents of the snapshot by providing *flag* and *phys_path*.

di_fini() destroys the snapshot of the kernel device tree and frees the associated memory. All handles associated with this snapshot become invalid after the call to di_fini().

di_init()

phys_path Physical path of the *root* node of the snapshot. See

di devfs path(3DEVINFO).

flags Snapshot content specification. The possible values may be a

bitwise OR of the following:

DINFOSUBTREE Include subtree.

DINFOPROP Include properties.

DINFOMINOR Include minor data.

DINFOCPYALL Include all of above. If *flags* is 0, the snapshot contains only a single node without properties or minor nodes.

di fini()

root

Handle obtained by calling di init().

di init()

Upon success, a handle is returned. Otherwise, DI_NODE_NIL is returned and errno is set to indicate the error.

ERRORS

di_init() may set errno to any error code that may also be set by open(2),
ioctl(2) or mmap(2). The most common error codes include:

EACCESS Insufficient privilege for accessing device configuration data.

ENXIO Either the device named by *phys_path* is not present in the system,

or the devinfo(7D) driver is not installed properly.

EINVAL Either *phys_path* is incorrectly formed or the *flags* argument is

invalid.

EXAMPLES

EXAMPLE 1 Using the libdevinfo() Interfaces To Print All Device Tree Node Names

The following is an example using the libdevinfo() interfaces to print all device tree node names:

```
/*
 * Code to print all device tree node names
 */
```

 $\begin{tabular}{ll} \textbf{EXAMPLE 1} Using the \verb|libdevinfo|()| Interfaces To Print All Device Tree Node Names (Continued) \\ \end{tabular}$

```
#include <stdio.h>
#include <libdevinfo.h>

int
prt_nodename(di_node_t node, void *arg)
{
    printf("%s\n", di_node_name(node));
    return (DI_WALK_CONTINUE);
}

main()
{
    di_node_t root_node;
    if((root_node = di_init("/", DINFOSUBTREE)) == DI_NODE_NIL) {
        fprintf(stderr, "di_init() failed\n");
        exit(1);
    }
    di_walk_node(root_node, DI_WALK_CLDFIRST, NULL, prt_nodename);
    di_fini(root_node);
}
```

EXAMPLE 2 Using the libdevinfo() Interfaces To Print The Physical Path Of SCSI Disks

The following example uses the libdevinfo() interfaces to print the physical path of SCSI disks:

```
* Code to print physical path of scsi disks
#include <stdio.h>
#include <libdevinfo.h>
#define DISK DRIVER "sd" /* driver name */
void
prt_diskinfo(di_node_t node)
   int instance;
       char *phys_path;
    * If the device node exports no minor nodes,
    * there is no physical disk.
    if (di minor next(node, DI MINOR NIL) == DI MINOR NIL) {
             return;
        instance = di_instance(node);
        phys_path = di_devfs_path(node);
        printf("%s%d: %s\n", DISK_DRIVER, instance, phys_path);
        di_devfs_path_free(phys_path);
```

 $\begin{tabular}{ll} \textbf{EXAMPLE 2} Using the \verb|libdevinfo|()| Interfaces To Print The Physical Path Of SCSI \\ Disks & (Continued) \end{tabular}$

```
void
walk_disknodes(di_node_t node)
       node = di_drv_first_node(DISK_DRIVER, node);
        while (node != DI_NODE_NIL) {
            prt_diskinfo(node);
            node = di_drv_next_node(node);
}
main()
    di_node_t root_node;
    if ((root_node = di_init("/", DINFOCPYALL)) == DI_NODE_NIL) {
       fprintf(stderr, "di init() failed\n");
        walk disknodes(root node);
        di_fini(root_node);
```

di_minor_devt(3DEVINFO)

NAME |

di_minor_devt, di_minor_name, di_minor_nodetype, di_minor_spectype – return libdevinfo minor node information

SYNOPSIS

#include <libdevinfo.h>

```
dev_t di_minor_devt(di_minor_t minor);
char *di_minor_name(di_minor_t minor);
char *di_minor_nodetype(di_minor_t minor);
int di minor spectype(di minor t minor);
```

DESCRIPTION

These interfaces are used to return libdevinfo minor node information.

PARAMETERS

minor A handle to minor data node.

RETURN VALUES

di minor name()

di_minor_name() returns the minor *name*. See ddi_create_minor_node(9F) for a description of the *name* parameter.

di minor devt()

The function di_minor_devt() returns the dev_t value of the minor node that is specified by SYS V ABI. See getmajor(9F), getminor(9F), and ddi create minor node(9F) for more information.

di minor spectype()

di_minor_spectype() returns the *spec_type* of the file, either S_IFCHR or S_IFBLK. See ddi_create_minor_node(9F) for a description of the *spec_type* parameter.

di minor nodetype()

di_minor_nodetype() returns the minor *node_type* of the minor node. See ddi_create_minor_node(9F) for a description of the *node_type* parameter.

ERRORS

No error codes are returned.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

di_minor_next(3DEVINFO)

NAME | di_minor_next – libdevinfo minor node traversal functions

SYNOPSIS | #include <libdevinfo.h>

di_minor_t di_minor_next(di_node_t node, di_minor_t minor);

DESCRIPTION di minor next () returns a handle to the next minor node for the device node *node*.

If *minor* is DI MINOR NIL, a handle to the first minor node is returned.

PARAMETERS | *node* Device node with which the minor node is associated.

minor Handle to the current minor node or DI_MINOR_NIL.

RETURN VALUES Upon successful completion, a handle to the next minor node is returned. Otherwise,

DI MINOR NIL is returned and errno is set to indicate the error.

ERRORS | errno is set as listed for the following conditions:

EINVAL Invalid argument.

ENXIO End of minor node list.

ENOTSUP Minor node information is not available in snapshot.

di_prom_init(3DEVINFO)

NAME |

di_prom_init, di_prom_fini - create and destroy a handle to the PROM device information

SYNOPSIS

#include <libdevinfo.h>

di_prom_handle_t di_prom_init();

void di prom fini(di prom handle t ph);

DESCRIPTION

For device nodes whose nodeid value is DI PROM NODEID (see di_nodeid(3DEVINFO)), additional properties may be retrieved from the PROM. di_prom_init() returns a handle that is used to retrieve such properties. This handle is passed to di_prom_prop_lookup_bytes(3DEVINFO) and di prom prop next(3DEVINFO). di prom fini() destroys the handle and all

handles to PROM device information obtained from that handle.

PARAMETERS

Handle to prom returned by di prom init(). ph

di prom init()

Upon successful completion, a handle is returned. Otherwise, DI PROM HANDLE NIL is returned and errno is set to indicate the error.

ERRORS

di_prom_init() sets errno to any error code that may also be set by openprom(7D) or malloc(3C).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NAME

di_prom_prop_data, di_prom_prop_next, di_prom_prop_name – access PROM device information

SYNOPSIS

#include <libdevinfo.h>

char *di prom prop name(di prom prop t prom_prop);

int di_prom_prop_data(di_prom_prop_t prom_prop, uchar_t
 **prop_data);

DESCRIPTION

di_prom_prop_next() obtains a handle to the next property on the PROM property list associated with *node*. If *prom_prop* is DI_PROM_PROP_NIL, the first property associated with *node* is returned.

di_prom_prop_name() returns the name of the prom_prop property.

di_prom_prop_data() returns the value of the *prom_prop* property. The return value is a non-negative integer specifying the size in number of bytes in *prop_data*.

All memory allocated by these functions is managed by the library and must not be freed by the caller.

All Interfaces

prom_prop Handle to a PROM property.

di prom prop nextph PROM handle

node Handle to a device node in the snapshot of kernel device tree.

di_prom_prop_datadl_prom_prop_data() returns the number of bytes in *prop_data* and *prop_data* is updated to point to a byte array containing the property value. If 0 is returned, the property is a boolean property, and the existence of this property indicates the value is

di_prom_prop_name() returns a pointer to a string that contains the name of prom_prop.

di_prom_prop_nextdl_prom_prop_next() returns a handle to the next PROM property.

DI PROM PROP NIL is returned if no additional properties exist.

ERRORS

See openprom(7D) for a description of possible errors.

di_prom_prop_lookup_bytes(3DEVINFO)

NAME |

di_prom_prop_lookup_bytes, di_prom_prop_lookup_ints, di_prom_prop_lookup_strings – search for a PROM property

SYNOPSIS

#include <libdevinfo.h>

- int di_prom_prop_lookup_strings(di_prom_handle_t ph, di_node_t
 node, const char *prop_name, char **prop_data);

DESCRIPTION

These functions are used for returning the value of a known PROM property name and value type. These functions will update the *prop_data* pointer to reference memory that contains the property value. All memory allocated by these functions is managed by the library and must not be freed by the caller.

PARAMETERS

The following parameter descriptions apply to all interfaces:

node Handle to device node in snapshot created by

di init(3DEVINFO).

ph Handle returned by di prom init(3DEVINFO).

prop_name Name of the property being searched.

The following parameter description applies to $\mbox{di_prom_prop_lookup_bytes}$ () only:

prop_data The address of a pointer to an array of unsigned characters.

The following parameter description applies to di_prom_prop_lookup_ints() only:

prop_data The address of a pointer to an integer.

The following parameter description applies to di prom prop lookup strings() only:

prop_data The address of pointer to a buffer.

RETURN VALUES

If the property is found, the number of entries in *prop_data* is returned. If the property is a boolean type, 0 is returned, and the existence of this property indicates the value is true. Otherwise, -1 is returned with errno set to indicate the error condition.

For di_prom_prop_lookup_bytes(), the number of entries is the number of unsigned characters contained in the buffer pointed to by *prop_data*.

For di_prom_prop_lookup_ints(), the number of entries is the number of integers contained in the buffer pointed to by *prop_data*.

di_prom_prop_lookup_bytes(3DEVINFO)

For di_prom_prop_lookup_strings(), the number of entries is the number of null-terminated strings contained in the buffer. The strings are stored in a concatenated format in the buffer.

ERRORS

These functions set errno as listed for the following conditions:

EINVAL Invalid argument.

ENXIO The property does not exist.

NAME

di_prop_bytes, di_prop_devt, di_prop_ints, di_prop_name, di_prop_strings, di_prop_type, di_prop_int64 - access property values and attributes

SYNOPSIS

```
#include <libdevinfo.h>
int di_prop_bytes(di_prop_t prop, uchar_t **prop_data);
dev t di prop devt(di prop t prop);
int di prop ints(di prop t prop, int **prop_data);
int di prop int64(di prop t prop, int64 t **prop_data);
char *di prop name(di prop t prop);
int di prop strings(di prop t prop, char **prop_data);
int di_prop_type(di_prop_t prop);
```

DESCRIPTION

These interfaces are used to access information associated with property values and attributes.

All memory allocated by these functions is managed by the library and must not be freed by the caller.

The di prop name () function returns the name of the property.

The di prop type () function returns the type of the property. The type determines the appropriate interface to access property values. The following is a list of possible types:

DI_PROP_TYPE_BOOLEAN	There is no interface to call since there is no property data associated with boolean properties. The existence of the property defines a TRUE value.
DI_PROP_TYPE_INT	Use di_prop_ints() to access property data.
DI_PROP_TYPE_INT64	Use di_prop_int64() to access property data.
DI_PROP_TYPE_STRING	Use di_prop_strings() to access property data.
DI_PROP_TYPE_BYTE	Use di_prop_bytes() to access property data.
DI_PROP_TYPE_UNKNOWN	Use di_prop_bytes() to access property data. Since the type of property is unknown, the caller is responsible for interpreting the contents of the data.
DI_PROP_TYPE_UNDEF_IT	The property has been undefined by the driver. No property data is available.

di_prop_bytes(3DEVINFO)

The di_prop_devt() function returns the dev_t with which this property is associated. If the value is DDI_DEV_T_NONE, the property is not associated with any specific minor node.

The di_prop_bytes() function returns the property data as a series of unsigned characters.

The di prop ints() function returns the property data as a series of integers.

The di_prop_int64() function returns the property data as a series of 64-bit integers.

The di_prop_strings() function returns the property data as a concatenation of null-terminated strings.

All Interfaces | prop Handle to a property returned by di_prop_next(3DEVINFO).

di_prop_bytes | *prop_data* The address of a pointer to an unsigned character.

di_prop_ints | *prop_data* The address of a pointer to an integer.

di_prop_strings | *prop_data* The address of pointer to a character.

di_prop_bytes, di_prop_ints, di_prop_int64, di_prop_strings

Upon successful completion, these interfaces return a non-negative value, indicating the number of entries in the property value buffer. See

di_prom_prop_lookup_bytes(3DEVINFO) for a description of the return values. Otherwise, -1 is returned and errno is set to indicate the error condition.

di_prop_devt | The di prop devt() function returns the dev t value associated with the property.

di_prop_name | The di_prop_name() function returns a pointer to a string containing the name of

the property.

di_prop_type The di_prop_type() function may return one of various types described in the DESCRIPTION section.

ERRORS These functions set errno as listed for the following conditions:

EINVAL Invalid argument. For example, the property type does not match

the interface.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

	<pre>int di_prop_lookup_int64(dev_t dev, di_node_t node, const char *prop_name, int64_t **prop_data);</pre>		
	<pre>int di_prop_lookup_strings(dev_t dev, di_node_t node, const char *prop_name, char **prop_data);</pre>		
DESCRIPTION	TION These functions are used for returning the value of a known property name type and dev_t value. All memory allocated by these functions is managed by the library and must not be freed by the caller.		
All Interfaces	dev	dev_t of minor node with which the property is associated. DDI_DEV_T_ANY is a wild card that matches all dev_t's, including DDI_DEV_T_NONE.	
	node	Handle to the device node with which the property is associated.	
	prop_name	Name of the property for which to search.	
di_prop_lookup_bytesprop_data		Address to a pointer to an array of unsigned characters containing the property data.	
di_prop_lookup_ints	prop_data	Address to a pointer to an array of integers containing the property data.	
di_prop_lookup_int6	54 prop_data	Address to a pointer to an array of 64-bit integers containing the property data.	
di_prop_lookup_stri	ngsop_data	Address to a pointer to a buffer containing a concatenation of null-terminated strings containing the property data.	
RETURN VALUES	If the property is found, the number of entries in <i>prop_data</i> is returned. If the property is a boolean type, 0 is returned, and the existence of this property indicates the value is true. Otherwise, -1 is returned with errno set to indicate the error condition.		
ERRORS	These functions set errno as listed for the following conditions:		
	EINVAL	Invalid argument.	
	ENOTSUP	The snapshot contains no property information.	
	ENXIO	The property does not exist; try di_prom_prop_lookup_*().

di_prop_next(3DEVINFO)

NAME | di_prop_next - libdevinfo property traversal function

SYNOPSIS #include <libdevinfo.h>

di_prop_t di_prop_next(di_node_t node, di_prop_t prop);

DESCRIPTION The function di prop next () returns a handle to the next property on the property

list. If *prop* is DI PROP NIL, the handle to the first property is returned.

PARAMETERS node Handle to a device node.

> prop Handle to a property.

RETURN VALUES Upon successful completion, di_prop_next() returns a handle. Otherwise

DI PROP NIL is returned, and errno is set to indicate the error condition.

ERRORS The di prop next () functions sets errno as listed for the following conditions:

> EINVAL Invalid argument.

ENOTSUP Snapshot does not contain property information.

ENXIO There are no more properties.

di_walk_minor(3DEVINFO)

NAME |

di_walk_minor - traverse libdevinfo minor nodes

SYNOPSIS

#include <libdevinfo.h>

int di_walk_minor(di_node_t root, const char *minor_nodetype, uint_t flag, void *arg, int (*minor_callback)di_node_t node, di_minor_t minor, void *arg);

DESCRIPTION

di walk minor() visits all minor nodes attached to device nodes in a subtree rooted at root. For each minor node that matches minor_nodetype, the caller-supplied function minor_callback() is invoked. The walk terminates immediately when minor callback() returns DI WALK TERMINATE.

di_walk_minor

Root of subtree to visit. root

minor_nodetype A character string specifying the minor data type, which may be

> one of the types defined by the Solaris DDI framework, for example, DDI NT BLOCK. NULL matches all minor_node types. See

ddi_create_minor_node(9F).

Specify 0. Reserved for future use. flag Pointer to caller-specific user data. arg

minor_callback

The device node with which to the minor node is associated. node

minor The minor node visited. Pointer to caller-specific data. arg

di_walk_minor

Upon successful completion, 0 is returned. Otherwise, -1 is returned and errno is set to indicate the error.

minor_callback

The allowed return values are:

DI WALK CONTINUE Continue to visit subsequent minor data nodes.

DI WALK TERMINATE Terminate the walk immediately.

di_walk_minor

EINVAL Invalid argument.

di_walk_node - traverse libdevinfo device nodes NAME

SYNOPSIS #include <libdevinfo.h>

> int di_walk_node(di_node_t root, uint_t flag, void *arg, int (*node_callback)di node t node, void *arg);

DESCRIPTION

di walk node () visits all nodes in the subtree rooted at root. For each node found, the caller-supplied function node callback () is invoked. The return value of node callback() specifies subsequent walking behavior.

di_walk_node

Handle to the root node of the subtree to visit. root

Specifies walking order, either DI WALK CLDFIRST (depth first) or flag DI WALK SIBFIRST (breadth first). DI WALK CLDFIRST is the default.

Pointer to caller-specific data. arg

node_callback

node The node being visited.

Pointer to caller-specific data. arg

di_walk_node

0 is returned upon success. Otherwise, -1 is returned, and errno is set to indicate the error.

node callback

The allowed return values are:

DI WALK CONTINUE Continue walking.

DI WALK PRUNESIB Continue walking, but skip siblings and their child

Continue walking, but skip subtree rooted at current DI WALK PRUNECHILD

node.

DI WALK TERMINATE Terminate the walk immediately.

di walk node

EINVAL Invalid argument.

DmiAddComponent(3DMI)

NAME |

DmiAddComponent, DmiAddGroup, DmiAddLanguage, DmiDeleteComponent, DmiDeleteGroup, DmiDeleteLanguage - Management Interface database administration functions

SYNOPSIS

```
cc [ flag ... ] file ... -ldmimi -ldmi -lnsl -lrwtool [ library ... ]
#include <dmi/server.h>
#include <dmi/miapi.h>
bool t DmiAddComponent (DmiAddComponentIN argin, DmiAddComponentOUT
    *result, DmiRpcHandle *dmi rpc handle);
bool t DmiAddGroup(DmiAddGroupIN argin, DmiAddGroupOUT *result,
    DmiRpcHandle *dmi_rpc_handle);
bool t DmiAddLanguage (DmiAddLanguageIN argin,
    DmiAddLanguageOUT*result, DmiRpcHandle *dmi rpc handle);
bool t DmiDeleteComponent (DmiDeleteComponentIN argin,
    DmiDeleteComponentOUT *result, DmiRpcHandle *dmi rpc handle);
bool t DmiDeleteGroup (DmiDeleteGroupIN argin, DmiDeleteGroupOUT
    *result, DmiRpcHandle *dmi_rpc_handle);
bool t DmiDeleteLanguage (DmiDeleteLanguageIN argin,
    DmiDeleteLanguageOUT *result, DmiRpcHandle *dmi_rpc_handle);
```

DESCRIPTION

The database administration functions add a new component to the database or add a new language mapping for an existing component. You may also remove an existing component, remove a specific language mapping, or remove a group from a component.

The DmiAddComponent () function adds a new component to the DMI database. It takes the name of a file, or the address of memory block containing MIF data, checks the data for adherence to the DMI MIF grammar, and installs the MIF in the database. The procedure returns a unique component ID for the newly installed component. The argin parameter is an instance of a DmiAddComponentIN structure containing the following members:

```
DmiHandle_t handle; /* an open session handle */
DmiFileDataList_t *fileData; /* MIF data for component */
```

The result parameter is a pointer to a DmiAddComponentOUT structure containing the following members:

```
DmiErrorStatus t error status;
DmiId_t compId; /* SP-allocated component ID */
DmiStringList_t *errors; /* installation error messages */
DmiId t
                                       /* SP-allocated component ID */
```

The DmiAddLanguage () function adds a new language mapping for an existing component in the database. It takes the name of a file, or the address of memory block containing translated MIF data, checks the data for adherence to the DMI MIF grammar, and installs the language MIF in the database. The argin parameter is an instance of a DmiAddLanguageIN structure containing the following members:

```
DmiHandle_t handle; /* an open session handle */
DmiFileDataList_t *fileData; /* language mapping file */
DmiId_t compId; /* component to access */
```

The result parameter is a pointer to a DmiAddLanguageOUT structure containing the following members:

```
DmiErrorStatus t error status;
DmiStringList_t
                                 /* installation error messages */
                 *errors;
```

The DmiAddGroup () function adds a new group to an existing component in the database. It takes the name of a file, or the address of memory block containing the group's MIF data, checks the data for adherence to the DMI MIF grammar, and installs the group MIF in the database. The argin parameter is an instance of a DmiAddGroupIN structure containing the following members:

```
DmiHandle_t handle; /* an open session handle */
DmiFileDataList_t *fileData; /* MIF file data for group */
DmiId_t compId; /* component to access */
```

The result parameter is a pointer to a DmiAddGroupOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
                   groupId; /* SP-allocated group ID */
*errors; /* installation error messages */
DmiId t
DmiStringList_t *errors;
```

The DmiDeleteComponent () function removes an existing component from the database. The argin parameter is an instance of a DmiDeleteComponentIN structure containing the following members:

```
DmiHandle t
                  handle;
                               /* an open session handle */
                               /* component to delete */
DmiId_t
                 compId;
```

The result parameter is a pointer to a DmiDeleteComponentOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
```

The DmiDeleteLanguage () function removes a specific language mapping for a component. You specify the language string and component ID. The argin parameter is an instance of a DmiDeleteLanguageIN structure containing the following members:

```
DmiHandle_t handle; /* an open session handle */
DmiString_t *language; /* language to delete */
                     compId; /* component to access */
DmiId t
```

The result parameter is a pointer to a DmiDeleteLanguageOUT structure containing the following members:

```
DmiErrorStatus t
                  error status;
```

DmiAddComponent(3DMI)

The DmiDeleteGroup() function removes a group from a component. The caller specifies the component and group IDs. The *argin* parameter is an instance of a DmiDeleteGroupIN structure containing the following members:

```
DmiHandle_t handle; /* an open session handle */
DmiId_t compId; /* component containing group */
DmiId_t groupId; /* group to delete */
```

The *result* parameter is a pointer to a DmiDeleteGroupOUT structure containing the following members:

```
DmiErrorStatus t error status;
```

RETURN VALUES

The DmiAddComponent () function returns the following possible values:

```
DMIERR_NO_ERROR

DMIERR_ILLEGAL_RPC_HANDLE

DMIERR_OUT_OF_MEMORY

DMIERR_ILLEGAL_PARAMETER

DMIERR_SP_INACTIVE

DMIERR_FILE_ERROR

DMIERR_BAD_SCHEMA_DESCRIPTION_FILE
```

The DmiAddGroup () function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
DMIERR_BAD_SCHEMA_DESCRIPTION_FILE
```

The DmiAddLanguage () function returns the following possible values:

```
DMIERR_NO_ERROR

DMIERR_ILLEGAL_RPC_HANDLE

DMIERR_OUT_OF_MEMORY

DMIERR_ILLEGAL_PARAMETER

DMIERR_SP_INACTIVE

DMIERR_COMPONENT_NOT_FOUND

DMIERR_FILE_ERROR

DMIERR_BAD_SCHEMA_DESCRIPTION_FILE
```

The DmiDeleteComponent () function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
```

DmiAddComponent(3DMI)

THe DmiDeleteGroup () function returns the following possible values:

DMIERR NO ERROR DMIERR ILLEGAL RPC HANDLE DMIERR_OUT_OF_MEMORY DMIERR_ILLEGAL_PARAMETER DMIERR_SP_INACTIVE DMIERR INSUFFICIENT PRIVILEGES DMIERR_COMPONENT_NOT_FOUND DMIERR FILE ERROR

The DmiDeleteLanguage() function returns the following possible values:

DMIERR NO ERROR DMIERR_ILLEGAL_RPC_HANDLE DMIERR_OUT_OF_MEMORY DMIERR ILLEGAL PARAMETER DMIERR_SP_INACTIVE DMIERR_COMPONENT_NOT_FOUND DMIERR_FILE_ERROR

    *result, DmiRpcHandle *dmi_rpc_handle);
bool t DmiGetMultiple (DmiGetMultipleIN argin, DmiGetMultipleOUT
    *result, DmiRpcHandle *dmi_rpc_handle);
bool t DmiSetAttribute (DmiSetAttributeIN argin, DmiSetAttributeOUT
    *result, DmiRpcHandle *dmi rpc handle);
bool t DmiSetMultiple (DmiSetMultipleIN argin, DmiSetMultipleOUT
```

DESCRIPTION

The operation functions provide a method for retrieving a single value from the Service Provider and for setting a single attribute value. In addition, you may also retrieve attribute values from the Service Provider. You may perform a set operation on an attribute or a list of attributes and add or delete a row from an existing table.

The DmiAddRow() function adds a row to an existing table. The rowData parameter contains the full data, including key attribute values, for a row. It is an error for the key list to specify an existing table row. The argin parameter is an instance of a DmiAddRowIN structure containing the following members:

```
DmiHandle t
                     handle;
                                   /* An open session handle */
DmiRowData t
                     *rowData;
                                   /* Attribute values to set */
```

*result, DmiRpcHandle *dmi_rpc_handle);

The result parameter is a pointer to a DmiAddRowOUT structure containing the following members:

```
DmiErrorStatus t
                      error status;
```

DmiDeleteRow() function removes a row from an existing table. The key list must specify valid keys for a table row. The argin parameter is an instance of a DmiDeleteRowIN structure containing the following members:

```
DmiHandle_t
                                   /* An open session handle */
                     handle;
DmiRowData t
                     *rowData;
                                   /* Row to delete */
```

The result parameter is a pointer to a DmiDeleteRowOUT structure containing the following members:

```
DmiErrorStatus t
                     error status;
```

The DmiGetAttribute() function provides a simple method for retrieving a single attribute value from the Service Provider. The compld, groupId, attribId, and keyList identify the desired attribute. The resulting attribute value is returned in a newly allocated DmiDataUnion structure. The address of this structure is returned through the value parameter. The argin parameter is an instance of a DmiListComponentsIN structure containing the following members:

```
DmiHandle t
                                 handle;
                                                     /* an open session handle */
                               compId; /* Component to access */
groupId; /* Group within component */
attribId; /* Attribute within a group */
*keyList; /* Keylist to specify a table row */
DmiId t
                              groupId;
DmiId t
Dmild t
DmiAttributeValues t *keyList;
```

The result parameter is a pointer to a DmiGetAttributeOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiDataUnion_t
                               /* Attribute value returned */
                  *value;
```

The DmiGetMultiple() function retrieves attribute values from the Service Provider. This procedure may get the value for an individual attribute, or for multiple attributes across groups, components, or rows of a table.

The DmiSetAttribute() function provides a simple method for setting a single attribute value. The compId, groupId, attribId, and keyList identify the desired attribute. The setMode parameter defines the procedure call as a Set, Reserve, or Release operation. The new attribute value is contained in the DmiDataUnion structure whose address is passed in the value parameter. The argin parameter is an instance of a DmiSetAttributeIN structure containing the following members:

```
DmiHandle t
                        handle:
                       compld;
DmiId t
                       groupId;
attribId;
DmiId t
DmiId t
DmiAttributeValues_t *keyList;
DmiSetMode_t setMode;
DmiDataUnion t *value;
```

The result parameter is a pointer to a DmiSetAttributeOUT structure containing the following members:

```
DmiErrorStatus t
                      error status;
```

The DmiSetMultiple () function performs a set operation on an attribute or list of attributes. Set operations include actually setting the value, testing and reserving the attribute for future setting, or releasing the set reserve. These variations on the set operation are specified by the parameter setMode. The argin parameter is an instance of a DmiSetMultipleIN structure containing the following members:

```
DmiHandle t
                          handle;
                                             /* An open session handle */
DmiSetMode_t setMode; /* set, reserve, or release *,
DmiMultiRowData_t *rowData; /* Attribute values to set */
                                          /* set, reserve, or release */
```

DmiAddRow(3DMI)

The *result* parameter is a pointer to a DmiSetMultipleOUT structure containing the following members:

```
DmiErrorStatus t error status;
```

The rowData array describes the attributes to set, and contains the new attribute values. Each element of rowData specifies a component, group, key list (for table accesses), and attribute list to set. No data is returned from this function.

RETURN VALUES

The DmiAddRow() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER

DmiGetConfig(3DMI)

NAME |

DmiGetConfig, DmiGetVersion, DmiRegister, DmiSetConfig, DmiUnregister – Management Interface initialization functions

SYNOPSIS

```
cc [ flag ... ] file ... -ldmimi -ldmi -lnsl -lrwtool [ library ... ]
#include <server.h>
#include <miapi.h>
```

bool_t DmiGetVersion(DmiGetVersionIN argin, DmiGetVersionOUT
 *result, DmiRpcHandle *dmi_rpc_handle);

bool_t DmiUnregister(DmiUnregisterIN argin, DmiUnregisterOUT
 *result, DmiRpcHandle *dmi_rpc_handle);

DESCRIPTION

The Management Interface initialization functions enable you to register management applications to the Service Provider. You may also retrieve information about the Service Provider, get and set session configuration information for your session.

The <code>DmiGetConfig()</code> function retrieves the per-session configuration information. The configuration information consists of a string describing the current language being used for the session. The <code>argin</code> parameter is an instance of a <code>DmiGetConfigIN</code> structure containing the following member:

```
DmiHandle_t handle; /* an open session handle */
```

The *result* parameter is a pointer to a DmiGetConfigOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiString_t *language; /* current session language */
```

The DmiGetVersion() function retrieves information about the Service Provider. The management application uses the DmiGetVersion() procedure to determine the DMI specification level supported by the Service Provider. This procedure also returns the service provided description string, and may contain version information about the Service Provider implementation. The *argin* parameter is an instance of a DmiGetVersionIN structure containing the following member:

```
DmiHandle t handle; /* an open session handle */
```

The *result* parameter is a pointer to a DmiGetVersionOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiString_t *dmiSpecLevel; /* DMI specification version */
DmiString_t *description; /* OS specific DMI SP version */
```

```
DmiFileTypeList t *fileTypes; /* file types for MIF installation */
```

The DmiRegister() function provides the management application with a unique per-session handle. The Service Provider uses this procedure to initialize to an internal state for subsequent procedure calls made by the application. This procedure must be the first command executed by the management application. <code>argin</code> is an instance of a <code>DmiRegisterIN</code> structure containing the following member:

```
DmiHandle t handle; /* an open session handle */
```

The *result* parameter is a pointer to a DmiRegisterOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiHandle t *handle; /* an open session handle */
```

The DmiSetConfig() function sets the per-session configuration information. The configuration information consists of a string describing the language required by the management application. The *argin* parameter is an instance of a DmiSetConfigIN structure containing the following member:

```
DmiHandle_t handle; /* an open session handle */
DmiString_t *language; /* current language required */
```

The *result* parameter is a pointer to a DmiSetConfigOUT structure containing the following member:

```
DmiErrorStatus_t error_status;
```

The <code>DmiUnregister()</code> function is used by the Service Provider to perform end-of-session cleanup actions. On return from this function, the session handle is no longer valid. This function must be the last <code>DMI</code> command executed by the management application. The <code>argin</code> parameter is an instance of a <code>DmiUnregisterIN</code> structure containing the following member:

```
DmiHandle t handle; /* an open session handle */
```

The result parameter is a pointer to a DmiUnregisterOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
```

RETURN VALUES

The DmiGetConfig() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR SP INACTIVE
```

The DmiGetVersion() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR SP INACTIVE
```

DmiGetConfig(3DMI)

The DmiRegister () function returns the following possible values:

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_SP_INACTIVE

The DmiSetConfig() function returns the following possible values:

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ILLEGAL_TO_SET

The DmiUnRegister () function returns the following possible values:

DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE

```

DESCRIPTION

The listing functions enables you to retrieve the names and the description of components in a system. You may also list components by class that match a specified criteria. The listing functions retrieve the set of language mappings installed for a specified component, retrieve class name strings for all groups in a component, retrieve a list of groups within a component, and retrieve the properties for one or more attributes in a group.

The DmiListComponents() function retrieves the name and (optionally) the description of components in a system. Use this to interrogate a system to determine what components are installed. The argin parameter is an instance of a DmiListComponentsIN structure containing the following members:

```
handle;
DmiHandle t
                                               /* an open session handle */
DmiRequestMode_t requestMode; /* Unique, first, or next */
DmiUnsigned_t maxCount; /* maximum number to return,
                                                   0 for all */
DmiBoolean_t getPragma; /* get optional pragma string */
DmiBoolean_t getDescription; /* get optional component
                                                  description */
                                               /* component ID to start with */
                         compId;
DmiId t
```

The result parameter is a pointer to a DmiListComponentsOUT structure containing the following members:

```
DmiErrorStatus_t
                   error_status;
DmiComponentList t *reply;
                                   /* list of components */
```

DmiListAttributes(3DMI)

An enumeration accesses a specific component or may be used to sequentially access all components in a system. The caller may choose not to retrieve the component description by setting the value getDescription to false. The caller may choose not to retrieve the pragma string by setting the value of gutta-percha to false. The maxCount, requestMode, and compId parameters allow the caller to control the information returned by the Service Provider. When the requestMode is DMI UNIQUE, compid specifies the first component requested (or only component if maxCount is one). When the requestMode is DMI NEXT, compld specifies the component just before the one requested. When requestMode is DMI FIRST, compld is unused.

To control the amount of information returned, the caller sets maxCount to something other than zero. The service provider must honor this limit on the amount of information returned. When maxCount is 0 the service provider returns information for all components, subject to the constraints imposed by requestMode and compId.

The DmiListComponentsByClass() function lists components that match specified criteria. Use this function to determine if a component contains a certain group or a certain row in a table. A filter condition may be that a component contains a specified group class name or that it contains a specific row in a specific group. As with DmiListComponents(), the description and pragma strings are optional return values. argin is an instance of a DmiListComponentsByClassIN structure containing the following members:

```
DmiHandle_t handle; /* an open session handle */
DmiRequestMode_t requestMode; /* Unique, first or next */
DmiBoolean_t getPragma; /* get the optional pragma
DmiBoolean_t getDescription; /* get optional component description */
                  description */
compId; /* component ID to start with */
*className; /* group class name string
to match*/
DmiString_t
_ to match*/
DmiAttributeValues_t *keyList; /* group row keys to match */
```

The result parameter is a pointer to a DmiListComponentsbyClassOUT structure containing the following members:

```
DmiErrorStatus t
                   error status;
DmiComponentList t *reply;
                                   /* list of components */
```

The DmiListLanguages () function retrieves the set of language mappings installed for the specified component. The argin parameter is an instance of a DmiListLanguagesIN structure containing the following members:

```
DmiHandle_t handle; /* An open session handle */
DmiUnsigned_t maxCount; /* maximum number to return,
                                          or 0 for all \star/
Dmild t compld; /* Component to access */
```

The result parameter is a pointer to a DmiListLanguagesOUT structure containing the following members:

```
DmiErrorStatus t
                  error status;
DmiStringList t
                 *reply;
                                 /* List of language strings */
```

The DmiListClassNames() function retrieves the class name strings for all groups in a component. This enables the management application to easily determine if a component contains a specific group, or groups. The argin parameter is an instance of a DmiListClassNamesIN structure containing the following members:

```
DmiHandle t
                  handle;
                                 /* An open session handle */
DmiUnsigned_t
                 maxCount;
                                /* maximum number to return,
                                   or 0 for all */
                 compId; /* Component to access */
DmiId t
```

The result parameter is a pointer to a DmiListClassNamesOUT structure containing the following members:

```
DmiErrorStatus_t
                   error_status;
DmiClassNameList_t *reply;
                                  /* List of class names and
                                     group IDs */
```

The DmiListGroups () function retrieves a list of groups within a component. With this function you can access a specific group or sequentially access all groups in a component. All enumerations of groups occur within the specified component and do not span components. The argin parameter is an instance of a DmiListGroupsIN structure containing the following members:

```
handle;
                                                                        /* An open session handle */
DmiHandle t
DmiRequestMode_t requestMode; /* Unique, first or next group */
DmiUnsigned_t maxCount; /* Maximum number to return,
or 0 for all */
DmiBoolean_t getPragma; /* Get the optional pragma string */
DmiBoolean_t getDescription; /* Get optional group description */
DmiId_t compId; /* Component to access */
DmiId_t groupId; /* Group to start with, refer to
                                                                               requestMode */
```

The *result* parameter is a pointer to a DmiListGroupsOUT structure containing the following members:

```
DmiErrorStatus t
                    error_status;
DmiGroupList t
                    *reply;
```

The caller may choose not to retrieve the group description by setting the value getDescription to false. The caller may choose not to retrieve the pragma string by setting the value of getPragma to false. The maxCount, requestMode, and groupId parameters allow the caller to control the information returned by the Service Provider. When the requestMode is DMI UNIQUE, groupId specifies the first group requested (or only group if maxCount is one). When the requestMode is DMI NEXT, groupId specifies the group just before the one requested. When requestMode is DMI FIRST, groupId is unused. To control the amount of information returned, the caller sets maxCount to something other than zero. The

DmiListAttributes(3DMI)

service provider must honor this limit on the amount of information returned. When maxCount is zero the service provider returns information for all groups, subject to the constraints imposed by requestMode and groupId.

The DmiListAttributes() function retrieves the properties for one or more attributes in a group. All enumerations of attributes occur within the specified group, and do not span groups. The *argin* parameter is an instance of a DmiListAttributesIN structure containing the following members:

```
DmiHandle_t handle; /* An open session handle */
DmiRequestMode_t requestMode; /* Unique, first or next group */
DmiUnsigned_t maxCount; /* Maximum number to return,
or 0 for all */
DmiBoolean_t getPragma; /* Get the optional pragma string */
DmiBoolean_t getDescription; /* Get optional group description */
DmiId_t compId; /* Component to access */
DmiId_t groupId; /* Group to access */
DmiId_t attribId; /* Attribute to start with, refer
to requestMode */
```

The *result* parameter is a pointer to a DmiListAttributesOUT structure containing the following members:

```
DmiErrorStatus_t error_status;
DmiAttributeList t *reply; /* List of attrbutes */
```

You may choose not to retrieve the description string by setting the value of getDescription to false. Likewise, you may choose not to retrieve the pragma string by setting the value of getPragma to false. The maxCount, requestMode, and attribId parameters allow you to control the information returned by the Service Provider. When the requestMode is DMI_UNIQUE, attribId specifies the first attribute requested (or only attribute if maxCount is one). When the requestMode is DMI_NEXT, attribId specifies the attribute just before the one requested. When requestMode is DMI_FIRST, attribId is unused. To control the amount of information returned, the caller sets maxCount to something other than zero. The Service Provider must honor this limit on the amount of information returned. When maxCount is zero the service provider returns information for all attributes, subject to the constraints imposed by requestMode and attribId.

RETURN VALUES

The DmiListAttributes () function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_FILE_ERROR
```

The DmiListClassNames() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR FILE ERROR
```

The DmiListComponents() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
```

The DmiListComponentsByClass() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_FILE_ERROR
```

The DmiListGroups () function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_FILE_ERROR
```

The DmiListLanguages () function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_RPC_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_PARAMETER
DMIERR_SP_INACTIVE
DMIERR_COMPONENT_NOT_FOUND
DMIERR FILE ERROR
```

DmiListAttributes (3DMI)

SEE ALSO | attributes(5)

NAME |

DmiRegisterCi, DmiUnRegisterCi, DmiOriginateEvent – Service Provider functions for components

SYNOPSIS

DESCRIPTION

These three functions provide component communication with the DMI through the Component Interface (CI).

Component instrumentation code may register with the Service Provider to override its current mechanism for the registered attributes. Instead of manipulating the data in the MIF database or invoking programs, the Service Provider calls the entry points provided in the registration call. Once the component unregisters, the Service Provider returns to a normal method of processing requests for the data as defined in the MIF. Component instrumentation can temporarily interrupt normal processing to perform special functions.

Registering attributes through the direct interface overrides attributes that are already being served through the direct interface. RPC is used for communication from the Service Provider to the component instrumentation.

For all three functions, *argin* is the parameter passed to initiate an RPC call, *result* is the result of the RPC call, and *dmi_rpc_handle* is an open session RPC handle.

The DmiRegisterCi() function registers a callable interface for components that have resident instrumentation code and/or to get the version of the Service Provider.

The DmiUnRegisterCi() function communicates to the Service Provider to remove a direct component instrumentation interface from the Service Provider table of registered interfaces.

The DmiOriginateEvent() function originates an event for filtering and delivery. Any necessary indication filtering is performed by this function (or by subsequent processing) before the event is forwarded to the management applications.

A component ID value of zero (0) specifies the event was generated by something that has not been installed as a component, and has no component ID.

RETURN VALUES

The DmiRegisterCi() function returns the following possible values:

```
DMIERR_NO_ERROR
DMIERR_ILLEGAL_HANDLE
```

DmiRegisterCi(3DMI)

DMIERR_OUT_OF_MEMORY
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_SP_INACTIVE
DMIERR_ATTRIBUTE_NOT_FOUND
DMIERR_COMPONENT_NOT_FOUND
DMIERR_GROUP_NOT_FOUND
DMIERR_DATABASE_CORRUPT
DMIERR_OUT_OF_MEMORY
DMIERR_ILLEGAL_DMI_LEVEL

The DmiUnRegisterCi() function returns the following possible values:

DMIERR_NO_ERROR
DMIERR_ILLEGAL_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_SP_INACTIVE
DMIERR_UNKNOWN CI REGISTRY

The DmiOriginateEvent() function returns the following possible values:

DMIERR_NO_ERROR
DMIERR_ILLEGAL_HANDLE
DMIERR_OUT_OF_MEMORY
DMIERR_INSUFFICIENT_PRIVILEGES
DMIERR_SP_INACTIVE
DMIERR_UNKNOWN_CI_REGISTRY

NAME | ea_error – error interface to extended accounting library

SYNOPSIS

```
cc [flag ...] file ... -lexacct [library ...]
#include <exacct.h>
```

int ea_error(void);

DESCRIPTION

The ea error () function returns the error value of the last failure recorded by the $\overline{\text{invocation}}$ of one of the functions of the extended accounting library, libexacct.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

read(2), libexacct(3LIB), attributes(5)

ea_open(3EXACCT)

NAME

ea_open, ea_close – open or close exacct files

SYNOPSIS

```
cc [flag...] file... -lexacct [library...]
#include <exacct.h>
```

int *ea_open(ea_file_t *efp, char *name, char *creator, int aflags, int
 oflags, mode t mode);

int ea close(ea file t *efp);

DESCRIPTION

The ea_open() function provides structured access to exact files. The *aflags* argument contains the appropriate exact flags necessary to describe the file. The *oflags* and *mode* arguments contain the appropriate flags and mode to open the file; see <fcntl.h>. If ea_open() is invoked with EO_HEAD specified in *aflags*, the resulting file is opened with the object cursor located at the first object of the file. If ea_open() is invoked with EO_TAIL specified in *aflags*, the resulting file is opened with the object cursor positioned beyond the last object in the file.

The ea close() function closes an open exacct file.

RETURN VALUES

Upon successful completion, ea_open() and ea_close() return 0. Otherwise they return -1 and call ea_error(3EXACCT) to return the extended accounting error value describing the error.

ERRORS

The ea open() and ea close() functions may fail if:

EXR_SYSCALL_FAIL A system call invoked by the function failed. The

errno variable contains the error value set by the

underlying call.

The ea_open() function may fail if:

EXR CORRUPT FILE The file referred to by *name* is not a valid exacct file.

EXR NO CREATOR In the case of file creation, the *creator* argument was

NULL. In the case of opening an existing file, a *creator* argument was specified and does not match the *creator*

item of the exacct file.

EXR UNKN VERSION The file referred to by *name* uses an exacct file version

that cannot be processed by this library.

USAGE

The exact file format can be used to represent data other than that in the extended accounting format. By using a unique creator type in the file header, application writers can develop their own format suited to the needs of their application.

EXAMPLES

EXAMPLE 1 Open and close exacct file.

The following example opens the extended accounting data file for processes. The exact file is then closed.

#include <exacct.h>

EXAMPLE 1 Open and close exacct file. (Continued)

```
ea_file_t ef;
if (ea_open(&ef, "/var/adm/exacct/proc", NULL, EO_HEAD,
  O_RDONLY, 0) == -1)
     exit(1);
(void) ea_close(ef);
```

ATTRIBUTES

SEE ALSO

ea_error(3EXACCT), ea_pack_object(3EXACCT), ea_set_item(3EXACCT), libexacct(3LIB), attributes(5)

ea_pack_object(3EXACCT)

NAME |

ea_pack_object, ea_unpack_object, ea_get_creator, ea_get_hostname, ea_next_object, ea_previous_object, ea_get_object, ea_write_object – construct, read, and write extended accounting records

SYNOPSIS

DESCRIPTION

The ea_pack_object() function converts exacct objects from their in-memory representation to their file representation. It is passed an object pointer that points to the top of an exacct object hierarchy representing one or more exacct records. It returns the size of the buffer required to contain the packed buffer representing the object hierarchy.

The ea_unpack_object() function reverses the packing process performed by ea_pack_object(). A packed buffer passed to ea_unpack_object() is unpacked into the original hierarchy of objects. If the unpack operation fails (presumably due to a corrupted or incomplete buffer), it returns -1; otherwise, the object type of the first object in the hierarchy is returned. If ea_unpack_object() is invoked with flag equal to EUP_ALLOC, it allocates memory for the variable length data in the included objects. Otherwise, with flag equal to EUP_NOALLOC, it sets the variable length data pointers within the unpacked object structures to point within the buffer indicated by buf. In both cases, ea_unpack_object() allocates all the necessary exact objects to represent the unpacked record. The resulting object hierarchy can be freed using ea_free_object(3EXACCT) with the same flag value.

The ea_get_creator() function returns a pointer to a string representing the recorded creator of the exacct file. The ea_get_hostname() function returns a pointer to a string representing the recorded hostname on which the exacct file was created. These functions will return NULL if their respective field was not recorded in the exacct file header.

The ea_next_object() function reads the basic fields into the ea_object_t indicated by obj from the exact file referred to by ef, and rewinds to the head of the

record. If the read object is corrupted, ea next object() returns -1 and records the extended accounting error code.

The ea previous object () function skips back one object in the file and reads its basic fields into the indicated ea object t. If the read object is corrupted, ea previous object () returns –1 and records the extended accounting error code.

The ea get object() function reads the value fields into the ea object t indicated by obj, allocating memory as necessary, and advances to the head of the next record. Once a record group object is retrieved using ea get object(), a call to ea next object() will track through the objects within the record group. If the read object is corrupted, ea get object() returns -1 and records the extended accounting error code.

The ea write object() function appends the given object to the open exacct file indicated by ef. If the write fails, ea write object() returns -1 and sets the extended accounting error code to indicate the error.

RETURN VALUES

The ea pack object () function returns the number of bytes associated with the exacct object being operated upon. If the returned size exceeds bufsize, the pack operation will not complete.

The ea get object() function returns 1 if the object was retrieved successfully. Otherwise, it returns 0 and sets errno to indicate the error. If the error occured during the execution of read(2), errno will be unchanged.

The ea_next_object() function returns the ea_object_type of the next exacct object in the file. It returns -1 if the exacct file is corrupted.

The ea unpack object () function returns the ea object type of the first exacct object unpacked from the buffer. It returns –1 if the exacct file is corrupted.

The ea write object() function returns 0 on success and -1 on failure.

In the case of failure, these functions will set an extended accounting error code reflecting one of the errors decsribed below. The extended account error code can be retrieved using ea error(3EXACCT).

ERRORS

These functions may fail if:

EXR_SYSCALL_FAIL	A system call invoked by the function failed. The errno variable contains the error value set by the underlying call.
EXR_CORRUPT_FILE	The file referred to by <i>name</i> is not a valid exacct file, or is unparsable, and therefore appears corrupted. This error is also used by ea_unpack_buffer() to indicate a corrupted buffer.
EXR_NO_MEMORY	A memory allocation required to complete the operation failed.

EXR EOF

The end of the file has been reached. In the case of ea_previous_record(), the previous record could not be reached, either because the head of the file was encountered or because the previous record could not be skipped over.

USAGE

The exact file format can be used to represent data other than that in the extended accounting format. By using a unique creator type in the file header, application writers can develop their own format suited to the needs of their application.

EXAMPLES

EXAMPLE 1 Open and close exacct file.

The following example opens the extended accounting data file for processes. The exacct file is then closed.

EXAMPLE 2 Construct an exacct file consisting of a single object containing the current process ID.

```
#include <sys/types.h>
#include <unistd.h>
#include <exacct.h>

...

ea_file_t ef;
ea_object_t obj;
pid_t my_pid;

ea_open(&ef, "foo", O_CREAT | O_WRONLY, ...);
```

EXAMPLE 2 Construct an exacct file consisting of a single object containing the current process ID. (Continued)

```
my_pid = getpid();
ea_set_item(&obj, EXD_UINT32 | EXC_DEFAULT | EXT_PROC_PID, &ny_pid, 0);
(void) ea_write_object(&ef, &obj);
ea_close(&ef);
```

ea set item(3EXACCT)

NAME |

ea set item, ea set group, ea match object catalog, ea attach to object, ea_attach_to_group, ea_free_item, ea_free_object - open or close exacct files

SYNOPSIS

```
cc [flag...] file ... -lexacct [library...]
#include <exacct.h>
int ea set item(ea object t *obj, ea catalog t tag, void *value,
    size tvalsize);
int ea set group (ea object t *obj, ea catalog t tag);
int ea match object catalog (ea object t *obj, ea catalog t
    catmask);
void ea attach to object(ea object t *head_obj, ea object t *obj);
void ea attach to group(ea object t *group_obj, ea object t *obj);
void ea free item(ea object t *obj, int flag);
void ea free object(ea object t *obj, int flag);
```

DESCRIPTION

The ea set item() function assigns the given exacct object to be a data item with value set according to the remaining arguments. For buffer-based data values, no copy is taken. The ea set group () function assigns the given exacct object to be a record group with 0 elements.

The ea match object catalog() function returns TRUE if the exacct object specified by *obj* has a catalog tag that matches the mask specified by *catmask*.

The ea attach to object() function attaches an object to the given object. The ea attach to group () function attaches a chain of objects as member items of the given group. Objects are inserted into the list of any previously attached objects.

The ea free item() function frees the value fields in the ea object tindicated by obj, if EUP ALLOC is specified. The object itself is not freed. The ea free object() function frees the specified object and any attached hierarchy of objects. If the flag argument is set to EUP ALLOC, ea free object() will also free any variable-length data in the object hierarchy; if set to EUP NOALLOC, ea free object() will not free variable-length data. In particular, these flags should correspond to those specified in calls to ea unpack object(3EXACCT).

RETURN VALUES

The ea_set_item() and ea_set_group() functions return 0 if the object was assigned successfuly. Otherwise these functions return -1 and set the extended accounting error code appropriately.

The ea match object catalog() function returns 0 if the object's catalog tag does not match the given mask, and 1 if there is a match.

ERRORS

The ea set item(), ea set group(), and ea match object catalog() functions may fail if:

ea_set_item(3EXACCT)

EXR_SYSCALL_FAIL A system call invoked by the function failed. The

errno variable contains the error value set by the

underlying call.

EXR_NO_MEMORY A memory allocation required to complete the

operation failed.

USAGE

The exact file format can be used to represent data other than that in the extended accounting format. By using a unique creator type in the file header, application writers can develop their own format suited to the needs of their application.

EXAMPLES

EXAMPLE 1 Open and close exacct file.

Construct an exacct file consisting of a single object containing the current process ID.

```
#include <sys/types.h>
>#include <unistd.h>
#include <exacct.h>

...

ea_file_t ef;
ea_object_t obj;
pid_t my_pid;

my_pid = getpid();
ea_set_item(&obj, EXD_UINT32 | EXC_DEFAULT | EXT_PROC_PID, &my_pid, 0);
...
```

elf32_checksum(3ELF)

NAME |

elf32_checksum, elf64_checksum - return checksum of elf image

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
long elf32_checksum(Elf *elf);
long elf64 checksum(Elf *elf);
```

DESCRIPTION

The elf32_checksum() function returns a simple checksum of selected sections of the image identified by *elf*. The value is typically used as the .dynamic tag DT CHECKSUM, recorded in dynamic executables and shared objects.

Selected sections of the image are used to calcluste the checksum in order that its value is not affected by utilities such as strip(1).

For the 64-bit class, replace 32 with 64 as appropriate.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

MT-Level	MT-Safe

SEE ALSO

elf(3ELF), elf version(3ELF), gelf(3ELF), libelf(3LIB), attributes(5)

NAME | elf32_fsize, elf64_fsize – return the size of an object file type

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
```

```
size t elf32 fsize(Elf Type type, size t count, unsigned ver);
size t elf64 fsize(Elf Type type, size t count, unsigned ver);
```

DESCRIPTION

elf32 fsize() gives the size in bytes of the 32-bit file representation of count data objects with the given type. The library uses version ver to calculate the size. See elf(3ELF) and elf version(3ELF).

Constant values are available for the sizes of fundamental types:

```
Elf Type File Size
                        Memory Size
ELF_T_BYTE 1 sizeof(unsigned char)
ELF_T_HALF ELF32_FSZ_HALF sizeof(Elf32_Half)
ELT_T_OFF ELF32_FSZ_OFF sizeof(Elf32_Off)
ELF T SWORD ELF32 FSZ SWORD sizeof(Elf32 Sword)
ELF T WORD ELF32 FSZ WORD sizeof(Elf32 Word)
```

elf32_fsize() returns 0 if the value of type or ver is unknown. See elf32 xlatetof(3ELF) for a list of the type values.

For the 64-bit class, replace 32 with 64 as appropriate.

ATTRIBUTES

elf32_getehdr(3ELF)

NAME

elf32_getehdr, elf64_getehdr, elf64_newehdr – retrieve class-dependent object file header

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
Elf32_Ehdr *elf32_getehdr(Elf *elf);
Elf32_Ehdr *elf32_newehdr(Elf *elf);
Elf64_Ehdr *elf64_getehdr(Elf *elf);
Elf64_Ehdr *elf64_newehdr(Elf *elf);
```

DESCRIPTION

For a 32-bit class file, elf32_getehdr() returns a pointer to an ELF header, if one is available for the ELF descriptor *elf*. If no header exists for the descriptor, elf32_newehdr() allocates a clean one, but it otherwise behaves the same as elf32_getehdr(). It does not allocate a new header if one exists already. If no header exists for elf32_getehdr(), one cannot be created for elf32_newehdr(), a system error occurs, the file is not a 32-bit class file, or *elf* is null, both functions return a null pointer.

For the 64-bit class, replace 32 with 64 as appropriate.

The header includes the following members:

```
unsigned char
                e_ident[EI_NIDENT];
Elf32_Half e_type;
Elf32 Half e machine;
Elf32_Word e_version;
Elf32_Addr e_entry;
Elf32_Off e_phoff;
            e_phoff;
Elf32 Off e shoff;
Elf32 Word e flags;
Elf32_Half e_ehsize;
Elf32 Half
            e_phentsize;
Elf32 Half
             e phnum;
Elf32 Half e_shentsize;
Elf32 Half e shnum;
Elf32_Half e_shstrndx;
```

 ${\tt elf32_newehdr()} \ automatically sets the {\tt ELF_F_DIRTY} \ bit. See \\ {\tt elf_flagdata(3ELF)}. \ A program may use {\tt elf_getident()} \ to inspect the identification bytes from a file.$

elf32_getphdr(3ELF)

NAME |

elf32_getphdr, elf32_newphdr, elf64_getphdr, elf64_newphdr – retrieve class-dependent program header table

SYNOPSIS

```
cc [ flag ... ] file... -lelf [ library ... ]
#include libelf.h>

Elf32_Phdr *elf32_getphdr(Elf *elf);

Elf32_Phdr *elf32_newphdr(Elf *elf, size_t count);

Elf64_Phdr *elf64_getphdr(Elf *elf);

Elf64_Phdr *elf64_newphdr(Elf *elf, size_t count);
```

DESCRIPTION

For a 32-bit class file, elf32_getphdr() returns a pointer to the program execution header table, if one is available for the ELF descriptor *elf*.

elf32_newphdr() allocates a new table with *count* entries, regardless of whether one existed previously, and sets the ELF_F_DIRTY bit for the table. See elf_flagdata(3ELF). Specifying a zero *count* deletes an existing table. Note this behavior differs from that of elf32_newehdr() allowing a program to replace or delete the program header table, changing its size if necessary. See elf32_getehdr(3ELF).

If no program header table exists, the file is not a 32-bit class file, an error occurs, or *elf* is NULL, both functions return a null pointer. Additionally, elf32_newphdr() returns a null pointer if *count* is 0.

The table is an array of Elf32_Phdr structures, each of which includes the following members:

```
Elf32_Word p_type;

Elf32_Off p_offset;

Elf32_Addr p_vaddr;

Elf32_Word p_filesz;

Elf32_Word p_memsz;

Elf32_Word p_flags;

Elf32_Word p_align;
```

The Elf64 Phdr structures include the following members:

```
Elf64_Word p_type;
Elf64_Word p_flags;
Elf64_Off p_offset;
Elf64_Addr p_vaddr;
Elf64_Addr p_paddr;
Elf64_Xword p_filesz;
Elf64_Xword p_memsz;
Elf64_Xword p_align;
```

For the 64-bit class, replace 32 with 64 as appropriate.

The ELF header's e phnum member tells how many entries the program header table has. See elf32_getehdr(3ELF). A program may inspect this value to determine the size of an existing table; elf32 newphdr() automatically sets the member's value to count. If the program is building a new file, it is responsible for creating the file's ELF header before creating the program header table.

elf32_getshdr(3ELF)

NAME

elf32_getshdr, elf64_getshdr - retrieve class-dependent section header

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
Elf32_Shdr *elf32_getshdr(Elf_Scn *scn);
Elf64_Shdr *elf64_getshdr(Elf_Scn *scn);
```

DESCRIPTION

For a 32-bit class file, elf32_getshdr() returns a pointer to a section header for the section descriptor *scn*. Otherwise, the file is not a 32-bit class file, *scn* was NULL, or an error occurred; elf32_getshdr() then returns NULL.

The elf32 getshdr header includes the following members:

```
Elf32_Word sh_name;
Elf32_Word sh_type;
Elf32_Word sh_flags;
Elf32_Addr sh_addr;
Elf32_Off sh_offset;
Elf32_Word sh_link;
Elf32_Word sh_info;
Elf32_Word sh_addralign;
Elf32_Word sh_entsize;
```

while the elf64 getshdr header includes the following members:

```
Elf64_Word sh_name;
Elf64_Word sh_type;
Elf64_Xword sh_addr;
Elf64_Off sh_offset;
Elf64_Xword sh_link;
Elf64_Word sh_link;
Elf64_Word sh_info;
Elf64_Xword sh_addralign;
Elf64_Xword sh_entsize;
```

For the 64-bit class, replace 32 with 64 as appropriate.

If the program is building a new file, it is responsible for creating the file's ELF header before creating sections.

elf32 xlatetof(3ELF)

NAME |

elf32 xlatetof, elf32 xlatetom, elf64 xlatetof, elf64 xlatetom - class-dependent data translation

SYNOPSIS

```
cc [ flag ... ] file... -lelf [ library ... ]
#include <libelf.h>
Elf Data *elf32 xlatetof(Elf Data *dst, const Elf Data *src,
    unsigned encode);
Elf Data *elf32 xlatetom(Elf Data *dst, const Elf Data *src,
    unsigned encode);
Elf Data *elf64 xlatetof(Elf Data *dst, const Elf Data *src,
    unsigned encode);
Elf Data *elf64 xlatetom(Elf Data *dst, const Elf Data *src,
    unsigned encode);
```

DESCRIPTION

elf32 xlatetom() translates various data structures from their 32-bit class file representations to their memory representations; elf32 xlatetof() provides the inverse. This conversion is particularly important for cross development environments. src is a pointer to the source buffer that holds the original data; dst is a pointer to a destination buffer that will hold the translated copy. *encode* gives the byte encoding in which the file objects are to be represented and must have one of the encoding values defined for the ELF header's e ident [EI DATA] entry (see elf getident(3ELF)). If the data can be translated, the functions return dst. Otherwise, they return NULL because an error occurred, such as incompatible types, destination buffer overflow, etc.

elf getdata(3ELF) describes the Elf Data descriptor, which the translation routines use as follows:

d_buf	Both the source and destination must have valid buffer pointers.
d_type	This member's value specifies the type of the data to which d_buf points and the type of data to be created in the destination. The program supplies a d_type value in the source; the library sets the destination's d_type to the same value. These values are summarized below.
d_size	This member holds the total size, in bytes, of the memory occupied by the source data and the size allocated for the destination data. If the destination buffer is not large enough, the routines do not change its original contents. The translation routines reset the destination's d_size member to the actual size required, after the translation occurs. The source and destination sizes may differ.
d_version	This member holds the version number of the objects (desired) in the buffer. The source and destination versions are independent.

Translation routines allow the source and destination buffers to coincide. That is, dst \rightarrow d_buf may equal src \rightarrow d_buf. Other cases where the source and destination buffers overlap give undefined behavior.

```
Elf_Type
              32-Bit Memory Type
ELF T ADDR Elf32 Addr
ELF_T_BYTE unsigned char
ELF_T_DYN Elf32_Dyn
ELF_T_EHDR Elf32_Ehdr
ELF_T_HALF Elf32_Half
ELT_T_OFF Elf32_Off
ELF T PHDR Elf32 Phdr
ELF_T_REL Elf32_Rel
ELF_T_RELA Elf32_Rela
ELF_T_SHDR
            Elf32_Shdr
ELF_T_SWORD
            Elf32_Sword
ELF T SYM Elf32 Sym
ELF_T_WORD Elf32_Word
```

Translating buffers of type ELF_T_BYTE does not change the byte order.

For the 64-bit class, replace 32 with 64 as appropriate.

elf(3ELF)

NAME |

elf – object file access library

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
```

DESCRIPTION

Functions in the ELF access library let a program manipulate ELF (Executable and Linking Format) object files, archive files, and archive members. The header provides type and function declarations for all library services.

Programs communicate with many of the higher-level routines using an *ELF descriptor*. That is, when the program starts working with a file, elf_begin(3ELF) creates an ELF descriptor through which the program manipulates the structures and information in the file. These ELF descriptors can be used both to read and to write files. After the program establishes an ELF descriptor for a file, it may then obtain *section descriptors* to manipulate the sections of the file (see elf_getscn(3ELF)). Sections hold the bulk of an object file's real information, such as text, data, the symbol table, and so on. A section descriptor "belongs" to a particular ELF descriptor, just as a section belongs to a file. Finally, *data descriptors* are available through section descriptors, allowing the program to manipulate the information associated with a section. A data descriptor "belongs" to a section descriptor.

Descriptors provide private handles to a file and its pieces. In other words, a data descriptor is associated with one section descriptor, which is associated with one ELF descriptor, which is associated with one file. Although descriptors are private, they give access to data that may be shared. Consider programs that combine input files, using incoming data to create or update another file. Such a program might get data descriptors for an input and an output section. It then could update the output descriptor to reuse the input descriptor's data. That is, the descriptors are distinct, but they could share the associated data bytes. This sharing avoids the space overhead for duplicate buffers and the performance overhead for copying data unnecessarily.

File Classes

ELF provides a framework in which to define a family of object files, supporting multiple processors and architectures. An important distinction among object files is the *class*, or capacity, of the file. The 32-bit class supports architectures in which a 32-bit object can represent addresses, file sizes, and so on, as in the following:

Name	Purpose
Elf32_Addr	Unsigned address
Elf32_Half	Unsigned medium integer
Elf32_Off	Unsigned file offset
Elf32_Sword	Signed large integer
Elf32_Word	Unsigned large integer
unsigned char	Unsigned small integer

The 64-bit class works the same as the 32-bit class, substituting 64 for 32 as necessary. Other classes will be defined as necessary, to support larger (or smaller) machines. Some library services deal only with data objects for a specific class, while others are class-independent. To make this distinction clear, library function names reflect their status, as described below.

Data Representation

Conceptually, two parallel sets of objects support cross compilation environments. One set corresponds to file contents, while the other set corresponds to the native memory image of the program manipulating the file. Type definitions supplied by the headers work on the native machine, which may have different data encodings (size, byte order, and so on) than the target machine. Although native memory objects should be at least as big as the file objects (to avoid information loss), they may be bigger if that is more natural for the host machine.

Translation facilities exist to convert between file and memory representations. Some library routines convert data automatically, while others leave conversion as the program's responsibility. Either way, programs that create object files must write file-typed objects to those files; programs that read object files must take a similar view. See elf32 xlatetof(3ELF) and elf32 fsize(3ELF) for more information.

Programs may translate data explicitly, taking full control over the object file layout and semantics. If the program prefers not to have and exercise complete control, the library provides a higher-level interface that hides many object file details. elf_begin() and related functions let a program deal with the native memory types, converting between memory objects and their file equivalents automatically when reading or writing an object file.

ELF Versions

Object file versions allow ELF to adapt to new requirements. *Three independent versions* can be important to a program. First, an application program knows about a particular version by virtue of being compiled with certain headers. Second, the access library similarly is compiled with header files that control what versions it understands. Third, an ELF object file holds a value identifying its version, determined by the ELF version known by the file's creator. Ideally, all three versions would be the same, but they may differ.

If a program's version is newer than the access library, the program might use information unknown to the library. Translation routines might not work properly, leading to undefined behavior. This condition merits installing a new library.

The library's version might be newer than the program's and the file's. The library understands old versions, thus avoiding compatibility problems in this case.

Finally, a file's version might be newer than either the program or the library understands. The program might or might not be able to process the file properly, depending on whether the file has extra information and whether that information can be safely ignored. Again, the safe alternative is to install a new library that understands the file's version.

elf(3ELF)

To accommodate these differences, a program must use elf_version(3ELF) to pass its version to the library, thus establishing the *working version* for the process. Using this, the library accepts data from and presents data to the program in the proper representations. When the library reads object files, it uses each file's version to interpret the data. When writing files or converting memory types to the file equivalents, the library uses the program's working version for the file data.

System Services

As mentioned above, eff_begin() and related routines provide a higher-level interface to ELF files, performing input and output on behalf of the application program. These routines assume a program can hold entire files in memory, without explicitly using temporary files. When reading a file, the library routines bring the data into memory and perform subsequent operations on the memory copy. Programs that wish to read or write large object files with this model must execute on a machine with a large process virtual address space. If the underlying operating system limits the number of open files, a program can use eff_cntl(3ELF) to retrieve all necessary data from the file, allowing the program to close the file descriptor and reuse it.

Although the elf_begin() interfaces are convenient and efficient for many programs, they might be inappropriate for some. In those cases, an application may invoke the elf32_xlatetom(3ELF) or elf32_xlatetof(3ELF) data translation routines directly. These routines perform no input or output, leaving that as the application's responsibility. By assuming a larger share of the job, an application controls its input and output model.

Library Names

Names associated with the library take several forms.

elf_name	These class-independent names perform some service, <i>name</i> , for the program.
elf32_name	Service names with an embedded class, 32 here, indicate they work only for the designated class of files.
Elf_Type	Data types can be class-independent as well, distinguished by <i>Type</i> .
Elf32_Type	Class-dependent data types have an embedded class name, 32 here.
ELF_C_CMD	Several functions take commands that control their actions. These values are members of the Elf_Cmd enumeration; they range from zero through ELF_C_NUM-1.
ELF_F_FLAG	Several functions take flags that control library status and/or actions. Flags are bits that may be combined.
ELF32_FSZ_TYPE	These constants give the file sizes in bytes of the basic ELF types for the 32-bit class of files. See elf32_fsize() for more information.

ELF_K_ <i>KIND</i>	The function elf_kind() identifies the <i>KIND</i> of file associated with an ELF descriptor. These values are members of the Elf_Kind enumeration; they range from zero through ELF_K_NUM-1.
ELF_T_ <i>TYPE</i>	When a service function, such as elf32_xlatetom() or elf32_xlatetof(), deals with multiple types, names of this form specify the desired <i>TYPE</i> . Thus, for example, ELF_T_EHDR is directly related to Elf32_Ehdr. These values are members of the Elf_Type enumeration; they range from zero through ELF_T_NUM-1.

EXAMPLES

EXAMPLE 1 An interpretation of elf file.

The basic interpretation of an ELF file consists of:

- opening an ELF object file
- obtaining an ELF descriptor
- analyzing the file using the descriptor.

The following example opens the file, obtains the ELF descriptor, and prints out the names of each section in the file.

```
#include
            <fcntl.h>
#include <stdlib.h>
#include <string.h>
static void failure(void);
void
main(int argc, char ** argv)
   Elf32_Shdr * shdr;
Elf32 Ehdr * ehdr;
   Elf * elf;
Elf_Scn * scn;
Elf_Data * data;
   int fd;
   unsigned int
         /* Open the input file */
   if ((fd = open(argv[1], O RDONLY)) == -1)
        exit(1);
        /* Obtain the ELF descriptor */
    (void) elf_version(EV_CURRENT);
    if ((elf = elf_begin(fd, ELF_C_READ, NULL)) == NULL)
       failure();
        /* Obtain the .shstrtab data buffer */
    if (((ehdr = elf32_getehdr(elf)) == NULL) | |
        ((scn = elf_getscn(elf, ehdr->e_shstrndx)) == NULL) | |
        ((data = elf getdata(scn, NULL)) == NULL))
```

EXAMPLE 1 An interpretation of elf file. (*Continued*)

ANSI C Programmer's Guide

SPARC only

a.out(4)

NOTES

Information in the ELF headers is separated into common parts and processor-specific parts. A program can make a processor's information available by including the appropriate header: <sys/elf_NAME</pre>. h> where NAME matches the processor name as used in the ELF file header.

Name	Processor
M32	AT&T WE 32100

Name	Processor
SPARC	SPARC
386	Intel 80386, 80486, Pentium

Other processors will be added to the table as necessary.

To illustrate, a program could use the following code to "see" the processor-specific information for the SPARC based system.

```
#include <libelf.h>
#include <sys/elf_SPARC.h>
```

Without the <sys/elf_SPARC.h> definition, only the common ELF information would be visible.

A program could use the following code to "see" the processor-specific information for the Intel 80386:

```
#include <libelf.h>
#include <sys/elf_386.h>
```

Without the <sys/elf 386.h> definition, only the common ELF information would be visible.

Although reading the objects is rather straightforward, writing/updating them can corrupt the shared offsets among sections. Upon creation, relationships are established among the sections that must be maintained even if the object's size is changed.

elf_begin(3ELF)

NAME

elf_begin, elf_end, elf_memory, elf_next, elf_rand - process ELF object files

SYNOPSIS

```
cc [ flag... ] file ... -lelf [ library ... ]
#include libelf.h>

Elf *elf_begin(int fildes, Elf_Cmd cmd, Elf *ref);
int elf_end(Elf *elf);

Elf *elf_memory(char *image, size_tsz);

Elf_Cmd elf_next(Elf *elf);
size_t elf_rand(Elf *elf, size_t offset);
```

DESCRIPTION

elf_begin(), elf_end(), elf_memory(), elf_next(), and elf_rand() work
together to process Executable and Linking Format (ELF) object files, either
individually or as members of archives. After obtaining an ELF descriptor from
elf_begin() or elf_memory(), the program may read an existing file, update an
existing file, or create a new file. fildes is an open file descriptor that elf_begin()
uses for reading or writing. elf is an ELF descriptor previously returned from
elf_begin(). The initial file offset (see lseek(2)) is unconstrained, and the resulting
file offset is undefined.

cmd may have the following values:

ELF C NULL

When a program sets *cmd* to this value, elf_begin() returns a null pointer, without opening a new descriptor. *ref* is ignored for this command. See the examples below for more information.

ELF C READ

When a program wishes to examine the contents of an existing file, it should set *cmd* to this value. Depending on the value of *ref*, this command examines archive members or entire files. Three cases can occur.

First, if ref is a null pointer, elf_begin() allocates a new ELF descriptor and prepares to process the entire file. If the file being read is an archive, elf_begin() also prepares the resulting descriptor to examine the initial archive member on the next call to elf_begin(), as if the program had used elf_next() or elf_rand() to "move" to the initial member.

Second, if *ref* is a non-null descriptor associated with an archive file, elf_begin() lets a program obtain a separate ELF descriptor associated with an individual member. The program should have used elf_next() or elf_rand() to position *ref* appropriately (except for the initial member, which elf_begin() prepares; see the example below). In this case, *fildes* should be the same file descriptor used for the parent archive.

Finally, if *ref* is a non-null ELF descriptor that is not an archive, elf_begin() increments the number of activations for the

descriptor and returns *ref*, without allocating a new descriptor and without changing the descriptor's read/write permissions. To terminate the descriptor for *ref*, the program must call elf_end() once for each activation. See the examples below for more information.

ELF C RDWR

This command duplicates the actions of ELF_C_READ and additionally allows the program to update the file image (see elf_update(3ELF)). That is, using ELF_C_READ gives a read-only view of the file, while ELF_C_RDWR lets the program read and write the file. ELF_C_RDWR is not valid for archive members. If ref is non-null, it must have been created with the ELF_C_RDWR command.

ELF C WRITE

If the program wishes to ignore previous file contents, presumably to create a new file, it should set *cmd* to this value. *ref* is ignored for this command.

elf_begin() "works" on all files (including files with zero bytes), providing it can allocate memory for its internal structures and read any necessary information from the file. Programs reading object files thus may call elf_kind(3ELF) or elf32_getehdr(3ELF) to determine the file type (only object files have an ELF header). If the file is an archive with no more members to process, or an error occurs, elf_begin() returns a null pointer. Otherwise, the return value is a non-null ELF descriptor.

Before the first call to elf_begin(), a program must call elf_version() to coordinate versions.

elf_end() is used to terminate an ELF descriptor, *elf*, and to deallocate data associated with the descriptor. Until the program terminates a descriptor, the data remain allocated. A null pointer is allowed as an argument, to simplify error handling. If the program wishes to write data associated with the ELF descriptor to the file, it must use elf_update() before calling elf_end().

Calling elf_end() removes one activation and returns the remaining activation count. The library does not terminate the descriptor until the activation count reaches 0. Consequently, a 0 return value indicates the ELF descriptor is no longer valid.

elf_memory() returns a pointer to an ELF descriptor, the ELF image has read operations enabled (ELF_C_READ). *image* is a pointer to an image of the Elf file mapped into memory, *sz* is the size of the ELF image. An ELF image that is mapped in with elf_memory() may be read and modified, but the ELF image size may not be changed.

elf_next() provides sequential access to the next archive member. That is, having
an ELF descriptor, elf, associated with an archive member, elf_next() prepares the
containing archive to access the following member when the program calls
elf begin(). After successfully positioning an archive for the next member,

elf_begin(3ELF)

elf next () returns the value ELF C READ. Otherwise, the open file was not an archive, elf was NULL, or an error occurred, and the return value is ELF C NULL. In either case, the return value may be passed as an argument to elf begin(), specifying the appropriate action.

elf rand() provides random archive processing, preparing elf to access an arbitrary archive member. elf must be a descriptor for the archive itself, not a member within the archive. offset gives the byte offset from the beginning of the archive to the archive header of the desired member. See elf getarsym(3ELF) for more information about archive member offsets. When elf rand() works, it returns offset. Otherwise, it returns 0, because an error occurred, elf was NULL, or the file was not an archive (no archive member can have a zero offset). A program may mix random and sequential archive processing.

System Services

When processing a file, the library decides when to read or write the file, depending on the program's requests. Normally, the library assumes the file descriptor remains usable for the life of the ELF descriptor. If, however, a program must process many files simultaneously and the underlying operating system limits the number of open files, the program can use elf cntl() to let it reuse file descriptors. After calling elf cntl() with appropriate arguments, the program may close the file descriptor without interfering with the library.

All data associated with an ELF descriptor remain allocated until elf end() terminates the descriptor's last activation. After the descriptors have been terminated, the storage is released; attempting to reference such data gives undefined behavior. Consequently, a program that deals with multiple input (or output) files must keep the ELF descriptors active until it finishes with them.

EXAMPLES

EXAMPLE 1 A sample program of calling the elf begin() function.

A prototype for reading a file appears on the next page. If the file is a simple object file, the program executes the loop one time, receiving a null descriptor in the second iteration. In this case, both elf and arf will have the same value, the activation count will be 2, and the program calls elf end() twice to terminate the descriptor. If the file is an archive, the loop processes each archive member in turn, ignoring those that are not object files.

```
if (elf version(EV CURRENT) == EV NONE)
    /* library out of date */
    /* recover from error */
cmd = ELF_C_READ;
arf = elf begin(fildes, cmd, (Elf *)0);
while ((elf = elf begin(fildes, cmd, arf)) != 0)
    if ((ehdr = elf32 getehdr(elf)) != 0)
        /* process the file . . . */
    cmd = elf_next(elf);
```

EXAMPLE 1 A sample program of calling the elf begin () function. (Continued)

```
elf_end(elf);
}
elf_end(arf);
```

Alternatively, the next example illustrates random archive processing. After identifying the file as an archive, the program repeatedly processes archive members of interest. For clarity, this example omits error checking and ignores simple object files. Additionally, this fragment preserves the ELF descriptors for all archive members, because it does not call elf end() to terminate them.

```
elf_version(EV_CURRENT);
arf = elf_begin(fildes, ELF_C_READ, (Elf *)0);
if (elf_kind(arf) != ELF_K_AR)
{
    /* not an archive */
}
/* initial processing */
/* set offset = . . . for desired member header */
while (elf_rand(arf, offset) == offset)
{
    if ((elf = elf_begin(fildes, ELF_C_READ, arf)) == 0)
        break;
    if ((ehdr = elf32_getehdr(elf)) != 0)
    {
        /* process archive member . . . */
    }
    /* set offset = . . . for desired member header */
}
```

An archive starts with a "magic string" that has SARMAG bytes; the initial archive member follows immediately. An application could thus provide the following function to rewind an archive (the function returns –1 for errors and 0 otherwise).

```
#include <ar.h>
#include <libelf.h>
int
rewindelf(Elf *elf)
{
    if (elf_rand(elf, (size_t)SARMAG) == SARMAG)
        return 0;
    return -1;
}
```

The following outline shows how one might create a new ELF file. This example is simplified to show the overall flow.

```
elf_version(EV_CURRENT);
fildes = open("path/name", O_RDWR|O_TRUNC|O_CREAT, 0666);
if ((elf = elf_begin(fildes, ELF_C_WRITE, (Elf *)0)) == 0)
    return;
ehdr = elf32_newehdr(elf);
phdr = elf32_newphdr(elf, count);
scn = elf_newscn(elf);
```

elf_begin(3ELF)

EXAMPLE 1 A sample program of calling the elf begin() function. (Continued)

```
shdr = elf32_getshdr(scn);
data = elf_newdata(scn);
elf_update(elf, ELF_C_WRITE);
elf_end(elf);
```

Finally, the following outline shows how one might update an existing ELF file. Again, this example is simplified to show the overall flow.

Notice that both file creation examples open the file with write *and* read permissions. On systems that support mmap(2), the library uses it to enhance performance, and mmap(2) requires a readable file descriptor. Although the library can use a write-only file descriptor, the application will not obtain the performance advantages of mmap(2).

NAME | elf_cntl – control an elf file descriptor

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
int elf_cntl(Elf *elf, Elf Cmd cmd);
```

DESCRIPTION

elf cntl() instructs the library to modify its behavior with respect to an ELF descriptor, elf. As elf begin(3ELF) describes, an ELF descriptor can have multiple activations, and multiple ELF descriptors may share a single file descriptor. Generally, elf cntl() commands apply to all activations of elf. Moreover, if the ELF descriptor is associated with an archive file, descriptors for members within the archive will also be affected as described below. Unless stated otherwise, operations on archive members do not affect the descriptor for the containing archive.

The *cmd* argument tells what actions to take and may have the following values:

ELF_C FDDONE

This value tells the library not to use the file descriptor associated with elf. A program should use this command when it has requested all the information it cares to use and wishes to avoid the overhead of reading the rest of the file. The memory for all completed operations remains valid, but later file operations, such as the initial elf getdata() for a section, will fail if the data are not in memory already.

ELF C FDREAD

This command is similar to ELF C FDDONE, except it forces the library to read the rest of the file. A program should use this command when it must close the file descriptor but has not yet read everything it needs from the file. After elf cntl() completes the ELF C FDREAD command, future operations, such as elf getdata(), will use the memory version of the file without needing to use the file descriptor.

If elf cntl() succeeds, it returns 0. Otherwise *elf* was NULL or an error occurred, and the function returns -1.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

SEE ALSO

elf(3ELF), elf begin(3ELF), elf getdata(3ELF), elf rawfile(3ELF), libelf(3LIB), attributes(5)

NOTES

If the program wishes to use the "raw" operations (see elf rawdata(), which elf getdata(3ELF) describes, and elf rawfile(3ELF)) after disabling the file

elf_cntl(3ELF)

descriptor with ELF_C_FDDONE or ELF_C_FDREAD, it must execute the raw operations explicitly beforehand. Otherwise, the raw file operations will fail. Calling elf_rawfile() makes the entire image available, thus supporting subsequent elf_rawdata() calls.

NAME | elf_errmsg, elf_errno – error handling

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
const char *elf errmsg(int err);
int elf errno(void);
```

DESCRIPTION

If an ELF library function fails, a program can call elf errno() to retrieve the library's internal error number. As a side effect, this function resets the internal error number to 0, which indicates no error.

The elf errmsq() function takes an error number, err, and returns a null-terminated error message (with no trailing new-line) that describes the problem. A zero err retrieves a message for the most recent error. If no error has occurred, the return value is a null pointer (not a pointer to the null string). Using err of -1 also retrieves the most recent error, except it guarantees a non-null return value, even when no error has occurred. If no message is available for the given number, elf_errmsg() returns a pointer to an appropriate message. This function does not have the side effect of clearing the internal error number.

EXAMPLES

EXAMPLE 1 A sample program of calling the elf errmsq() function.

The following fragment clears the internal error number and checks it later for errors. Unless an error occurs after the first call to elf errno(), the next call will return 0.

```
(void)elf_errno();
/* processing . . . */
while (more to do)
    if ((err = elf errno()) != 0)
        /* print msg */
       msg = elf errmsg(err);
}
```

elf_fill(3ELF)

NAME | elf_fill – set fill byte

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
```

void elf fill(int fill);

DESCRIPTION

Alignment constraints for ELF files sometimes require the presence of "holes." For example, if the data for one section are required to begin on an eight-byte boundary, but the preceding section is too "short," the library must fill the intervening bytes. These bytes are set to the *fill* character. The library uses zero bytes unless the application supplies a value. See elf getdata(3ELF) for more information about these holes.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

SEE ALSO

elf(3ELF), elf flagdata(3ELF), elf getdata(3ELF), elf update(3ELF), libelf(3LIB), attributes(5)

NOTES

An application can assume control of the object file organization by setting the ELF F LAYOUT bit (see elf flagdata(3ELF)). When this is done, the library does not fill holes.

NAME

elf_flagdata, elf_flagehdr, elf_flagelf, elf_flagphdr, elf_flagscn, elf_flagshdr manipulate flags

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
unsigned elf flagdata (Elf Data *data, Elf Cmd cmd, unsigned flags);
unsigned elf flagehdr (Elf *elf, Elf Cmd cmd, unsigned flags);
unsigned elf flagelf(Elf *elf, Elf Cmd cmd, unsigned flags);
unsigned elf flagphdr (Elf *elf, Elf Cmd cmd, unsigned flags);
unsigned elf flagscn(Elf Scn *scn, Elf Cmd cmd, unsigned flags);
unsigned elf flagshdr (Elf Scn *scn, Elf Cmd cmd, unsigned flags);
```

DESCRIPTION

These functions manipulate the flags associated with various structures of an ELF file. Given an ELF descriptor (elf), a data descriptor (data), or a section descriptor (scn), the functions may set or clear the associated status bits, returning the updated bits. A null descriptor is allowed, to simplify error handling; all functions return 0 for this degenerate case.

cmd may have the following values:

ELF_C_CLR	The functions clear the bits that are asserted in <i>flags</i> . Only the non-zero bits in <i>flags</i> are cleared; zero bits do not change the status of the descriptor.
ELF_C_SET	The functions set the bits that are asserted in <i>flags</i> . Only the non-zero bits in <i>flags</i> are set; zero bits do not change the status of the descriptor.

Descriptions of the defined *flags* bits appear below:

ELF_F_DIRTY	When the program intends to write an ELF file, this flag asserts the associated information needs to be written to the file. Thus, for example, a program that wished to update the ELF header of an existing file would call elf_flagehdr() with this bit set in flags and cmd equal to ELF_C_SET. A later call to elf_update() would write the marked header to the file.
ELF_F_LAYOUT	Normally, the library decides how to arrange an output file. That is, it automatically decides where to place sections, how to align them in the file, etc. If this bit is set for an ELF descriptor, the program assumes responsibility for determining all file positions.

When a flag bit is set for an item, it affects all the subitems as well. Thus, for example, if the program sets the ELF F DIRTY bit with elf flagelf(), the entire logical file is "dirty."

entire file associated with the descriptor.

This bit is meaningful only for elf flagelf () and applies to the

elf_flagdata(3ELF)

EXAMPLES

EXAMPLE 1 A sample display of calling the elf_flagdata() function.

The following fragment shows how one might mark the ELF header to be written to the output file:

```
/* dirty ehdr . . . */
ehdr = elf32_getehdr(elf);
elf_flagehdr(elf, ELF_C_SET, ELF_F_DIRTY);
```

 ${\tt elf(3ELF), elf_32_getehdr(3ELF), elf_getdata(3ELF), elf_update(3ELF), attributes(5)}$

NAME | elf_getarhdr – retrieve archive member header

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library... ]
#include <libelf.h>
Elf Arhdr *elf getarhdr(Elf *elf);
```

DESCRIPTION

elf getarhdr() returns a pointer to an archive member header, if one is available for the ELF descriptor elf. Otherwise, no archive member header exists, an error occurred, or elf was null; elf getarhdr() then returns a null value. The header includes the following members.

```
char
        *ar name;
time_t
        ar_date;
        ar_uid;
uid t
gid_t
        ar_gid;
        ar_mode;
mode_t
off t
        ar size;
char
       *ar_rawname;
```

An archive member name, available through ar name, is a null-terminated string, with the ar format control characters removed. The ar_rawname member holds a null-terminated string that represents the original name bytes in the file, including the terminating slash and trailing blanks as specified in the archive format.

In addition to "regular" archive members, the archive format defines some special members. All special member names begin with a slash (/), distinguishing them from regular members (whose names may not contain a slash). These special members have the names (ar name) defined below.

- This is the archive symbol table. If present, it will be the first archive member. A program may access the archive symbol table through elf getarsym(). The information in the symbol table is useful for random archive processing (see elf rand() on elf begin(3ELF)).
- // This member, if present, holds a string table for long archive member names. An archive member's header contains a 16-byte area for the name, which may be exceeded in some file systems. The library automatically retrieves long member names from the string table, setting ar name to the appropriate value.

Under some error conditions, a member's name might not be available. Although this causes the library to set ar name to a null pointer, the ar rawname member will be set as usual.

NAME

elf_getarsym – retrieve archive symbol table

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
Elf Arsym *elf getarsym(Elf *elf, size t *ptr);
```

DESCRIPTION

The elf_getarsym() function returns a pointer to the archive symbol table, if one is available for the ELF descriptor *elf*. Otherwise, the archive doesn't have a symbol table, an error occurred, or *elf* was null; elf_getarsym() then returns a null value. The symbol table is an array of structures that include the following members.

```
char *as_name;
size_t as_off;
unsigned long as_hash;
```

These members have the following semantics:

as name A pointer to a null-terminated symbol name resides here.

as_off This value is a byte offset from the beginning of the archive to the

member's header. The archive member residing at the given offset defines the associated symbol. Values in as_off may be passed as arguments to $elf_rand()$. See $elf_begin(3ELF)$ to access the

desired archive member.

as_hash This is a hash value for the name, as computed by elf_hash().

If ptr is non-null, the library stores the number of table entries in the location to which ptr points. This value is set to 0 when the return value is NULL. The table's last entry, which is included in the count, has a null as_name, a zero value for as_off, and ~OUL for as_hash.

The hash value returned is guaranteed not to be the bit pattern of all ones (~0UL).

elf_getbase(3ELF)

NAME |

elf_getbase – get the base offset for an object file

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
```

off t elf getbase(Elf *elf);

DESCRIPTION

The $elf_getbase()$ function returns the file offset of the first byte of the file or archive member associated with elf, if it is known or obtainable, and -1 otherwise. A null elf is allowed, to simplify error handling; the return value in this case is -1. The base offset of an archive member is the beginning of the member's information, not the beginning of the archive member header.

NAME | elf_getdata, elf_newdata, elf_rawdata - get section data

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
Elf Data *elf getdata(Elf Scn *scn, Elf Data *data);
Elf Data *elf newdata(Elf Scn *scn);
Elf Data *elf rawdata(Elf Scn *scn, Elf Data *data);
```

DESCRIPTION

These functions access and manipulate the data associated with a section descriptor, scn. When reading an existing file, a section will have a single data buffer associated with it. A program may build a new section in pieces, however, composing the new data from multiple data buffers. For this reason, the data for a section should be viewed as a list of buffers, each of which is available through a data descriptor.

The elf_getdata() function lets a program step through a section's data list. If the incoming data descriptor, data, is null, the function returns the first buffer associated with the section. Otherwise, data should be a data descriptor associated with scn, and the function gives the program access to the next data element for the section. If scn is null or an error occurs, elf getdata() returns a null pointer.

The elf getdata() function translates the data from file representations into memory representations (see elf32 xlatetof(3ELF)) and presents objects with memory data types to the program, based on the file's class (see elf(3ELF)). The working library version (see elf version(3ELF)) specifies what version of the memory structures the program wishes elf getdata() to present.

The elf_newdata() function creates a new data descriptor for a section, appending it to any data elements already associated with the section. As described below, the new data descriptor appears empty, indicating the element holds no data. For convenience, the descriptor's type (d type below) is set to ELF T BYTE, and the version (d version below) is set to the working version. The program is responsible for setting (or changing) the descriptor members as needed. This function implicitly sets the ELF F DIRTY bit for the section's data (see elf flagdata(3ELF)). If scn is null or an error occurs, elf newdata() returns a null pointer.

The elf rawdata() function differs from elf getdata() by returning only uninterpreted bytes, regardless of the section type. This function typically should be used only to retrieve a section image from a file being read, and then only when a program must avoid the automatic data translation described below. Moreover, a program may not close or disable (see elf cnt1(3ELF)) the file descriptor associated with elf before the initial raw operation, because elf_rawdata() might read the data from the file to ensure it doesn't interfere with elf getdata(). See elf rawfile(3ELF) for a related facility that applies to the entire file. When elf_getdata() provides the right translation, its use is recommended over elf rawdata(). If scn is null or an error occurs, elf rawdata() returns a null pointer.

elf_getdata(3ELF)

The ${\tt Elf_Data}$ structure includes the following members:

void	*d_buf;
Elf_Type	<pre>d_type;</pre>
size_t	d_size;
off_t	d_off;
size_t	d_align;
unsigned	<pre>d_version;</pre>

These members are available for direct manipulation by the program. Descriptions appear below.

appear below.	
d_buf	A pointer to the data buffer resides here. A data element with no data has a null pointer.
d_type	This member's value specifies the type of the data to which d_buf points. A section's type determines how to interpret the section contents, as summarized below.
d_size	This member holds the total size, in bytes, of the memory occupied by the data. This may differ from the size as represented in the file. The size will be zero if no data exist. (See the discussion of SHT_NOBITS below for more information.)
d_off	This member gives the offset, within the section, at which the buffer resides. This offset is relative to the file's section, not the memory object's.
d_align	This member holds the buffer's required alignment, from the beginning of the section. That is, <code>d_off</code> will be a multiple of this member's value. For example, if this member's value is 4, the beginning of the buffer will be four-byte aligned within the section. Moreover, the entire section will be aligned to the maximum of its constituents, thus ensuring appropriate alignment for a buffer within the section and within the file.
d_version	This member holds the version number of the objects in the buffer. When the library originally read the data from the object file, it used the working version to control the translation to memory objects.

Data Alignment

As mentioned above, data buffers within a section have explicit alignment constraints. Consequently, adjacent buffers sometimes will not abut, causing "holes" within a section. Programs that create output files have two ways of dealing with these holes.

First, the program can use $elf_fill()$ to tell the library how to set the intervening bytes. When the library must generate gaps in the file, it uses the fill byte to initialize the data there. The library's initial fill value is 0, and $elf_fill()$ lets the application change that.

Second, the application can generate its own data buffers to occupy the gaps, filling the gaps with values appropriate for the section being created. A program might even use different fill values for different sections. For example, it could set text sections' bytes to no-operation instructions, while filling data section holes with zero. Using this technique, the library finds no holes to fill, because the application eliminated them.

Section and **Memory Types**

The elf getdata() function interprets sections' data according to the section type, as noted in the section header available through elf32_getshdr(). The following table shows the section types and how the library represents them with memory data types for the 32-bit file class. Other classes would have similar tables. By implication, the memory data types control translation by elf32_xlatetof(3ELF)

Section Type	Elf_Type	32-bit Type

SHT_SUNW_verneed	ELF_T_VNEED	Elf32_Verneed

Section Type	Elf_Type	32-bit Type
SHT_SUNW_versym	ELF_T_HALF	Elf32_Versym
other	ELF_T_BYTE	unsigned char

The elf rawdata() function creates a buffer with type ELF T BYTE.

As mentioned above, the program's working version controls what structures the library creates for the application. The library similarly interprets section types according to the versions. If a section type belongs to a version newer than the application's working version, the library does not translate the section data. Because the application cannot know the data format in this case, the library presents an untranslated buffer of type <code>ELF_T_BYTE</code>, just as it would for an unrecognized section type.

A section with a special type, SHT_NOBITS, occupies no space in an object file, even when the section header indicates a non-zero size. elf_getdata() and elf_rawdata() work on such a section, setting the *data* structure to have a null buffer pointer and the type indicated above. Although no data are present, the d_size value is set to the size from the section header. When a program is creating a new section of type SHT_NOBITS, it should use elf_newdata() to add data buffers to the section. These empty data buffers should have the d_size members set to the desired size and the d_buf members set to NULL.

EXAMPLES

EXAMPLE 1 A sample program of calling elf_getdata().

The following fragment obtains the string table that holds section names (ignoring error checking). See elf strptr(3ELF) for a variation of string table handling.

```
ehdr = elf32_getehdr(elf);
scn = elf_getscn(elf, (size_t)ehdr->e_shstrndx);
shdr = elf32_getshdr(scn);
if (shdr->sh_type != SHT_STRTAB)
{
   /* not a string table */
}
data = 0;
if ((data = elf_getdata(scn, data)) == 0 || data->d_size == 0)
{
   /* error or no data */
}
```

The e_shstrndx member in an ELF header holds the section table index of the string table. The program gets a section descriptor for that section, verifies it is a string table, and then retrieves the data. When this fragment finishes, data->d_buf points at the first byte of the string table, and data->d size holds the string table's size in bytes.

elf_getident(3ELF)

NAME |

elf_getident - retrieve file identification data

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ] #include <libelf.h>
```

char *elf_getident(Elf *elf, size_t *ptr);

DESCRIPTION

As elf(3ELF) explains, ELF provides a framework for various classes of files, where basic objects may have 32 bits, 64 bits, etc. To accommodate these differences, without forcing the larger sizes on smaller machines, the initial bytes in an ELF file hold identification information common to all file classes. Every ELF header's e_ident has EI_NIDENT bytes with the following interpretation:

e_ident Index	Value	Purpose
EI_MAG0	ELFMAG0	File identification
EI_MAG1	ELFMAG1	
EI_MAG2	ELFMAG2	
EI_MAG3	ELFMAG3	
EI_CLASS	ELFCLASSNONE	File class
	ELFCLASS32	
	ELFCLASS64	
EI_DATA	ELFDATANONE	Data encoding
	ELFDATA2LSB	
	ELFDATA2MSB	
EI_VERSION	EV_CURRENT	File version
7-15	0	Unused, set to zero

Other kinds of files (see $elf_kind(3ELF)$) also may have identification data, though they would not conform to e ident.

elf_getident() returns a pointer to the file's "initial bytes." If the library
recognizes the file, a conversion from the file image to the memory image may occur.
In any case, the identification bytes are guaranteed not to have been modified, though

elf_getident(3ELF)

the size of the unmodified area depends on the file type. If ptr is non-null, the library stores the number of identification bytes in the location to which ptr points. If no data are present, *elf* is null, or an error occurs, the return value is a null pointer, with 0 stored through *ptr*, if *ptr* is non-null.

elf getscn(3ELF)

NAME |

elf getscn, elf ndxscn, elf newscn, elf nextscn – get section information

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
Elf Scn *elf getscn(Elf *elf, size t index);
size t elf ndxscn(Elf Scn *scn);
Elf Scn *elf newscn(Elf *elf);
Elf Scn *elf nextscn(Elf *elf, Elf Scn *scn);
```

DESCRIPTION

These functions provide indexed and sequential access to the sections associated with the ELF descriptor elf. If the program is building a new file, it is responsible for creating the file's ELF header before creating sections; see elf32 getehdr(3ELF).

The elf getscn() function returns a section descriptor, given an index into the file's section header table. Note that the first "real" section has an index of 1. Although a program can get a section descriptor for the section whose index is 0 (SHN UNDEF, the undefined section), the section has no data and the section header is "empty" (though present). If the specified section does not exist, an error occurs, or elf is NULL, elf getscn() returns a null pointer.

The elf newscn() function creates a new section and appends it to the list for *elf*. Because the SHN UNDEF section is required and not "interesting" to applications, the library creates it automatically. Thus the first call to elf newscn() for an ELF descriptor with no existing sections returns a descriptor for section 1. If an error occurs or elf is NULL, elf newscn() returns a null pointer.

After creating a new section descriptor, the program can use elf32_getshdr() to retrieve the newly created, "clean" section header. The new section descriptor will have no associated data (see elf getdata(3ELF)). When creating a new section in this way, the library updates the e shnum member of the ELF header and sets the ELF F DIRTY bit for the section (see elf flagdata(3ELF)). If the program is building a new file, it is responsible for creating the file's ELF header (see elf32 getehdr(3ELF)) before creating new sections.

The elf nextscn() function takes an existing section descriptor, scn, and returns a section descriptor for the next higher section. One may use a null scn to obtain a section descriptor for the section whose index is 1 (skipping the section whose index is SHN UNDEF). If no further sections are present or an error occurs, elf nextscn() returns a null pointer.

The elf ndxscn() function takes an existing section descriptor, scn, and returns its section table index. If scn is null or an error occurs, elf ndxscn() returns SHN UNDEF.

EXAMPLES

EXAMPLE 1 A sample of calling elf_getscn() function.

An example of sequential access appears below. Each pass through the loop processes the next section in the file; the loop terminates when all sections have been processed.

```
while ((scn = elf_nextscn(elf, scn)) != 0)
    /* process section */
```

elf_hash(3ELF)

NAME | elf_hash – compute hash value

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
```

unsigned long elf hash (const char *name);

DESCRIPTION

The elf hash() function computes a hash value, given a null terminated string, *name*. The returned hash value, h, can be used as a bucket index, typically after computing $h \mod x$ to ensure appropriate bounds.

Hash tables may be built on one machine and used on another because elf hash() uses unsigned arithmetic to avoid possible differences in various machines' signed arithmetic. Although *name* is shown as char* above, elf hash() treats it as unsigned char* to avoid sign extension differences. Using char* eliminates type conflicts with expressions such as elf hash (name).

ELF files' symbol hash tables are computed using this function (see elf getdata(3ELF) and elf32 xlatetof(3ELF)). The hash value returned is guaranteed not to be the bit pattern of all ones (~0UL).

NAME | elf_kind – determine file type

SYNOPSIS

```
cc [ flag \dots ] file \dots -lelf [ library \dots ]
#include <libelf.h>
```

Elf_Kind elf_kind(Elf *elf);

DESCRIPTION

This function returns a value identifying the kind of file associated with an ELF descriptor (elf). Defined values are below:

ELF_K_AR	The file is an archive [see ar(3HEAD)]. An ELF descriptor may also be associated with an archive <i>member</i> , not the archive itself, and then elf_kind() identifies the member's type.
ELF_K_COFF	The file is a COFF object file. elf_begin(3ELF) describes the library's handling for COFF files.
ELF_K_ELF	The file is an ELF file. The program may use elf_getident() to determine the class. Other functions, such as elf32_getehdr(), are available to retrieve other file information.

ELF K NONE This indicates a kind of file unknown to the library.

Other values are reserved, to be assigned as needed to new kinds of files. elf should be a value previously returned by elf_begin(). A null pointer is allowed, to simplify error handling, and causes elf kind() to return ELF K NONE.

elf rawfile(3ELF)

NAME |

elf_rawfile – retrieve uninterpreted file contents

SYNOPSIS

```
cc [ flag... ] file ... -lelf [ library ... ]
#include libelf.h>
```

```
char *elf rawfile(Elf *elf, size t *ptr);
```

DESCRIPTION

The elf_rawfile() function returns a pointer to an uninterpreted byte image of the file. This function should be used only to retrieve a file being read. For example, a program might use elf_rawfile() to retrieve the bytes for an archive member.

A program may not close or disable (see elf_cntl(3ELF)) the file descriptor associated with <code>elf</code> before the initial call to elf_rawfile(), because elf_rawfile() might have to read the data from the file if it does not already have the original bytes in memory. Generally, this function is more efficient for unknown file types than for object files. The library implicitly translates object files in memory, while it leaves unknown files unmodified. Thus, asking for the uninterpreted image of an object file may create a duplicate copy in memory.

elf_rawdata() is a related function, providing access to sections within a file. See elf_getdata(3ELF).

If *ptr* is non-null, the library also stores the file's size, in bytes, in the location to which *ptr* points. If no data are present, *elf* is null, or an error occurs, the return value is a null pointer, with 0 stored through *ptr*, if *ptr* is non-null.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

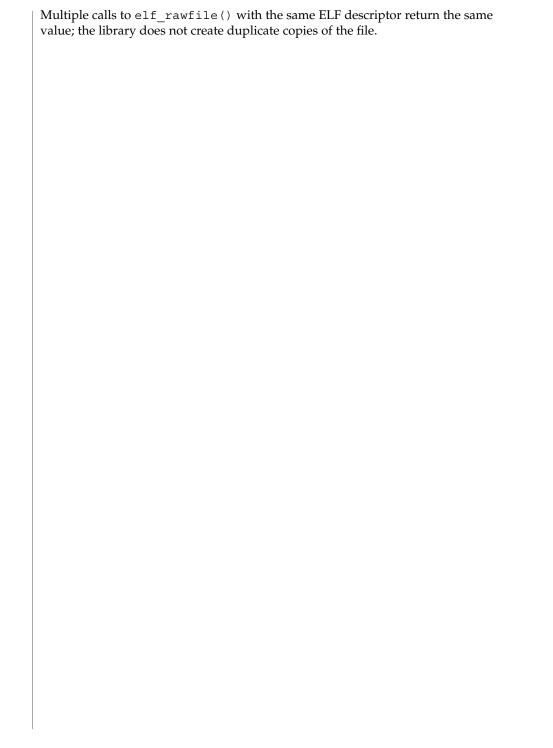

SEE ALSO

elf(3ELF), elf32_getehdr(3ELF), elf_begin(3ELF), elf_cntl(3ELF),
elf_getdata(3ELF), elf_getident(3ELF), elf_kind(3ELF), libelf(3LIB),
attributes(5)

NOTES

A program that uses elf_rawfile() and that also interprets the same file as an object file potentially has two copies of the bytes in memory. If such a program requests the raw image first, before it asks for translated information (through such functions as elf32_getehdr(), elf_getdata(), and so on), the library "freezes" its original memory copy for the raw image. It then uses this frozen copy as the source for creating translated objects, without reading the file again. Consequently, the application should view the raw file image returned by elf_rawfile() as a read-only buffer, unless it wants to alter its own view of data subsequently translated. In any case, the application may alter the translated objects without changing bytes visible in the raw image.

elf_rawfile(3ELF)

elf_strptr(3ELF)

NAME

elf_strptr - make a string pointer

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
char *elf strptr(Elf *elf, size t section, size t offset);
```

DESCRIPTION

The elf_strptr() function converts a string section *offset* to a string pointer. *elf* identifies the file in which the string section resides, and *section* identifies the section table index for the strings. elf_strptr() normally returns a pointer to a string, but it returns a null pointer when *elf* is null, *section* is invalid or is not a section of type SHT_STRTAB, the section data cannot be obtained, *offset* is invalid, or an error occurs.

EXAMPLES

EXAMPLE 1 A sample program of calling elf_strptr() function.

A prototype for retrieving section names appears below. The file header specifies the section name string table in the e_shstrndx member. The following code loops through the sections, printing their names.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

SEE ALSO

elf(3ELF), elf32_getshdr(3ELF), elf32_xlatetof(3ELF), elf_getdata(3ELF),
libelf(3LIB), attributes(5)

NOTES

A program may call elf_getdata() to retrieve an entire string table section. For some applications, that would be both more efficient and more convenient than using elf strptr().

NAME | elf_update – update an ELF descriptor

SYNOPSIS

```
cc [ \mathit{flag} ... ] \mathit{file} ... -lelf [ \mathit{library} ... ]
#include <libelf.h>
```

off t **elf update**(Elf *elf, Elf Cmd cmd);

DESCRIPTION

The elf update () function causes the library to examine the information associated with an ELF descriptor, elf, and to recalculate the structural data needed to generate the file's image.

The *cmd* argument can have the following values:

ELF C NULL

This value tells elf update() to recalculate various values, updating only the ELF descriptor's memory structures. Any modified structures are flagged with the ELF F DIRTY bit. A program thus can update the structural information and then reexamine them without changing the file associated with the ELF descriptor. Because this does not change the file, the ELF descriptor may allow reading, writing, or both reading and writing (see elf begin (3ELF)).

ELF C WRITE

If cmd has this value, elf update () duplicates its ELF C NULL actions and also writes any "dirty" information associated with the ELF descriptor to the file. That is, when a program has used elf getdata(3ELF) or the elf flagdata(3ELF) facilities to supply new (or update existing) information for an ELF descriptor, those data will be examined, coordinated, translated if necessary (see elf32 xlatetof(3ELF)), and written to the file. When portions of the file are written, any ELF F DIRTY bits are reset, indicating those items no longer need to be written to the file (see elf flagdata(3ELF)). The sections' data are written in the order of their section header entries, and the section header table is written to the end of the file. When the ELF descriptor was created with elf begin(), it must have allowed writing the file. That is, the elf begin() command must have been either ELF C RDWR or ELF C WRITE.

If elf update () succeeds, it returns the total size of the file image (not the memory image), in bytes. Otherwise an error occurred, and the function returns −1.

When updating the internal structures, elf update() sets some members itself. Members listed below are the application's responsibility and retain the values given by the program.

The following table shows ELF Header members:

The following table shows the Data Descriptor members:

Member	Notes
d_buf	
d_type	
d_size	
d_off	Only when ELF_F_LAYOUT asserted
d_align	
d_version	

Note that the program is responsible for two particularly important members (among others) in the ELF header. The e_version member controls the version of data structures written to the file. If the version is EV_NONE, the library uses its own internal version. The e_ident [EI_DATA] entry controls the data encoding used in the file. As a special case, the value may be ELFDATANONE to request the native data encoding for the host machine. An error occurs in this case if the native encoding doesn't match a file encoding known by the library.

Further note that the program is responsible for the sh_entsize section header member. Although the library sets it for sections with known types, it cannot reliably know the correct value for all sections. Consequently, the library relies on the program to provide the values for unknown section types. If the entry size is unknown or not applicable, the value should be set to 0.

When deciding how to build the output file, elf_update() obeys the alignments of individual data buffers to create output sections. A section's most strictly aligned data buffer controls the section's alignment. The library also inserts padding between buffers, as necessary, to ensure the proper alignment of each buffer.

elf_update(3ELF)

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

SEE ALSO

elf(3ELF), elf32_fsize(3ELF), elf32_getehdr(3ELF), elf32_getshdr(3ELF), elf32 xlatetof(3ELF), elf begin(3ELF), elf flagdata(3ELF), elf_getdata(3ELF), libelf(3LIB), attributes(5)

NOTES

As mentioned above, the ELF C WRITE command translates data as necessary, before writing them to the file. This translation is *not* always transparent to the application program. If a program has obtained pointers to data associated with a file (for example, see elf32_getehdr(3ELF) and elf_getdata(3ELF)), the program should reestablish the pointers after calling elf_update().

NAME | elf version – coordinate ELF library and application versions

SYNOPSIS

```
cc [ flag ... ] file ... -lelf [ library ... ]
#include <libelf.h>
unsigned elf version (unsigned ver);
```

DESCRIPTION

As elf(3ELF) explains, the program, the library, and an object file have independent notions of the latest ELF version. elf version() lets a program query the ELF library's internal version. It further lets the program specify what memory types it uses by giving its own working version, ver, to the library. Every program that uses the ELF library must coordinate versions as described below.

The header <libelf.h> supplies the version to the program with the macro EV CURRENT. If the library's internal version (the highest version known to the library) is lower than that known by the program itself, the library may lack semantic knowledge assumed by the program. Accordingly, elf version() will not accept a working version unknown to the library.

Passing ver equal to EV NONE causes elf version() to return the library's internal version, without altering the working version. If ver is a version known to the library, elf version() returns the previous (or initial) working version number. Otherwise, the working version remains unchanged and elf version() returns EV NONE.

EXAMPLES

EXAMPLE 1 A sample display of using the elf version() function.

The following excerpt from an application program protects itself from using an older library:

```
if (elf version(EV CURRENT) == EV NONE) {
   /* library out of date */
    /* recover from error */
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

SEE ALSO

elf(3ELF), elf32 xlatetof(3ELF), elf begin(3ELF), libelf(3LIB), attributes(5)

NOTES

The working version should be the same for all operations on a particular ELF descriptor. Changing the version between operations on a descriptor will probably not give the expected results.

erf(3M)

NAME | erf, erfc – error and complementary error functions

SYNOPSIS

cc [
$$flag$$
 ...] $file$... -lm [$library$...] #include

double erf(double x);

double erfc(double x);

DESCRIPTION

The erf () function computes the error function of x, defined as:

$$\frac{2}{\sqrt{\pi}}\int\limits_{0}^{x}e^{-t^{2}}dt$$

The erfc() function computes 1.0 - erf(x).

RETURN VALUES

Upon successful completion, erf() and erfc() return the value of the error function and complementary error function, respectively.

If *x* is NaN, NaN is returned.

ERRORS

No errors will occur.

USAGE

The erfc() function is provided because of the extreme loss of relative accuracy if erf(x) is called for large x and the result subtracted from 1.0.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

isnan(3M), attributes(5)

NAME | exp – exponential function

SYNOPSIS

```
\texttt{cc} [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double exp(double x);

DESCRIPTION

The exp () function computes the exponential of x, defined as e^x .

RETURN VALUES

Upon successful completion, exp() returns the exponential of x.

If the correct value would cause overflow, exp() returns HUGE VAL and sets errno to ERANGE.

If the correct value would cause underflow to zero, $\exp()$ returns 0 and may set errno to ERANGE.

If x is NaN, NaN is returned.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The exp() function will fail if:

ERANGE The result overflows.

The exp() function may fail if:

ERANGE The result underflows.

USAGE

An application wishing to check for error situations should set errno to 0 before calling exp(). If errno is non-zero on return, or the return value is NaN an error has occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

isnan(3M), log(3M), matherr(3M), mp(3MP), attributes(5), standards(5)

NOTES

Prior to Solaris 2.6, there was a conflict between the pow function in this library and the pow function in the libmp library. This conflict was resolved by prepending mp to all functions in the libmp library. See mp(3MP) for details.

expm1(3M)

NAME | expm1 – computes exponential functions

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double expm1 (double x);

DESCRIPTION

The expm1 () function computes e^x –1.0.

RETURN VALUES

If *x* is NaN, then the function returns NaN.

If x is positive infinity, expm1 () returns positive infinity.

If x is negative infinity, expm1 () returns -1.0.

If the value overflows, expm1() returns HUGE VAL.

ERRORS

No errors will occur.

USAGE

The value of expm1 (x) may be more accurate than exp (x) –1.0 for small values of x.

The expm1 () and log1p(3M) functions are useful for financial calculations of $((1+x)^n-1)/x$, namely:

```
expml(n * loglp(x)) / x
```

when *x* is very small (for example, when performing calculations with a small daily interest rate). These functions also simplify writing accurate inverse hyperbolic functions.

ATTRIBUTES

floor(3M)

NAME | floor – floor function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
```

#include <math.h>

double **floor** (double x);

DESCRIPTION

The floor () function computes the largest integral value not greater than x.

RETURN VALUES

Upon successful completion, floor() returns the largest integral value not greater than x, expressed as a double.

If *x* is NaN, NaN is returned.

If x is $\pm Inf$ or ± 0 , x is returned.

ERRORS

No errors will occur.

USAGE

The integral value returned by floor () as a double might not be expressible as an int or long int. The return value should be tested before assigning it to an integer type to avoid the undefined results of an integer overflow.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NAME | fmod – floating-point remainder value function

SYNOPSIS

```
\texttt{cc} [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double fmod(double x, double y);

DESCRIPTION

The fmod () function returns the floating-point remainder of the division of x by y.

RETURN VALUES

The fmod () function returns the value x - i * y, for some integer i such that, if y is non-zero, the result has the same sign as *x* and magnitude less than the magnitude of

If x or y is NaN, NaN is returned. If y is 0, NaN is returned and errno is set to EDOM. If x is \pm Inf, NaN is returned. If y is non-zero, \pm mod (\pm 0, y) returns the value of x. If x is not $\pm Inf$, fmod $(x, \pm Inf)$ returns the value of x.

ERRORS

The fmod() function may fail if:

EDOM

y is 0.

No other errors will occur.

USAGE

Portable applications should not call fmod() with y equal to 0, because the result is implementation-dependent. The application should verify y is non-zero before calling fmod().

An application wishing to check for error situations should set errno to 0 before calling fmod(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

DESCRIPTION

GE1f is a generic, ELF class-independent API, for manipulating ELF object files. GE1f provides a single, common interface for handling 32-bit and 64-bit ELF format object files. GElf is a translation layer between the application and the class-dependent parts of the ELF library. Thus, the application can use GElf, which in turn, will call the corresponding elf32 or elf64 functions on behalf of the application. The data structures returned are all large enough to hold 32-bit and 64-bit data.

GE1f provides a simple, class-independent layer of indirection over the class-dependent ELF32 and ELF64 APIs. GElf is stateless, and may be used along side the ELF32 and ELF64 API's.

GElf always returns a copy of the underlying ELF32 or ELF64 structure, and therefore the programming practice of using the address of an ELF header as the base offset for the ELF's mapping into memory should be avoided. Also, data accessed by type-casting the Elf_Data buffer to a class-dependent type and treating it like an array, for example, a symbol table, will not work under GElf, and the gelf get functions must be used instead. See the EXAMPLE section.

Programs which create or modify ELF files using libelf(3LIB) need to perform an extra step when using GElf. Modifications to GElf values must be explicitly flushed to the underlying ELF32 or ELF64 structures by way of the gelf update interfaces. Use of elf update or elf flagelf and the like remains the same.

The sizes of versioning structures remains the same between ELF32 and ELF64. The GElf API only defines types for versioning, rather than a functional API. The processing of versioning information will stay the same in the GElf environment as it was in the class-dependent ELF environment.

List of Functions

gelf_checksum()	An analog to elf32_checksum(3ELF) and elf64_checksum(3ELF).
gelf_getclass()	Returns one of the constants ELFCLASS32, ELFCLASS64 or ELFCLASSNONE.
gelf_fsize()	An analog to elf32_fsize(3ELF) and elf64_fsize(3ELF).
gelf_getehdr()	An analog to elf32_getehdr(3ELF) and elf64_getehdr(3ELF). dst points to the location where the GElf_Ehdr header will be stored.
gelf_update_ehdr()	Copies the contents of the GElf_Ehdr ELF header to the underlying Elf32_Ehdr or Elf64_Ehdr structure.
gelf_newehdr()	An analog to elf32_newehdr(3ELF) and elf64_newehdr(3ELF).

gelf(3ELF)

An analog toelf32_getphdr(3ELF) and elf64_getphdr(3ELF). dst points to the location where the GEIf_Phdr program header will be stored. Gelf_update_phdr()		9 . ,
to underlying the Elf32_Phdr or Elf64_Phdr structure. gelf_newphdr() An analog to elf32_newphdr(3ELF) and elf64_newphdr(3ELF) and elf64_newphdr(3ELF). dst points to the location where the GElf_Shdr section header will be stored. gelf_update_shdr() Copies of the contents of GElf_Shdr section header to underlying the Elf32_Shdr or Elf64_Shdr structure. gelf_xlatetof() An analog to elf32_xlatetof(3ELF) and elf64_xlatetof(3ELF) gelf_xlatetom() An analog to elf32_xlatetom(3ELF) and elf64_xlatetom(3ELF) gelf_getsym() Retrieves the Elf32_Sym or Elf64_Sym information from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Sym structure at the given index. gelf_getdyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at the given index.	gelf_getphdr()	elf64_getphdr(3ELF). dst points to the location
elf64_newphdr(3ELF). gelf_getshdr() An analog to elf32_getshdr(3ELF) and elf64_getshdr(3ELF). dst points to the location where the GElf_Shdr section header will be stored. Gelf_update_shdr() Copies of the contents of GElf_Shdr section header to underlying the Elf32_Shdr or Elf64_Shdr structure. gelf_xlatetof() An analog to elf32_xlatetof(3ELF) and elf64_xlatetof(3ELF) gelf_xlatetom() An analog to elf32_xlatetom(3ELF) and elf64_xlatetom(3ELF) gelf_getsym() Retrieves the Elf32_Sym or Elf64_Sym information from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Copies the Gelf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Plyn structure at the given index. gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information the location where the GElf_Rela relocation where the GElf_Rela relocation where the GElf_Rela relocation where the GElf_Rela structure at underlying Elf32_Rela or Elf64_Rela structure at underlying Elf32_Rela or	gelf_update_phdr()	to underlying the Elf32_Phdr or Elf64_Phdr
elf64_getshdr(3ELF). dst points to the location where the GElf_Shdr section header will be stored. Gelf_update_shdr() Copies of the contents of GElf_Shdr section header to underlying the Elf32_Shdr or Elf64_Shdr structure. Gelf_xlatetof() An analog to elf32_xlatetof(3ELF) and elf64_xlatetom(3ELF) Gelf_xlatetom() An analog to elf32_xlatetom(3ELF) and elf64_xlatetom(3ELF) Gelf_getsym() Retrieves the Elf32_Sym or Elf64_Sym information from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. Gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Sym structure at the given index. Gelf_getdyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. Gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. Gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. Gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information table at the given index. Gelf_Rela relocation entry will be stored. Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at the given index.	gelf_newphdr()	
underlying the Elf32_Shdr or Elf64_Shdr structure. gelf_xlatetof() An analog to elf32_xlatetof(3ELF) and elf64_xlatetom(3ELF) gelf_xlatetom() An analog to elf32_xlatetom(3ELF) and elf64_xlatetom(3ELF) gelf_getsym() Retrieves the Elf32_Sym or Elf64_Sym information from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. gelf_getrela() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Rela information from the relocation table at the given index. gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information where the GElf_Rela relocation entry will be stored. Gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at the given index.	gelf_getshdr()	elf64_getshdr(3ELF). dst points to the location
elf64_xlatetof(3ELF) gelf_xlatetom() An analog to elf32_xlatetom(3ELF) and elf64_xlatetom(3ELF) gelf_getsym() Retrieves the Elf32_Sym or Elf64_Sym information from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Sym structure at the given index. gelf_getdyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela information entry will be stored. gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at the	gelf_update_shdr()	underlying the Elf32_Shdr or Elf64_Shdr
elf64_xlatetom(3ELF) Retrieves the Elf32_Sym or Elf64_Sym information from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. Gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Sym structure at the given index. gelf_getdyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. Gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. Gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela relocation entry will be stored. Gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at underlying Elf32_Rela or Elf64_Rela structure at underlying Elf32_Rela or Elf64_Rela structure at	gelf_xlatetof()	
from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be stored. Gelf_update_sym() Copies the GElf_Sym information back into the underlying Elf32_Sym or Elf64_Sym structure at the given index. Gelf_getdyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. Gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. Gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela relocation entry will be stored. Gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at	gelf_xlatetom()	
underlying Elf32_Sym or Elf64_Sym structure at the given index. gelf_getdyn() Retrieves the Elf32_Dyn or Elf64_Dyn information from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela relocation entry will be stored. gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at	gelf_getsym()	from the symbol table at the given index. dst points to the location where the GElf_Sym symbol entry will be
from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry will be stored. gelf_update_dyn() Copies the GElf_Dyn information back into the underlying Elf32_Dyn or Elf64_Dyn structure at the given index. gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela relocation entry will be stored. gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at	<pre>gelf_update_sym()</pre>	underlying Elf32_Sym or Elf64_Sym structure at the
underlying Elf32_Dyn or Elf64_Dyn structure at the given index. gelf_getrela() Retrieves the Elf32_Rela or Elf64_Rela information from the relocation table at the given index. dst points to the location where the GElf_Rela relocation entry will be stored. gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at	gelf_getdyn()	from the dynamic table at the given index. dst points to the location where the GElf_Dyn dynamic entry
information from the relocation table at the given index. dst points to the location where the GElf_Rela relocation entry will be stored. Gelf_update_rela() Copies the GElf_Rela information back into the underlying Elf32_Rela or Elf64_Rela structure at	gelf_update_dyn()	underlying Elf32_Dyn or Elf64_Dyn structure at the
underlying Elf32_Rela or Elf64_Rela structure at	gelf_getrela()	information from the relocation table at the given index. dst points to the location where the
	gelf_update_rela()	underlying Elf32_Rela or Elf64_Rela structure at

gelf(3ELF)

```
qelf qetrel()
                            Retrieves the Elf32 Rel or Elf64 Rel information
                            from the relocation table at the given index. dst points
                            to the location where the GElf Rel relocation entry
                            will be stored.
gelf update rel()
                            Copies the GElf Rel information back into the
                            underlying Elf32 Rel or Elf64 Rel structure at the
                            given index.
qelf qetsyminfo()
                            Retrieves the Elf32 Syminfo or Elf64 Syminfo
                            information from the relocation table at the given
                            index. dst points to the location where the
                            GElf Syminfo symbol information entry will be
                            stored.
gelf update syminfo()
                            Copies the GElf Syminfo information back into the
                            underlying Elf32_Syminfo or Elf64_Syminfo
                            structure at the given index.
gelf getmove()
                            Retrieves the Elf32 Move or Elf64 Move
                            information from the move table at the given index.
                            dst points to the location where the GElf Move move
                            entry will be stored.
gelf update move()
                            Copies the GElf Move information back into the
                            underlying Elf32 Move or Elf64 Move structure at
                            the given index.
```

RETURN VALUES

Upon failure, all GElf functions return 0 and set elf errno. See elf errno(3ELF)

EXAMPLES

EXAMPLE 1 Printing the ELF Symbol Table

```
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <libelf.h>
#include <gelf.h>
void
main(int argc, char **argv)
                *elf;
    Elf
              *scn = NULL;
   Elf Scn
    GElf Shdr shdr;
   Elf_Data *data;
int fd, ii, count;
    elf version(EV CURRENT);
    fd = open(argv[1], O RDONLY);
    elf = elf_begin(fd, ELF_C_READ, NULL);
    while ((scn = elf nextscn(elf, scn)) != NULL) {
```

EXAMPLE 1 Printing the ELF Symbol Table (Continued)

```
gelf_getshdr(scn, &shdr);
   if (shdr.sh_type == SHT_SYMTAB) {
        /* found a symbol table, go print it. */
        break;
   }
}

data = elf_getdata(scn, NULL);
count = shdr.sh_size / shdr.sh_entsize;

/* print the symbol names */
for (ii = 0; ii < count; ++ii) {
    GElf_Sym sym;
    gelf_getsym(data, ii, &sym);
    printf("%s\n", elf_strptr(elf, shdr.sh_link, sym.st_name));
}
elf_end(elf);
close(fd);
}</pre>
```

getacinfo(3BSM)

NAME

getacinfo, getacdir, getacflg, getacmin, getacna, setac, endac – get audit control file information

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket -lnsl -lintl [ library ... ]
#include <bsm/libbsm.h>

int getacdir( char *dir, int len);
int getacmin( int *min_val);
int getacflg( char *auditstring, int len);
int getacna( char *auditstring, int len);
void setac( void);
```

DESCRIPTION

When first called, <code>getacdir()</code> provides information about the first audit directory in the <code>audit_control</code> file; thereafter, it returns the next directory in the file. Successive calls list all the directories listed in <code>audit_control(4)</code> The parameter <code>len</code> specifies the length of the buffer <code>dir</code>. On return, <code>dir</code> points to the directory entry.

getacmin() reads the minimum value from the audit_control file and returns the value in min_val. The minimum value specifies how full the file system to which the audit files are being written can get before the script audit warn(1M) is invoked.

getacflg() reads the system audit value from the audit_control file and returns
the value in auditstring. The parameter len specifies the length of the buffer auditstring.

getacna() reads the system audit value for non-attributable audit events from the audit_control file and returns the value in *auditstring*. The parameter *len* specifies the length of the buffer *auditstring*. Non-attributable events are events that cannot be attributed to an individual user. inetd(1M) and several other daemons record non-attributable events.

Calling *setac* rewinds the audit_control file to allow repeated searches.

Calling *endac* closes the audit control file when processing is complete.

FILES

```
\begin{tabular}{ll} \beg
```

RETURN VALUES

- −1 on EOF.
- if the directory search had to start from the beginning because one of the other functions was called between calls to getacdir().

These functions return:

-3 if the directory entry format in the audit_control file is incorrect.

getacdir(), getacflg() and getacna() return:

-3 if the input buffer is too short to accommodate the record.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe.

SEE ALSO

 $audit_warn(1M)$, bsmconv(1M), inetd(1M), $audit_control(4)$, attributes(5)

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

getauclassent(3BSM)

NAME |

getauclassent, getauclassnam, setauclass, endauclass, getauclassnam_r, getauclassent_r – get audit_class entry

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket -lnsl -lintl [ library ... ]
#include <sys/param.h>
#include <bsm/libbsm.h>

struct au_class_ent *getauclassnam( const char *name);

struct au_class_ent *getauclassnam_r( au_class_ent_t *class_int, const char *name);

struct au_class_ent *getauclassent( void);

struct au_class_ent *getauclassent_r( au_class_ent_t *class_int);

void setauclass( void);

void endauclass( void);
```

DESCRIPTION

getauclassent() and getauclassnam() each return an audit_class entry.

getauclassnam() searches for an audit_class entry with a given class name name.

getauclassent() enumerates audit_class entries: successive calls to getauclassent() will return either successive audit_class entries or NULL.

setauclass() "rewinds" to the beginning of the enumeration of audit_class entries. Calls to getauclassnam() may leave the enumeration in an indeterminate state, so setauclass() should be called before the first getauclassent().

endauclass () may be called to indicate that audit_class processing is complete; the system may then close any open audit_class file, deallocate storage, and so forth.

getauclassent_r() and getauclassnam_r() both return a pointer to an audit_class entry as do their similarly named counterparts. They each take an additional argument, a pointer to pre-allocated space for an au_class_ent_t, which is returned if the call is successful. To assure there is enough space for the information returned, the applications programmer should be sure to allocate

AU_CLASS_NAME_MAX and AU_CLASS_DESC_MAX bytes for the ac_name and ac_desc elements of the au_class_ent_t data structure.

The internal representation of an audit_user entry is an au_class_ent structure defined in <bsm/libbsm.h> with the following members:

```
char *ac_name;
au_class_t ac_class;
char *ac_desc;
```

RETURN VALUES

 $\label{lem:getauclassnam} \begin{subarray}{l} \tt getauclassnam_r() \ return \ a \ pointer \ to \ a \ struct \\ \tt au_class_ent \ if \ they \ successfully \ locate \ the \ requested \ entry; \ otherwise \ they \ return \ NULL. \\ \end{subarray}$

 $\label{eq:getauclassent} getauclassent_r() \ \ return\ a\ pointer\ to\ a\ struct$ $au_class_ent\ if\ they\ successfully\ enumerate\ an\ entry;\ otherwise\ they\ return\ NULL,$ indicating the end of the enumeration.

FILES

/etc/security/audit_class Maps audit class numbers to audit class names

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions.

All of the functions described in this man-page are MT-Safe except getauclassent() and getauclassnam. The two functions, getauclassent_r() and getauclassnam_r() have the same functionality as the unsafe functions, but have a slightly different function call interface in order to make them MT-Safe.

SEE ALSO

NOTES

All information is contained in a static area, so it must be copied if it is to be saved.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

getauditflags(3BSM)

NAME |

getauditflags, getauditflagsbin, getauditflagschar – convert audit flag specifications

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket
                                        -lnsl
                                                 -lintl [ library ... ]
#include <sys/param.h>
#include <bsm/libbsm.h>
int getauditflagsbin(char *auditstring, au mask t *masks);
int getauditflagschar (char *auditstring, au mask t *masks, int
    verbose);
```

DESCRIPTION

getauditflagsbin() converts the character representation of audit values pointed to by auditstring into au mask t fields pointed to by masks. These fields indicate which events are to be audited when they succeed and which are to be audited when they fail. The character string syntax is described in audit control(4).

getauditflagschar() converts the au mask t fields pointed to by masks into a string pointed to by auditstring. If verbose is zero, the short (2-character) flag names are used. If verbose is non-zero, the long flag names are used. auditstring should be large enough to contain the ASCII representation of the events.

auditstring contains a series of event names, each one identifying a single audit class, separated by commas. The au mask t fields pointed to by masks correspond to binary values defined in <bsm/audit.h>, which is read by <bsm/libbsm.h>.

RETURN VALUES

qetauditflaqsbin() and getauditflaqschar():-1 is returned on error and 0 on success.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe.

SEE ALSO

bsmconv(1M), audit.log(4), audit control(4), attributes(5)

BUGS

This is not a very extensible interface.

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

NAME

getauevent, getauevnam, getauevnum, getauevnonam, setauevent, endauevent, getauevent_r, getauevnam_r, getauevnum_r - get audit_event entry

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket
                                   -lnsl -lintl [ library ... ]
#include <sys/param.h>
#include <bsm/libbsm.h>
struct au_event_ent *getauevent(void);
struct au event ent *getauevnam(char *name);
struct au event ent *getauevnum(au event t event_number);
au event t *getauevnonam(char *event_name);
void setauevent(void);
void endauevent(void);
struct au event ent *getauevent r(au event ent t *e);
struct au event ent *getauevnam r(au event ent t *e, char *name);
struct au event ent *getauevnum r(au event ent t *e, au event t
    event_number);
```

DESCRIPTION

These interfaces document the programming interface for obtaining entries from the audit event(4) file.getauevent(),getauevnam(),getauevnum(), getauevent(), getauevnam(), and getauevnum() each return a pointer to an audit event structure.

getauevent () and getauevent r() enumerate audit event entries; successive calls to these functions will return either successive audit event entries or NULL.

getauevnam() and getauevnam r() search for an audit event entry with a given event_name.

getauevnum() and getauevnum r() search for an audit event entry with a given *event_number*.

getauevnonam() searches for an audit_event entry with a given event_name and returns the corresponding event number.

setauevent () "rewinds" to the beginning of the enumeration of audit event entries. Calls to getauevnam(), getauevnum(), getauevnonum(), getauevnam r(), or getauevnum r() may leave the enumeration in an indeterminate state; setauevent () should be called before the first getauevent () or getauevent r().

endauevent () may be called to indicate that audit event processing is complete; the system may then close any open audit event file, deallocate storage, and so forth.

getauevent(3BSM)

The three functions getauevent r(), getauevnam r(), and getauevnum r()each take an argument e which is a pointer to an au event ent t. This pointer is returned on a successful function call. To assure there is enough space for the information returned, the applications programmer should be sure to allocate AU EVENT NAME MAX and AU EVENT DESC MAX bytes for the ae name and ac desc elements of the au event ent t data structure.

The internal representation of an audit event entry is an struct au event ent structure defined in <bsm/libbsm.h> with the following members:

```
ae number
au event t
char
               *ae_name;
               *ae_desc*;
char
              ae_class;
au_class_t
```

RETURN VALUES

getauevent(), getauevnam(), getauevnum(), getauevent r(), getauevnam r(), and getauevnum r() return a pointer to a struct au event ent if the requested entry is successfully located; otherwise it returns NULL.

getauevnonam() returns an event number of type au event t if it successfully enumerates an entry; otherwise it returns NULL, indicating it could not find the requested event name.

FILES

/etc/security/audit event Maps audit event numbers to audit event

names.

/etc/passwd Stores user-ID to username mappings.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions.

The functions getauevent(), getauevnam(), and getauevnum() are not MT-Safe; however, there are equivalent functions: getauevent r(), getauevnam r(), and getauevnum r() — all of which provide the same functionality and a MT-Safe function call interface.

SEE ALSO

bsmconv(1M), getauclassent(3BSM), getpwnam(3C), audit class(4), audit event(4), passwd(4), attributes(5)

NOTES

All information for the functions getauevent(), getauevnam(), and getauevnum() is contained in a static area, so it must be copied if it is to be saved.

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

NAME |

getauthattr, getauthnam, free_authattr, setauthattr, endauthattr, chkauthattr - get authorization entry

SYNOPSIS

```
cc [ flag... ] file... -lsecdb -lsocket -lnsl -lintl [ library... ]
#include <auth attr.h>
#include <secdb.h>
authattr t *getauthattr(void);
authattr t *getauthnam(const char *name);
void free authattr (authattr t *auth);
void setauthattr(void);
void endauthattr(void);
int chkauthattr(const char *authname, const char *username);
```

DESCRIPTION

The getauthattr() and getauthnam() functions each return an auth attr(4) entry. Entries can come from any of the sources specified in the nsswitch.conf(4) file.

The getauthattr() function enumerates auth_attr entries. The getauthnam() function searches for an auth attrentry with a given authorization name *name*. Successive calls to these functions return either successive auth attr entries or NULL.

Th internal representation of an auth_attr entry is an authattr_t structure defined in <auth attr.h> with the following members:

```
/* name of the authorization */
char name:
                    /* reserved for future use */
char res1;
char res2;  /* reserved for future use */
char short_desc; /* short description */
char long desc; /* long description */
kva t *attr;
                     /* array of key-value pair attributes */
```

The setauthattr() function "rewinds" to the beginning of the enumeration of auth attr entries. Calls to getauthnam() can leave the enumeration in an indeterminate state. Therefore, setauthattr() should be called before the first call to getauthattr().

The endauthattr() function may be called to indicate that auth attr processing is complete; the system may then close any open auth attr file, deallocate storage, and so forth.

The chkauthattr() function verifies whether or not a user has a given authorization. It first reads the AUTHS GRANTED key in the /etc/security/policy.conf file and returns 1 if it finds a match for the given authorization. If chkauthattr () does not find a match, it reads the PROFS GRANTED key in /etc/security/policy.conf and returns 1 if the given authorization is in any profiles specified with the PROFS GRANTED keyword. If a

getauthattr(3SECDB)

match is not found from the default authorizations and default profiles, chkauthattr() reads the user_attr(4) database. If it does not find a match in user_attr, it reads the prof_attr(4) database, using the list of profiles assigned to the user, and checks if any of the profiles assigned to the user has the given authorization. The chkauthattr() function returns 0 if it does not find a match in any of the three sources.

A user is considered to have been assigned an authorization if either of the following are true:

- The authorization name matches exactly any authorization assigned in the user attrorprof attr databases (authorization names are case-sensitive).
- The authorization name suffix is not the key word grant and the authorization name matches any authorization up to the asterisk (*) character assigned in the user attrorprof attr databases.

The examples in the following table illustrate the conditions under which a user is assigned an authorization.

	/etc/security/policy.conf or	Is user
Authorization name	user_attr or prof_attr entry	authorized?
com.sun.printer.postscript	com.sun.printer.postscript	Yes
com.sun.printer.postscript	com.sun.printer.*	Yes
com.sun.printer.grant	com.sun.printer.*	No

The free_authattr() function releases memory allocated by the getauthnam() and getauthattr() functions.

RETURN VALUES

The getauthattr() function returns a pointer to an authattr_t if it successfully enumerates an entry; otherwise it returns NULL, indicating the end of the enumeration.

The getauthnam() function returns a pointer to an authattr_t if it successfully locates the requested entry; otherwise it returns NULL.

The chkauthattr() function returns 1 if the user is authorized and 0 otherwise.

USAGE

The getauthattr() and getauthnam() functions both allocate memory for the pointers they return. This memory should be de-allocated with the free authattr() call.

Applications that use the interfaces described in this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time. Note that these interfaces are reentrant even though they do not use the _r suffix naming convention.

Individual attributes in the \mathtt{attr} structure can be referred to by calling the \mathtt{kva} match(3SECDB) function.

WARNINGS

Because the list of legal keys is likely to expand, code must be written to ignore unknown key-value pairs without error.

getauusernam(3BSM)

NAME | getauusernam, getauuserent, setauuser, endauuser – get audit user entry

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm -lsocket
                                     -lnsl -lintl [ library ... ]
#include <sys/param.h>
#include <bsm/libbsm.h>
struct au user ent *getauusernam(const char *name);
struct au user ent *getauuserent(void);
void setauuser(void);
void endauuser(void);
struct au user ent *getauusernam r(au user ent t * u, const char
    *name);
struct au user ent *getauuserent r(au user ent t *u);
```

DESCRIPTION

The getauuserent (), getauusernam (), getauuserent r(), and getauusernam r() functions each return an audit user entry. Entries can come from any of the sources specified in the /etc/nsswitch.conf file (see nsswitch.conf(4)).

The getauusernam() and getauusernam r() functions search for an audit user entry with a given login name name.

The getauuserent () and getauuserent r() functions enumerate audit user entries; successive calls to these functions will return either successive audit user entries or NULL.

The setauuser () function "rewinds" to the beginning of the enumeration of audit user entries. Calls to getauusernam() and getauusernam r() may leave the enumeration in an indeterminate state, so setauuser () should be called before the first call to getauuserent () or getauuserent r().

The endauuser () function may be called to indicate that audit user processing is complete; the system may then close any open audit user file, deallocate storage, and so forth.

The getauuserent r() and getauusernam r() functions both take an argument *u*, which is a pointer to an au user ent. This is the pointer that is returned on successful function calls.

The internal representation of an audit user entry is an au user ent structure defined in <bsm/libbsm.h> with the following members:

```
*au_name;
char
au_mask_t au_always;
au_mask_t au_never;
```

RETURN VALUES

The getauusernam() function returns a pointer to a struct au user ent if it successfully locates the requested entry; otherwise it returns NULL.

The getauuserent () function returns a pointer to a struct au user ent if it successfully enumerates an entry; otherwise it returns NULL, indicating the end of the enumeration.

USAGE

The functionality described in this manual page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

FILES

/etc/security/audit user stores per-user audit event mask

/etc/passwd stores user-id to username mappings

/etc/security/audit user stores per-user audit event mask

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions.

SEE ALSO

NOTES

All information for the getauuserent () and getauusernam() functions is contained in a static area, so it must be copied if it is to be saved.

The getauusernam() and getauuserent() functions are not MT-safe. The getauusernam r() and getauuserent r() functions provide the same functionality with interfaces that are MT-Safe.

getddent(3BSM)

NAME |

getddent, getddnam, setddent, endddent, setddfile - get device deallocate entry

SYNOPSIS

```
#include <bsm/devices.h>
devdealloc t *getddent(void);
devdealloc t *getddnam(char *name);
void setddent(void);
void endddent(void);
void setddfile(char *file);
```

cc [flag...] file... -lbsm [library...]

DESCRIPTION

The getddent() and getddnam() functions each return a device deallocate entry. The getddent () function enumerates all device deallocate entries. Successive calls to this function return either successive device_deallocate entries or NULL. The getddnam() function searches for a device deallocate entry with a given device name.

The internal representation of a device_deallocate entry is a devdealloc_t structure defined in <bsm/devices.h> with the following members:

```
char *dd_devname; /* device allocation name */
char *dd boot; /* deallocation action on system boot */
```

The setddent () function "rewinds" to the beginning of the enumeration of device deallocate entries. Calls to getddnam() may leave the enumeration in an indeterminate state, so setddent () should be called before the first call to getddent().

The endddent() function can be called to indicate that device deallocate processing is complete. The library can then close any opendevice deallocate file, deallocate any internal storage, and so forth.

The setddfile() function changes the pathname used by the other functions for opening the device deallocate file, allowing use of device deallocate files other than the default file, /etc/security/device deallocate.

RETURN VALUES

The getddent () function returns a pointer to a devdealloc t if it successfully enumerates an entry. Otherwise it returns NULL, indicating the end of the enumeration.

The getddnam() function returns a pointer to a devdealloc t if it successfully locates the requested entry. Otherwise it returns NULL.

FILES

/etc/security/device deallocate Administrative file defining parameters for device deallocation.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

free(3C), attributes(5)

NOTES

The ${\tt getddent}$ () and ${\tt getddnam}$ () functions allocate memory for the pointers they return. This memory can be deallocated with the free(3C) function.

getdmapent(3BSM)

NAME

getdmapent, getdmapnam, getdmaptype, getdmaptdev, setdmapent, enddmapent, setdmapfile – get device_maps entry

SYNOPSIS

```
cc [flag...] file... -lbsm [library...]
#include <bsm/devices.h>
devmap_t *getdmapent(void);
devmap_t *getdmapnam(char *name);
devmap_t *getdmapdev(char *name);
devmap_t *getdmaptype(char *type);
void setdmapent(void);
void enddmapent(void);
```

DESCRIPTION

The getdmapent(), getdmapnam(), getdmapdev(), and getdmaptype() functions each return a device_deallocate entry. The getdmapent() function enumerates all device_maps entries. The getdmaptype() function enumerates device_maps entries with a given device type. Successive calls to these functions return either successive device_maps entries or NULL. The getdmapnam() function searches for a device_maps entry with a given device allocation name. The getdmapdev() function searches for a device_maps entry containing a given device special file.

The internal representation of a device_maps entry is a devmap_t structure defined in <bsm/devices.h> with the following members:

The setdmapent() function "rewinds" to the beginning of the enumeration of device_maps entries. Calls to getdmapnam() may leave the enumeration in an indeterminate state, so setdmapent() should be called before the first call to getdmapent() or getdmaptype().

The enddmapent () function can be called to indicate that device_maps processing is complete. The library can then close any open device_maps file, deallocate any internal storage, and so forth.

The setdmapfile() function changes the pathname used by the other functions for opening the device_maps file, allowing use of device_maps files other than the default file, /etc/security/device maps.

RETURN VALUES

The getdmapent () and getdmaptype () functions return a pointer to a devmap_t if they successfully enumerate an entry. Otherwise they return NULL, indicating the end of the enumeration.

getdmapent(3BSM)

The getdmapnam() function returns a pointer to a devmap_t if it successfully locates the requested entry. Otherwise it returns NULL.

FILES

/etc/security/device maps

Administrative file defining the mapping of device special files to allocatable device names.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

allocate(1), free(3C), device_maps(4), attributes(5)

NOTES

The getdmapent (), getdmapnam(), getdmapdev(), and getdmaptype() functions allocate memory for the pointers they return. This memory can be deallocated with the free(3C) function.

getexecattr(3SECDB)

NAME |

getexecattr, free execattr, setexecattr, endexecattr, getexecuser, getexecprof, match_execattr - get execution profile entry

SYNOPSIS

```
cc [ flag... ] file... -lsecdb -lsocket -lnsl -lintl [ library... ]
#include <exec_attr.h>
#include <secdb.h>
execattr t *getexecattr(void);
void free execattr (execattr t *ep);
void setexecattr(void);
void endexecattr(void);
execattr t *getexecuser(const char *username, const char *type,
    const char *id, int search_flag);
execattr t *getexecprof(const char *profname, const char *type,
    const char *id, int search_flag);
execattr t *match execattr (execattr t *ep, char *profname, char
    *type, char *id);
```

DESCRIPTION

The getexecattr() function returns a single exec attr entry. Entries can come from any of the sources specified in the nsswitch.conf(4) file.

Successive calls to getexecattr() return either successive exec attr entries or NULL. Because getexecattr() always returns a single entry, the next pointer in the execattr t data structure points to NULL.

The internal representation of an exec attr entry is an execattr t structure defined in <exec attr.h> with the following members:

```
/* name of the profile */
                    type; /* type of profile */
char
                    policy; /* policy under which the attributes are */
char
                               /* relevant*/
                   res1; /* reserved for future use */
res2; /* reserved for future use */
id; /* unique identifier */
char
char
char
                   attr; /* attributes */
kva t
struct execattr s next; /* optional pointer to next profile */
```

The free execattr () function releases memory. It follows the next pointers in the execattr t structure so that the entire linked list is released.

The setexecattr () function "rewinds" to the beginning of the enumeration of exec attr entries. Calls to getexecuser() can leave the enumeration in an indeterminate state. Therefore, setexecattr() should be called before the first call to getexecattr().

The endexecattr() function can be called to indicate that exec_attr processing is complete; the library can then close any open exec_attr file, deallocate any internal storage, and so forth.

The <code>getexecuser()</code> function returns a linked list of entries filtered by the function's arguments. Only entries assigned to the specified <code>username</code>, as described in the <code>passwd(4)</code> database, and containing the specified <code>type</code> and <code>id</code>, as described in the <code>exec_attr(4)</code> database, are placed in the list. The <code>getexecuser()</code> function is different from the other functions in its family because it spans two databases. It first looks up the list of profiles assigned to a user in the <code>user_attr</code> database and the list of default profiles in <code>/etc/security/policy.conf</code>, then looks up each profile in the <code>exec_attr</code> database.

The <code>getexecprof()</code> function returns a linked list of entries that have components matching the function's arguments. Only entries in the database matching the argument <code>profname</code>, as described in <code>exec_attr</code>, and containing the <code>type</code> and <code>id</code>, also described in <code>exec_attr</code>, are placed in the list.

Using getexecuser() and getexecprof(), programmers can search for any type argument, such as the manifest constant KV_COMMAND. The arguments are logically AND-ed together so that only entries exactly matching all of the arguments are returned. Wildcard matching applies if there is no exact match for an ID. Any argument can be assigned the NULL value to indicate that it is not used as part of the matching criteria. The search_flag controls whether the function returns the first match (GET_ONE), setting the next pointer to NULL or all matching entries (GET_ALL), using the next pointer to create a linked list of all entries that meet the search criteria. See EXAMPLES.

Once a list of entries is returned by <code>getexecuser()</code> or <code>getexecprof()</code>, the convenience function <code>match_execattr()</code> can be used to identify an individual entry. It returns a pointer to the individual element with the same profile name (<code>profname</code>), type name (<code>type</code>), and <code>id</code>. Function parameters set to <code>NULL</code> are not used as part of the matching criteria. In the event that multiple entries meet the matching criteria, only a pointer to the first entry is returned. The <code>kva_match(3SECDB)</code> function can be used to look up a key in a key-value array.

RETURN VALUES

Those functions returning data only return data related to the active policy. The getexecattr() function returns a pointer to a execattr_t if it successfully enumerates an entry; otherwise it returns NULL, indicating the end of the enumeration.

USAGE

The getexecattr(), getexecuser(), and getexecprof() functions all allocate memory for the pointers they return. This memory should be deallocated with the free_execattr() call. The match_execattr()(function does not allocate any memory. Therefore, pointers returned by this function should not be deallocated.

Applications that use the interfaces described in this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and

getexecattr(3SECDB)

linking of shared objects at run time. Note that these interfaces are reentrant even though they do not use the r suffix naming convention.

Individual attributes may be referenced in the attr structure by calling the kva match(3SECDB) function.

EXAMPLES

EXAMPLE 1 The following finds all profiles that have the ping command.

EXAMPLE 2 The following finds the entry for the ping command in the Network Administration Profile.

EXAMPLE 3 The following tells everything that can be done in the Filesystem Security profile.

EXAMPLE 4 The following tells if the tar command is in a profile assigned to user wetmore. If there is no exact profile entry, the wildcard (*), if defined, is returned.

getfauditflags(3BSM)

NAME |

getfauditflags – generates the process audit state

au mask t *lastmasks);

SYNOPSIS

```
cc [ flag ... ] file ... -lbsm    -lsocket    -lnsl    -lintl [ library ... ]
#include <sys/param.h>
#include <bsm/libbsm.h>
int getfauditflags(au mask t *usremasks, au mask t *usrdmasks,
```

DESCRIPTION

getfauditflags() generates a process audit state by combining the audit masks passed as parameters with the system audit masks specified in the audit_control(4) file.getfauditflags() obtains the system audit value by calling getacflg() (see getacinfo(3BSM)).

usremasks points to au_mask_t fields which contains two values. The first value defines which events are *always* to be audited when they succeed. The second value defines which events are always to be audited when they fail.

usrdmasks also points to au_mask_t fields which contains two values. The first value defines which events are *never* to be audited when they succeed. The second value defines which events are never to be audited when they fail.

The structures pointed to by *usremasks* and *usrdmasks* may be obtained from the audit_user(4) file by calling getauusernam() which returns a pointer to a structure containing all audit_user(4) fields for a user.

The output of this function is stored in *lastmasks* which is a pointer of type au_mask_t as well. The first value defines which events are to be audited when they succeed and the second defines which events are to be audited when they fail.

Both usremasks and usrdmasks override the values in the system audit values.

RETURN VALUES

−1 is returned on error and 0 on success.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NOTES

The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

NAME

getprofattr, getprofnam, free_profattr, setprofattr, endprofattr, getproflist, free_proflist – get profile description and attributes

SYNOPSIS

```
cc [ flag... ] file... -lsecdb -lsocket -lnsl -lintl [ library... ]
#include <prof.h>
profattr_t *getprofattr(void);
profattr_t *getprofnam(const char *name);
void free_profattr(profattr_t *pd);
void setprofattr(void);
void endprofattr(void);
void getproflist(const char *profname, char **proflist, int *profcnt);
void free_proflist(char **proflist, int profcnt);
```

DESCRIPTION

The getprofattr() and getprofnam() functions each return a prof_attr entry. Entries can come from any of the sources specified in the nsswitch.conf(4) file.

The <code>getprofattr()</code> function enumerates <code>prof_attr</code> entries. The <code>getprofnam()</code> function searches for a <code>prof_attr</code> entry with a given <code>name</code>. Successive calls to these functions return either successive <code>prof_attr</code> entries or <code>NULL</code>.

The internal representation of a prof_attr entry is a profattr_t structure defined in <prof attr.h> with the following members:

```
char name; /* Name of the profile */
char res1; /* Reserved for future use */
char res2; /* Reserved for future use */
char desc; /* Description/Purpose of the profile */
kva t attr; /* Profile attributes */
```

The free_profattr() function releases memory allocated by the getprofattr() and getprofnam() functions.

The setprofattr() function "rewinds" to the beginning of the enumeration of prof_attr entries. Calls to getprofnam() can leave the enumeration in an indeterminate state. Therefore, setprofattr() should be called before the first call to getprofattr().

The endprofattr() function may be called to indicate that prof_attr processing is complete; the system may then close any open prof_attr file, deallocate storage, and so forth.

The <code>getproflist()</code> function searches for the list of sub-profiles found in the given <code>profname</code> and allocates memory to store this list in <code>proflist</code>. The given <code>profname</code> will be included in the list of sub-profiles. The <code>profcnt</code> argument indicates the number of items currently valid in <code>proflist</code>. Memory allocated by <code>getproflist()</code> should be freed using the <code>free_proflist()</code> function.

getprofattr(3SECDB)

The free_proflist() function frees memory allocated by the getproflist() function. The *profcnt* argument specifies the number of items to free from the *proflist* argument.

RETURN VALUES

The getprofattr() function returns a pointer to a profattr_t if it successfully enumerates an entry; otherwise it returns NULL, indicating the end of the enumeration.

The getprofnam() function returns a pointer to a profattr_t if it successfully locates the requested entry; otherwise it returns NULL.

USAGE

Individual attributes in the prof_attr_t structure can be referred to by calling the kva match(3SECDB) function.

Because the list of legal keys is likely to expand, any code must be written to ignore unknown key-value pairs without error.

The <code>getprofattr()</code> and <code>getprofnam()</code> functions both allocate memory for the pointers they return. This memory should be deallocated with the <code>free_profattr()</code> function.

Applications that use the interfaces described in this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time. Note that these interfaces are reentrant even though they do not use the _r suffix naming convention.

NAME |

getprojent, getprojbyname, getprojbyid, getdefaultproj, inproj, getprojidbyname, setprojent, endprojent, fgetprojent – project database entry functions

SYNOPSIS

```
cc [ flag... ] file... -lproject [ library... ]
#include oject.h>
struct project *getprojent(struct project *proj, void *buffer, size t
    bufsize);
struct project *getprojbyname(const char *name, struct project
    *proj, void *buffer, size t bufsize);
struct project *getprojbyid(projid t projid, struct project *proj,
    void *buffer, size t bufsize);
struct project *qetdefaultproj(const char *username, struct
    project *proj, void *buffer, size t bufsize);
int inproj (const char *username, const char *projname, void *buffer,
    size t bufsize);
projid t getprojidbyname(const char *name);
void setprojent(void);
void endprojent(void);
struct project *fgetprojent(FILE *f, struct project *proj, void
    *buffer, size t bufsize);
```

DESCRIPTION

These functions are used to obtain entries describing user projects. Entries can come from any of the sources for a project specified in the /etc/nsswitch.conf file (see nsswitch.conf(4)).

The setprojent (), getprojent (), and endprojent () functions are used to enumerate project entries from the database.

The setprojent () function effectively rewinds the project database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of project entries. This function should be called before the first call to getprojent().

The getprojent () function returns a pointer to a structure containing the broken-out fields of an entry in the project database. When first called, getprojent() returns a pointer to a project structure containing the first project structure in the project database. Successive calls can be used to read the entire database.

The endprojent () function closes the project database and deallocates resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more project functions after calling endprojent ().

The getprojbyname () function searches the project database for an entry with the project name specified by the character string name.

getprojent(3PROJECT)

The <code>getprojbyid()</code> function searches the project database for an entry with the (numeric) project ID specified by *projid*.

The <code>getdefaultproj()</code> function first looks up the project key word in the <code>user_attr</code> database used to define user attributes in restricted Solaris environments. If the database is available and the keyword is present, the function looks up the named project, returning <code>NULL</code> if it cannot be found or if the user is not a member of the named project. If absent, the function looks for a match in the project database for the special project <code>user.username</code>. If no match is found, the function looks at the default group entry of the <code>passwd</code> database for the user, and looks for a match in the project database for the special name <code>group.groupname</code>, where <code>groupname</code> is the default group associated with the password entry corresponding to the given <code>username</code>. If no match is found, the function returns <code>NULL</code>. A special project entry called 'default' can be looked up and used as a last resort. By convention, machines with no entry for default do not allow access to non-root users without a default project. On successful lookup, this function returns a pointer to the valid <code>project</code> structure.

The inproj () function checks if the user specified by *username* is able to use the project specified by *projname*. This function returns 1 if the user belongs to the list of project's users, if there is a project's group that contains the specified user, or if project is a user's default project; otherwise it returns 0.

The getprojidbyname() function searches the project database for an entry with the project name specified by the character string name. This function returns the project ID if the requested entry is found; otherwise it returns -1.

The fgetprojent () function, unlike the other functions described above, does not use nsswitch.conf; it reads and parses the next line from the stream f, which is assumed to have the format of the project(4) file. This function returns the same values as getprojent().

The <code>getprojent()</code>, <code>getprojbyname()</code>, <code>getprojbyid()</code>, <code>getdefaultproj()</code>, and <code>inproj()</code> functions are reentrant interfaces for operations with the <code>project</code> database. These functions use buffers supplied by the caller to store returned results and are safe for use in both single-threaded and multithreaded applications.

Reentrant interfaces require the additional arguments *proj*, *buffer*, and *bufsize*. The *proj* argument must be a pointer to a struct project structure allocated by the caller. On successful completion, the function returns the project entry in this structure. Storage referenced by the project structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* bytes in size.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The setprojent() function can be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to getprojent(), the threads will enumerate disjoint subsets of the project database. The inproj(),

getprojbyname(), getprojbyid(), and getdefaultproj() functions leave the enumeration position in an indeterminate state.

RETURN VALUES

Project entries are represented by the struct project structure defined in <project.h>.

The getprojbyname() and getprojbyid() functions each return a pointer to a struct project if they successfully locate the requested entry; otherwise they return NULL.

The getprojent () function returns a pointer to a struct project if it successfully enumerates an entry; otherwise it returns NULL, indicating the end of the enumeration.

The getprojidbyname() function returns the project ID if the requsted entry is found; otherwise it returns -1 and sets errno to indicate the error.

When the pointer returned by the reentrant functions <code>getprojbyname()</code>, <code>getprojbyid()</code>, and <code>getprojent()</code> is non-null, it is always equal to the *proj* pointer that was supplied by the caller.

Upon failure, NULL is returned and errno is set to indicate the error.

ERRORS

The getprojent(), getprojbyname(), getprojbyid(), inproj(), getprojidbyname(), fgetprojent(), and getdefaultproj() functions will fail if:

EINTR	A signal was caught during the operation.
EIO	An I/O error has occurred.
EMFILE	There are ${\tt OPEN_MAX}$ file descriptors currently open in the calling process.
ENFILE	The maximum allowable number of files is currently open in the system.
ERANGE	Insufficient storage was supplied by buffer and bufsize to contain

USAGE

When compiling multithreaded applications, see intro(3), Notes On Multithreaded Applications.

the data to be referenced by the resulting project structure.

getprojent(3PROJECT)

Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at runtime.

Use of the enumeration interface getprojent () is discouraged. Enumeration is supported for the project file, NIS, and LDAP but in general is not efficient. The semantics of enumeration are discussed further in nsswitch.conf(4).

NAME |

getuserattr, getusernam, getuseruid, free userattr, setuserattr, enduserattr – get user_attr entry

SYNOPSIS

```
cc [ flag... ] file...- lsecdb - lsocket - lnsl - lintl [ library... ]
#include <user attr.h>
userattr t *getuserattr(void);
userattr t *getusernam(const char *name);
userattr t *getuseruid(uid t uid);
void free userattr (userattr t *userattr);
void setuserattr(void);
void enduserattr(void);
```

DESCRIPTION

The getuserattr(), getusernam(), and getuseruid() functions each return a user attr(4) entry. Entries can come from any of the sources specified in the nsswitch.conf(4) file. The getuserattr() function enumerates user attr entries. The getusernam() function searches for a user attrentry with a given user name name. The getuseruid() function searches for a user attrentry with a given user id uid. Successive calls to these functions return either successive user attrentries or NULL.

The free userattr() function releases memory allocated by the getusernam() and getuserattr() functions.

The internal representation of a user attrentry is a userattr t structure defined in <user attr.h> with the following members:

```
char
      name;
             /* name of the user */
char qualifier; /* reserved for future use */
char res1; /* reserved for future use */
char res2; /* reserved for future use */
kva t attr; /* list of attributes */
```

The setuserattr() function "rewinds" to the beginning of the enumeration of user attrentries. Calls to getusernam() may leave the enumeration in an indeterminate state, so setuserattr() should be called before the first call to getuserattr().

The enduserattr() function may be called to indicate that user attr processing is complete; the library may then close any open user attr file, deallocate any internal storage, and so forth.

RETURN VALUES

The getuserattr() function returns a pointer to a userattr t if it successfully enumerates an entry; otherwise it returns NULL, indicating the end of the enumeration.

The getusernam() function returns a pointer to a userattr tif it successfully locates the requested entry; otherwise it returns NULL.

getuserattr(3SECDB)

USAGE |

The <code>getuserattr()</code> and <code>getusernam()</code> functions both allocate memory for the pointers they return. This memory should be deallocated with the <code>free_userattr()</code> function.

Applications that use the interfaces described in this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time. Note that these interfaces are reentrant even though they do not use the <code>r</code> suffix naming convention.

Individual attributes may be referenced in the attr structure by calling the kva match(3SECDB) function.

WARININGS

Because the list of legal keys is likely to expand, code must be written to ignore unknown key-value pairs without error.

NAME

gmatch - shell global pattern matching

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
```

int gmatch(const char *str, const char *pattern);

DESCRIPTION

gmatch() checks whether the null-terminated string str matches the null-terminated pattern string pattern. See the sh(1), section File Name Generation, for a discussion of pattern matching. A backslash (\) is used as an escape character in pattern strings.

RETURN VALUES

 ${\tt gmatch}\,()$ returns non-zero if the pattern matches the string, zero if the pattern does not.

EXAMPLES

EXAMPLE 1 Examples of gmatch () function.

In the following example, gmatch() returns non-zero (true) for all strings with "a" or "-" as their last character.

```
char *s;
gmatch (s, "*[a\-]" )
```

ATTRIBUTES

NOTES

When compiling multithreaded applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications.

hypot(3M)

NAME | hypot – Euclidean distance function

SYNOPSIS

```
\texttt{cc} [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double hypot (double x, double y);

DESCRIPTION

The hypot () function computes the length of the hypotenuse of a right-angled triangle:

$$\sqrt{x*x+y*y}$$

RETURN VALUES

Upon successful completion, hypot () returns the length of the hypotenuse of a right angled triangle with sides of length *x* and *y*.

If the result would cause overflow, HUGE VAL is returned and errno may be set to ERANGE.

If *x* or *y* is NaN, NaN is returned.

ERRORS

The hypot () function may fail if:

ERANGE

The result overflows.

USAGE

The hypot () function takes precautions against underflow and overflow during intermediate steps of the computation.

An application wishing to check for error situations should set errno to 0 before calling hypot (). If errno is non-zero on return, or the return value is HUGE VAL or NaN, an error has occurred.

NAME | ilogb – returns an unbiased exponent

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

int ilogb(double x);

DESCRIPTION

The ilogb() function returns the exponent part of x. Formally, the return value is the integral part of $log_r |x|$ as a signed integral value, for non-zero finite x, where r is the radix of the machine's floating point arithmetic.

RETURN VALUES

Upon successful completion, ilogb() returns the exponent part of x.

If x is 0, ilogb() returns –INT MAX.

If x is NaN or \pm Inf, ilogb() returns INT_MAX.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

isencrypt(3GEN)

NAME

isencrypt – determine whether a buffer of characters is encrypted

SYNOPSIS

cc [flag...] [file...] -lgen [library...]

#include<libgen.h>

int isencrypt(const char *fbuf, size t ninbuf);

DESCRIPTION

isencrypt() uses heuristics to determine whether a buffer of characters is encrypted. It requires two arguments: a pointer to an array of characters and the number of characters in the buffer.

isencrypt() assumes that the file is not encrypted if all the characters in the first block are ASCII characters. If there are non-ASCII characters in the first ninbuf characters, and if the setlocale() LC_CTYPE category is set to C or ascii, isencrypt() assumes that the buffer is encrypted

If the LC_CTYPE category is set to a value other than C or ascii, then isencrypt () uses a combination of heuristics to determine if the buffer is encrypted. If *ninbuf* has at least 64 characters, a chi-square test is used to determine if the bytes in the buffer have a uniform distribution; if it does, then isencrypt() assumes the buffer is encrypted. If the buffer has less than 64 characters, a check is made for null characters and a terminating new-line to determine whether the buffer is encrypted.

RETURN VALUES

If the buffer is encrypted, 1 is returned; otherwise, zero is returned.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

setlocale(3C), attributes(5)

NOTES

When compiling multithreaded applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications.

NAME | isnan – test for NaN

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

int isnam(double x);

DESCRIPTION

The isnan() function tests whether x is NaN.

RETURN VALUES

The isnan() function returns non-zero if x is NaN. Otherwise, 0 is returned.

USAGE

On systems not supporting NaN, isnan() always returns 0.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

attributes(5)

j0(3M)

NAME | j0, j1, jn – Bessel functions of the first kind

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
double j0 (double x);
double j1(double x);
```

double jn(int n, double x);

DESCRIPTION

The j0(), j1() and jn() functions compute Bessel functions of x of the first kind of orders 0, 1 and n respectively.

RETURN VALUES

Upon successful completion, j0(), j1() and jn() return the relevant Bessel value of *x* of the first kind.

If the *x* argument is too large in magnitude, 0 is returned and errno may be set to ERANGE.

If *x* is NaN, NaN is returned.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The j0(), j1() and jn() functions may fail if:

ERANGE The value of x was too large in magnitude.

USAGE

An application wishing to check for error situations should set errno to 0 before calling j0(), j1() or jn(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

ATTRIBUTES

NAME | kstat – Perl tied hash interface to the kstat facility

SYNOPSIS

```
use Sun::Solaris::Kstat;
Sun::Solaris::Kstat->new();
Sun::Solaris::Kstat->update();
Sun::Solaris::Kstat->{module}{instance}{name}{statistic}
```

DESCRIPTION

Kernel statistics are categorized using a 3-part key consisting of the module, the instance, and the statistic name. For example, CPU information can be found under cpu stat:0:cpu stat0, as in the above example. The method Sun::Solaris::Kstat->new() creates a new 3-layer tree of Perl hashes with the same structure; that is, the statistic for CPU 0 can be accessed as \$ks->{cpu stat}{0}{cpu stat0}. The fourth and lowest layer is a tied hash used to hold the individual statistics values for a particular system resource.

For performance reasons, the creation of a Sun::Solaris::Kstat object is not accompanied by a following read of all possible statistics. Instead, the 3-layer structure described above is created, but reads of a statistic's values are done only when referenced. For example, accessing \$ks->{cpu stat}{0}{cpu stat0}{syscall} will read in all the statistics for CPU 0, including user, system, and wait times, and the other CPU statistics, as well as the number of system call entries. Once you have accessed a lowest level statistics value, calling \$ks->update will automatically update all the individual values of any statistics you have accessed.

Note that there are two values of the lowest-level hash that can be read without causing the full set of statistics to be read from the kernel. These are "class", which is the kstat class of the statistics, and "crtime", which is the time that the kstat was created. See kstat(3KSTAT) for full details of these fields.

Methods

new() Create a new kstat statistics hierarchy and return a reference to the top-level hash. Use it like any normal hash to access the statistics.

update()

Update all the statistics that have been accessed so far. In scalar context, update() returns 1 if the kstat structure has changed, and 0 otherwise. In list context, update () returns references to two arrays: the first holds the keys of any kstats that have been added, and the second holds the keys of any kstats that have been deleted. Each key will be returned in the form "module:instance:name".

EXAMPLES

EXAMPLE 1 Sun::Solaris::Kstat example

```
use Sun::Solaris::Kstat;
my $kstat = Sun::Solaris::Kstat->new();
my ($usr1, $sys1, $wio1, $idle1) =
   @{$kstat->{cpu stat}{0}{cpu stat0}}{qw(user kernel wait idle)};
print("usr sys wio idle\n");
while (1) {
   sleep 5;
   if ($kstat->update()) {
```

EXAMPLE 1 Sun::Solaris::Kstat example (Continued)

```
print("Configuration changed\n");
}
my ($usr2, $sys2, $wio2, $idle2) =
   @{$kstat->{cpu_stat}{0}{cpu_stat0}}{qw(user kernel wait idle)};
printf(" %.2d %.2d %.2d %.2d\n",
     ($usr2 - $usr1) / 5, ($sys2 - $sys1) / 5,
     ($wio2 - $wio1) / 5, ($idle2 - $idle1) / 5);
$usr1 = $usr2;
$sys1 = $sys2;
$wio1 = $wio2;
$idle1 = $idle2;
```

SEE ALSO

perl(1), kstat(1M), kstat(3KSTAT), kstat chain update(3KSTAT), kstat close(3KSTAT), kstat open(3KSTAT), kstat read(3KSTAT)

NOTES

As the statistics are stored in a tied hash, taking additional references of members of the hash, such as

```
 \label{eq:my stat} $$  \  = \ \sh -> {cpu_stat} {0} {cpu_stat0} {syscall}; 
print("$$ref\n");
```

will be recorded as a hold on that statistic's value, preventing it from being updated by refresh(). Copy the values explicitly if persistence is necessary.

Several of the statistics provided by the kstat facility are stored as 64-bit integer values. Perl 5 does not yet internally support 64-bit integers, so these values are approximated in this module. There are two classes of 64-bit value to be dealt with:

64-bit intervals and times

These are the crtime and snaptime fields of all the statistics hashes, and the wtime, wlentime, wlastupdate, rtime, rlentime and rlastupdate fields of the kstat I/O statistics structures. These are measured by the kstat facility in nanoseconds, meaning that a 32-bit value would represent approximately 4 seconds. The alternative is to store the values as floating-point numbers, which offer approximately 53 bits of precision on present hardware. 64-bit intervals and timers as floating point values expressed in seconds, meaning that time-related kstats are being rounded to approximately microsecond resolution.

64-bit counters

It is not useful to store these values as 32-bit values. As noted above, floating-point values offer 53 bits of precision. Accordingly, all 64-bit counters are stored as floating-point values.

NAME

kstat – kernel statistics facility

DESCRIPTION

The kstat facility is a general-purpose mechanism for providing kernel statistics to users.

The kstat model

The kernel maintains a linked list of statistics structures, or kstats. Each kstat has a common header section and a type-specific data section. The header section is defined by the kstat t structure:

kstat header

The fields that are of significance to the user are:

ks crtime

The time the kstat was created. This allows you to compute the rates of various counters since the kstat was created; "rate since boot" is replaced by the more general concept of "rate since kstat creation". All times associated with kstats (such as creation time, last snapshot time, kstat_timer_t and kstat_io_t timestamps, and the like) are 64-bit nanosecond values. The accuracy of kstat timestamps is machine dependent, but the precision (units) is the same across all platforms. See gethrtime(3C) for general information about high-resolution timestamps.

ks_next

kstats are stored as a linked list, or chain. ks_next points to the next kstat in the chain.

kstat(3KSTAT)

ks_kid	A unique identifier for the kstat.	
ks_module, ks_instance	contain the name and instance of the the module that created the kstat. In cases where there can only be one instance, ks_instance is 0.	
ks_name	gives a meaningful name to a kstat. The full kstat namespace is <ks_module,ks_instance,ks_name>, so the name only need be unique within a module.</ks_module,ks_instance,ks_name>	
ks_type	The type of data in this kstat. kstat data types are discussed below.	
ks_class	Each kstat can be characterized as belonging to some broad class of statistics, such as disk, tape, net, vm, and streams. This field can be used as a filter to extract related kstats. The following values are currently in use: disk, tape, controller, net, rpc, vm, kvm, hat, streams, kmem, kmem_cache, kstat, and misc. (The kstat class encompasses things like kstat_types.)	
ks_data,		
ks_ndata, ks_data_size	ks_data is a pointer to the kstat's data section. The type of data stored there depends on ks_type. ks_ndata indicates the number of data records. Only some kstat types support multiple data records. Currently, KSTAT_TYPE_RAW, KSTAT_TYPE_NAMED and KSTAT_TYPE_TIMER kstats support multiple data records. KSTAT_TYPE_INTR and KSTAT_TYPE_IO kstats support only one data record. ks_data_size is the total size of the data section, in bytes.	
ks_snaptime	The timestamp for the last data snapshot. This allows you to compute activity rates:	
	rate = (new_count - old_count) / (new_snaptime - old_snaptime);	
The following types of kstats are currently available:		
#define KSTAT_TYP #define KSTAT_TYP #define KSTAT_TYP #define KSTAT_TYP #define KSTAT_TYP	E_NAMED 1 /* name/value pairs */ E_INTR 2 /* interrupt statistics */ E_IO 3 /* I/O statistics */	

To get a list of all kstat types currently supported in the system, tools can read out the standard system kstat <code>kstat_types</code> (full name spec is <code><"unix"</code>, <code>0</code>, "<code>kstat_types"</code>>). This is a <code>KSTAT_TYPE_NAMED</code> kstat in which the <code>name</code> field describes the type of kstat, and the <code>value</code> field is the kstat type number (for example, <code>KSTAT_TYPE_IO</code> is type 3 -- see

above).

Raw kstat

kstat data types

KSTAT_TYPE_RAW raw data

The "raw" kstat type is just treated as an array of bytes. This is generally used to export well-known structures, like *sysinfo*.

Name=value kstat

KSTAT_TYPE_NAMED A list of arbitrary name=value statistics.

```
typedef struct kstat_named {
   charname[KSTAT STRLEN];
                                /* name of counter */
  uchar_tdata_type;
                                /* data type */
  union {
           charc[16];
                               /* enough for 128-bit ints */
           struct {
             union {
                char *ptr; /* NULL-terminated string */
              } addr;
             uint32 t len; /* length of string */
           } string;
           int32_ti32;
           uint32 tui32;
           int64_ti64;
           uint64_tui64;
  /* These structure members are obsolete */
           int32 t 1;
           uint32_t ul;
           int64_t ll;
uint64_t ull;
        } value;
                               /* value of counter */
} kstat named t;
                         0 /* char[16] */

#define KSTAT_DATA FLOAT
#define KSTAT DATA DOUBLE
                             6
```

Some devices need to publish strings that exceed the maximum value for KSTAT_DATA_CHAR in length; KSTAT_DATA_STRING is a data type that allows arbitrary-length strings to be associated with a named kstat. The macros below are the supported means to read the pointer to the string and its length.

```
#define KSTAT_NAMED_STR_PTR(knptr) ((knptr)->value.string.addr.ptr)
#define KSTAT_NAMED_STR_BUFLEN(knptr) ((knptr)->value.string.len)
```

KSTAT_NAMED_STR_BUFLEN() returns the number of bytes required to store the
string pointed to by KSTAT_NAMED_STR_PTR(); that is,
strlen(KSTAT_NAMED_STR_PTR()) + 1.

Interrupt kstat

KSTAT TYPE INTR Interrupt statistics.

An interrupt is a hard interrupt (sourced from the hardware device itself), a soft interrupt (induced by the system via the use of some system interrupt source), a watchdog interrupt (induced by a periodic timer call), spurious (an interrupt entry point was entered but there was no interrupt to service), or multiple service (an interrupt was detected and serviced just prior to returning from any of the other types).

Event timer kstat

KSTAT TYPE TIMER Event timer statistics.

These provide basic counting and timing information for any type of event.

I/O kstat

KSTAT TYPE IO I/O statistics.

```
typedef struct kstat_io {
    /*
    * Basic counters.
    */
    u_longlong_t nread;    /* number of bytes read */
    u_longlong_t nwritten; /* number of bytes written */
    uint_t reads;    /* number of read operations */
    uint_t writes;    /* number of write operations */
    /*
    * Accumulated time and queue length statistics.
    *
```

```
* Time statistics are kept as a running sum of "active" time.
* Queue length statistics are kept as a running sum of the
* product of queue length and elapsed time at that length --
* that is, a Riemann sum for queue length integrated against time.
             | i4 |
       8
            1 1
    Queue 6 | | |
Length | ____ | |
4 | i2 | ____ | |
       | | i3 |
       Time-> t1 t2 t3 t4
* At each change of state (entry or exit from the queue),
* we add the elapsed time (since the previous state change)
* to the active time if the queue length was non-zero during
* that interval; and we add the product of the elapsed time
* times the queue length to the running length*time sum.
* This method is generalizable to measuring residency
* in any defined system: instead of queue lengths, think
* of "outstanding RPC calls to server X".
* A large number of I/O subsystems have at least two basic
* "lists" of transactions they manage: one for transactions
* that have been accepted for processing but for which processing
* has yet to begin, and one for transactions which are actively
* being processed (but not done). For this reason, two cumulative
* time statistics are defined here: pre-service (wait) time,
* and service (run) time.
* The units of cumulative busy time are accumulated nanoseconds.
* The units of cumulative length*time products are elapsed time
* times queue length.
hrtime_t wtime;
                    /* cumulative wait (pre-service) time */
hrtime_t wlentime; /* cumulative wait length*time product*/
hrtime_t wlastupdate; /* last time wait queue changed */
                   /* cumulative run (service) time */
hrtime_t rtime;
hrtime_t rlentime; /* cumulative run length*time product */
hrtime_t rlastupdate; /* last time run queue changed */
```

```
uint_t wcnt;  /* count of elements in wait state */
uint_t rcnt;  /* count of elements in run state */
} kstat_io_t;
```

Using libkstat

The kstat library, libkstat, defines the user interface (API) to the system's kstat facility.

You begin by opening libkstat with kstat_open(3KSTAT), which returns a pointer to a fully initialized kstat control structure. This is your ticket to subsequent libkstat operations:

Only the first two fields, kc_chain_id and kc_chain, are of interest to libkstat clients. (kc_kd is the descriptor for /dev/kstat, the kernel statistics driver. libkstat functions are built on top of /dev/kstat ioctl(2) primitives. Direct interaction with /dev/kstat is strongly discouraged, since it is *not* a public interface.)

kc_chain points to your copy of the kstat chain. You typically walk the chain to find and process a certain kind of kstat. For example, to display all I/O kstats:

kc_chain_id is the kstat chain ID, or KCID, of your copy of the kstat chain. See kstat chain update(3KSTAT) for an explanation of KCIDs.

NAME | kstat_chain_update - update the kstat header chain

SYNOPSIS

```
cc [ flag ... ] file ... -lkstat [ library ...]
#include <kstat.h>
```

kid t kstat chain update(kstat ctl t *kc);

DESCRIPTION

The kstat chain update () function brings the user's kstat header chain in sync with that of the kernel. The kstat chain is a linked list of kstat headers (kstat t's) pointed to by kc->kc chain, which is initialized by kstat open(3KSTAT). This chain constitutes a list of all kstats currently in the system.

During normal operation, the kernel creates new kstats and delete old ones as various device instances are added and removed, thereby causing the user's copy of the kstat chain to become out of date. The kstat chain update() function detects this condition by comparing the kernel's current kstat chain ID(KCID), which is incremented every time the kstat chain changes, to the user's KCID, kc->kc chain id. If the KCIDs match, kstat chain update() does nothing. Otherwise, it deletes any invalid kstat headers from the user's kstat chain, adds any new ones, and sets kc->kc chain id to the new KCID. All other kstat headers in the user's kstat chain are unmodified.

RETURN VALUES

The kstat chain update() function returns the new KCID if the kstat chain has changed, 0 if it hasn't, or −1 on failure.

kstat_lookup(3KSTAT)

NAME |

kstat_lookup, kstat_data_lookup - find a kstat by name

SYNOPSIS

```
cc [ flag ... ] file ... -lkstat [ library ...]
#include <kstat.h>
```

void *kstat data lookup(kstat t *ksp, char *name);

DESCRIPTION

The kstat_lookup() function traverses the kstat chain, kc->kc_chain, searching for a kstat with the same ks_module, ks_instance, and ks_name fields; this triplet uniquely identifies a kstat. If ks_module is NULL, ks_instance is -1, or ks_name is NULL, then those fields will be ignored in the search. For example, kstat_lookup(kc, NULL, -1, "foo") will simply find the first kstat with name "foo".

The kstat_data_lookup() function searches the kstat's data section for the record with the specified *name*. This operation is valid only for kstat types which have named data records. Currently, only the KSTAT_TYPE_NAMED and KSTAT_TYPE_TIMER kstats have named data records.

RETURN VALUES

The kstat_lookup() function returns a pointer to the requested kstat if it is found, or NULL if it is not.

The kstat_data_lookup() function returns a pointer to the requested data record if it is found. If the requested record is not found, or if the kstat type is invalid, kstat_data_lookup() returns NULL.

NAME | kstat_open, kstat_close – initialize kernel statistics facility

SYNOPSIS

```
cc[ flag ... ] file ... -lkstat [ library ...]
#include <kstat.h>
```

kstat ctl t *kstat open(void);

int kstat close(kstat ctl t *kc);

DESCRIPTION

The kstat open () function initializes a kstat control structure, which provides access to the kernel statistics library. It returns a pointer to this structure, which must be supplied as the *kc* argument in subsequent libkstat function calls.

The kstat close() function frees all resources that were associated with kc. This is done automatically on exit(2) and execve() (see exec(2)).

RETURN VALUES

The kstat open () function returns a pointer to a kstat control structure. On failure, it returns NULL and no resources are allocated.

The kstat close() function returns 0 on success and -1 on failure.

FILES

/dev/kstat kernel statistics driver

kstat read(3KSTAT)

NAME | kstat_read, kstat_write - read or write kstat data

SYNOPSIS

```
cc [ flag ... ] file ... -lkstat [ library ... ]
#include <kstat.h>
```

```
kid t kstat read(kstat ctl t *kc, kstat t *ksp, void *buf);
kid t kstat write(kstat ctl t *kc, kstat t *ksp, void *buf);
```

DESCRIPTION

The kstat read() function gets data from the kernel for the kstat pointed to by ksp. ksp->ks_data is automatically allocated (or reallocated) to be large enough to hold all of the data. ksp->ks_ndata is set to the number of data fields, ksp->ks_data_size is set to the total size of the data, and *ksp->ks_snaptime* is set to the high-resolution time at which the data snapshot was taken. If buf is non-NULL, the data is copied from ksp->ks_data into buf.

The kstat write() function writes data from *buf*, or from *ksp->ks_data* if *buf* is NULL, to the corresponding kstat in the kernel. Only the superuser can use kstat write().

RETURN VALUES

On success, kstat read() and kstat write() return the current kstat chain ID (KCID). On failure, they return -1.

NAME | kva_match – look up a key in a key-value array

SYNOPSIS

```
cc [ \mathit{flag}\ldots ] \mathit{file}\ldots- lsecdb [ \mathit{library}\ldots ]
#include <secdb.h>
```

char *kva_match(kva_t *kva, char *key);

DESCRIPTION

The kva match () function searches a kva t structure, which is part of the authattr t, execattr t, profattr t, or userattr t structures. The function takes two arguments: a pointer to a key value array, and a key. If the key is in the array, the function returns a pointer to the first corresponding value that matches that key. Otherwise, the function returns NULL.

RETURN VALUES

Upon successful completion, the function returns a pointer to the value sought. Otherwise, it returns NULL.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

getauthattr(3SECDB), getexecattr(3SECDB), getprofattr(3SECDB), getuserattr(3SECDB)

NOTES

The kva match() function returns a pointer to data that already exists in the key-value array. It does not allocate its own memory for this pointer but obtains it from the key-value array that is passed as its first argument.

kvm_getu(3KVM)

NAME |

kvm_getu, kvm_getcmd – get the u-area or invocation arguments for a process

SYNOPSIS

```
#include <kvm.h>
#include <sys/param.h>
#include <sys/user.h>
#include <sys/proc.h>
struct user *kvm_getu(kvm_t *kd, struct proc *proc);
int kvm_getcmd(kvm_t *kd, struct proc *proc, struct user *u, char ***arg, char ***env);
```

kvm getu()

The kvm_getu() function reads the u-area of the process specified by proc to an area of static storage associated with kd and returns a pointer to it. Subsequent calls to kvm_getu() will overwrite this static area.

The *kd* argument is a pointer to a kernel descriptor returned by kvm_open(3KVM). The proc argument is a pointer to a copy in the current process' address space of a proc structure, obtained, for instance, by a prior kvm_nextproc(3KVM) call.

kvm getcmd()

The kvm_getcmd() function constructs a list of string pointers that represent the command arguments and environment that were used to initiate the process specified by proc.

The kd argument is a pointer to a kernel descriptor returned by $kvm_open(3KVM)$. The u argument is a pointer to a copy in the current process' address space of a user structure, obtained, for instance, by a prior $kvm_getu()$ call. If arg is not NULL, the command line arguments are formed into a null-terminated array of string pointers. The address of the first such pointer is returned in arg. If env is not NULL, then the environment is formed into a null-terminated array of string pointers. The address of the first of these is returned in env.

The pointers returned in arg and env refer to data allocated by malloc(3C) and should be freed by a call to free() when no longer needed. See malloc(3C) Both the string pointers and the strings themselves are deallocated when freed.

Since the environment and command line arguments may have been modified by the user process, there is no guarantee that it will be possible to reconstruct the original command at all. Thus, kvm_getcmd() will make the best attempt possible, returning -1 if the user process data is unrecognizable.

RETURN VALUES

On success, kvm_getu() returns a pointer to a copy of the u-area of the process specified by proc. On failure, it returns NULL.

The kvm getcmd() function returns 0 on success and -1 on failure.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

kvm nextproc(3KVM), kvm open(3KVM), kvm read(3KVM), malloc(3C), libkvm(3LIB), attributes (5)

NOTES

If kvm_getcmd() returns -1, the caller still has the option of using the command line fragment that is stored in the u-area.

On systems that support both 32-bit and 64-bit processes, the 64-bit implementation of libkvm ensures that the arg and env pointer arrays for kvm_getcmd() are translated to the same form as if they were 64-bit processes. Applications that wish to access the raw 32-bit stack directly can use kvm_uread(). See kvm_read(3KVM).

kvm_nextproc(3KVM)

NAME |

kvm_nextproc, kvm_getproc, kvm_setproc – read system process structures

SYNOPSIS

```
#include <kvm.h>
#include <sys/param.h>
#include <sys/time.h>
#include <sys/proc.h>
struct proc *kvm_nextproc(kvm_t *kd);
int kvm_setproc(kvm_t *kd);
struct proc *kvm getproc(kvm t *kd, pid t pid);
```

kvm nextproc()

The kvm_nextproc() function may be used to sequentially read all of the system process structures from the kernel identified by kd (see kvm_open(3KVM)). Each call to kvm_nextproc() returns a pointer to the static memory area that contains a copy of the next valid process table entry. There is no guarantee that the data will remain valid across calls to kvm_nextproc(), kvm_setproc(), or kvm_getproc(). Therefore, if the process structure must be saved, it should be copied to non-volatile storage.

For performance reasons, many implementations will cache a set of system process structures. Since the system state is liable to change between calls to kvm_nextproc(), and since the cache may contain obsolete information, there is no guarantee that *every* process structure returned refers to an active process, nor is it certain that *all* processes will be reported.

kvm setproc()

The kvm_setproc() function rewinds the process list, enabling kvm_nextproc() to rescan from the beginning of the system process table. This function will always flush the process structure cache, allowing an application to re-scan the process table of a running system.

kvm getproc()

The kvm_getproc() function locates the proc structure of the process specified by *pid* and returns a pointer to it. This function does not interact with the process table pointer manipulated by kvm_nextproc(); however, the restrictions regarding the validity of the data still apply.

RETURN VALUES

On success, kvm_nextproc() returns a pointer to a copy of the next valid process table entry. On failure, it returns NULL.

On success, kvm_getproc() returns a pointer to the proc structure of the process specified by *pid*. On failure, it returns NULL.

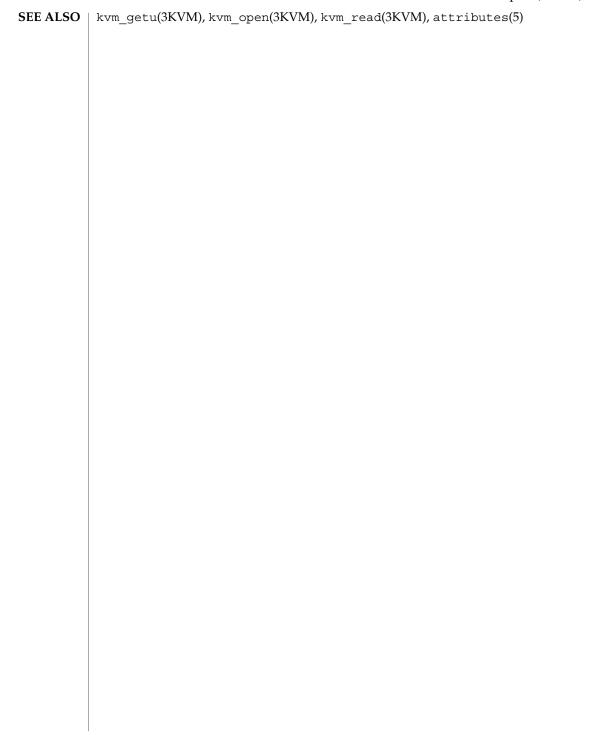

The $kvm_setproc()$ function returns 0 on success -1 on failure.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

kvm_nextproc(3KVM)

kvm_nlist(3KVM)

NAME |

kvm_nlist – get entries from kernel symbol table

SYNOPSIS

#include <kvm.h>
#include <nlist.h>

int kvm_nlist(kvm_t *kd, struct nlist *nl);

DESCRIPTION

kvm_nlist() examines the symbol table from the kernel image identified by kd (see kvm_open(3KVM)) and selectively extracts a list of values and puts them in the array of nlist structures pointed to by nl. The name list pointed to by nl consists of an array of structures containing names, types and values. The n_name field of each such structure is taken to be a pointer to a character string representing a symbol name. The list is terminated by an entry with a NULL pointer (or a pointer to a null string) in the n_name field. For each entry in nl, if the named symbol is present in the kernel symbol table, its value and type are placed in the n_name fields. If a symbol cannot be located, the corresponding n_name field of nl is set to zero.

RETURN VALUES

 $kvm_nlist()$ returns the value of nlist(3UCB) or nlist(3ELF), depending on the library used.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

nlist(3UCB), nlist(3ELF), kvm open(3KVM), kvm read(3KVM), attributes(5)

NAME | kvm_open, kvm_close – specify a kernel to examine

SYNOPSIS

```
#include <kvm.h>
#include <fcntl.h>
kvm t *kvm open(char *namelist, char *corefile, char *swapfile, int flag,
     char *errstr);
int kvm close(kvm t *kd);
```

kvm_open()

The kvm open () function initializes a set of file descriptors to be used in subsequent calls to kernel virtual memory (VM) routines. It returns a pointer to a kernel identifier that must be used as the kd argument in subsequent kernel VM function calls.

The *namelist* argument specifies an unstripped executable file whose symbol table will be used to locate various offsets in corefile. If namelist is NULL, the symbol table of the currently running kernel is used to determine offsets in the core image. In this case, it is up to the implementation to select an appropriate way to resolve symbolic references, for instance, using /dev/ksyms as a default namelist file.

The corefile argument specifies a file that contains an image of physical memory, for instance, a kernel crash dump file (see savecore(1M)) or the special device /dev/mem. If corefile is NULL, the currently running kernel is accessed, using /dev/mem and /dev/kmem.

The swapfile argument specifies a file that represents the swap device. If both corefile and *swapfile* are NULL, the swap device of the currently running kernel is accessed. Otherwise, if swapfile is NULL, kvm open () may succeed but subsequent kvm getu(3KVM) function calls may fail if the desired information is swapped out.

The *flag* function is used to specify read or write access for *corefile* and may have one of the following values:

O RDONLY open for reading

O RDWR open for reading and writing

The errstr argument is used to control error reporting. If it is a null pointer, no error messages will be printed. If it is non-null, it is assumed to be the address of a string that will be used to prefix error messages generated by kvm open. Errors are printed to stderr. A useful value to supply for errstr would be argv[0]. This has the effect of printing the process name in front of any error messages.

Applications using libkvm are dependent on the underlying data model of the kernel image, that is, whether it is a 32-bit or 64-bit kernel.

The data model of these applications must match the data model of the kernel in order to correctly interpret the size and offsets of kernel data structures. For example, a 32-bit application that uses the 32-bit version of the libkym interfaces will fail to open a 64-bit kernel image. Similarly, a 64-bit application that uses the 64-bit version of the libkvm interfaces will fail to open a 32-bit kernel image.

kvm_open(3KVM)

kvm_close()

The kvm_close() function closes all file descriptors that were associated with kd. These files are also closed on exit(2) and execve() (see exec(2)). kvm_close() also resets the proc pointer associated with kvm_nextproc(3KVM) and flushes any cached kernel data.

RETURN VALUES

The kvm_open() function returns a non-null value suitable for use with subsequent kernel VM function calls. On failure, it returns NULL and no files are opened.

The kvm close() function returns 0 on success -1 on failure.

FILES

/dev/kmem

/dev/ksyms

/dev/mem

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

 $\label{eq:savecore} savecore(1M), exec(2), exit(2), pathconf(2), getloadavg(3C), kstat(3KSTAT), \\ kvm_getu(3KVM), kvm_nextproc(3KVM), kvm_nlist(3KVM), kvm_read(3KVM), \\ sysconf(3C), libkvm(3LIB), proc(4), attributes(5), lfcompile(5) \\$

NOTES

Kernel core dumps should be examined on the platform on which they were created. While a 32-bit application running on a 64-bit kernel can examine a 32-bit core dump, a 64-bit application running on a 64-bit kernel cannot examine a kernel core dump from the 32-bit system.

Applications using libkvm are likely to be platform- and release-dependent.

On 32-bit systems, applications that use libkvm to access the running kernel must be 32-bit applications. On systems that support both 32-bit and 64-bit applications, applications that use the libkvm interfaces to access the running kernel must themselves be 64-bit applications.

Most of the traditional uses of libkvm have been superseded by more stable interfaces that allow the same information to be extracted more efficiently, yet independent of the kernel data model. For examples, see sysconf(3C), proc(4), kstat(3KSTAT), getloadavg(3C), and pathconf(2).

NAME

kvm_read, kvm_write, kvm_uread, kvm_uwrite, kvm_kread, kvm_kwrite – copy data to or from a kernel image or running system

SYNOPSIS

#include <kvm.h>

- ssize_t kvm_kwrite(kvm_t *kd, uintptr_t addr, void *buf, size_t
 nbytes);

kvm kread()

The kvm_kread() function transfers data from the kernel address space to the address space of the process. *nbytes* bytes of data are copied from the kernel virtual address given by *addr* to the buffer pointed to by *buf*.

kvm kwrite()

The kvm_kwrite() function is like kvm_kread(), except that the direction of the transfer is reversed. To use this function, the kvm_open(3KVM) call that returned *kd* must have specified write access.

kvm uread()

The kvm_uread() function transfers data from the address space of the processes specified in the most recent kvm_getu(3KVM) call. *nbytes* bytes of data are copied from the user virtual address given by addr to the buffer pointed to by *buf*.

kvm uwrite()

The kvm_uwrite() function is like kvm_uread(), except that the direction of the transfer is reversed. To use this function, the kvm_open(3KVM) call that returned kd must have specified write access. The address is resolved in the address space of the process specified in the most recent kvm_getu(3KVM) call.

kvm read()

The kvm_read() function transfers data from the kernel image specified by kd (see kvm_open(3KVM)) to the address space of the process. nbytes bytes of data are copied from the kernel virtual address given by addr to the buffer pointed to by buf.

kvm write()

The kvm_write() function is like kvm_read(), except that the direction of data transfer is reversed. To use this function, the kvm_open(3KVM) call that returned kd must have specified write access. If a user virtual address is given, it is resolved in the address space of the process specified in the most recent kvm_getu(3KVM) call.

USAGE

The use of kvm_read() and kvm_write() is strongly discouraged. On some platforms, there is considerable ambiguity over which address space is to be accessed by these functions, possibly leading to unexpected results. The kvm kread(),

kvm_read(3KVM)

kvm_kwrite(), kvm_uread(), and kvm_uwrite() functions are much more clearly defined in this respect.

RETURN VALUES

On success, these functions return the number of bytes actually transferred. On failure, they return −1.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

lgamma(3M)

NAME

lgamma, lgamma_r, gamma, gamma_r – log gamma function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
extern int signgam;
double lgamma (double x);
double gamma (double x);
double lgamma_r (double x, int *signgamp);
double gamma_r (double x, int *signgamp);
```

DESCRIPTION

The lgamma(), gamma(), lgamma_r(), and gamma_r() functions return

 $\ln |\Gamma(x)|$

where

$$\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} dt$$

for x > 0 and

$$\Gamma(x) = \pi/(\Gamma(1-x)\sin(\pi x))$$

for x < 1.

The lgamma() and gamma() functions use the external integer signgam to return the sign of $|\sim(x)$ while lgamma_r() and gamma_r() use the user-allocated space addressed by signgamp.

IDIOSYNCRASIES

In the case of lgamma(), do *not* use the expression signgam*exp(lgamma(x)) to compute

$$g := \Gamma(x)$$

Instead compute lgamma() first:

```
lg = lgamma(x); g = signgam*exp(lg);
```

only after lgamma () has returned can signgam be correct. Note that $|\sim(x)|$ must overflow when x is large enough, underflow when -x is large enough, and generate a division by 0 exception at the singularities x a nonpositive integer.

RETURN VALUES

For exceptional cases, $\mathtt{matherr}(3M)$ tabulates the values to be returned as dictated by various Standards.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO

matherr(3M), attributes(5), standards(5)

NOTES

Although $lgamma_r()$ is not mentioned by POSIX 1003.1c, it was added to complete the functionality provided by similar thread-safe functions.

The gamma() function is currently maintained for compatibility with SVID3 (see $\mathtt{standards}(5)$). It and the \mathtt{gamma}_r () function may be removed from a future release. The \mathtt{lgamma} () and \mathtt{lgamma}_r () functions should be used instead.

When compiling multi-thread applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multi-thread applications.

The lgamma() function is unsafe in multithreaded applications. The $lgamma_r()$ function should be used instead.

libdevinfo(3DEVINFO)

NAME |

libdevinfo – library of device information functions

SYNOPSIS

```
cc [flag ...] file ...-ldevinfo [library ...]
#include libdevinfo.h>
```

DESCRIPTION

The libdevinfo library contains a set of interfaces for accessing device configuration data.

Device configuration data is organized as a tree of device nodes, defined as di_node_t in the libdevinfo interfaces. Each di_node_t represents a physical or logical (pseudo) device. Three types of data are associated with device nodes:

- data defined for all device nodes (attributes)
- properties specific to each device
- minor node data

All device nodes have a set of common attributes, such as a node name, an instance number, and a driver binding name. Common device node attributes are accessed by calling interfaces listed on the di_binding_name(3DEVINFO) man page. Each device node also has a physical path, which is accessed by calling di_devfs_path(3DEVINFO).

Properties provide device specific information for device configuration and usage. Properties may be defined by software (di_prop_t) or by firmware (di_prom_prop_t). One way to access each di_prop_t is to make successive calls to di_prop_next(3DEVINFO) until DI_PROP_NIL is returned. For each di_prop_t, use interfaces on the di_prop_bytes(3DEVINFO) man page to obtain property names and values. Another way to access these properties is to call di_prop_lookup_bytes(3DEVINFO) to find the value of a property with a given name. Accessing a di_prom_prop_t is similar to accessing a di_prop_t, except that the interface names start with di_prom_prop and additional calls to di_prom_init(3DEVINFO) and di_prom_fini(3DEVINFO) are required.

Minor nodes contain information exported by the device for creating special files for the device. Each device node has 0 or more minor nodes associated with it. A list minor nodes (di_minor_t) may be obtained by making successive calls to di_minor_next(3DEVINFO) until DI_MINOR_NIL is returned. For each minor node, di_minor_devt(3DEVINFO) and related interfaces are called to get minor node data.

Using libdevinfo involves three steps:

- Creating a snapshot of the device tree
- Traversing the device tree to get information of interest
- Destroying the snapshot of the device tree

A snapshot of the device tree is created by calling di_init(3DEVINFO) and destroyed by calling di_fini(3DEVINFO). An application can specify the data to be included in the snapshot (full or partial tree, include or exclude properties and minor

nodes) and get a handle to the root of the device tree. See di_init(3DEVINFO) for details. The application then traverses the device tree in the snapshot to obtain device configuration data.

The device tree is normally traversed through parent-child-sibling linkage. Each device node contains references to its parent, its next sibling, and the first of its children. Given the di_node_t returned from di_init(3DEVINFO), one can find all children by first calling di_child_node(3DEVINFO), followed by successive calls to di_sibling_node(3DEVINFO), until DI_NODE_NIL is returned. By following this procedure recursively, an application can visit all device nodes contained in the snapshot. Two interfaces, di_walk_node(3DEVINFO) and di_walk_minor(3DEVINFO), are provided to facilitate device tree traversal. The di_walk_node(3DEVINFO) interface visits all device nodes and executes a user-supplied callback function for each node visited. The di_walk_minor(3DEVINFO) does the same for each minor node in the device tree.

An alternative way to traverse the device tree is through the per-driver device node linkage. Device nodes contain a reference to the next device node bound to the same driver. Given the di_node_t returned from di_init(3DEVINFO), an application can find all device nodes bound to a driver by first calling di_drv_first_node(3DEVINFO), followed by successive calls to di_drv_next_node(3DEVINFO) until DI_NODE_NIL is returned. Note that traversing the per-driver device node list works only when the snapshot includes all device nodes.

See libdevinfo(3LIB) for a complete list of libdevinfo interfaces. See di_init(3DEVINFO) for examples of libdevinfo usage. See Writing Device Drivers for details of Solaris device configuration.

EXAMPLES

EXAMPLE 1 Information Accessible Through libdevinfo Interfaces

The following example illustrates the kind of information accessible through libdevinfo interfaces for a device node representing a hard disk (sd2):

```
Attributes
   node name: sd
   instance: 2
   physical path: /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@2,0
   target=2
   lun=0
Minor nodes
   (disk partition /dev/dsk/c0t2d0s0)
      name: a
                 0x0080010 (32/16)
       spectype: IF_BLK (block special)
    (disk partition /dev/rdsk/c0t2d0s2)
       name:
                  c,raw
       dev_t:
                 0x0080012 (32/18)
       spectype: IF CHR (character special)
```

NAME

libnvpair – library of name-value pair functions

SYNOPSIS

```
cc [flag ...] file ...-lnvpair [library ...]
#include <libnvpair.h>
```

DESCRIPTION

The libnvpair library exports a set of functions for managing name-value pairs.

The library defines two opaque handles:

nvpair t handle to a name-value pair

nvlist t handle to a list of name-value pairs

The library supports the following operations:

- Allocate and free an nvlist t.
- Add and remove an nvpair_t from a list.
- Search nvlist t for a specified name pair.
- Pack an nvlist t into a contiguous buffer.
- Expand a packed nvlist into a searchable nvlist t.

See libnvpair(3LIB) for a complete list of libnvpair functions.

libpicl(3PICL)

NAME | libpicl – PICL interface library

SYNOPSIS

```
cc [ flag . . . ] file . . . -lpicl [ library . . . ]
#include <picl.h>
```

DESCRIPTION

The PICL interface is the platform-independent interface for clients to access the platform information. The set of functions and data structures of this interface are defined in the <picl.h> header.

The information published through PICL is organized in a tree, where each node is an instance of a well-defined PICL class. The functions in the PICL interface allow the clients to access the properties of the nodes.

The name of the base PICL class is picl, which defines a basic set of properties that all nodes in the tree must possess. The following table shows the property set of a picl class node.

Property Name	Property Value
name	The name of the node
_class	The PICL class name of the node
_parent	Node handle of the parent node
_child	Node handle of the first child node
_peer	Node handle of the next peer node

Property names with a a leading underscore ('_') are reserved for use by the PICL framework. The property names class, parent, child, and peer are reserved names of the PICL framework, and are used to refer to a node's parent, child, and peer nodes, respectively. A client shall access a reserved property by their names only as they do not have an associated handle. The property name is not a reserved property, but a mandatory property for all nodes.

Properties are classified into different types. Properties of type integer, unsigned-integer, and float have integer, unsigned integer, and floating-point values, respectively. A table property type has the handle to a table as its value. A table is a matrix of properties. A reference property type has a handle to a node in the tree as its value. A reference property may be used to establish an association between any two nodes in the tree. A timestamp property type has the value of time in seconds since Epoch. A bytearray property type has an array of bytes as its value. A charstring property type has a nul ('\0') terminated sequence of ASCII characters. The size of a property specifies the size of its value in bytes. A void property type denotes a property that exists but has no value.

The following table lists the different PICL property types enumerated in picl prop type t.

Property Type	Property Value
PICL_PTYPE_VOID	None
PICL_PTYPE_INT	Is an integer
PICL_PTYPE_UNSIGNED_INT	Is an unsigned integer
PICL_PTYPE_FLOAT	Is a floating-point number
PICL_PTYPE_REFERENCE	Is a PICL node handle

Reference Property Naming Convention

Reference properties may be used by plug-ins to publish properties in nodes of different classes. To make these property names unique, their names must be prefixed by <code>_picl_class_name_</code>, where <code>picl_class_name</code> is the class name of the node referenced by the property. Valid PICL class names are combinations of uppercase and lowercase letters 'a' through 'z', digits '0' through '9', and '-' (minus) characters. The string that follows the '_picl_class_name_' portion of a reference property name may be used to indicate a specific property in the referenced class, when applicable.

Property Information

The information about a node's property that can be accessed by PICL clients is defined by the picl propinfo t structure.

The type member specifies the property value type and the accessmode specifies the allowable access to the property. The plug-in module that adds the property to the PICL tree also sets the access mode of that property. The volatile nature of a property created by the plug-in is not visible to the PICL clients. The size member specifies the number of bytes occupied by the property's value. The maximum allowable size of property value is PICL PROPSIZE MAX, which is set to 512KB.

Property Access Modes

The plug-in module may publish a property granting a combination of the following access modes to the clients:

```
#define PICL_READ 0x1 /* read permission */
#define PICL WRITE 0x2 /* write permission */
```

Property Names

The maximum length of the name of any property is specified by PICL PROPNAMELEN MAX.

Class Names

The maximum length of a PICL class name is specified by PICL_CLASSNAMELEN_MAX.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NAME | libpicltree – PTree and Plug-in Registration interface library

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

DESCRIPTION

The PTree interface is the set of functions and data structures to access and manipulate the PICL tree. The daemon and the plug-in modules use the PTree interface.

The Plug-in Registration interface is used by the plug-in modules to register themselves with the daemon.

The plug-in modules create the nodes and properties of the tree. At the time of creating a property, the plug-ins specify the property information in the ptree propinfo t structure defined as:

```
typedef struct {
        int version; /* version */
picl_propinfo_t piclinfo; /* info to clients */
                       (*read) (ptree rarg t *arg, void *buf);
                                      /* read access function for */
                                      /* volatile prop */
        int
                         (*write) (ptree warg t *arg, const void *buf);
                                     /* write access function for */
                                      /* volatile prop */
} ptree propinfo t;
```

See libpic1(3PICL) for more information on PICL tree nodes and properties.

The maximum size of a property value cannot exceed PICL PROPSIZE MAX. It is currently set to 512KB.

Volatile Properties

In addition to PICL READ and PICL WRITE property access modes, the plug-in modules specify whether a property is volatile or not by setting the bit PICL VOLATILE.

```
#define PICL_VOLATILE
```

For a volatile property, the plug-in module provides the access functions to read and/or write the property in the ptree propinfo t argument passed when creating the property.

The daemon invokes the access functions of volatile properties when clients access their values. Two arguments are passed to the read access functions. The first argument is a pointer to ptree rarg t, which contains the handle of the node, the handle of the accessed property and the credentials of the caller. The second argument is a pointer to the buffer where the value is to be copied.

```
typedef struct {
        picl nodehdl t nodeh;
        picl_prophdl_t proph;
        door cred t cred;
} ptree rarg t;
```

The prototype of the read access function for volatile property is:

libpicltree(3PICLTREE)

```
int read(ptree_rarg_t *rarg, void *buf);
```

The read function returns PICL SUCCESS to indicate successful completion.

Similarly, when a write access is performed on a volatile property, the daemon invokes the write access function provided by the plug-in for that property and passes it two arguments. The first argument is a pointer to ptree_warg_t, which contains the handle to the node, the handle of the accessed property and the credentials of the caller. The second argument is a pointer to the buffer containing the value to be written.

The prototype of the write access function for volatile property is:

```
int write(ptree_warg_t *warg, const void *buf);
```

The write function returns PICL SUCCESS to indicate successful completion.

For all volatile properties, the 'size' of the property must be specified to be the maximum possible size of the value. The maximum size of the value cannot exceed PICL_PROPSIZE_MAX. This allows a client to allocate a sufficiently large buffer before retrieving a volatile property's value

Plug-in Modules

Plug-in modules are shared objects that are located in well-known directories for the daemon to locate and load them. Plug-in module's are located in the one of the following plug-in directories depending on the plaform-specific nature of the data they collect and publish.

```
/usr/platform/picl/plugins/'uname -i'/
/usr/platform/picl/plugins/'uname -m'/
/usr/lib/picl/plugins/
```

A plug-in module may specify its dependency on another plug-in module using the -1 linker option. The plug-ins are loaded by the PICL daemon using dlopen(3DL) according to the specified dependencies. Each plug-in module must define a .init section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See picld_plugin_register(3PICLTREE) for more information on plug-in registration.

The plug-in modules may use the picld_log(3PICLTREE) function to log their messages to the system log file.

libtnfctl(3TNF)

NAME |

libtnfctl – library for TNF probe control in a process or the kernel

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
```

DESCRIPTION

The libtnfctl library provides an API to control TNF ("Trace Normal Form") probes within a process or the kernel. See tracing(3TNF) for an overview of the Solaris tracing architecture. The client of libtnfctl controls probes in one of four modes:

internal mode The target is the controlling process itself; that is, the client

controls its own probes.

direct mode The target is a separate process; a client can either exec(2) a

> program or attach to a running process for probe control. The libtnfctl library uses proc(4) on the target process for probe and process control in this mode, and additionally provides basic

process control features.

indirect mode The target is a separate process, but the controlling process is

> already using proc(4) to control the target, and hence libtnfctl cannot use those interfaces directly. Use this mode to control probes from within a debugger. In this mode, the client must provide a set of functions that libtnfctl can use to query and

update the target process.

kernel mode The target is the Solaris kernel.

A process is controlled "externally" if it is being controlled in either direct mode or indirect mode. Alternatively, a process is controlled "internally" when it uses internal mode to control its own probes.

There can be only one client at a time doing probe control on a given process. Therefore, it is not possible for a process to be controlled internally while it is being controlled externally. It is also not possible to have a process controlled by multiple external processes. Similarly, there can be only one process at a time doing kernel probe control. Note, however, that while a given target may only be controlled by one libtnfctl client, a single client may control an arbitrary number of targets. That is, it is possible for a process to simultaneously control its own probes, probes in other processes, and probes in the kernel.

The following tables denotes the modes applicable to all libtnfctl interfaces (INT = internal mode; D = direct mode; IND = indirect mode; K = kernel mode).

These interfaces create handles in the specified modes:

```
INT
tnfctl_internal_open()
tnfctl exec open()
                                           D
                                           D
tnfctl_pid_open()
```

tnfctl_indirect_open()			IND		
tnfctl_kernel_open()				K	
These interfaces are used with the sp	ecified	modes:			
tnfctl_continue()		D			
tnfctl probe connect()	INT	D	IND		
tnfctl probe disconnect all ()		D	IND		
tnfctl_trace_attrs_get()	INT	D	IND	K	
tnfctl buffer alloc()	INT	D	IND	K	
tnfctl register funcs()	INT	D	IND	K	
tnfctl probe apply()	INT	D	IND	K	
tnfctl_probe_apply_ids()	INT	D	IND	K	
	INT	D	IND	K	
tnfctl_probe_state_get ()					
tnfctl_probe_enable()	INT	D	IND	K	
tnfctl_probe_disable()	INT	D	IND	K	
<pre>tnfctl_probe_trace()</pre>	INT	D	IND	K	
<pre>tnfctl_probe_untrace()</pre>	INT	D	IND	K	
tnfctl_check_libs()	INT	D	IND	K	
tnfctl_close()	INT	D	IND	K	
tnfctl_strerror()	INT	D	IND	K	
tnfctl_buffer_dealloc()				K	
tnfctl_trace_state_set()				K	
<pre>tnfctl_filter_state_set()</pre>				K	
tnfctl_filter_list_get()				K	
tnfctl_filter_list_add()				K	

When using libtnfctl, the first task is to create a handle for controlling probes. The tnfctl_internal_open() function creates an internal mode handle for controlling probes in the same process, as described above. The ${\tt tnfctl_pid_open}$ () and tnfctl_exec_open() functions create handles in direct mode. The tnfctl_indirect_open() function creates an indirect mode handle, and the

tnfctl_filter_list_delete()

K

libtnfctl(3TNF)

tnfctl kernel open() function creates a kernel mode handle. A handle is required for use in nearly all other libtnfctl functions. The tnfctl close() function releases the resources associated with a handle.

The tnfctl continue() function is used in direct mode to resume execution of the target process.

The tnfctl buffer alloc() function allocates a trace file or, in kernel mode, a trace buffer.

The tnfctl_probe_apply() and tnfctl_probe_apply_ids() functions call a specified function for each probe or for a designated set of probes.

The tnfctl register funcs() function registers functions to be called whenever new probes are seen or probes have disappeared, providing an opportunity to do one-time processing for each probe.

The tnfctl check libs() function is used primarily in indirect mode to check whether any new probes have appeared, that is, they have been made available by dlopen(3DL), or have disappeared, that is, they have disassociated from the process by dlclose(3DL).

The tnfctl probe enable() and tnfctl probe disable() functions control whether the probe, when hit, will be ignored.

The tnfctl probe trace() and tnfctl probe untrace() functions control whether an enabled probe, when hit, will cause an entry to be made in the trace file.

The tnfctl probe connect() and tnfctl probe disconnect all() functions control which functions, if any, are called when an enabled probe is hit.

The tnfctl probe state get() function returns information about the status of a probe, such as whether it is currently enabled.

The tnfctl_trace_attrs_get() function returns information about the tracing session, such as the size of the trace buffer or trace file.

The tnfctl strerror() function maps a tnfctl error code to a string, for reporting purposes.

The remaining functions apply only to kernel mode.

The tnfctl trace state set() function controls the master switch for kernel tracing. See prex(1) for more details.

The tnfctl_filter_state_set(), tnfctl_filter_list_get(), tnfctl filter list add(), and tnfctl filter list delete() functions allow a set of processes to be specified for which probes will not be ignored when hit. This prevents kernel activity caused by uninteresting processes from cluttering up the kernel's trace buffer.

The ${\tt tnfctl_buffer_dealloc}()$ function deallocates the kernel's internal trace buffer.

RETURN VALUES

Upon successful completion, these functions returnTNFCTL ERR NONE.

ERRORS

The error codes for libtnfctl are:

TNFCTL ERR ACCES Permission denied.

TNFCTL_ERR_NOTARGET The target process completed.

TNFCTL ERR ALLOCFAIL A memory allocation failure occurred.

TNFCTL ERR INTERNAL An internal error occurred.

TNFCTL_ERR_SIZETOOSMALL The requested trace size is too small.

TNFCTL_ERR_SIZETOOBIG The requested trace size is too big.

TNFCTL ERR BADARG Bad input argument.

TNFCTL_ERR_NOTDYNAMIC The target is not a dynamic executable.

TNFCTL ERR NOLIBTNFPROBE libtnfprobe.so not linked in target.

TNFCTL_ERR_BUFBROKEN Tracing is broken in the target.

TNFCTL ERR BUFEXISTS A buffer already exists.

TNFCTL ERR NOBUF No buffer exists.

TNFCTL_ERR_BADDEALLOC Cannot deallocate buffer.

TNFCTL ERR NOPROCESS No such target process exists.

TNFCTL_ERR_FILENOTFOUND File not found.

TNFCTL ERR BUSY Cannot attach to process or kernel because

it is already tracing.

TNFCTL_ERR_INVALIDPROBE Probe no longer valid.

TNFCTL_ERR_USR1 Error code reserved for user.

TNFCTL_ERR_USR2 Error code reserved for user.

TNFCTL_ERR_USR3 Error code reserved for user.

TNFCTL_ERR_USR4 Error code reserved for user.

TNFCTL_ERR_USR5 Error code reserved for user.

Linker and Libraries Guide

NOTES

This API is MT-Safe. Multiple threads may concurrently operate on independent tnfctl handles, which is the typical behavior expected. The libtnfctl library does not support multiple threads operating on the same tnfctl handle. If this is desired, it is the client's responsibility to implement locking to ensure that two threads that use the same tnfctl handle are not simultaneously in a libtnfctl interface.

NAME | log10 – base 10 logarithm function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double log10 (double x);

DESCRIPTION

The log10 () function computes the base 10 logarithm of x, $\log_{10}(x)$. The value of xmust be positive.

RETURN VALUES

Upon successful completion, log10 () returns the base 10 logarithm of x.

If *x* is NaN, NaN is returned. If *x* is less than 0, -HUGE_VAL or NaN is returned, and errno is set to EDOM. If x is 0, -HUGE VAL is returned and errno may be set to ERANGE.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The log10() function will fail if:

EDOM The value of *x* is negative.

The log10() function may fail if:

The value of x is 0. **ERANGE**

No other errors will occur.

USAGE

An application wishing to check for error situations should set errno to 0 before calling log10(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

log1p(3M)

NAME | log1p – compute natural logarithm

SYNOPSIS

cc [flag ...] file ... -lm [library ...]

#include <math.h>

double log1p(double x);

DESCRIPTION

The log1p() function computes $\log_e(1.0 + x)$. The value of x must be greater than

RETURN VALUES

Upon successful completion, log1p() returns the natural logarithm of 1.0 + x.

If x is NaN, log1p() returns NaN.

If x is less than -1.0, log1p() returns -HUGE VAL or NaN and sets errno to EDOM.

If x is -1.0, log1p () returns -HUGE VAL and may set errno to ERANGE.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by

Standards other than XPG4.

ERRORS

The log1p() function will fail if:

EDOM

The value of x is less than -1.0.

The log1p() function may fail and set errno to:

ERANGE

The value of x is -1.0.

NAME | log – natural logarithm function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double log(double x);

DESCRIPTION

The log() function computes the natural logarithm of x, $\log_e(x)$. The value of x must be positive.

RETURN VALUES

Upon successful completion, log() returns the natural logarithm of x.

If *x* is NaN, NaN is returned.

If x is less than 0, -HUGE VAL or NaN is returned and errno is set to EDOM.

If x is 0, -HUGE VAL is returned and errno may be set to ERANGE.

In IEEE 754 mode (the -Xlibmieee cc compilation option), if x is Inf or a quiet NaN, x is returned; if x is a signaling NaN, a quiet NaN is returned and the invalid operation exception is raised; if x is 1, 0 is returned; for all other positive x, a normalized number is returned and the inexact exception is raised.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The log() function will fail if:

EDOM The value of x is negative.

The log() function may fail if:

The value of x is 0. ERANGE

No other errors will occur.

USAGE

An application wishing to check for error situations should set errno to 0 before calling log(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

logb(3M)

NAME | logb – radix-independent exponent

SYNOPSIS

```
cc [ flag \dots ] file \dots -lm [ library \dots ]
```

#include <math.h>

double logb(double x);

DESCRIPTION

The logb () function computes the exponent of x, which is the integral part of \log_{r} |x|, as a signed floating point value, for non-zero x, where r is the radix of the machine's floating-point arithmetic.

RETURN VALUES

Upon successful completion, logb() returns the exponent of x.

If x is 0.0, logb() returns -HUGE VAL and sets errno to EDOM.

If x is \pm Inf, logb() returns +Inf.

If x is NaN, logb() returns NaN.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by various Standards.

ERRORS

The logb() function will fail if:

EDOM

The *x* argument is 0.0.

NAME | maillock, mailunlock, touchlock – functions to manage lockfile(s) for user's mailbox

SYNOPSIS

```
cc [ flag ... ] file ... -lmail [ library ... ]
#include <maillock.h>
int maillock(const char *user, int retrycnt);
void mailunlock(void);
void touchlock(void);
```

DESCRIPTION

The maillock () function attempts to create a lockfile for the user's mailfile. If a lockfile already exists, and it has not been modified in the last 5 minutes, maillock() will remove the lockfile and set its own lockfile.

It is crucial that programs locking mail files refresh their locks at least every three minutes to maintain the lock. Refresh the lockfile by calling the touchlock () function with no arguments.

The algorithm used to determine the age of the lockfile takes into account clock drift between machines using a network file system. A zero is written into the lockfile so that the lock will be respected by systems running the standard version of System V.

If the lockfile has been modified in the last 5 minutes the process will sleep until the lock is available. The sleep algorithm is to sleep for 5 seconds times the attempt number. That is, the first sleep will be for 5 seconds, the next sleep will be for 10 seconds, etc. until the number of attempts reaches retrycnt.

When the lockfile is no longer needed, it should be removed by calling mailunlock().

The user argument is the login name of the user for whose mailbox the lockfile will be created. maillock() assumes that user's mailfiles are in the "standard" place as defined in <maillock.h>.

RETURN VALUES

Upon successful completion, .maillock () returns 0. Otherwise it returns −1.

FILES

/var/mail/* user mailbox files /var/mail/*.lock user mailbox lockfiles

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE		
MT-Level	Unsafe		

SEE ALSO

libmail(3LIB),attributes(5)

NOTES

The mailunlock() function will only remove the lockfile created from the most previous call to maillock(). Calling maillock() for different users without

intervening calls to ${\tt mailunlock()}$ will cause the initially created lockfile(s) to remain, potentially blocking subsequent message delivery until the current process finally terminates.

maillock(3MAIL)

NAME

matherr – math library exception-handling function

SYNOPSIS

```
#include <math.h>
int matherr(struct exception *exc);
```

DESCRIPTION

The The System V Interface Definition, Third Edition (SVID3) specifies that certain libm functions call matherr() when exceptions are detected. Users may define their own mechanisms for handling exceptions, by including a function named matherr() in their programs. The matherr() function is of the form described above. When an exception occurs, a pointer to the exception structure <code>exc</code> will be passed to the user-supplied matherr() function. This structure, which is defined in the <code><math.h></code> header file, is as follows:

```
struct exception {
   int type;
   char *name;
   double arg1, arg2, retval;
};
```

The type member is an integer describing the type of exception that has occurred, from the following list of constants (defined in the header file):

DOMAIN argument domain exception

SING argument singularity

OVERFLOW overflow range exception
UNDERFLOW underflow range exception
TLOSS total loss of significance
PLOSS partial loss of significance

Note that both TLOSS and PLOSS reflect limitations of particular algorithms for trigonometric functions that suffer abrupt declines in accuracy at definite boundaries. Since the implementation does not suffer such abrupt declines, PLOSS is never signaled. TLOSS is signaled for Bessel functions *only* to satisfy SVID3 requirements.

The name member points to a string containing the name of the function that incurred the exception. The arg1 and arg2 members are the arguments with which the function was invoked. retval is set to the default value that will be returned by the function unless the user's matherr() sets it to a different value.

If the user's matherr() function returns non-zero, no exception message will be printed, and errno will not be set.

SVID3 STANDARD CONFORMANCE

When an application is built as a SVID3 conforming application (see standards(5)), if matherr() is not supplied by the user, the default matherr exception-handling mechanisms, summarized in the table below, will be invoked upon exception:

matherr(3M)

DOMAIN	0.0 is usually returned, errno is set to EDOM, and a message is usually printed on standard error.
SING	The largest finite single-precision number, HUGE of appropriate sign is returned, errno is set to EDOM, and a message is printed on standard error.
OVERFLOW	The largest finite single-precision number, HUGE of appropriate sign is usually returned, errno is set to ERANGE.
UNDERFLOW	0.0 is returned, and errno is set to ERANGE.
TLOSS	0.0 is returned, errno is set to ERANGE, and a message is printed on standard error.

In general, errno is not a reliable error indicator in that it may be unexpectedly set by a function in a handler for an asynchronous signal.

SVID3 ERROR HANDLING PROCEDURES (compile with cc \-Xt)

(x = 0)	_	Md, –HUGE	_	_	_
$(x > X_TLOSS)$	_	_	-	-	Mt, 0.0

Abbreviations

Md Message is printed (DOMAIN error).

Ms Message is printed (SING error).

Mt Message is printed (TLOSS error).

NaN IEEE NaN result and invalid operation exception.

HUGE Maximum finite single-precision floating-point number.

HUGE_VAL IEEE ∞ result and division-by-zero exception.

 X_{TLOSS} The value X_{TLOSS} is defined in <values.h>.

The interaction of IEEE arithmetic and matherr() is not defined when executing under IEEE rounding modes other than the default round to nearest: matherr() is not always called on overflow or underflow, and the matherr() may return results that differ from those in this table.

X/OPEN
COMMON
APPLICATION
ENVIRONMENT
(CAE)
SPECIFICATIONS
CONFORMANCE

The X/Open System Interfaces and Headers (XSH) Issue 3 and later revisions of that specification no longer sanctions the use of the matherr() interface. The following table summarizes the values returned in the exceptional cases. In general, XSH dictates that as long as one of the input argument(s) is a NaN, NaN shall be returned. In particular, pow(NaN, 0) = NaN.

NAME | m_create_layout – initialize a layout object

SYNOPSIS

```
cc [ flag... ] file... -llayout [ library... ]
#include <sys/layout.h>
```

LayoutObject m create layout(const AttrObject attrobj, const char* modifier);

DESCRIPTION

The m create layout() function creates a LayoutObject associated with the locale identified by attrobj.

The LayoutObject is an opaque object containing all the data and methods necessary to perform the layout operations on context-dependent or directional characters of the locale identified by the *attrobj*. The memory for the LayoutObject is allocated by m create layout(). The LayoutObject created has default layout values. If the modifier argument is not NULL, the layout values specified by the modifier overwrite the default layout values associated with the locale. Internal states maintained by the layout transformation function across transformations are set to their initial values.

The attrobj argument is or may be an amalgam of many opaque objects. A locale object is just one example of the type of object that can be attached to an attribute object. The attrobj argument specifies a name that is usually associated with a locale category. If attrobj is NULL, the created LayoutObject is associated with the current locale as set by the setlocale(3C) function.

The *modifier* argument announces a set of layout values when the LayoutObject is created.

RETURN VALUES

Upon successful completion, the m create layout() function returns a LayoutObject for use in subsequent calls to m * layout() functions. Otherwise the m create layout() function returns (LayoutObject) 0 and sets errno to indicate the error.

ERRORS

The m create layout() function may fail if:

The attribute object is invalid or the locale associated with the EBADF

attribute object is not available.

The *modifier* string has a syntax error or it contains unknown EINVAL

layout values.

EMETLE There are {OPEN MAX} file descriptors currently open in the

calling process.

ENOMEM Insufficient storage space is available.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NAME | md5, md5 calc, MD5Init, MD5Update, MD5Final – MD5 digest functions

SYNOPSIS

```
cc [ flag ... ] file ... -lmd5 [ library ... ]
#include <md5.h>
void md5 calc (unsigned char *output, unsigned char *input, unsigned
     int inlen);
void MD5Init (MD5 CTX *context);
void MD5Update(MD5 CTX *context, unsigned char *input, unsigned int
```

void MD5Final(unsigned char *output, MD5 CTX *context);

DESCRIPTION

These functions implement the MD5 message-digest algorith, which takes as input a message of arbitrary length and produces as output a 128-bit "fingerprint" or "message digest" of the input. It is intended for digital signature applications, where large file must be "compressed" in a secure manner before being encrypted with a private (secret) key under a public-key cryptosystem such as RSA.

md5 calc()

The md5 calc() function computes an MD5 digest on a single message block. The inlen-byte block is pointed to by input, and the 16-byte MD5 digest is written to output.

MD5Init(), MD5Update(), MD5Final() The MD5Init(), MD5Update(), and MD5Final() functions allow an MD5 digest to be computed over multiple message blocks; between blocks, the state of the MD5 computation is held in an MD5 context structure, allocated by the caller. A complete digest computation consists of one call to MD5Init(), one or more calls to MD5Update(), and one call to MD5Final(), in that order.

The MD5Init () function initializes the MD5 context structure pointed to by *context*.

The MD5Update () function computes a partial MD5 digest on the *inlen*-byte message block pointed to by input, and updates the MD5 context structure pointed to by context accordingly.

The MD5Final () function generates the final MD5 digest, using the MD5 context structure pointed to by *context*; the 16-byte MD5 digest is written to *output*. After calling MD5Final(), the state of the context structure is undefined; it must be reinitialized with MD5Init() before being used again.

RETURN VALUES

These functions do not return a value.

EXAMPLES

EXAMPLE 1 Authenticate a message found in multiple buffers

The following is a sample function that must authenticate a message that is found in multiple buffers. The calling function provides an authentication buffer that will contain the result of the MD5 digest.

```
AuthenticateMsg(unsigned char *auth_buffer, struct iovec
                *messageIov, unsigned int num_buffers)
```

EXAMPLE 1 Authenticate a message found in multiple buffers (Continued)

EXAMPLE 2 Use $md5_calc()$ to generate the MD5 digest

Since the buffer to be computed is contiguous, the $md5_calc()$ function can be used to generate the MD5 digest.

ATTRIBUTES

NAME | m_destroy_layout – destroy a layout object

SYNOPSIS cc [flag...] file... -llayout [library...]

#include <sys/layout.h>

int m destroy layout(const LayoutObject layoutobject);

DESCRIPTION The m destroy layout () function destroys a LayoutObject by deallocating the

layout object and all the associated resources previously allocated by the

m_create_layout(3LAYOUT) function.

RETURN VALUES Upon successful completion, 0 is returned. Otherwise -1 is returned and errno is set

to indicate the error.

ERRORS The m destroy layout() function may fail if:

EBADF The attribute object is erroneous.

EFAULT Errors occurred while processing the request.

media findname(3VOLMGT)

NAME |

media_findname – convert a supplied name into an absolute pathname that can be used to access removable media

SYNOPSIS

char *media findname(char *start);

DESCRIPTION

media_findname() converts the supplied *start* string into an absolute pathname that can then be used to access a particular piece of media.

The *start* parameter can be one of the following types of specifications:

/dev/... An absolute pathname in /dev, such as

/dev/rdiskette0, in which case a copy of that string

is returned (see NOTES on this page).

/vol/... An absolute Volume Management pathname, such as

/vol/dev/aliases/floppy0 or /vol/dsk/fred. If this supplied pathname is not a symbolic link, then a copy of that pathname is returned. If the supplied pathname is a symbolic link then it is dereferenced and a copy of that dereferenced pathname is returned.

volume_name The Volume Management volume name for a particular

volume, such as fred (see fdformat(1) for a description of how to label floppies). In this case a pathname in the Volume Management namespace is

returned.

volmgt_symname The Volume Management symbolic name for a device,

such as floppy0 or cdrom2 (see volfs(7FS) for more information on Volume Management symbolic names), in which case a pathname in the Volume Management

namespace is returned.

media_type The Volume Management generic media type name.

For example, floppy or cdrom. In this case

media_findname() looks for the first piece of media that matches that media type, starting at 0 (zero) and continuing on until a match is found (or some fairly large maximum number is reached). In this case, if a match is found, a copy of the pathname to the volume

found is returned.

RETURN VALUES

Upon successful completion media_findname() returns a pointer to the pathname found. In the case of an error a null pointer is returned.

ERRORS

For cases where the supplied *start* parameter is an absolute pathname, media_findname() can fail, returning a null string pointer, if an lstat(2) of that supplied pathname fails. Also, if the supplied absolute pathname is a symbolic link,

media_findname() can fail if a readlink(2) of that symbolic link fails, or if a stat(2) of the pathname pointed to by that symbolic link fails, or if any of the following is true:

ENXIO

The specified absolute pathname was not a character special device, and it was not a directory with a character special device in it.

EXAMPLES

EXAMPLE 1 Sample programs of the media_findname() function.

The following example attempts to find what the Volume Management pathname is to a piece of media called fred. Notice that a volmgt_check() is done first (see the NOTES section on this page).

```
(void) volmgt_check(NULL);
if ((nm = media_findname("fred")) != NULL) {
          (void) printf("media named \"fred\" is at \"%s\"\n", nm);
} else {
          (void) printf("media named \"fred\" not found\n");
}
```

This example looks for whatever volume is in the first floppy drive, letting media_findname() call volmgt_check() if and only if no floppy is currently known to be the first floppy drive.

```
if ((nm = media_findname("floppy0")) != NULL) {
        (void) printf("path to floppy0 is \"%s\"\n", nm);
} else {
        (void) printf("nothing in floppy0\n");
}
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Unsafe

SEE ALSO

cc(1B), fdformat(1), vold(1M), lstat(2), readlink(2), stat(2), free(3C),
malloc(3C), volmgt_check(3VOLMGT), volmgt_inuse(3VOLMGT),
volmgt_root(3VOLMGT), volmgt_running(3VOLMGT),
volmgt_symname(3VOLMGT), attributes(5), volfs(7FS)

NOTES

If media_findname() cannot find a match for the supplied name, it performs a volmgt_check(3VOLMGT) and tries again, so it can be more efficient to perform volmgt_check() before calling media_findname().

Upon success media_findname() returns a pointer to string which has been allocated; this should be freed when no longer in use (see free(3C)).

media_getattr(3VOLMGT)

NAME | media_getattr, media_setattr – get and set media attributes

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
```

```
char *media getattr(char *vol_path, char *attr);
```

int media setattr(char *vol_path, char *attr, char *value);

DESCRIPTION

media setattr() and media getattr() respectively set and get attribute-value pairs (called properties) on a per-volume basis.

Volume Management supports system properties and user properties. System properties are ones that Volume Management predefines. Some of these system properties are writable, but only by the user that owns the volume being specified, and some system properties are read only:

Attribute	Writable	Value	Description
s-access	RO	"seq", "rand"	sequential or random access
s-density	RO	"low", "medium", "high"	media density
s-parts	RO	comma separated list of slice numbers	list of partitions on this volume
s-location	RO	pathname	Volume Management pathname to media
s-mejectable	RO	"true", "false"	whether or not media is manually ejectable
s-rmoneject	R/W	"true", "false"	should media access points be removed from database upon ejection
s-enxio	R/W	"true", "false"	if set return ENXIO when media access attempted

Properties can also be defined by the user. In this case the value can be any string the user wishes.

RETURN VALUES

Upon successful completion media getattr() returns a pointer to the value corresponding to the specified attribute. A null pointer is returned if the specified volume doesn't exist, if the specified attribute for that volume doesn't exist, if the specified attribute is boolean and its value is false, or if malloc(3C) fails to allocate space for the return value.

media_setattr() returns 1 upon success, and 0 upon failure.

ERRORS

Both media_getattr() and media_setattr() can fail returning a null pointer if an open(2) of the specified *vol_path* fails, if an fstat(2) of that pathname fails, or if that pathname is not a block or character special device.

media_getattr() can also fail if the specified attribute was not found, and
media_setattr() can also fail if the caller doesn't have permission to set the
attribute, either because it's is a system attribute, or because the caller doesn't own the
specified volume.

Additionally, either routine can fail returning the following error values:

ENXIO The Volume Management daemon, vold, is not running

EINTR The routine was interrupted by the user before finishing

EXAMPLES

```
EXAMPLE 1 Using media_getattr()
```

The following example checks to see if the volume called *fred* that Volume Management is managing can be ejected by means of software, or if it can only be manually ejected:

```
if (media_getattr("/vol/rdsk/fred", "s-mejectable") != NULL) {
          (void) printf("\"fred\" must be manually ejected\n");
} else {
          (void) printf("software can eject \"fred\"\n");
}
```

This example shows setting the *s-enxio* property for the floppy volume currently in the first floppy drive:

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

```
\label{eq:cc1B}  \mbox{cc(1B), vold(1M), lstat(2), open(2), readlink(2), stat(2), free(3C), malloc(3C), media_findname(3VOLMGT), volmgt_check(3VOLMGT), volmgt_inuse(3VOLMGT), volmgt_root(3VOLMGT), volmgt_running(3VOLMGT), volmgt_symname(3VOLMGT), attributes(5)   \mbox{}
```

NOTES

Upon success media_getattr() returns a pointer to a string which has been allocated, and should be freed when no longer in use (see free(3C)).

media_getid(3VOLMGT)

NAME |

media_getid - return the id of a piece of media

SYNOPSIS

```
cc [flag ...] file ...-lvolgmt [library ...]
#include <volmqt.h>
ulonglong t media getid(char *vol_path);
```

DESCRIPTION

media getid() returns the id of a piece of media. Volume Management must be running. See volmgt running(3VOLMGT).

PARAMETERS

vol_path

Path to the block or character special device.

RETURN VALUES

media getid() returns the *id* of the volume. This value is unique for each volume. If media getid() returns 0, the path provided is not valid, for example, it is a block or char device.

EXAMPLES

EXAMPLE 1 Using media_getid()

The following example first checks if Volume Management is running, then checks the volume management name space for path, and then returns the id for the piece of media.

```
char *path;
if (volmgt_running()) {
    if (volmgt_ownspath(path)) {
         (void) printf("id of %s is %lld\n",
              path, media getid(path));
    }
```

If a program using media getid() does not check whether or not Volume Management is running, then any NULL return value will be ambiguous, as it could mean that either Volume Management does not have path in its name space, or Volume Management is not running.

NAME | m_getvalues_layout – query layout values of a LayoutObject

SYNOPSIS

```
cc [ flag... ] file... -llayout [ library... ]
#include <sys/layout.h>
```

int m getvalues layout(const LayoutObject layout_object, LayoutValues values, int *index_returned);

DESCRIPTION

The m getvalues layout () function queries the current setting of layout values within a LayoutObject.

The layout_object argument specifies a LayoutObject returned by the m create layout(3LAYOUT) function.

The values argument specifies the list of layout values that are to be queried. Each value element of a LayoutValueRec must point to a location where the layout value is stored. That is, if the layout value is of type T, the argument must be of type T*. The values are queried from the LayoutObject and represent its current state.

It is the user's responsibility to manage the space allocation for the layout values queried. If the layout value name has QueryValueSize OR-ed to it, instead of the value of the layout value, only its size is returned. The caller can use this option to determine the amount of memory needed to be allocated for the layout values queried.

RETURN VALUES

Upon successful completion, the m getvalues layout () function returns 0. If any value cannot be queried, the index of the value causing the error is returned in *index_returned*, −1 is returned and errno is set to indicate the error.

ERRORS

The m getvalues layout() function may fail if:

EINVAL

The layout value specified by *index_returned* is unknown, its value is invalid, or the *layout_object* argument is invalid. In the case of an invalid *layout_object* argument, the value returned in *index_returned* is -1.

mkdirp(3GEN)

NAME |

mkdirp, rmdirp – create or remove directories in a path

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
int mkdirp(const char *path, mode_t mode);
int rmdirp(char *dir, char *dir1);
```

DESCRIPTION

The mkdirp() function creates all the missing directories in *path* with *mode*. See chmod(2) for the values of *mode*.

The rmdirp() function removes directories in path *dir*. This removal begins at the end of the path and moves backward toward the root as far as possible. If an error occurs, the remaining path is stored in *dir1*.

RETURN VALUES

If path already exists or if a needed directory cannot be created, mkdirp() returns -1 and sets errno to one of the error values listed for mkdir(2). It returns zero if all the directories are created.

The rmdirp() function returns 0 if it is able to remove every directory in the path. It returns -2 if a "." or ".." is in the path and -3 if an attempt is made to remove the current directory. Otherwise it returns-1.

EXAMPLES

EXAMPLE 1 Example of creating scratch directories.

The following example creates scratch directories.

```
/* create scratch directories */
if(mkdirp("/tmp/sub1/sub2/sub3", 0755) == -1) {
    fprintf(stderr, "cannot create directory");
    exit(1);
}
chdir("/tmp/sub1/sub2/sub3");
.
.
.
/* cleanup */
chdir("/tmp");
rmdirp("sub1/sub2/sub3");
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

mp(3MP)

NAME

mp, mp_madd, mp_msub, mp_mult, mp_mdiv, mp_mcmp, mp_min, mp_mout, mp_pow, mp_gcd, mp_rpow, mp_itom, mp_xtom, mp_mtox, mp_mfree – multiple precision integer arithmetic

SYNOPSIS

```
cc [ flag ... ] file ... -lmp [ library ... ]
#include <mp.h>
void mp madd(MINT *a, MINT *b, MINT *c);
void mp msub (MINT *a, MINT *b, MINT *c);
void mp mult(MINT *a, MINT *b, MINT *c);
void mp mdiv (MINT *a, MINT *b, MINT *q, MINT *r);
int mp mcmp (MINT *a, MINT *b);
int mp min(MINT *a);
void mp mout(MINT *a);
void mp pow(MINT *a, MINT *b, MINT *c, MINT *d);
void mp gcd(MINT *a, MINT *b, MINT *c);
void mp rpow (MINT *a, short n, MINT *b);
int mp msqrt (MINT *a, MINT *b, MINT *r);
void mp sdiv(MINT *a, short n, MINT *q, short *r);
MINT * mp itom(short n);
MINT * mp xtom(char *a);
char * mp mtox(MINT *a);
void mp mfree(MINT *a);
```

DESCRIPTION

These routines perform arithmetic on integers of arbitrary length. The integers are stored using the defined type MINT. Pointers to a MINT should be initialized using the function $mp_itom(n)$, which sets the initial value to n. Alternatively, $mp_xtom(a)$ may be used to initialize a MINT from a string of hexadecimal digits. $mp_mfree(a)$ may be used to release the storage allocated by the $mp_itom(a)$ and $mp_xtom(a)$ routines.

The mp_madd(a,b,c), mp_msub(a,b,c) and mp_mult(a,b,c) functions assign to their third arguments the sum, difference, and product, respectively, of their first two arguments. The mp_mdiv(a,b,q,r) function assigns the quotient and remainder, respectively, to its third and fourth arguments. The mp_sdiv(a,n,q,r) function is similar to mp_mdiv(a,b,q,r) except that the divisor is an ordinary integer. The mp_msqrt(a,b,r) function produces the square root and remainder of its first argument. The mp_mcmp(a,b) function compares the values of its arguments and returns 0 if the two values are equal, a value greater than 0 if the first argument is greater than the second, and a value less than 0 if the second argument is greater than the first. The mp_rpow(a,n,b) function raises a to the nth power and assigns this value to b. The

<code>mp_pow(a,b,c,d)</code> function raises a to the bth power, reduces the result modulo c and assigns this value to d. The <code>mp_min(a)</code> and <code>mp_mout(a)</code> functions perform decimal input and output. The <code>mp_gcd(a,b,c)</code> function finds the greatest common divisor of the first two arguments, returning it in the third argument. The <code>mp_mtox(a)</code> function provides the inverse of <code>mp_xtom(a)</code>. To release the storage allocated by <code>mp_mtox(a)</code> use <code>free()</code> (see <code>malloc(3C)</code>).

Use the -1mp loader option to obtain access to these functions.

DIAGNOSTICS

Illegal operations and running out of memory produce messages and core images.

WARNINGS

The function pow() exists in both libmp and libm with widely differing semantics. This is why libmp.so.2 exists.libmp.so.1 exists solely for reasons of backward compatibility, and should not be used otherwise. Use the mp_*() functions instead. See libmp(3LIB).

m_setvalues_layout(3LAYOUT)

NAME | m_setvalues_layout - set layout values of a LayoutObject

SYNOPSIS

```
cc [ flag... ] file... -llayout [ library... ]
#include <sys/layout.h>
```

int m_setvalues_layout(LayoutObject layout_object, const LayoutValues values, int *index_returned);

DESCRIPTION

The m setvalues layout() function changes the layout values of a LayoutObject.

The layout object argument specifies a LayoutObject returned by the m create layout(3LAYOUT) function.

The values argument specifies the list of layout values that are to be changed. The values are written into the LayoutObject and may affect the behavior of subsequent layout functions. Some layout values do alter internal states maintained by a LayoutObject.

The m setvalues layout () function can be implemented as a macro that evaluates the first argument twice.

RETURN VALUES

Upon successful completion, the requested layout values are set and 0 is returned. Otherwise -1 is returned and errno is set to indicate the error. If any value cannot be set, none of the layout values are changed and the (zero-based) index of the first value causing the error is returned in *index_returned*.

ERRORS

The m setvalues layout() function may fail if:

EINVAL The layout value specified by *index_returned* is unknown, its value

is invalid, or the *layout_object* argument is invalid.

EMFILE There are {OPEN MAX} file descriptors currently open in the

calling process.

USAGE

Do not use expressions with side effects such as auto-increment or auto-decrement within the first argument to the m_setvalues_layout() function.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO | m create layout(3LAYOUT), attributes(5)

NAME | m_transform_layout – layout transformation

SYNOPSIS

```
cc [ flag... ] file... -llayout [ library... ]
#include <sys/layout.h>
```

```
int m transform layout (LayoutObject layout object, const char *InpBuf,
    const size t ImpSize, const void *OutBuf, size t *Outsize, size t
    *InpToOut, size t *OutToInp, unsigned char *Property, size t
    *InpBufIndex);
```

DESCRIPTION

The m transform layout () function performs layout transformations (reordering, shaping, cell determination) or provides additional information needed for layout transformation (such as the expected size of the transformed layout, the nesting level of different segments in the text and cross-references between the locations of the corresponding elements before and after the layout transformation). Both the input text and output text are character strings.

The m transform layout () function transforms the input text in *InpBuf* according to the current layout values in *layout_object*. Any layout value whose value type is LayoutTextDescriptor describes the attributes of the *InpBuf* and *OutBuf* arguments. If the attributes are the same for both *InpBuf* and *OutBuf*, a null transformation is performed with respect to that specific layout value.

The InpBuf argument specifies the source text to be processed. The InpBuf may not be NULL, unless there is a need to reset the internal state.

The InpSize argument is the number of bytes within InpBuf to be processed by the transformation. Its value will not change after return from the transformation. InpSize set to -1 indicates that the text in *InpBuf* is delimited by a null code element. If *InpSize* is not set to −1, it is possible to have some null elements in the input buffer. This might be used, for example, for a "one shot" transformation of several strings, separated by

Output of this function may be one or more of the following depending on the setting of the arguments:

OutBuf Any transformed data is stored in OutBuf, converted to	OutBuf	Any transformed	l data is stored	in OutBuf	, converted to
---	--------	-----------------	------------------	-----------	----------------

ShapeCharset.

Outsize The number of bytes in *OutBuf*.

InpToOut A cross-reference from each InpBuf code element to the

> transformed data. The cross-reference relates to the data in *InpBuf* starting with the first element that *InpBufIndex* points to (and not

necessarily starting from the beginning of the *InpBuf*).

OutToInp A cross-reference to each *InpBuf* code element from the

transformed data. The cross-reference relates to the data in *InpBuf*

starting with the first element that InpBufIndex points to (and not

necessarily starting from the beginning of the *InpBuf*).

m_transform_layout(3LAYOUT)

Property

A weighted value that represents peculiar input string transformation properties with different connotations as explained below. If this argument is not a null pointer, it represents an array of values with the same number of elements as the source substring text before the transformation. Each byte will contain relevant "property" information of the corresponding element in *InpBuf* starting from the element pointed by *InpBufIndex*. The four rightmost bits of each "property" byte will contain information for bidirectional environments (when ActiveDirectional is True) and they will mean "NestingLevels." The possible value from $\boldsymbol{0}$ to 15 represents the nesting level of the corresponding element in the *InpBuf* starting from the element pointed by *InpBufIndex*. If ActiveDirectional is false the content of NestingLevel bits will be ignored. The leftmost bit of each "property" byte will contain a "new cell indicator" for composed character environments, and will have a value of either 1 (for an element in *InpBuf* that is transformed to the beginning of a new cell) or 0 (for the "zero-length" composing character elements, when these are grouped into the same presentation cell with a non-composing character). Here again, each element of "property" pertains to the elements in the *InpBuf* starting from the element pointed by *InpBufIndex*. (Remember that this is not necessarily the beginning of *InpBuf*). If none of the transformation properties is required, the argument *Property* can be NULL. The use of "property" can be enhanced in the future to pertain to other possible usage in other environments.

The <code>InpBufIndex</code> argument is an offset value to the location of the transformed text. When <code>m_transform_layout()</code> is called, <code>InpBufIndex</code> contains the offset to the element in <code>InpBuf</code> that will be transformed first. (Note that this is not necessarily the first element in <code>InpBuf</code>). At the return from the transformation, <code>InpBufIndex</code> contains the offset to the first element in the <code>InpBuf</code> that has not been transformed. If the entire substring has been transformed successfully, <code>InpBufIndex</code> will be incremented by the amount defined by <code>InpSize</code>.

Each of these output arguments may be NULL to specify that no output is desired for the specific argument, but at least one of them should be set to a non-null value to perform any significant work.

The layout object maintains a directional state that keeps track of directional changes, based on the last segment transformed. The directional state is maintained across calls to the layout transformation functions and allows stream data to be processed with the layout functions. The directional state is reset to its initial state whenever any of the layout values TypeOfText, Orientation, or ImplicitAlg is modified by means of a call to m_setvalues_layout().

The *layout_object* argument specifies a LayoutObject returned by the m create layout() function.

The *OutBuf* argument contains the transformed data. This argument can be specified as a null pointer to indicate that no transformed data is required.

The encoding of the *OutBuf* argument depends on the ShapeCharset layout value defined in *layout_object*. If the ActiveShapeEditing layout value is not set (False), the encoding of *OutBuf* is guaranteed to be the same as the codeset of the locale associated with the LayoutObject defined by *layout_object*.

On input, the *OutSize* argument specifies the size of the output buffer in number of bytes. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the ActiveShapeEditing layout value is set (True) the *OutBuf* should be allocated to contain at least the *InpSize* multiplied by ShapeCharsetSize.

On return, the *OutSize* argument is modified to the actual number of bytes placed in *OutBuf*.

When the *OutSize* argument is specified as zero, the function calculates the size of an output buffer large enough to contain the transformed text, and the result is returned in this field. The content of the buffers specified by *InpBuf* and *OutBuf*, and the value of *InpBufIndex*, remain unchanged. If *OutSize* = NULL, the EINVAL error condition should be returned.

If the *InpToOut* argument is not a null pointer, it points to an array of values with the same number of bytes in *InpBuf* starting with the one pointed by *InpBufIndex* and up to the end of the substring in the buffer. On output, the nth value in *InpToOut* corresponds to the nth byte in *InpBuf*. This value is the index (in units of bytes) in *OutBuf* that identifies the transformed ShapeCharset element of the nth byte in *InpBuf*. In the case of multibyte encoding, the index points (for each of the bytes of a code element in the *InpBuf*) to the first byte of the transformed code element in the *OutBuf*.

InpToOut may be specified as NULL if no index array from *InpBuf* to *OutBuf* is desired.

If the *OutToInp* argument is not a null pointer, it points to an array of values with the same number of bytes as contained in *OutBuf*. On output, the nth value in *OutToInp* corresponds to the nth byte in *OutBuf* This value is the index in *InpBuf*, starting with the byte pointed to by *InpBufIndex*, that identifies the logical code element of the nth byte in *OutBuf*. In the case of multibyte encoding, the index will point for each of the bytes of a transformed code element in the *OutBuf* to the first byte of the code element in the *InpBuf*.

OutToInp may be specified as NULL if no index array from OutBuf to InpBuf is desired.

To perform shaping of a text string without reordering of code elements, the <code>layout_object</code> should be set with input and output layout value <code>TypeOfText</code> set to <code>TEXT_VISUAL</code> and both in and out of <code>Orientation</code> set to the same value.

m transform layout(3LAYOUT)

RETURN VALUES |

If successful, the m transform layout () function returns 0. If unsuccessful, the returned value is -1 and the errno is set to indicate the source of error. When the size of OutBuf is not large enough to contain the entire transformed text, the input text state at the end of the uncompleted transformation is saved internally and the error condition E2BIG is returned in errno.

ERRORS

The m transform layout() function may fail if:

processed.

EBADF The layout values are set to a meaningless combination or the

layout object is not valid.

EILSEQ Transformation stopped due to an input code element that cannot

> be shaped or is invalid. The *InpBufIndex* argument is set to indicate the code element causing the error. The suspect code element is either a valid code element but cannot be shaped into the ShapeCharset layout value, or is an invalid code element not defined by the codeset of the locale of <code>layout_object</code>. The <code>mbtowc()</code> and wctomb() functions, when used in the same locale as the LayoutObject, can be used to determine if the code element is

valid.

EINVAL Transformation stopped due to an incomplete composite sequence

at the end of the input buffer, or *OutSize* contains NULL.

ERANGE More than 15 embedding levels are in source text or *InpBuf* contain

> unbalanced directional layout information (push/pop) or an incomplete composite sequence has been detected in the input buffer at the beginning of the string pointed to by *InpBufIndex*.

An incomplete composite sequence at the end of the input buffer is not always detectable. Sometimes, the fact that the sequence is incomplete will only be detected when additional character elements belonging to the composite sequence are found at the

beginning of the next input buffer.

USAGE

A LayoutObject will have a meaningful combination of default layout values. Whoever chooses to change the default layout values is responsible for making sure that the combination of layout values is meaningful. Otherwise, the result of m transform layout () might be unpredictable or implementation-specific with errno set to EBADF.

m_wtransform_layout(3LAYOUT)

NAME | m wtransform layout – layout transformation for wide character strings

SYNOPSIS

```
cc [ flag... ] file... -llayout [ library... ]
#include <sys/layout.h>
```

int m wtransform layout (Layout Object layout object, const wchar t *InpBuf, const size t ImpSize, const void *OutBuf, size t *Outsize, size t *InpToOut, size t *OutToInp, unsignedchar *Property, size t *InpBufIndex);

DESCRIPTION

The m wtransform layout() function performs layout transformations (reordering, shaping, cell determination) or provides additional information needed for layout transformation (such as the expected size of the transformed layout, the nesting level of different segments in the text and cross-references between the locations of the corresponding elements before and after the layout transformation). Both the input text and output text are wide character strings.

The m wtransform layout () function transforms the input text in *InpBuf* according to the current layout values in layout_object. Any layout value whose value type is LayoutTextDescriptor describes the attributes of the *InpBuf* and *OutBuf* arguments. If the attributes are the same for both *InpBuf* and *OutBuf*, a null transformation is performed with respect to that specific layout value.

The InpBuf argument specifies the source text to be processed. The InpBuf may not be NULL, unless there is a need to reset the internal state.

The InpSize argument is the number of bytes within InpBuf to be processed by the transformation. Its value will not change after return from the transformation. InpSize set to -1 indicates that the text in *InpBuf* is delimited by a null code element. If *InpSize* is not set to -1, it is possible to have some null elements in the input buffer. This might be used, for example, for a "one shot" transformation of several strings, separated by

Output of this function may be one or more of the following depending on the setting of the arguments:

ShapeCharset.

Outsize The number of wide characters in *OutBuf*.

InpToOut A cross-reference from each InpBuf code element to the

> transformed data. The cross-reference relates to the data in *InpBuf* starting with the first element that *InpBufIndex* points to (and not

necessarily starting from the beginning of the *InpBuf*).

OutToInp A cross-reference to each InpBuf code element from the

transformed data. The cross-reference relates to the data in InpBuf starting with the first element that InpBufIndex points to (and not

necessarily starting from the beginning of the *InpBuf*).

Property

A weighted value that represents peculiar input string transformation properties with different connotations as explained below. If this argument is not a nullpointer, it represents an array of values with the same number of elements as the source substring text before the transformation. Each byte will contain relevant "property" information of the corresponding element in *InpBuf* starting from the element pointed by *InpBufIndex*. The four rightmost bits of each "property" byte will contain information for bidirectional environments (when ActiveDirectional is True) and they will mean "NestingLevels." The possible value from 0 to 15 represents the nesting level of the corresponding element in the *InpBuf* starting from the element pointed by *InpBufIndex*. If ActiveDirectional is false the content of NestingLevel bits will be ignored. The leftmost bit of each "property" byte will contain a "new cell indicator" for composed character environments, and will have a value of either 1 (for an element in *InpBuf* that is transformed to the beginning of a new cell) or 0 (for the "zero-length" composing character elements, when these are grouped into the same presentation cell with a non-composing character). Here again, each element of "property" pertains to the elements in the *InpBuf* starting from the element pointed by *InpBufIndex*. (Remember that this is not necessarily the beginning of *InpBuf*). If none of the transformation properties is required, the argument *Property* can be NULL. The use of "property" can be enhanced in the future to pertain to other possible usage in other environments.

The <code>InpBufIndex</code> argument is an offset value to the location of the transformed text. When <code>m_wtransform_layout()</code> is called, <code>InpBufIndex</code> contains the offset to the element in <code>InpBuf</code> that will be transformed first. (Note that this is not necessarily the first element in <code>InpBuf</code>). At the return from the transformation, <code>InpBufIndex</code> contains the offset to the first element in the <code>InpBuf</code> that has not been transformed. If the entire substring has been transformed successfully, <code>InpBufIndex</code> will be incremented by the amount defined by <code>InpSize</code>.

Each of these output arguments may be null to specify that no output is desired for the specific argument, but at least one of them should be set to a non-null value to perform any significant work.

In addition to the possible outputs above, <code>layout_object</code> maintains a directional state across calls to the transform functions. The directional state is reset to its initial state whenever any of the layout values <code>TypeOfText</code>, <code>Orientation</code>, or <code>ImplicitAlg</code> is modified by means of a call to <code>m setvalues layout()</code>.

The *layout_object* argument specifies a LayoutObject returned by the m create layout() function.

m_wtransform_layout(3LAYOUT)

The *OutBuf* argument contains the transformed data. This argument can be specified as a null pointer to indicate that no transformed data is required.

The encoding of the *OutBuf* argument depends on the ShapeCharset layout value defined in layout_object. If the ActiveShapeEditing layout value is not set (False), the encoding of OutBuf is guaranteed to be the same as the codeset of the locale associated with the LayoutObject defined by *layout_object*.

On input, the OutSize argument specifies the size of the output buffer in number of wide characters. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the ActiveShapeEditing layout value is set (True) the OutBuf should be allocated to contain at least the *InpSize* multiplied by ShapeCharsetSize.

On return, the OutSize argument is modified to the actual number of code elements in OutBuf.

When the OutSize argument is specified as zero, the function calculates the size of an output buffer large enough to contain the transformed text, and the result is returned in this field. The content of the buffers specified by *InpBuf* and *OutBuf*, and the value of *InpBufIndex*, remain unchanged. If *OutSize* = NULL, the EINVAL error condition should be returned.

If the InpToOut argument is not a null pointer, it points to an array of values with the same number of wide characters in *InpBuf* starting with the one pointed by *InpBufIndex* and up to the end of the substring in the buffer. On output, the nth value in InpToOut corresponds to the nth byte in InpBuf. This value is the index (in units of wide characters) in *OutBuf* that identifies the transformed ShapeCharset element of the nth byte in *InpBuf*.

InpToOut may be specified as NULL if no index array from InpBuf to OutBuf is desired.

If the OutToInp argument is not a null pointer, it points to an array of values with the same number of wide characters as contained in *OutBuf*. On output, the nth value in OutToInp corresponds to the nth byte in OutBuf. This value is the index in InpBuf, starting with wide character byte pointed to by InpBufIndex, that identifies the logical code element of the nth wide character in *OutBuf*.

OutToInp may be specified as NULL if no index array from OutBuf to InpBuf is desired.

To perform shaping of a text string without reordering of code elements, the layout_object should be set with input and output layout value TypeOfText set to TEXT VISUAL and both in and out of Orientation set to the same value.

RETURN VALUES

If successful, the m wtransform layout() function returns 0. If unsuccessful, the returned value is -1 and the errno is set to indicate the source of error. When the size of OutBuf is not large enough to contain the entire transformed text, the input text state at the end of the uncompleted transformation is saved internally and the error condition E2BIG is returned in errno.

ERRORS

The m wtransform layout() function may fail if:

E2BIG The output buffer is full and the source text is not entirely

processed.

EBADF The layout values are set to a meaningless combination or the

layout object is not valid.

EILSEQ Transformation stopped due to an input code element that cannot

be shaped or is invalid. The <code>InpBufIndex</code> argument is set to indicate the code element causing the error. The suspect code element is either a valid code element but cannot be shaped into the <code>ShapeCharset</code> layout value, or is an invalid code element not defined by the codeset of the locale of <code>layout_object</code>. The <code>mbtowc()</code> and <code>wctomb()</code> functions, when used in the same locale as the <code>LayoutObject</code>, can be used to determine if the code element is

valid.

EINVAL Transformation stopped due to an incomplete composite sequence

at the end of the input buffer, or *OutSize* contains NULL.

ERANGE More than 15 embedding levels are in source text or *InpBuf* contain

unbalanced directional layout information (push/pop) or an incomplete composite sequence has been detected in the input buffer at the beginning of the string pointed to by *InpBufIndex*.

An incomplete composite sequence at the end of the input buffer is not always detectable. Sometimes the fact that the sequence is incomplete will only be detected when additional character elements belonging to the composite sequence are found at the

beginning of the next input buffer.

USAGE

A LayoutObject will have a meaningful combination of default layout values. Whoever chooses to change the default layout values is responsible for making sure that the combination of layout values is meaningful. Otherwise, the result of <code>m_wtransform_layout()</code> might be unpredictable or implementation-specific with <code>errno</code> set to <code>EBADF</code>.

EXAMPLES

EXAMPLE 1 Shaping and reordering input string into output buffer

The following example illustrated what the different arguments of m_wtransform_layout() look like when a string in *InpBuf* is shaped and reordered into *OutBuf*. Upper-case letters in the example represent left-to-right letters while lower-case letters represent right-to-left letters. xyz represents the shapes of cde.

Position:	0123456789
InpBuf:	AB cde 12z
Position:	0123456789
OutBuf:	AB 12 zyxZ
Position:	0123456789

m_wtransform_layout(3LAYOUT)

EXAMPLE 1 Shaping and reordering input string into output buffer (Continued)

OutToInp:	0127865439
Position:	0123456789
Property.NestLevel:	0001111220
Property.CelBdry:	1111111111

The values (encoded in bianry) returned in the *Property* argument define the directionality of each code element in the source text as defined by the type of algorithm used within the *layout_object*. While the algorithm may be implementation dependent, the resulting values and levels are defined such as to allow a single method to be used in determining the directionality of the source text. The base rules are:

- Odd levels are always RTL.
- Even levels are always LTR.
- The Orientation layout value setting determines the initial level (0 or 1) used.

Within a *Property* array each increment in the level indicates the corresponding code elements should be presented in the opposite direction. Callers of this function should realize that the *Property* values for certain code elements is dependent on the context of the given character and the layout values: Orientation and ImplicitAlg. Callers should not assume that a given code element always has the same *Property* value in all cases.

EXAMPLE 2 Algorithm to handle nesting

The following is an example of a standard presentation algorithm that handles nesting correctly. The goal of this algorithm is ultimately to return to a zero nest level. Note that more efficient algorithms do exist; the following is provided for clarity rather than for efficiency.

- 1. Search for the highest next level in the string.
- 2. Reverse all surrounding code elements of the same level. Reduce the nest level of these code elements by 1.
- 3. Repeat 1 and 2 until all code elements are of level 0.

The following shows the progression of the example from above:

Position:	0123456789	0123456789	0123456789
InpBuf:	AB cde 12Z	AB cde 21Z	AB 12 edcZ
Property.NestLevel:	0001111220	0001111110	000000000
Property CellEdry.	111111111	111111111	1111111111

newDmiOctetString(3DMI)

NAME | newDmiOctetString – create DmiOctetString in dynamic memory

SYNOPSIS

```
cc [ flag ... ] file ... -ldmi -lnsl -lrwtool [ library ... ]
#include <dmi/util.hh>
```

DmiOctetString t *newDmiOctetString(DmiOctetString t *str);

DESCRIPTION

The newDmiOctetString() function creates a DmiOctetString in dynamic memory and returns a pointer to the newly created DmiOctetString. The function returns NULL if no memory is available.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

nextafter(3M)

NAME | nextafter – next representable double-precision floating-point number

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double **nextafter** (double x, double y);

DESCRIPTION

The nextafter () function computes the next representable double-precision floating-point value following *x* in the direction of *y*. Thus, if *y* is less than *x*, nextafter() returns the largest representable floating-point number less than x.

RETURN VALUES

The nextafter () function returns the next representable double-precision floating-point value following *x* in the direction of *y*.

If x or y is NaN, then nextafter () returns NaN.

If *x* is finite and the correct function value would overflow, nextafter () returns \pm HUGE_VAL (according to the sign of x) and sets errno to ERANGE.

ERRORS

The nextafter () function will fail if:

ERANGE

The correct value would overflow.

NAME | nlist – get entries from name list

SYNOPSIS

```
cc [ flag... ] file ... -lelf [ library ... ]
#include <nlist.h>
```

int nlist(const char *filename, struct nlist *nl);

DESCRIPTION

nlist() examines the name list in the executable file whose name is pointed to by filename, and selectively extracts a list of values and puts them in the array of nlist() structures pointed to by nl. The name list nl consists of an array of structures containing names of variables, types, and values. The list is terminated with a null name, that is, a null string is in the name position of the structure. Each variable name is looked up in the name list of the file. If the name is found, the type, value, storage class, and section number of the name are inserted in the other fields. The type field may be set to 0 if the file was not compiled with the -g option to cc(1B).

nlist() will always return the information for an external symbol of a given name if the name exists in the file. If an external symbol does not exist, and there is more than one symbol with the specified name in the file (such as static symbols defined in separate files), the values returned will be for the last occurrence of that name in the file. If the name is not found, all fields in the structure except n name are set to 0.

This function is useful for examining the system name list kept in the file /dev/ksyms. In this way programs can obtain system addresses that are up to date.

RETURN VALUES

All value entries are set to 0 if the file cannot be read or if it does not contain a valid name list.

nlist() returns 0 on success, -1 on error.

NOTE(3EXT)

NAME |

NOTE, NOTE – annotate source code with info for tools

SYNOPSIS

```
#include <note.h>
NOTE (NoteInfo);
or
#include<sys/note.h>
_NOTE (NoteInfo);
```

DESCRIPTION

These macros are used to embed information for tools in program source. A use of one of these macros is called an "annotation". A tool may define a set of such annotations which can then be used to provide the tool with information that would otherwise be unavailable from the source code.

Annotations should, in general, provide documentation useful to the human reader. If information is of no use to a human trying to understand the code but is necessary for proper operation of a tool, use another mechanism for conveying that information to the tool (one which does not involve adding to the source code), so as not to detract from the readability of the source. The following is an example of an annotation which provides information of use to a tool and to the human reader (in this case, which data are protected by a particular lock, an annotation defined by the static lock analysis tool lock lint).

```
NOTE (MUTEX PROTECTS DATA (foo lock, foo list Foo))
```

Such annotations do not represent executable code; they are neither statements nor declarations. They should not be followed by a semicolon. If a compiler or tool that analyzes C source does not understand this annotation scheme, then the tool will ignore the annotations. (For such tools, NOTE (x) expands to nothing.)

Annotations may only be placed at particular places in the source. These places are where the following C constructs would be allowed:

- a top-level declaration (that is, a declaration not within a function or other construct)
- a declaration or statement within a block (including the block which defines a function)
- a member of a struct or union.

Annotations are not allowed in any other place. For example, the following are illegal:

```
x = y + NOTE(...) z;
typedef NOTE(...) unsigned int uint ;
```

While NOTE and _NOTE may be used in the places described above, a particular type of annotation may only be allowed in a subset of those places. For example, a particular annotation may not be allowed inside a struct or union definition.

NOTE vs _NOTE

Ordinarily, NOTE should be used rather than _NOTE, since use of _NOTE technically makes a program non-portable. However, it may be inconvenient to use NOTE for this purpose in existing code if NOTE is already heavily used for another purpose. In this case one should use a different macro and write a header file similar to /usr/include/note.h which maps that macro to _NOTE in the same manner. For example, the following makes FOO such a macro:

```
#ifndef _FOO_H
#define _FOO_H
#define FOO _NOTE
#include <sys/note.h>
#endif
```

Public header files which span projects should use _NOTE rather than NOTE, since NOTE may already be used by a program which needs to include such a header file.

NoteInfo Argument

The actual *NoteInfo* used in an annotation should be specified by a tool that deals with program source (see the documentation for the tool to determine which annotations, if any, it understands).

NoteInfo must have one of the following forms:

NoteName NoteName (Args)

where *NoteName* is simply an identifier which indicates the type of annotation, and *Args* is something defined by the tool that specifies the particular *NoteName*. The general restrictions on *Args* are that it be compatible with an ANSI C tokenizer and that unquoted parentheses be balanced (so that the end of the annotation can be determined without intimate knowledge of any particular annotation).

nvlist_add_boolean, nvlist_add_byte, nvlist_add_int16, nvlist_add_uint16, nvlist_add_int32, nvlist_add_uint32, nvlist_add_int64, nvlist_add_uint64, nvlist_add_string, nvlist_add_byte_array, nvlist_add_int16_array, nvlist_add_uint16_array, nvlist_add_int32_array, nvlist_add_uint32_array, nvlist_add_int64_array, nvlist_add_uint64_array, nvlist_add_string_array – add new name-value pair to nvlist_t

SYNOPSIS

```
cc [flag ...] file ...-lnvpair [library ...]
#include <libnvpair.h>
int nvlist add boolean(nvlist t *nvl, char *name);
int nvlist add byte(nvlist t *nvl, char *name, uchar t val);
int nvlist add int16 (nvlist t *nvl, char *name, int16 t val);
int nvlist add uint16 (nvlist t *nvl, char *name, uint16 t val);
int nvlist add int32(nvlist t *nvl, char *name, int32 t val);
int nvlist add uint32 (nvlist t *nvl, char *name, uint32 t val);
int nvlist add int64 (nvlist t *nvl, char *name, int64 t val);
int nvlist add uint64 (nvlist t *nvl, char *name, uint64 t val);
int nvlist add string(nvlist t *nvl, char *name, char *val);
int nvlist add byte array (nvlist t *nvl, char *name, uchar t *val,
    uint t nelem);
int nvlist add int16 array (nvlist t *nvl, char *name, int16 t *val,
    uint t nelem);
int nvlist add uint16 array(nvlist t *nvl, char *name, uint16 t
    *val, uint t nelem);
int nvlist add int32 array (nvlist t *nvl, char *name, int32 t *val,
    uint t nelem);
int nvlist add uint32 array(nvlist t *nvl, char *name, uint32 t
    *val, uint t nelem);
int nvlist add int64 array (nvlist t *nvl, char *name, int64 t *val,
    uint_t nelem);
int nvlist add uint64 array (nvlist t *nvl, char *name, uint64 t
    *val, uint t nelem);
int nvlist add string array(nvlist t *nvl, char *name, char **val,
    uint t nelem);
```

PARAMETERS

nvl The nvlist_t (name-value pair list) to be processed.

name Name of the nvpair (name-value pair).

nelem Number of elements in value (that is, array size).

val Value or starting address of the array value.

DESCRIPTION

These functions add a new name-value pair to an nvlist_t. The uniqueness of nvpair name and data types follows the *nvflag* argument specified for nvlist_alloc(). See nvlist_alloc(3NVPAIR).

If NV_UNIQUE_NAME was specified for *nvflag*, existing nvpairs with matching names are removed before the new nvpair is added.

If NV_UNIQUE_NAME_TYPE was specified for *nvflag*, existing nvpairs with matching names and data types are removed before the new nvpair is added.

If neither was specified for *nvflag*, the new nvpair is unconditionally added at the end of the list. The library preserves the order of the name-value pairs across packing, unpacking, and duplication.

RETURN VALUES

These functions return 0 on success and an error value on failure.

ERRORS

These functions will fail if:

EINVAL There is an invalid argument.

ENOMEM There is insufficient memory.

ATTRIBUTES

nvlist alloc(3NVPAIR)

NAME nvlist alloc, nvlist free, nvlist size, nvlist pack, nvlist unpack, nvlist dup – manage a name-value pair list **SYNOPSIS** cc [flag ...] file ...-lnvpair [library ...] #include <libnvpair.h> int nvlist alloc(nvlist t **nvlp, uint t nvflag, int flag); void nvlist free(nvlist t *nvl); int nvlist size (nvlist t *nvl, size t *size, int encoding); int nvlist pack(nvlist t *nvl, char **bufp, size t *buflen, int encoding, int flag); int nvlist unpack (char *buf, size t buflen, nvlist t **nvlp, int flag); int nvlist dup(nvlist t *nvl, nvlist t **nvlp, int flag); **PARAMETERS** nvlp Address of a pointer to nvlist t. nvflag Specify bit fields defining nvlist properties: NV UNIQUE NAME The nvpair names are unique. Name-data type combination is NV UNIQUE NAME TYPE flag Specify 0. Reserved for future use. The nvlist to be processed. nvl Pointer to buffer to contain the encoded size. size bufp Address of buffer to pack nvlist into. Must be 8-byte aligned. If NULL, library will allocate memory. buf Buffer containing packed nvlist. buflen Size of buffer bufp or buf points to. encoding Encoding method for packing. DESCRIPTION The nvlist alloc() function allocates a new name-value pair list and updates nvlp to point to the handle. The argument *nvflag* specifies nvlist properties to remain persistent across packing, unpacking, and duplication. The nvlist free() function frees a name-value pair list. The nvlist size() function returns the minimum size of a contiguous buffer large enough to pack nvl. The encoding parameter specifies the method of encoding when packing nvl. Supported encoding methods are:

Straight bcopy () as described in bcopy(3C).

NV ENCODE NATIVE

NV_ENCODE_XDR

Use XDR encoding, suitable for sending to another host.

The nvlist_pack() function packs *nvl* into contiguous memory starting at *bufp. The *encoding* parameter specifies the method of encoding (see above).

- If *bufp is not NULL, *bufp is expected to be a caller-allocated buffer of size *buflen.
- If *bufp is NULL, the library will allocate memory and update *bufp to point to the memory and update *buflen to contain the size of the allocated memory.

The nvlist_unpack() function takes a buffer with a packed nvlist_t and unpacks it into a searchable nvlist_t. The library allocates memory for nvlist_t. The caller is responsible for freeing the memory by calling nvlist free().

The nvlist_dup() function makes a copy of *nvl* and updates *nvlp* to point to the copy.

RETURN VALUES

These functions return 0 on success and an error value on failure.

ERRORS

All five functions will fail if:

EINVAL There is an invalid argument.

The nvlist_alloc(), nvlist_dup(), nvlist_pack(), and nvlist_unpack() functions will fail if:

ENOMEM

There is insufficient memory.

The nvlist pack() and nvlist unpack() functions will fail if:

EFAULT An encode/decode error occurs.

ENOTSUP An encode/decode method is not supported.

EXAMPLES

```
\star Program to read or create an {\tt nvlist.}

    **val, uint t *nelem);
int nvlist lookup string array(nvlist t *nvl, char *name, char
    ***val, uint t *nelem);
```

PARAMETERS

nvl The nvlist_t to be processed.

name Name of the name-value pair to search.

nvlist_lookup_boolean(3NVPAIR)

nelem Address to store the number of elements in value.

val Address to store the starting address of the value.

DESCRIPTION

These functions find the nvpair (name-value pair) that matches the name and type as indicated by the interface name. If one is found, *nelem* and *val* are modified to contain the number of elements in value and the starting address of data, respectively.

These functions work for nvlists (lists of name-value pairs) allocated with NV_UNIQUE_NAME or NV_UNIQUE_NAME_TYPE specified in nvlist_alloc(). (See nv_list_alloc(3NVPAIR).) If this is not the case, the function returns ENOTSUP because the list potentially contains multiple nvpairs with the same name and type.

All memory required for storing the array elements, including string value, are managed by the library. References to such data remain valid until nvlist_free() is called on *nvl*.

RETURN VALUES

Upon successful completion, 0 is returned. Otherwise, –1 is returned and errno is set to indicate the error.

ERRORS

These functions will fail if:

EINVAL There is an invalid argument.

ENOENT No matching name-value pair is found

ENOTSUP An encode/decode method is not supported.

NAME

nvlist_next_nvpair, nvpair_name, nvpair_type – return data regarding name-value pairs

SYNOPSIS

```
cc [flag ...] file ...-Invpair [library ...]
#include <libnvpair.h>
nvpair_t *nvlist_next_nvpair (nvlist_t *nvl, nvpair_t *nvpair);
char *nvpair_name (nvpair_t *nvpair);
data_type_t nvpair_type (nvpair_t *nvpair);
```

PARAMETERS

nvl The nvlist_t to be processed.

nupair Handle to a name-value pair.

DESCRIPTION

The nvlist_next_nvpair() function returns a handle to the next nvpair in the list following nvpair. If nvpair is NULL, the first pair is returned. If nvpair is the last pair in the nvlist, NULL is returned.

The nvpair name () function returns a string containing the name of nvpair.

The nvpair_type() function retrieves the value of the nvpair in the form of enumerated type data_type_t. This is used to determine the appropriate nvpair *() function to call for retrieving the value.

RETURN VALUES

Upon successful completion, nvpair_name() returns a string containing the name of the name-value pair.

Upon successful completion, nvpair_type() returns an enumerated data type data type t. Possible values for data type t are as follows:

```
DATA TYPE BOOLEAN
DATA TYPE_BYTE
DATA TYPE INT16
DATA TYPE UINT16
DATA TYPE INT32
DATA TYPE UINT32
DATA TYPE INT64
DATA TYPE UINT64
DATA_TYPE_STRING
DATA TYPE BYTE ARRAY
DATA_TYPE_INT16_ARRAY
DATA TYPE UINT16 ARRAY
DATA TYPE INT32 ARRAY
DATA_TYPE_UINT32_ARRAY
DATA TYPE INT64 ARRAY
DATA TYPE UINT64 ARRAY
DATA_TYPE_STRING_ARRAY
```

Upon reaching the end of a list, nvlist_next_pair() returns NULL. Otherwise, the function returns a handle to next nvpair in the list.

ERRORS

No errors are defined.

nvlist_next_nvpair(3NVPAIR)

NAME | nvlist_remove, nvlist_remove_all – remove name-value pairs

SYNOPSIS co

cc [flag ...] file ...-lnvpair [library ...]
#include <libnvpair.h>

void nvlist remove(nvlist t *nvl, char *name, data type t type);

void nvlist remove all(nvlist t *nvl, char *name);

PARAMETERS

nvl The nvlist t to be processed.

name Name of the name-value pair to be removed.

type Data type of the nvpair to be removed.

DESCRIPTION

The nvlist_remove() function removes the first occurrence of nvpair that matches the name and the type.

The nvlist_remove_all() function removes all occurrences of nvpair that match the name, regardless of type.

RETURN VALUES

No return values are defined.

nvpair_value_byte(3NVPAIR)

NAME |

nvpair_value_byte, nvpair_value_int16, nvpair_value_uint16, nvpair_value_int32, nvpair_value_uint32, nvpair_value_int64, nvpair_value_uint64, nvpair_value_string, nvpair_value_byte_array, nvpair_value_int16_array, nvpair_value_uint32_array, nvpair_value_int64_array, nvpair_value_uint64_array, nvpair_value_uint64_array, nvpair_value_string_array – retrieve value from a name-value pair

SYNOPSIS

```
cc [flag ...] file ...-lnvpair [library ...]
#include <libnvpair.h>
int nvpair value byte(nvpair t *nvpair, uchar t *val);
int nvpair value int16(nvpair t *nvpair, int16 t *val);
int nvpair value uint16(nvpair t *nvpair, uint16 t *val);
int nvpair value int32(nvpair t *nvpair, int32 t *val);
int nvpair value uint32(nvpair t *nvpair, uint32 t *val);
int nvpair value int64 (nvpair t *nvpair, int64 t *val);
int nvpair value uint64(nvpair t *nvpair, uint64 t *val);
int nvpair value string(nvpair t *nvpair, char **val);
int nvpair value byte array (nvpair t *nvpair, uchar t **val, uint t
    *nelem):
int nvpair value int16 array (nvpair t *nvpair, int16 t **val,
    uint t *nelem);
int nvpair value uint16 array(nvpair t *nvpair, uint16 t **val,
    uint t *nelem);
int nvpair value int32 array (nvpair t *nvpair, int32 t **val,
    uint t *nelem);
int nvpair value uint32 array(nvpair t *nvpair, uint32 t **val,
    uint t *nelem);
int nvpair value int64 array(nvpair t *nvpair, int64 t **val,
    uint t *nelem);
int nvpair_value_uint64_array(nvpair_t *nvpair, uint64_t **val,
    uint t *nelem);
int nvpair value string array (nvpair t *nvpair, char ***val, uint t
    *nelem);
```

PARAMETERS

nvpair Name-value pair to be processed.

nelem Address to store the number of elements in value.

val Address to store the value or the starting address of the array

value.

nvpair_value_byte(3NVPAIR)

DESCRIPTION

These functions retrieve the value of *nvpair*. The data type of *nvpair* must match the interface name for the call to be successful.

There is no nvpair_value_boolean(); the existence of the name implies the value is true.

For array data types, including string, the memory containing the data is managed by the library and references to the value remains valid until nvlist_free() is called on the nvlist t from which *nvpair* is obtained. See nvlist free(3NVPAIR).

RETURN VALUES

These functions return 0 on success and an error value on failure.

ERRORS

These functions will fail if:

EINVAL Ei

Either one of the arguments is NULL or the type of *nvpair* does not

match the function name.

ATTRIBUTES

p2open(3GEN)

NAME | p2open, p2close – open, close pipes to and from a command

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
int p2open(const char *cmd, FILE *fp[2]);
int p2close(FILE *fp[2]);
```

DESCRIPTION

p2open() forks and execs a shell running the command line pointed to by cmd. On return, fp [0] points to a FILE pointer to write the command's standard input and fp[1] points to a FILE pointer to read from the command's standard output. In this way the program has control over the input and output of the command.

The function returns 0 if successful; otherwise, it returns −1.

p2close() is used to close the file pointers that p2open() opened. It waits for the process to terminate and returns the process status. It returns 0 if successful; otherwise, it returns −1.

RETURN VALUES

A common problem is having too few file descriptors. p2close() returns -1 if the two file pointers are not from the same p2open().

EXAMPLES

EXAMPLE 1 Example of file descriptors.

```
#include <stdio.h>
#include <libgen.h>
main(argc,argv)
int argc;
char **argv;
    FILE *fp[2];
    pid_t pid;
    char buf[16];
        pid=p2open("/usr/bin/cat", fp);
        if (pid == -1) {
        fprintf(stderr, "p2open failed\n");
        exit(1);
    write(fileno(fp[0]), "This is a test\n", 16);
    if(read(fileno(fp[1]), buf, 16) <=0)</pre>
        fprintf(stderr, "p2open failed\n");
    else
        write(1, buf, 16);
    (void)p2close(fp);
}
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

fclose(3C), popen(3C), setbuf(3C), attributes(5)

NOTES

Buffered writes on fp[0] can make it appear that the command is not listening. Judiciously placed fflush() calls or unbuffering fp[0] can be a big help; see fclose(3C).

Many commands use buffered output when connected to a pipe. That, too, can make it appear as if things are not working.

Usage is not the same as for popen (), although it is closely related.

pam(3PAM)

NAME | pam – PAM (Pluggable Authentication Module)

SYNOPSIS

```
#include <security/pam appl.h>
cc [ flag... ] file ... -lpam [ library ... ]
```

DESCRIPTION

The PAM framework, libpam, consists of an interface library and multiple authentication service modules. The PAM interface library is the layer implementing the Application Programming Interface (API). The authentication service modules are a set of dynamically loadable objects invoked by the PAM API to provide a particular type of user authentication. PAM gives system administrators the flexibility of choosing any authentication service available on the system to perform authentication. This framework also allows new authentication service modules to be plugged in and made available without modifying the applications.

Interface Overview

The PAM library interface consists of six categories of functions, the names for which all start with the prefix pam .

The first category contains functions for establishing and terminating an authentication activity, which are pam start(3PAM) and pam end(3PAM). The functions pam set data(3PAM) and pam get data(3PAM) maintain module specific data. The functions pam set item(3PAM) and pam get item(3PAM) maintain state information. pam strerror(3PAM) is the function that returns error status information.

The second category contains the functions that authenticate an individual user and set the credentials of the user, pam authenticate(3PAM) and pam setcred(3PAM).

The third category of PAM interfaces is account management. The function pam acct mgmt(3PAM) checks for password aging and access-hour restrictions.

Category four contains the functions that perform session management after access to the system has been granted. See pam open session(3PAM) and pam close session(3PAM)

The fifth category consists of the function that changes authentication tokens, pam chauthtok(3PAM). An authentication token is the object used to verify the identity of the user. In UNIX, an authentication token is a user's password.

The sixth category of functions can be used to set values for PAM environment variables. See pam_putenv(3PAM), pam_getenv(3PAM), and pam getenvlist(3PAM).

The pam *() interfaces are implemented through the library libpam. For each of the categories listed above, excluding categories one and six, dynamically loadable shared modules exist that provides the appropriate service layer functionality upon demand. The functional entry points in the service layer start with the pam sm prefix. The only difference between the pam sm *() interfaces and their corresponding pam interfaces is that all the pam sm *() interfaces require extra

parameters to pass service-specific options to the shared modules. Refer to pam sm(3PAM) for an overview of the PAM service module APIs.

Stateful Interface

A sequence of calls sharing a common set of state information is referred to as an authentication transaction. An authentication transaction begins with a call to pam start().pam start() allocates space, performs various initialization activities, and assigns a PAM authentication handle to be used for subsequent calls to the library.

After initiating an authentication transaction, applications can invoke pam authenticate() to authenticate a particular user, and pam acct mgmt() to perform system entry management. For example, the application may want to determine if the user's password has expired.

If the user has been successfully authenticated, the application calls pam setcred() to set any user credentials associated with the authentication service. Within one authentication transaction (between pam start () and pam end ()), all calls to the PAM interface should be made with the same authentication handle returned by pam start(). This is necessary because certain service modules may store module-specific data in a handle that is intended for use by other modules. For example, during the call to pam authenticate(), service modules may store data in the handle that is intended for use by pam setcred().

To perform session management, applications call pam open session(). Specifically, the system may want to store the total time for the session. The function pam close session() closes the current session.

When necessary, applications can call pam get item() and pam set item() to access and to update specific authentication information. Such information may include the current username.

To terminate an authentication transaction, the application simply calls pam end(), which frees previously allocated space used to store authentication information.

Service Interactive Interface

Application—Authentitation uthen tication service in PAM does not communicate directly with the user; instead it relies on the application to perform all such interactions. The application passes a pointer to the function, conv(), along with any associated application data pointers, through a pam conv structure to the authentication service when it initiates an authentication transaction, via a call to pam start(). The service will then use the function, conv(), to prompt the user for data, output error messages, and display text information. Refer to pam start(3PAM) for more information.

Stacking Multiple Schemes

The PAM architecture enables authentication by multiple authentication services through *stacking*. System entry applications, such as login(1), stack multiple service modules to authenticate users with multiple authentication services. The order in which authentication service modules are stacked is specified in the configuration file, pam. conf(4). A system administrator determines this ordering, and also determines whether the same password can be used for all authentication services.

pam(3PAM)

Administrative Interface

The authentication library, /usr/lib/libpam.so.1, implements the framework interface. Various authentication services are implemented by their own loadable modules whose paths are specified through the pam.conf(4) file.

RETURN VALUES

The PAM functions may return one of the following generic values, or one of the values defined in the specific man pages:

PAM SUCCESS The function returned successfully.

PAM OPEN ERR dlopen() failed when dynamically loading a service

module.

PAM SYMBOL ERR Symbol not found.

PAM SERVICE ERR Error in service module.

PAM SYSTEM ERR System error.

PAM_BUF_ERR Memory buffer error.

PAM_CONV_ERR Conversation failure.

PAM PERM DENIED Permission denied.

NOTES

NAME

pam_acct_mgmt - perform PAM account validation procedures

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

int pam acct mgmt(pam handle t *pamh, int flags);

DESCRIPTION

The pam_acct_mgmt() function is called to determine if the current user's account is valid. It checks for password and account expiration, and verifies access hour restrictions. This function is typically called after the user has been authenticated with pam authenticate(3PAM).

The *pamh* argument is an authentication handle obtained by a prior call to pam start(). The following flags may be set in the *flags* field:

PAM SILENT The account management service should

not generate any messages.

PAM DISALLOW NULL AUTHTOK The account management service should

return PAM_NEW_AUTHTOK_REQD if the user has a null authentication token.

RETURN VALUES

Upon successful completion, PAM_SUCCESS is returned. In addition to the error return values described in pam(3PAM), the following values may be returned:

PAM USER UNKNOWN User not known to underlying account

management module.

PAM AUTH ERR Authentication failure.

PAM_NEW_AUTHTOK_REQD New authentication token required. This is

normally returned if the machine security policies require that the password should be changed because the password is NULL or

has aged.

PAM ACCT EXPIRED User account has expired.

ATTRIBUTES

NOTES

pam_authenticate(3PAM)

NAME |

pam_authenticate – perform authentication within the PAM framework

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

int pam authenticate (pam handle t *pamh, int flags);

DESCRIPTION

The pam_authenticate() function is called to authenticate the current user. The user is usually required to enter a password or similar authentication token depending upon the authentication service configured within the system. The user in question should have been specified by a prior call to pam_start() or pam_set_item().

The following flags may be set in the *flags* field:

PAM SILENT Authentication service should not generate

any messages.

PAM DISALLOW NULL AUTHTOK The authentication service should return

PAM AUTH ERROR if the user has a null

authentication token.

RETURN VALUES

Upon successful completion, PAM_SUCCESS is returned. In addition to the error return values described in pam(3PAM), the following values may be returned:

PAM AUTH ERR Authentication failure.

PAM CRED INSUFFICIENT Cannot access authentication data due to

insufficient credentials.

PAM AUTHINFO UNAVAIL Underlying authentication service cannot

retrieve authentication information.

PAM_USER_UNKNOWN User not known to the underlying

authentication module.

PAM MAXTRIES An authentication service has maintained a

retry count which has been reached. No further retries should be attempted.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

pam(3PAM), pam_open_session(3PAM), pam_set_item(3PAM),
pam_setcred(3PAM), pam_start(3PAM), libpam(3LIB), attributes(5)

NOTES

In the case of authentication failures due to an incorrect username or password, it is the responsibility of the application to retry pam authenticate() and to maintain

the retry count. An authentication service module may implement an internal retry count and return an error PAM_MAXTRIES if the module does not want the application to retry.

If the PAM framework cannot load the authentication module, then it will return PAM_ABORT. This indicates a serious failure, and the application should not attempt to retry the authentication.

For security reasons, the location of authentication failures is hidden from the user. Thus, if several authentication services are stacked and a single service fails, pam_authenticate() requires that the user re-authenticate each of the services.

A null authentication token in the authentication database will result in successful authentication unless PAM_DISALLOW_NULL_AUTHTOK was specified. In such cases, there will be no prompt to the user to enter an authentication token.

pam_chauthtok(3PAM)

NAME

pam_chauthtok - perform password related functions within the PAM framework

SYNOPSIS

cc [flag ...] file ... -lpam [library ...]
#include <security/pam_appl.h>

int pam chauthtok(pam handle t *pamh, const intflags);

DESCRIPTION

The pam_chauthtok() function is called to change the authentication token associated with a particular user referenced by the authentication handle *pamh*.

The following flag may be passed in to pam chauthtok():

PAM SILENT The password service should not generate

any messages.

PAM CHANGE EXPIRED AUTHTOK The password service should only update

those passwords that have aged. If this flag is not passed, all password services should

update their passwords.

Upon successful completion of the call, the authentication token of the user will be changed in accordance with the password service configured in the system through pam.conf(4).

RETURN VALUES

Upon successful completion, PAM_SUCCESS is returned. In addition to the error return values described in pam(3PAM), the following values may be returned:

PAM PERM DENIED No permission.

PAM AUTHTOK ERR Authentication token manipulation error.

PAM AUTHTOK RECOVERY ERR Authentication information cannot be

recovered.

PAM AUTHTOK LOCK BUSY Authentication token lock busy.

PAM_AUTHTOK_DISABLE_AGING Authentication token aging disabled.

PAM_USER_UNKNOWN User unknown to password service.

PAM TRY AGAIN Preliminary check by password service

failed.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

login(1), passwd(1), pam(3PAM), pam_authenticate(3PAM), pam_start(3PAM),
attributes

NOTES

The flag PAM_CHANGE_EXPIRED_AUTHTOK is typically used by a login application which has determined that the user's password has aged or expired. Before allowing the user to login, the login application may invoke pam_chauthtok() with this flag to allow the user to update the password. Typically, applications such as passwd(1) should not use this flag.

The pam_chauthtok() functions performs a preliminary check before attempting to update passwords. This check is performed for each password module in the stack as listed in pam.conf(4). The check may include pinging remote name services to determine if they are available. If pam_chauthtok() returns PAM_TRY_AGAIN, then the check has failed, and passwords are not updated.

pam_getenv(3PAM)

NAME |

pam_getenv – returns the value for a PAM environment name

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

char *pam getenv(pam handle t *pamh, const char *name);

DESCRIPTION

The pam_getenv() function searches the PAM handle pamh for a value associated with name. If a value is present, pam_getenv() makes a copy of the value and returns a pointer to the copy back to the calling application. If no such entry exists, pam_getenv() returns NULL. It is the responsibility of the calling application to free the memory returned by pam_getenv().

RETURN VALUES

If successful, pam_getenv() returns a copy of the *value* associated with *name* in the PAM handle; otherwise, it returns a NULL pointer.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

pam(3PAM), pam_getenvlist(3PAM), pam_putenv(3PAM), libpam(3LIB),
attributes(5)

NOTES

NAME

pam_getenvlist – returns a list of all the PAM environment variables

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

char **pam getenvlist(pam handle t *pamh);

DESCRIPTION

The pam_getenvlist() function returns a list of all the PAM environment variables stored in the PAM handle *pamh*. The list is returned as a null-terminated array of pointers to strings. Each string contains a single PAM environment variable of the form *name=value*. The list returned is a duplicate copy of all the environment variables stored in *pamh*. It is the responsibility of the calling application to free the memory returned by pam getenvlist().

RETURN VALUES

If successful, pam_getenvlist() returns in a null-terminated array a copy of all the PAM environment variables stored in *pamh*. Otherwise, pam_getenvlist() returns a null pointer.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NOTES

pam_get_user(3PAM)

NAME |

pam_get_user - PAM routine to retrieve user name

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

int pam get user (pam handle t *pamh, char **user, const char *prompt);

DESCRIPTION

The pam get user () function is used by PAM service modules to retrieve the current user name from the PAM handle. If the user name has not been set with pam start() or pam set item(), the PAM conversation function will be used to prompt the user for the user name with the string "prompt". If prompt is NULL, then pam get item() is called and the value of PAM USER PROMPT is used for prompting. If the value of PAM USER PROMPT is NULL, the following default prompt is used:

Please enter user name:

After the user name is gathered by the conversation function, pam set item() is called to set the value of PAM USER. By convention, applications that need to prompt for a user name should call pam set item() and set the value of PAM USER PROMPT before calling pam authenticate(). The service module's pam_sm_authenticate() function will then call pam_get_user() to prompt for the user name.

Note that certain PAM service modules, such as a smart card module, may override the value of PAM USER PROMPT and pass in their own prompt. Applications that call pam authenticate() multiple times should set the value of PAM USER to NULL with pam set item() before calling pam authenticate(), if they want the user to be prompted for a new user name each time. The value of user retrieved by pam get user() should not be modified or freed. The item will be released by pam end().

RETURN VALUES

Upon success, pam get user() returns PAM SUCCESS; otherwise it returns an error code. Refer to pam(3PAM) for information on error related return values.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

pam_get_user(3PAM)

application uses its own PAM handle.

 $\textbf{NOTES} \hspace{0.1cm} | \hspace{0.1cm} \textbf{The interfaces in libpam are MT-Safe only if each thread within the multithreaded}$

pam_open_session(3PAM)

NAME |

pam_open_session, pam_close_session – perform PAM session creation and termination operations

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
int pam_open_session(pam_handle_t *pamh, int flags);
int pam close session(pam handle t *pamh, int flags);
```

DESCRIPTION

The pam_open_session() function is called after a user has been successfully authenticated. See pam_authenticate(3PAM) and pam_acct_mgmt(3PAM). It is used to notify the session modules that a new session has been initiated. All programs that use the pam(3PAM) library should invoke pam_open_session() when beginning a new session. Upon termination of this activity, pam_close_session() should be invoked to inform pam(3PAM) that the session has terminated.

The pamh argument is an authentication handle obtained by a prior call to pam_start(). The following flag may be set in the flags field for pam open session() and pam close session():

PAM SILENT The session service should not generate any messages.

RETURN VALUES

Upon successful completion, PAM_SUCCESS is returned. In addition to the return values defined in pam(3PAM), the following value may be returned on error:

PAM_SESSION_ERR Cannot make or remove an entry for the specified session.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

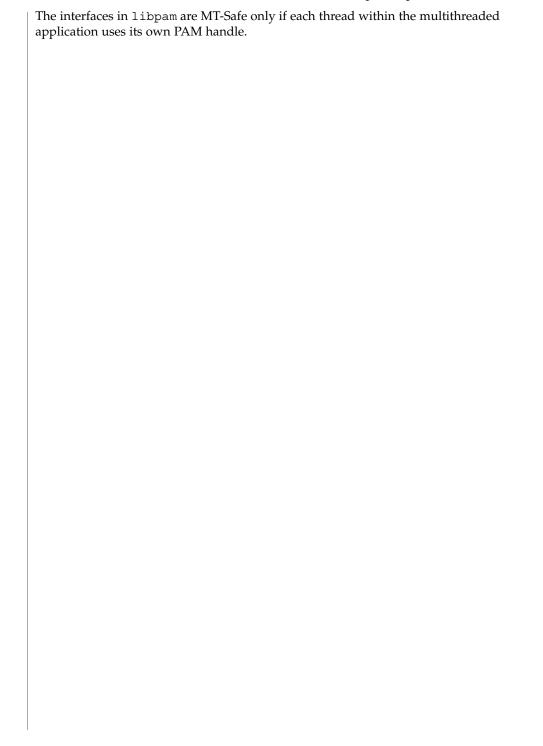

SEE ALSO

 $\verb|getutxent(3C), pam(3PAM), pam_acct_mgmt(3PAM), pam_authenticate(3PAM), pam_start(3PAM), attributes(5)|$

NOTES

In many instances, the pam_open_session() and pam_close_session() calls may be made by different processes. For example, in UNIX the login process opens a session, while the init process closes the session. In this case, UTMP/WTMP entries may be used to link the call to pam_close_session() with an earlier call to pam_open_session(). This is possible because UTMP/WTMP entries are uniquely identified by a combination of attributes, including the user login name and device name, which are accessible through the PAM handle, pamh. The call to pam_open_session() should precede UTMP/WTMP entry management, and the call to pam_close_session() should follow UTMP/WTMP exit management.

pam_open_session(3PAM)

pam_putenv(3PAM)

NAME |

pam_putenv – change or add a value to the PAM environment

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

int pam puterv(pam handle t *pamh, const char *name_value);

DESCRIPTION

The pam_putenv() function sets the value of the PAM environment variable *name* equal to *value* either by altering an existing PAM variable or by creating a new one.

The <code>name_value</code> argument points to a string of the form <code>name=value</code>. A call to <code>pam_putenv()</code> does not immediately change the environment. All <code>name_value</code> pairs are stored in the PAM handle <code>pamh</code>. An application such as <code>login(1)</code> may make a call to <code>pam_getenv(3PAM)</code> or <code>pam_getenvlist(3PAM)</code> to retrieve the PAM environment variables saved in the PAM handle and set them in the environment if appropriate. <code>login</code> will not set PAM environment values which overwrite the values for <code>SHELL</code>, <code>HOME</code>, <code>LOGNAME</code>, <code>MAIL</code>, <code>CDPATH</code>, <code>IFS</code>, and <code>PATH</code>. Nor will <code>login</code> set PAM environment values which overwrite any value that begins with <code>LD</code>.

If name_value equals NAME=, then the value associated with NAME in the PAM handle will be set to an empty value. If name_value equals NAME, then the environment variable NAME will be removed from the PAM handle.

RETURN VALUES

The pam putenv() function may return one of the following values:

PAM SUCCESS The function returned successfully.

PAM OPEN ERR dlopen() failed when dynamically loading a service

module.

PAM_SYMBOL_ERR Symbol not found.

PAM SERVICE ERR Error in service module.

PAM SYSTEM ERR System error.

PAM_BUF_ERR Memory buffer error.

PAM_CONV_ERR Conversation failure.

PAM PERM DENIED Permission denied.

NOTES	The interfaces in libpam are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.	

pam_setcred(3PAM)

NAME |

pam_setcred – modify/delete user credentials for an authentication service

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

int pam_setcred(pam_handle_t *pamh, int flags);

DESCRIPTION

The pam_setcred() function is used to establish, modify, or delete user credentials. It is typically called after the user has been authenticated and after a session has been opened. See pam_authenticate(3PAM), pam_acct_mgmt(3PAM), and pam open session(3PAM).

The user is specified by a prior call to pam_start() or pam_set_item(), and is referenced by the authentication handle, *pamh*. The following flags may be set in the *flags* field. Note that the first four flags are mutually exclusive:

PAM ESTABLISH CRED Set user credentials for an authentication

service.

PAM DELETE CRED Delete user credentials associated with an

authentication service.

PAM REINITIALIZE CRED Reinitialize user credentials.

PAM REFRESH CRED Extend lifetime of user credentials.

PAM SILENT Authentication service should not generate

any messages.

If no flag is set, PAM ESTABLISH CRED is used as the default.

RETURN VALUES

Upon success, pam_setcred() returns PAM_SUCCESS. In addition to the error return values described in pam(3PAM) the following values may be returned upon error:

PAM_CRED_UNAVAIL Underlying authentication service can not

retrieve user credentials unavailable.

PAM_CRED_EXPIRED User credentials expired.

PAM_USER_UNKNOWN User unknown to underlying authentication

service.

PAM_CRED_ERR Failure setting user credentials.

NAME | pam set data, pam get data – PAM routines to maintain module specific state

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam appl.h>
```

int pam set data (pam handle t *pamh, const char *module_data_name, void *data, void (*cleanup) (pam_handle_t *pamh, void *data, int pam_end_status));

int pam_get_data(const pam_handle_t *pamh, const char *module_data_name, const void **data);

DESCRIPTION

The pam set data() and pam get data() functions allow PAM service modules to access and update module specific information as needed. These functions should not be used by applications.

The pam set data() function stores module specific data within the PAM handle pamh. The module_data_name argument uniquely identifies the data, and the data argument represents the actual data. The module_data_name argument should be unique across all services.

The *cleanup* function frees up any memory used by the *data* after it is no longer needed, and is invoked by pam end(). The cleanup function takes as its arguments a pointer to the PAM handle, pamh, a pointer to the actual data, data, and a status code, pam_end_status. The status code determines exactly what state information needs to be purged.

If pam set data() is called and module data already exists from a prior call to pam set data() under the same *module_data_name*, then the existing *data* is replaced by the new data, and the existing cleanup function is replaced by the new cleanup function.

The pam get data() function retrieves module-specific data stored in the PAM handle, pamh, identified by the unique name, module_data_name. The data argument is assigned the address of the requested data. The data retrieved by pam get data() should not be modified or freed. The data will be released by pam end().

RETURN VALUES

In addition to the return values listed in pam(3PAM), the following value may also be returned:

PAM NO MODULE DATA

No module specific data is present.

ATTRIBUTES

NOTES

The interfaces in \mbox{libpam} are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

pam set item(3PAM)

NAME |

pam set item, pam get item – authentication information routines for PAM

SYNOPSIS

```
#include <security/pam_appl.h>
int pam set item(pam handle t *pamh, int item_type, const void
int pam get item(const pam handle t *pamh, int item_type, void
    **item):
```

DESCRIPTION

The pam get item() and pam set item() functions allow applications and PAM service modules to access and to update PAM information as needed. The information is specified by *item_type*, and can be one of the following:

PAM SERVICE The service name. PAM USER The user name.

cc [flag ...] file ... -lpam [library ...]

The user authentication token. PAM AUTHTOK

The old user authentication token. PAM OLDAUTHTOK

The tty name. PAM TTY

The remote host name. PAM RHOST PAM RUSER The remote user name. PAM CONV The pam conv structure.

The default prompt used by pam get user(). PAM USER PROMPT

For security reasons, the *item_type* PAM AUTHTOK and PAM OLDAUTHTOK are available only to the module providers. The authentication module, account module, and session management module should treat PAM AUTHTOK as the current authentication token and ignore PAM OLDAUTHTOK. The password management module should treat PAM OLDAUTHTOK as the current authentication token and PAM AUTHTOK as the new authentication token.

The pam set item() function is passed the authentication handle, *pamh*, returned by pam start (), a pointer to the object, *item*, and its type, *item_type*. If successful, pam set item() copies the item to an internal storage area allocated by the authentication module and returns PAM SUCCESS. An item that had been previously set will be overwritten by the new value.

The pam get item() function is passed the authentication handle, pamh, returned by pam start (), an *item type*, and the address of the pointer, *item*, which is assigned the address of the requested object. The object data is valid until modified by a subsequent call to pam set item() for the same *item_type*, or unless it is modified by any of the underlying service modules. If the item has not been previously set, pam get item() returns a null pointer. An item retrieved by pam get item() should not be modified or freed. The item will be released by pam end().

RETURN VALUES

Upon success, $pam_get_item()$ returns PAM_SUCCESS; otherwise it returns an error code. Refer to pam(3PAM) for information on error related return values.

pam_sm(3PAM)

NAME | pam_sm – PAM Service Module APIs

SYNOPSIS

```
#include <security/pam appl.h>
#include <security/pam modules.h>
cc [ flag ...] file ... -lpam [ library ...]
```

DESCRIPTION

PAM gives system administrators the flexibility of choosing any authentication service available on the system to perform authentication. The framework also allows new authentication service modules to be plugged in and made available without modifying the applications.

The PAM framework, libpam, consists of an interface library and multiple authentication service modules. The PAM interface library is the layer implementing the Application Programming Interface (API). The authentication service modules are a set of dynamically loadable objects invoked by the PAM API to provide a particular type of user authentication.

This manual page gives an overview of the PAM APIs for the service modules.

Interface Overview

The PAM service module interface consists of functions which can be grouped into four categories. The names for all the authentication library functions start with pam sm. The only difference between the pam *() interfaces and their corresponding pam_sm_*() interfaces is that all the pam_sm_*() interfaces require extra parameters to pass service-specific options to the shared modules. They are otherwise identical.

The first category contains functions to authenticate an individual user, pam sm authenticate(3PAM), and to set the credentials of the user, pam sm setcred(3PAM). These back-end functions implement the functionality of pam authenticate(3PAM) and pam setcred(3PAM) respectively.

The second category contains the function to do account management: pam sm acct mgmt(3PAM). This includes checking for password aging and access-hour restrictions. This back-end function implements the functionality of pam acct mgmt(3PAM).

The third category contains the functions pam_sm_open_session(3PAM) and pam sm close session(3PAM) to perform session management after access to the system has been granted. These back-end functions implement the functionality of pam open session(3PAM) and pam close session(3PAM), respectively.

The fourth category consists a function to change authentication tokens pam sm chauthtok(3PAM). This back-end function implements the functionality of pam chauthtok(3PAM).

Stateful Interface

A sequence of calls sharing a common set of state information is referred to as an authentication transaction. An authentication transaction begins with a call to pam start().pam start() allocates space, performs various initialization activities, and assigns an authentication handle to be used for subsequent calls to the library. Note that the service modules do not get called or initialized when pam_start() is called. The modules are loaded and the symbols resolved upon first use of that function.

The PAM handle keeps certain information about the transaction that can be accessed through the pam_get_item() API. Though the modules can also use pam_set_item() to change any of the item information, it is recommended that nothing be changed except PAM AUTHTOK and PAM OLDAUTHTOK.

If the modules want to store any module specific state information then they can use the pam_set_data(3PAM) function to store that information with the PAM handle. The data should be stored with a name which is unique across all modules and module types. For example, SUNW_PAM_UNIX_AUTH_userid can be used as a name by the UNIX module to store information about the state of user's authentication. Some modules use this technique to share data across two different module types.

Also, during the call to pam_authenticate(), the UNIX module may store the authentication status (success or reason for failure) in the handle, using a unique name such as SUNW_SECURE_RPC_DATA. This information is intended for use by pam setcred().

During the call to pam_acct_mgmt(), the account modules may store data in the handle to indicate which passwords have aged. This information is intended for use by pam_chauthtok().

The module can also store a cleanup function associated with the data. The PAM framework calls this cleanup function, when the application calls pam_end() to close the transaction.

Interaction with the User

The PAM service modules do not communicate directly with the user; instead they rely on the application to perform all such interactions. The application passes a pointer to the function, ${\tt conv()}, {\tt along with any associated application data pointers}, \\ {\tt through the pam_conv structure when it initiates an authentication transaction (via a call to pam_start(). The service module will then use the function, <math display="block">{\tt conv()}, \\ {\tt to prompt the user for data}, \\ {\tt output error messages}, \\ {\tt and display text information}. \\ {\tt Refer to pam_start(3PAM)} \\ {\tt for more information}. \\ {\tt The modules are responsible for the localization of all messages to the user}. \\$

CONVENTIONS

By convention, applications that need to prompt for a user name should call pam_set_item() and set the value of PAM_USER_PROMPT before calling pam_authenticate(). The service module's pam_sm_authenticate() function will then call pam_get_user() to prompt for the user name. Note that certain PAM service modules (such as a smart card module) may override the value of PAM_USER_PROMPT and pass in their own prompt.

Though the PAM framework enforces no rules about the module's names, location, options and such, there are certain conventions that all module providers are expected to follow.

pam_sm(3PAM)

By convention, the modules should be located in the /usr/lib/security directory. Additional modules may be located in /opt/<pkg>/lib.

By convention, the modules are named

pam_<service_name>_<module_type>.so.1. If the given module implements more than one module type (for example, pam_unix.so.1 module), then the module_type suffix should be dropped.

For every such module, there should be a corresponding manual page in section 5 which should describe the <code>module_type</code> it supports, the functionality of the module, along with the options it supports. The dependencies should be clearly identified to the system administrator. For example, it should be made clear whether this module is a stand-alone module or depends upon the presence of some other module. One should also specify whether this module should come before or after some other module in the stack.

By convention, the modules should support the following options:

debug Syslog debugging information at LOG_DEBUG level. Be

careful as to not log any sensitive information such as

passwords.

nowarn Turn off warning messages such as "password is about

to expire."

In addition, it is recommended that the auth and the password module support the following options:

use first pass Instead of prompting the user for the password, use the

user's initial password (entered when the user was authenticated to the first authentication module in the stack) for authentication. If the passwords do not match, or if no password has been entered, return failure and do not prompt the user for a password. Support for this scheme allows the user to type only

one password for multiple schemes.

try first pass Instead of prompting the user for the password, use the

user's initial password (entered when the user was authenticated to the first authentication module in the stack) for authentication. If the passwords do not match, or if no password has been entered, prompt the user for a password after identifying which type of password (ie. UNIX, etc.) is being requested. Support for this scheme allows the user to try to use only one password for multiple schemes, and type multiple

passwords only if necessary.

If an unsupported option is passed to the modules, it should syslog the error at ${\tt LOG}\ {\tt ERR}\ {\tt level}.$

The permission bits on the service module should be set such that it is not writable by either "group" or "other." The PAM framework will not load the module if the above permission rules are not followed.

ERROR LOGGING

If there are any errors, the modules should log them using syslog(3C) at the LOG ERR level.

RETURN VALUES

The PAM service module functions may return any of the PAM error numbers specified in the specific man pages. It can also return a PAM_IGNORE error number to mean that the PAM framework should ignore this module regardless of whether it is required, optional or sufficient. This error number is normally returned when the module does not want to deal with the given user at all.

pam_sm_acct_mgmt(3PAM)

NAME | pam sm acct mgmt - service provider implementation for pam acct mgmt

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam appl.h>
#include <security/pam modules.h>
```

int pam sm acct mgmt (pam handle t *pamh, int flags, int argc, const char **argv);

DESCRIPTION

In response to a call to pam acct mgmt(3PAM), the PAM framework calls pam sm acct mgmt () from the modules listed in the pam. conf(4) file. The account management provider supplies the back-end functionality for this interface function. Applications should not call this API directly.

The pam sm acct mgmt() function determines whether or not the current user's account and password are valid. This includes checking for password and account expiration, and valid login times. The user in question is specified by a prior call to pam start(), and is referenced by the authentication handle, pamh, which is passed as the first argument to pam sm acct mgmt(). The following flags may be set in the flags field:

PAM SILENT The account management service should

not generate any messages.

PAM DISALLOW NULL AUTHTOK The account management service should

return PAM_NEW_AUTHTOK_REQD if the user has a null authentication token.

The argc argument represents the number of module options passed in from the configuration file pam.conf(4). argv specifies the module options, which are interpreted and processed by the account management service. Please refer to the specific module man pages for the various available options. If an unknown option is passed to the module, an error should be logged through syslog(3C) and the option ignored.

If an account management module determines that the user password has aged or expired, it should save this information as state in the authentication handle, pamh, using pam set data().pam chauthok() uses this information to determine which passwords have expired.

RETURN VALUES

If there are no restrictions to logging in, PAM SUCCESS is returned. The following error values may also be returned upon error:

PAM USER UNKNOWN User not known to underlying

authentication module.

PAM NEW AUTHTOK REQD New authentication token required.

User account has expired. PAM ACCT EXPIRED

User denied access to account at this time. PAM PERM DENIED

pam_sm_acct_mgmt(3PAM)

PAM IGNORE

Ignore underlying account module regardless of whether the control flag is *required*, *optional* or *sufficient*.

pam_sm_authenticate(3PAM)

NAME | pam sm authenticate – service provider implementation for pam authenticate

SYNOPSIS

```
cc [ flag ...] file ... -lpam [ library ...]
#include <security/pam appl.h>
#include <security/pam modules.h>
int pam sm authenticate (pam handle t *pamh, int flags, int argc,
     const char **argv);
```

DESCRIPTION

In response to a call to pam authenticate(3PAM), the PAM framework calls pam sm authenticate() from the modules listed in the pam.conf(4) file. The authentication provider supplies the back-end functionality for this interface function.

The pam sm authenticate() function is called to verify the identity of the current user. The user is usually required to enter a password or similar authentication token depending upon the authentication scheme configured within the system. The user in question is specified by a prior call to pam start(), and is referenced by the authentication handle pamh.

If the user is unknown to the authentication service, the service module should mask this error and continue to prompt the user for a password. It should then return the error, PAM USER UNKNOWN.

The following flag may be passed in to pam sm authenticate():

PAM SILENT The authentication service should not

generate any messages.

The authentication service should return PAM DISALLOW NULL AUTHTOK

PAM AUTH ERROR The user has a null authentication token.

The argc argument represents the number of module options passed in from the configuration file pam. conf(4). argv specifies the module options, which are interpreted and processed by the authentication service. Please refer to the specific module man pages for the various available options. If any unknown option is passed in, the module should log the error and ignore the option.

Before returning, pam sm authenticate() should call pam get item() and retrieve PAM AUTHTOK. If it has not been set before and the value is NULL, pam sm authenticate() should set it to the password entered by the user using pam set item().

An authentication module may save the authentication status (success or reason for failure) as state in the authentication handle using pam set data(3PAM). This information is intended for use by pam setcred().

RETURN VALUES

Upon successful completion, PAM SUCCESS must be returned. In addition, the following values may be returned:

PAM MAXTRIES Maximum number of authentication

attempts exceeded.

pam_sm_authenticate(3PAM)

PAM AUTH ERR Authentication failure.

PAM CRED INSUFFICIENT Cannot access authentication data due to

insufficient credentials.

PAM_AUTHINFO_UNAVAIL Underlying authentication service can not

retrieve authentication information.

PAM_USER_UNKNOWN User not known to underlying

authentication module.

PAM IGNORE Ignore underlying authentication module

regardless of whether the control flag is

required, optional, or sufficient 1.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

pam(3PAM), pam_authenticate(3PAM), pam_get_item(3PAM),
pam_set_data(3PAM), pam_set_item(3PAM), pam_setcred(3PAM),
pam_start(3PAM), libpam(3LIB), pam.conf(4), attributes(5)

NOTES

Modules should not retry the authentication in the event of a failure. Applications handle authentication retries and maintain the retry count. To limit the number of retries, the module can return a PAM MAXTRIES error.

The interfaces in libpam are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

pam_sm_chauthtok(3PAM)

NAME | pam sm chauthtok – service provider implementation for pam chauthtok

SYNOPSIS

```
cc [ flag ...] file ... -lpam [ library ... ]
#include <security/pam appl.h>
#include <security/pam modules.h>
int pam sm chauthtok (pam handle t *pamh, int flags, int argc, const
     char **argv);
```

DESCRIPTION

In response to a call to pam chauthtok () the PAM framework calls pam sm chauthtok(3PAM) from the modules listed in the pam.conf(4) file. The password management provider supplies the back-end functionality for this interface function.

The pam sm chauthtok() function changes the authentication token associated with a particular user referenced by the authentication handle *pamh*.

The following flag may be passed to pam chauthtok():

PAM SILENT The password service should not generate

any messages.

PAM CHANGE_EXPIRED_AUTHTOK The password service should only update

> those passwords that have aged. If this flag is not passed, the password service should

update all passwords.

PAM PRELIM CHECK The password service should only perform

preliminary checks. No passwords should

be updated.

PAM UPDATE AUTHTOK The password service should update

passwords.

Note that PAM PRELIM CHECK and PAM UPDATE AUTHTOK cannot be set at the same time.

Upon successful completion of the call, the authentication token of the user will be ready for change or will be changed, depending upon the flag, in accordance with the authentication scheme configured within the system.

The argc argument represents the number of module options passed in from the configuration file pam. conf(4). The argv argument specifies the module options, which are interpreted and processed by the password management service. Please refer to the specific module man pages for the various available options.

It is the responsibility of pam sm chauthtok () to determine if the new password meets certain strength requirements. pam sm chauthtok() may continue to re-prompt the user (for a limited number of times) for a new password until the password entered meets the strength requirements.

pam_sm_chauthtok(3PAM)

Before returning, pam_sm_chauthtok() should call pam_get_item() and retrieve both PAM_AUTHTOK and PAM_OLDAUTHTOK. If both are NULL, pam_sm_chauthtok() should set them to the new and old passwords as entered by

the user.

RETURN VALUES

Upon successful completion, PAM_SUCCESS must be returned. The following values may also be returned:

PAM_PERM_DENIED No permission.

PAM_AUTHTOK_ERR Authentication token manipulation error.

PAM_AUTHTOK_RECOVERY_ERR Old authentication token cannot be

recovered.

PAM AUTHTOK LOCK BUSY Authentication token lock busy.

PAM_AUTHTOK_DISABLE_AGING Authentication token aging disabled.

PAM_USER_UNKNOWN User unknown to password service.

PAM TRY AGAIN Preliminary check by password service

failed.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

ping(1M), pam(3PAM), pam_chauthtok(3PAM), pam_get_data(3PAM),
pam_get_item(3PAM), pam_set_data(3PAM), libpam(3LIB), pam.conf(4),
attributes(5)

NOTES

The PAM framework invokes the password services twice. The first time the modules are invoked with the flag, PAM_PRELIM_CHECK. During this stage, the password modules should only perform preliminary checks. For example, they may ping remote name services to see if they are ready for updates. If a password module detects a transient error such as a remote name service temporarily down, it should return PAM_TRY_AGAIN to the PAM framework, which will immediately return the error back to the application. If all password modules pass the preliminary check, the PAM framework invokes the password services again with the flag, PAM_UPDATE_AUTHTOK. During this stage, each password module should proceed to update the appropriate password. Any error will again be reported back to application.

If a service module receives the flag PAM_CHANGE_EXPIRED_AUTHTOK, it should check whether the password has aged or expired. If the password has aged or expired,

pam_sm_chauthtok(3PAM)

then the service module should proceed to update the password. If the status indicates that the password has not yet aged or expired, then the password module should return PAM IGNORE.

If a user's password has aged or expired, a PAM account module could save this information as state in the authentication handle, <code>pamh</code>, using <code>pam_set_data()</code>. The related password management module could retrieve this information using <code>pam_get_data()</code> to determine whether or not it should prompt the user to update the password for this particular module.

The interfaces in libpam are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

NAME | pam sm open session, pam sm close session – service provider implementation for pam_open_session and pam_close_session

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
#include <security/pam modules.h>
int pam sm open session (pam handle t *pamh, int flags, int argc,
    const char **argv);
int pam sm close session (pam handle t *pamh, int flags, int argc,
    const char **argv);
```

DESCRIPTION

In response to a call to pam open session(3PAM) and pam close session(3PAM), the PAM framework calls pam sm open session() and pam sm close session(), respectively from the modules listed in the pam. conf(4) file. The session management provider supplies the back-end functionality for this interface function.

The pam sm open session() function is called to initiate session management. Thepam sm close session() function is invoked when a session has terminated. The argument pamh is an authentication handle. The following flag may be set in the flags field:

PAM SILENT Session service should not generate any messages.

The *argc* argument represents the number of module options passed in from the configuration file pam. conf(4). argv specifies the module options, which are interpreted and processed by the session management service. If an unknown option is passed in, an error should be logged through syslog(3C) and the option ignored.

RETURN VALUES

Upon successful completion, PAM SUCCESS should be returned. The following values may also be returned upon error:

PAM SESSION ERR Cannot make or remove an entry for the speci
--

session.

PAM IGNORE Ignore underlying session module regardless of

whether the control flag is required, optional or sufficient.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

pam(3PAM), pam open session(3PAM), syslog(3C), libpam(3LIB), pam.conf(4), attributes(5)

pam_sm_open_session(3PAM) The interfaces in libpam are MT-Safe only if each thread within the multithreaded NOTES | application uses its own PAM handle.

NAME | pam sm setcred – service provider implementation for pam setcred

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam appl.h>
#include <security/pam modules.h>
int pam sm setcred (pam handle t *pamh, int flags, int argc, const
     char **argv);
```

DESCRIPTION

In response to a call to pam setcred(3PAM), the PAM framework calls pam sm setcred() from the modules listed in the pam. conf(4) file. The authentication provider supplies the back-end functionality for this interface function.

The pam sm setcred() function is called to set the credentials of the current user associated with the authentication handle, pamh. The following flags may be set in the *flags* field. Note that the first four flags are mutually exclusive:

Set user credentials for the authentication PAM ESTABLISH CRED

service.

PAM DELETE CRED Delete user credentials associated with the

authentication service.

PAM REINITIALIZE CRED Reinitialize user credentials.

Extend lifetime of user credentials. PAM REFRESH CRED

Authentication service should not generate PAM SILENT

messages

If no flag is set, PAM ESTABLISH CRED is used as the default.

The argc argument represents the number of module options passed in from the configuration file pam. conf(4). argv specifies the module options, which are interpreted and processed by the authentication service. If an unknown option is passed to the module, an error should be logged and the option ignored.

If the PAM SILENT flag is not set, then pam sm setcred() should print any failure status from the corresponding pam sm authenticate() function using the conversation function.

The authentication status (success or reason for failure) is saved as module-specific state in the authentication handle by the authentication module. The status should be retrieved using pam get data(), and used to determine if user credentials should be set.

RETURN VALUES

Upon successful completion, PAM SUCCESS should be returned. The following values may also be returned upon error:

Underlying authentication service can not PAM_CRED_UNAVAIL

retrieve user credentials.

User credentials have expired. PAM CRED EXPIRED

pam_sm_setcred(3PAM)

PAM USER UNKNOWN User unknown to the authentication service.

PAM CRED ERR Failure in setting user credentials.

PAM_IGNORE Ignore underlying authentication module

regardless of whether the control flag is

required, optional, or sufficient.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

pam(3PAM), pam_authenticate(3PAM), pam_get_data(3PAM)
pam_setcred(3PAM), pam_sm_authenticate(3PAM), libpam(3LIB),
pam.conf(4), attributes(5)

NOTES

The $pam_sm_setcred()$ function is passed the same module options that are used by $pam_sm_authenticate()$.

The interfaces in libpam are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

NAME |

pam_start, pam_end – authentication transaction routines for PAM

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
int pam_start(const char *service, const char *user, const struct
    pam_conv *pam_conv, pam_handle_t **pamh);
int pam_end(pam_handle_t *pamh, int status);
```

DESCRIPTION

The pam_start() function is called to initiate an authentication transaction. pam_start() takes as arguments the name of the current service, service, the name of the user to be authenticated, user, the address of the conversation structure, pam_conv, and the address of a variable to be assigned the authentication handle pamh. Upon successful completion, pamh refers to a PAM handle for use with subsequent calls to the authentication library.

The *pam_conv* structure contains the address of the conversation function provided by the application. The underlying PAM service module invokes this function to output information to and retrieve input from the user. The <code>pam_conv</code> structure has the following entries:

The conv () function is called by a service module to hold a PAM conversation with the application or user. For window applications, the application can create a new pop-up window to be used by the interaction.

The *num_msg* parameter is the number of messages associated with the call. The parameter *msg* is a pointer to an array of length *num_msg* of the *pam_message* structure.

The pam_message structure is used to pass prompt, error message, or any text information from the authentication service to the application or user. It is the responsibility of the PAM service modules to localize the messages. The memory used by pam_message has to be allocated and freed by the PAM modules. The pam_message structure has the following entries:

```
struct pam_message{
    int         msg_style;
    char    *msg;
};
```

The message style, msg_style, can be set to one of the following values:

```
PAM_PROMPT_ECHO_OFF Prompt user, disabling echoing of response.

PAM_PROMPT_ECHO_ON Prompt user, enabling echoing of response.
```

pam_start(3PAM)

PAM ERROR MSG Print error message.

PAM TEXT INFO Print general text information.

PAM MSG NOCONF Print general text information without user

acknowledgment.

PAM_CONV_INTERRUPT Return from the conversation function.

The maximum size of the message and the response string is PAM_MAX_MSG_SIZE as defined in <security/pam.appl.h>.

The structure <code>pam_response</code> is used by the authentication service to get the user's response back from the application or user. The storage used by <code>pam_response</code> has to be allocated by the application and freed by the <code>PAM</code> modules. The <code>pam_response</code> structure has the following entries:

It is the responsibility of the conversation function to strip off NEWLINE characters for PAM_PROMPT_ECHO_OFF and PAM_PROMPT_ECHO_ON message styles, and to add NEWLINE characters (if appropriate) for PAM_ERROR_MSG and PAM_TEXT_INFO message styles.

The <code>appdata_ptr</code> argument is an application data pointer which is passed by the application to the PAM service modules. Since the PAM modules pass it back through the conversation function, the applications can use this pointer to point to any application-specific data.

The pam_end() function is called to terminate the authentication transaction identified by *pamh* and to free any storage area allocated by the authentication module. The argument, *status*, is passed to the cleanup(|) function stored within the pam handle, and is used to determine what module-specific state must be purged. A cleanup function is attached to the handle by the underlying PAM modules through a call to pam_set_data(3PAM) to free module-specific data.

RETURN VALUES

Refer to pam(3PAM) for information on error related return values.

ATTRIBUTES

NOTES

The interfaces in libpam are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

pam_strerror(3PAM)

NAME |

pam_strerror - get PAM error message string

SYNOPSIS

```
cc [ flag ... ] file ... -lpam [ library ... ]
#include <security/pam_appl.h>
```

const char *pam_strerror(pam_handle_t*pamh, int errnum);

DESCRIPTION

The pam strerror() function maps the PAM error number in errnum to a PAM error message string, and returns a pointer to that string. The application should not free or modify the string returned.

The pamh argument is the PAM handle obtained by a prior call to pam start(). If pam start() returns an error, a null PAM handle should be passed.

ERRORS

The pam strerror() function returns NULL if *errnum* is out-of-range.

ATTRIBUTES

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe with exceptions

SEE ALSO

pam(3PAM), pam start(3PAM), attributes(5)

NOTES

The interfaces in libpam are MT-Safe only if each thread within the multithreaded application uses its own PAM handle.

NAME | pathfind – search for named file in named directories

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
```

char *pathfind(const char *path, const char *name, const char *mode);

DESCRIPTION

The pathfind () function searches the directories named in path for the file name. The directories named in path are separated by colons (:). The mode argument is a string of option letters chosen from the set [rwxfbcdpugks]:

Letter	Meaning
r	readable
w	writable
x	executable
f	normal file
b	block special
С	character special
d	directory
p	FIFO (pipe)
u	set user ID bit
g	set group ID bit
k	sticky bit
s	size non-zero

Options read, write, and execute are checked relative to the real (not the effective) user ID and group ID of the current process.

If *name* begins with a slash, it is treated as an absolute path name, and *path* is ignored.

An empty path member is treated as the current directory. A slash (/) character is not prepended at the occurrence of the first match; rather, the unadorned *name* is returned.

EXAMPLES

EXAMPLE 1 Example of finding the 1s command using the PATH environment variable.

To find the 1s command using the PATH environment variable:

pathfind (getenv ("PATH"), "ls", "rx")

pathfind(3GEN)

RETURN VALUES

The pathfind() function returns a (char *) value containing static, thread-specific data that will be overwritten upon the next call from the same thread.

If the file *name* with all characteristics specified by *mode* is found in any of the directories specified by *path*, then pathfind() returns a pointer to a string containing the member of *path*, followed by a slash character (/), followed by *name*.

If no match is found, pathname() returns a null pointer, ((char *) 0).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

sh(1), test(1), access(2), mknod(2), stat(2), getenv(3C), attributes(5)

NOTES

The string pointed to by the returned pointer is stored in an area that is reused on subsequent calls to pathfind(). The string should not be deallocated by the caller.

When compiling multithreaded applications, the _REENTRANT flag must be defined on the compile line. This flag should only be used in multithreadedapplications.

NAME |

pctx_capture, pctx_create, pctx_run, pctx_release – process context library

SYNOPSIS

```
cc [ flag... ] file... -lpctx [ library... ]
#include <libpctx.h>

typedef void (pctx_errfn_t) (const char *fn, const char *fmt,
    va_list ap);

pctx_t *pctx_create(const char *filename, char *const *argv, void
    *arg, int verbose, pctx_errfn_t *errfn);

pctx_t *pctx_capture(pid_t pid, void *arg, int verbose, pctx_errfn_t
    *errfn);

int pctx_run(pctx_t *pctx, uint_t sample, uint_t nsamples, int
    (*tick) (pctx *, pid_t, id_t, void *));

void pctx release(pctx t *pctx);
```

DESCRIPTION

This family of functions allows a controlling process (the process that invokes them) to create or capture controlled processes. The functions allow the occurrence of various events of interest in the controlled process to cause the controlled process to be stopped, and to cause callback routines to be invoked in the controlling process.

 There are two ways a process can be acquired by the process context functions. First, a named application can be invoked with the usual argv[] array using pctx_create(), which forks the caller and execs the application in the child. Alternatively, an existing process can be captured by its process ID using pctx capture().

Both functions accept a pointer to an opaque handle, *arg*; this is saved and treated as a caller-private handle that is passed to the other functions in the library. Both functions accept a pointer to a fork(3C)-like error routine *errfn*; a default version is provided if NULL is specified.

A freshly-created process is created stopped; similarly, a process that has been successfully captured is stopped by the act of capturing it, thereby allowing the caller to specify the handlers that should be called when various events occur in the controlled process. The set of handlers is listed on the pctx_set_events(3CPC) manual page.

pctx run()

Once the callback handlers have been set with pctx_set_events(), the application can be set running using pctx_run(). This function starts the event handling loop; it returns only when either the process has exited, the number of time samples has expired, or an error has occurred (for example, if the controlling process is not privileged, and the controlled process has exec-ed a setuid program).

Every *sample* milliseconds the process is stopped and the *tick*() routine is called so that, for example, the performance counters can be sampled by the caller. No periodic sampling is performed if *sample* is 0.

pctx_capture(3CPC)

pctx release()

Once pctx run () has returned, the process can be released and the underlying storage freed using pctx release(). Releasing the process will either allow the controlled process to continue (in the case of an existing captured process and its children) or kill the process (if it and its children were created using pctx create()).

RETURN VALUES

Upon successful completion, pctx capture() and pctx create() return a valid handle. Otherwise, the functions print a diagnostic message and return NULL.

Upon successful completion, pctx run() returns 0 with the controlled process either stopped or exited (if the controlled process has invoked exit(2).) If an error has occurred (for example, if the controlled process has exec-ed a set-ID executable, if certain callbacks have returned error indications, or if the process was unable to respond to proc(4) requests) an error message is printed and the function returns -1.

USAGE

Within an event handler in the controlling process, the controlled process can be made to perform various system calls on its behalf. No system calls are directly supported in this version of the API, though system calls are executed by the cpc pctx family of interfaces in libcpc such as cpc pctx bind event(3CPC). A specially created agent LWP is used to execute these system calls in the controlled process. See proc(4) for more details.

While executing the event handler functions, the library arranges for the signals SIGTERM, SIGQUIT, SIGABRT, and SIGINT to be blocked to reduce the likelihood of a keyboard signal killing the controlling process prematurely, thereby leaving the controlled process permanently stopped while the agent LWP is still alive inside the controlled process.

NAME |

pctx_set_events – associate callbacks with process events

SYNOPSIS

```
cc [ flag... ] file... -lpctx [ library... ]
#include <libpctx.h>
typedef
          enum {
       PCTX_NULL_EVENT = 0,
       PCTX_SYSC_EXEC_EVENT,
       PCTX SYSC FORK EVENT,
       PCTX SYSC EXIT EVENT,
       PCTX_SYSC_LWP_CREATE_EVENT,
       PCTX INIT LWP EVENT,
       PCTX FINI LWP EVENT,
       PCTX SYSC LWP EXIT EVENT
} pctx event t;
typedef int pctx sysc execfn t (pctx t *pctx, pid t pid, id t lwpid,
     char *cmd, void *arg);
typedef void pctx sysc forkfn t(pctx t *pctx, pid t pid, id t lwpid,
    pid t child, void *arg);
typedef void pctx sysc exitfn t(pctx t *pctx, pid t pid, id t lwpid,
     void *arg);
typedef int pctx sysc lwp createfn t(pctx t *pctx, pid t pid, id t
    lwpid, void *arg);
typedef int pctx init lwpfn t(pctx t *pctx, pid t pid, id t lwpid,
     void *arg);
typedef int pctx_fini_lwpfn_t(pctx_t *pctx, pid_t pid, id_t lwpid,
     void *arg);
typedef int pctx sysc lwp exitfn t(pctx t *pctx, pid t pid, id t
    lwpid, void *arg);
int pctx set events(pctx t *pctx, ...);
```

DESCRIPTION

The pctx_set_events() function allows the caller (the controlling process) to express interest in various events in the controlled process. See pctx_capture(3CPC) for information about how the controlling process is able to create, capture and manipulate the controlled process.

The pctx_set_events() function takes a pctx_t handle, followed by a variable length list of pairs of pctx_event_t tags and their corresponding handlers, terminated by a PCTX_NULL_EVENT tag.

Most of the events correspond closely to various classes of system calls, though two additional pseudo-events (<code>init_lwp</code> and <code>fini_lwp</code>) are provided to allow callers to perform various housekeeping tasks. The <code>init_lwp</code> handler is called as soon as the library identifies a new LWP, while <code>fini_lwp</code> is called just before the LWP disappears. Thus the classic "hello world" program would see an <code>init_lwp</code> event, a <code>fini_lwp</code> event

pctx_set_events(3CPC)

and (process) *exit* event, in that order. The table below displays the interactions between the states of the controlled process and the handlers executed by users of the library.

System Calls and pctx Handlers		
System call	Handler	Comments
exec(2), execve(2)	fini_lwp	Invoked serially on all lwps in the process.
	exec	Only invoked if the exec() system call succeeded.
	init_lwp	If the exec succeeds, only invoked on lwp 1. If the exec fails, invoked serially on all lwps in the process.
fork(2), vfork(2), fork1(2)	fork	Only invoked if the fork() system call succeeded.
exit(2)	fini_lwp	Invoked on all lwps in the process.
	exit	Invoked on the exiting lwp.
_lwp_create(2)	init_lwp	Only if the corresponding _lwp_create() system call succeeded.
	lwp_create	
_lwp_exit(2)	fini_lwp	
	lwp_exit	

Each of the handlers is passed the caller's opaque handle, a pctx_t handle, the pid, and lwpid of the process and lwp generating the event. The lwp_exit, and (process) exit events are delivered before the underlying system calls begin, while the exec, fork, and lwp_create events are only delivered after the relevant system calls complete successfully. The exec handler is passed a string that describes the command being executed. Catching the fork event causes the calling process to fork(2), then capture the child of the controlled process using pctx_capture() before handing control to the fork handler. The process is released on return from the handler.

RETURN VALUES

Upon successful completiion, $pctx_set_events()$ returns 0. Otherwise, the function returns -1.

EXAMPLES

EXAMPLE 1 HandleExec example.

This example captures an existing process whose process identifier is *pid*, and arranges to call the *HandleExec* routine when the process performs an exec(2).

```
static void
HandleExec(pctx t *pctx, pid t pid, id t lwpid, char *cmd, void *arg)
```

EXAMPLE 1 HandleExec example. (Continued)

picld_log(3PICLTREE)

NAME |

picld_log - log a message in system log

SYNOPSIS

cc [flag ...] file ... -lpicltree [library ...]

#include <picltree.h>

void picld_log(const char *msg);

DESCRIPTION

The picld log() function logs the message specified in msg to the system log file using syslog(3C). This function is used by the PICL daemon and the plug-in modules to log messages to inform users of any error or warning conditions.

RETURN VALUES

This function does not return a value.

ERRORS

No errors are defined.

NAME |

picld_plugin_register - register plug-in with the daemon

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
int picld plugin register(picld plugin reg t *regp);
```

DESCRIPTION

The picld_plugin_register() function is the function used by a plug-in module to register itself with the PICL daemon upon initialization. The plug-in provides its name and the entry points of the initialization and cleanup routines in the *regp* argument.

The plug-in module also specifies whether it is a critical module for the proper system operation. The critical field in the registration information is set to PICLD_PLUGIN_NON_CRITICAL by plug-in modules that are not critical to system operation, and is set to PICLD_PLUGIN_CRITICAL by plug-in modules that are critical to the system operation. An environment control plug-in module is an example for a PICLD_PLUGIN_CRITICAL type of plug-in module.

The PICL daemon saves the information passed during registration in *regp* in the order in which the plug-ins registered.

Upon initialization, the PICL daemon invokes the plugin_init() routine of each of the registered plug-in modules in the order in which they registered. In their plugin_init() routines, the plug-in modules collect the platform configuration data and add it to the PICL tree using PICLTREE interfaces (3PICLTREE).

On reinitialization, the PICL daemon invokes the plugin_fini() routines of the registered plug-in modules in the reverse order of registration. Then, the plugin_init() entry points are invoked again in the order in which the plug-ins registered.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a negative value is returned.

ERRORS

NAME | picl_get_first_prop, picl_get_next_prop - get a property handle of a node

SYNOPSIS

```
cc [flag ...] file ... -lpicl [library ...]
#include <picl.h>
```

int picl get first prop(picl nodehdl t nodeh, piclprop hdl t *proph);

int picl get next prop(picl_prophdl_t proph, picl_prophdl_t *nextprop);

DESCRIPTION

The picl get first prop() function gets the handle of the first property of the node specified by *nodeh* and copies it into the location given by *proph*.

The picl get next prop() function gets the handle of the next property after the one specified by *proph* from the property list of the node, and copies it into the location specified by nextprop.

If there are no more properties, this function returns PICL ENDOFLIST.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL ENDOFLIST is returned to indicate that there are no more properties.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

ERRORS

NAME | picl get next by row, picl get next by col – access a table property

SYNOPSIS

```
cc [flag ...] file ... -lpicl [library ...]
#include <picl.h>
```

int picl get next by row(picl prophdl t proph, picl prophdl t

int picl get next by col(picl prophdl t proph, picl prophdl t *colh);

DESCRIPTION

The picl get next by row() function copies the handle of the property that is in the next column of the table and on the same row as the property *proph*. The handle is copied into the location given by rowh.

The picl get next by col() function copies the handle of the property that is in the next row of the table and on the same column as the property *proph*. The handle is copied into the location given by colh.

If there are no more rows or columns, this function returns the value PICL ENDOFLIST.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

NAME | picl_get_prop_by_name – get the handle of the property by name

SYNOPSIS

```
cc [flag ...] file ... -lpicl [library ...]
#include <picl.h>
```

int picl_get_prop_by_name(picl nodehdl t nodeh, char *name, picl prophdl t *proph);

DESCRIPTION

The picl get prop by name () function gets the handle of the property of node nodeh whose name is specified in name. The handle is copied into the location specified by proph.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL PROPNOTFOUND is returned if the property of the specified name does not exist.

PICL RESERVEDNAME is returned if the property name specified is one of the reserved property names.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

NAME |

picl_get_propinfo – get the information about a property

SYNOPSIS

cc [flag ...] file ... -lpicl [library ...]
#include <picl.h>

int picl_get_propinfo(picl_prophdl_t proph, picl_propinfo_t
 *pinfo);

DESCRIPTION

The picl_get_propinfo() function gets the information about the property specified by handle *proph* and copies it into the location specified by *pinfo*. The property information includes the property type, access mode, size, and the name of the property as described on libpicl(3PICL) manual page.

The maximum size of a property value is specified by PICL_PROPSIZE_MAX. It is currently set to 512KB.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL_STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL_INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

NAME |

picl_get_propval, picl_get_propval_by_name – get the value of a property

SYNOPSIS

```
cc [flag ...] file ... -lpicl [library ...]
#include <picl.h>
```

int picl get propval (picl prophdl t proph, void *valbuf, size t

int picl get propval by name(picl_nodehdl_t nodeh, char *propname, void *valbuf, size t nbytes);

DESCRIPTION

The picl get propval() function copies the value of the property specified by the handle *proph* into the buffer location given by *valbuf*. The size of the buffer *valbuf* in bytes is specified in *nbytes*.

The picl get propval by name() function gets the value of property named propriame of the node specified by handle nodeh. The value is copied into the buffer location given by valbuf. The size of the buffer valbuf in bytes is specified in nbytes.

The picl get propval by name () function is used to get a reserved property's value. An example of a reserved property is "_parent". Please refer to libpic1(3PICL) for a complete list of reserved property names.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL PROPNOTFOUND is returned if the property of the specified name does not exist.

PICL PERMDENIED is returned if the client does not have sufficient permission to access the property.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

```

int picl_set_propval_by_name(picl_nodehdl_t nodeh, const char
 *pname, void *valbuf, size t nbytes);

DESCRIPTION

The picl_set_propval() function sets the value of the property specified by the handle *proph* to the value contained in the buffer *valbuf*. The argument *nbytes* specifies the size of the buffer *valbuf*.

The picl_set_propval_by_name() function sets the value of the property named *pname* of the node specified by the handle *nodeh* to the value contained in the buffer *valbuf*. The argument *nbytes* specifies the size of the buffer *valbuf*.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL_PERMDENIED is returned if the client does not have sufficient permission to access the property.

PICL_STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL_INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

Session not initialized

ERRORS

_	
PICL_NORESPONSE	Daemon not responding
PICL_PERMDENIED	Insufficient permission
PICL_NOTWRITABLE	Property is read-only
PICL_VALUETOOBIG	Value too big
PICL_NOTPROP	Not a property
PICL_NOTNODE	Not a node

PICL_INVALIDHANDLE Invalid handle specified
PICL_STALEHANDLE Stale handle specified
PICL_FAILURE General system failure

NAME | picl_strerror – get error message string

SYNOPSIS cc [flag ...] file ... -lpicl [library ...]

#include <picl.h>

char *picl_strerror(int errnum);

DESCRIPTION The picl strerror() function maps the error number in *errnum* to an error

message string, and returns a pointer to that string. The returned string should not be

overwritten.

RETURN VALUES The picl_strerror() function returns NULL if *errnum* is out-of-range.

NAME | picl_walk_tree_by_class - walk subtree by class

SYNOPSIS

```
cc [flag ...] file ... -lpicl [library ...]
#include <picl.h>
```

int picl walk tree by class(picl nodehdl t rooth, const char *classname, void *c_args, int (*callback) (picl nodehdl t nodeh, void *c_args));

DESCRIPTION

The picl walk tree by class() function visits all the nodes of the subtree under the node specified by rooth. The PICL class name of the visited node is compared with the class name specified by classname. If the class names match, then the callback function specified by callback is called with the matching node handle and the argument provided in c_args . If the class name specified in *classname* is NULL, then the callback function is invoked for all the nodes.

The return value from the callback function is used to determine whether to continue or terminate the tree walk. The callback function returns PICL WALK CONTINUE or PICL WALK TERMINATE to continue or terminate the tree walk.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed. This error may be returned for a previously valid handle if the daemon was brought down and restarted. When this occurs a client must revalidate any saved handles.

ERRORS

PICL NOTINITIALIZED Session not initialized PICL NORESPONSE Daemon not responding

PICL NOTNODE Not a node

PICL INVALIDHANDLE Invalid handle specified PICL STALEHANDLE Stale handle specified PICL FAILURE General system failure

pow(3M)

NAME | pow – power function

SYNOPSIS

cc [flag ...] file ... -lm [library ...]

#include <math.h>

double **pow**(double x, double y);

DESCRIPTION

The pow () function computes the value of x raised to the power y, x^y . If x is negative, y must be an integer value.

RETURN VALUES

Upon successful completion, pow() returns the value of x raised to the power y.

If x is 0 and y is 0, 1.0 is returned.

If *y* is NaN, or *y* is non-zero and *x* is NaN, NaN is returned. If *y* is 0.0 and *x* is NaN, NaN is returned.

If x is 0.0 and y is negative, -HUGE VAL is returned and errno may be set to EDOM or ERANGE.

If the correct value would cause overflow, ±HUGE VAL is returned, and errno is set to ERANGE.

If the correct value would cause underflow to 0, 0 is returned and errno may be set to ERANGE.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The pow() function will fail if:

EDOM The value of *x* is negative and *y* is non-integral.

ERANGE The value to be returned would have caused overflow.

The pow() function may fail if:

EDOM The value of x is 0.0 and y is negative.

The correct value would cause underflow. ERANGE

USAGE

An application wishing to check for error situations should set errno to 0 before calling pow(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

NAME | project – access project files from Perl

SYNOPSIS

```
use Sun::Solaris::Project qw(:ALL);
```

```
my ($name, $projid, $comment, $users, $groups, $attr) = getprojent();
($name, $projid, $comment, $users, $groups, $attr) = getprojbyname("proj");
my $proj = getdefaultproj("root");
```

DESCRIPTION

This module provides perl access to the project file library as documented in getprojent(3PROJECT). The interface is similar to the standard perl getxxx () functions such as getpwent () and gethostent (). For detailed descriptions of the individual functions, refer to the getprojent(3PROJECT) and project(4) manual pages.

CONSTANTS

PROJNAME MAX maximum length of a project name

FUNCTIONS

getprojent()

Returns the next entry from the projects file. When called in a scalar context, getprojent () returns just the name of the project, or undef when the end of the file is reached. When called in a list context, getprojent () returns a 6-element list consisting of (\$name, \$projid, \$comment, \@users, \@groups, \$attr). \@users and \@groups are returned as references to arrays containing the appropriate user or project lists. On end of file, undef is returned.

```
setprojent()
```

Rewinds the project database to the beginning of the file.

```
endprojent()
```

Closes the project file.

```
getprojid()
```

Returns the current numeric project ID.

```
getprojbyname($name)
```

Searches the project database for an entry with the specified name, returning undef if it cannot be found or a 6-element list as returned by getprojent () if it can be found.

```
getprojbyid($id)
```

Searches the project database for an entry with the specified ID, returning undef if it cannot be found or a 6-element list as returned by getprojent () if it can be found.

```
getdefaultproj($user)
```

Returns the default project entry for the specified user in the same format as getprojent (), or undef if the user cannot be found. For full details of the lookup process, see the manual page for getdefaultproj(3PROJECT).

```
fgetprojent($filehandle)
```

Returns the next project entry from \$filehandle, which is a perl file handle, and must refer to a previously opened file in project(4) format. Return values are the same as for getprojent().

project(3EXT)

```
inproj($user, $project)
```

Checks to see if the specified user is able to use the project. Returns TRUE if the user can use the project and FALSE otherwise.

```
getprojidbyname($project)
```

Searches the project database for the specified project and returns the project ID if it is found. If not found, undef is returned.

EXPORTS

By default nothing is exported from this namespace. The following tags can be used to selectively import constants and functions defined in this namespace:

```
:LIBCALLS PROJNAME_MAX, getprojent(), setprojent(), endprojent(), getprojbyname(), getprojbyid(), getdefaultproj(), fgetprojent(), inproj(), getprojidbyname(), getprojid()
```

:ALL :LIBCALLS

EXAMPLES

EXAMPLE 1 Get the record for the default project and print its list of attributes.

```
use Sun::Solaris::Project qw(:ALL);
my ($name, $projid, $comment, $users, $groups, $attr) =
getprojbyname("default");
die("Can't find default project\n") if (! defined($name));
print("Project $name:\n");
print(" Project id: $projid\n");
print(" Comment: $comment\n");
print(" Users: @$users\n");
print(" Groups: @$groups\n");
print(" Attributes: $attr\n");
```

SEE ALSO

perl(1), getdefaultproj(3PROJECT), getprojent(3PROJECT), project(4)

NAME

| project_walk – visit active project IDs on current system

SYNOPSIS

DESCRIPTION

The project_walk() function provides a mechanism for the application author to examine all active projects on the current system. The *callback* function provided by the application is given the ID of an active project at each invocation and can use the *walk_data* to record its own state. The callback function should return non-zero if it encounters an error condition or attempts to terminate the walk prematurely; otherwise the callback function should return 0.

RETURN VALUES

Upon successful completion, project_walk() returns 0. It returns -1 if the *callback* function returned a non-zero value or if the walk encountered an error, in which case errno is set to indicate the error.

ERRORS

The project walk() function will fail if:

ENOMEM

There is insufficient memory available to set up the initial data for the walk.

Other returned error values are presumably caused by the *callback* function.

EXAMPLES

EXAMPLE 1 Count the number of projects available on the system.

The following example counts the number of projects available on the system.

```
#include <sys/types.h>
#include <project.h>
#include <stdio.h>

typedef struct wdata {
        uint_t count;
} wdata_t;

wdata_t total_count;

int
simple_callback(const projid_t p, void *pvt)
{
        wdata_t *w = (wdata_t *)pvt;
        w->count++;
        return (0);
}

...

total_count.count = 0;
errno = 0;
if (n=project_walk(simple_callback, &total_count)) >= 0)
        (void) printf("count = %u\n", total_count.count);
```

project_walk(3PROJECT)

NAME

ptree_add_node, ptree_delete_node - add or delete node to or from tree

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree add node(picl nodehdl t parh, picl nodehdl t chdh);

int ptree delete node(ptree delete node nodeh);

DESCRIPTION

The ptree_add_node() function adds the node specified by handle *chdh* as a child node to the node specified by the handle *parh*. PICL_CANTPARENT is if the child node already has a parent.

The ptree_delete_node() function deletes the node specified by handle *nodeh* and all its descendant nodes from the tree.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL_STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ERRORS

PICL NOTNODE Node a node

PICL_CANTPARENT Already has a parent
PICL_TREEBUSY PICL tree is busy
PICL_INVALIDHANDLE Invalid handle
PICL_STALEHANDLE Stale handle

PICL_FAILURE General system failure

ptree_add_prop(3PICLTREE)

NAME | ptree_add_prop, ptree_delete_prop – add or delete a property

SYNOPSIS

cc [flag ...] file ... -lpicltree [library ...]

#include <picltree.h>

int ptree add prop(picl nodehdl t nodeh, picl prophdl t proph);

int proph(picl prophdl t proph);

DESCRIPTION

The ptree add prop() function adds the property specified by the handle proph to the list of properties of the node specified by handle *nodeh*.

The ptree delete prop() function deletes the property from the property list of

the node. For a table property, the entire table is deleted.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ERRORS

PICL NOTTABLE Not a table

PICL NOTPROP Not a property Invalid handle PICL INVALIDHANDLE PICL STALEHANDLE Stale handle

PICL PROPEXISTS Property already exists PICL FAILURE General system failure

NAME | ptree create and add node - create and add node to tree and return node handle

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree create and add node (picl nodehdl t parh, const char *name, const char *classname, picl nodehdl t *nodeh);

DESCRIPTION

The ptree create and add node() function creates a node with the name and PICL class specified by name and classname respectively. It then adds the node as a a child to the node specified by *parh*. The handle of the new node is returned in *nodeh*.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

NAME | ptree_create_node, ptree_destroy_node - create or destroy a node

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree create node (char *name, char *clname, picl nodehdl t *nodeh);

int ptree destroy node(picl nodehdl t nodeh);

DESCRIPTION

The ptree create node () function creates a node and sets the "name" property value to the string specified in name and the "class" property value to the string specified in *clname*. The handle of the new node is copied into the location given by nodeh.

The ptree destroy node () function destroys the node specified by *nodeh* and frees up any allocated space. The node to be destroyed must have been previously deleted by ptree_delete_node (see ptree add node(3PICLTREE)). Otherwise, PICL CANTDESTROY is returned.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ERRORS

NAME | ptree_create_prop, ptree_destroy_prop - create or destroy a property

SYNOPSIS

cc [flag ...] file ... -lpicltree [library ...] #include <picltree.h>

int ptree create prop(ptree propinfo t *pinfo, void *valbuf, picl prophdl t *proph);

int ptree destroy prop(picl prophdl t proph);

DESCRIPTION

The ptree create prop() function creates a property using the information specified in pinfo, which includes the name, type, access mode, and size of the property, as well as the read access function for a volatile property. The value of the property is specified in the buffer valbuf, which may be NULL for volatile properties. The handle of the property created is copied into the location given by proph. See libpicltree(3PICLTREE) for more information on the structure of ptree propinfo t structure.

The ptree destroy prop() function destroys the property specified by the handle *proph.* For a table property, the entire table is destroyed. The property to be destroyed must have been previously deleted.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ptree_create_table(3PICLTREE)

NAME | ptree create table, ptree add row to table - create a table object

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
```

#include <picltree.h>

int ptree create table (picl prophdl t *tbl_hdl);

int ptree add row to table (picl prophdl t tbl_hdl, int nprops, picl prophdl t *proph);

DESCRIPTION

The ptree create table() function creates a table object and returns the handle of the table in *tbl_hdl*.

The ptree add row to table () function adds a row of properties to the table specified by tbl_hdl. The handles of the properties of the row are specified in the proph array and *nprops* specifies the number of handles in the array. The number of columns in the table is determined from the first row added to the table. If extra column values are specified in subsequent rows, they are ignored. The row is appended to the end of the table.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

NAME | ptree_find_node – find node with given property and value

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree find node (picl nodehdl t rooth, char *pname, picl prop type t ptype, void *pval, size t valsize, picl nodehdl t *retnodeh);

DESCRIPTION

The ptree find node () function visits the nodes in the subtree under the node specified by rooth. The handle of the node that has the property whose name, type, and value matches the name, type, and value specified in pname, ptype, and pval respectively, is returned in the location given by retnodeh. The argument valsize gives the size of the value in *pval*. The first *valsize* number of bytes of the property value is compared with pval.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL NODENOTFOUND is returned if there is no node that matches the property criteria can be found.

ERRORS

PICL NOTNODE Not a node

ptree_get_first_prop(3PICLTREE)

NAME | ptree_get_first_prop, ptree_get_next_prop - get a property handle of the node

SYNOPSIS

cc [flag ...] file ... -lpicltree [library ...]

#include <picltree.h>

int ptree get first prop(picl nodehdl t nodeh, picl prophdl t

int ptree get next prop(picl prophdl t proph, picl prophdl t *nextproph);

DESCRIPTION

The ptree get first prop() function gets the handle of the first property of the node specified by *nodeh* and copies it into the location specified by *proph*.

The ptree get next prop () function gets the handle of the next property after the one specified by *proph* from the list of properties of the node and copies it into the location specified by nextproph.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ERRORS

PICL NOTPROP Not a property

ptree_get_prop_by_name(3PICLTREE), attributes(5)

NAME | ptree_get_next_by_row, ptree_get_next_by_col – access a table property

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree get next by row(picl prophdl t proph, picl prophdl t

int ptree get next by col(picl prophdl t proph, picl prophdl t *colh);

DESCRIPTION

The ptree_get_next_by_row() function copies the handle of the property that is in the next column of the table and on the same row as the property *proph*. The handle is copied into the location given by rowh.

The ptree get next by col() function copies the handle of the property that is in the next row of the table and on the same column as the property *proph*. The handle is copied into the location given by colh.

If there are no more rows or columns, this function returns the value PICL ENDOFLIST.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ptree_get_node_by_path(3PICLTREE)

NAME | ptree get node by path - get handle of node specified by PICL tree path

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree get node by path (const char *ptreepath, picl nodehdl t

DESCRIPTION

The ptree get node by path() function copies the handle of the node in the PICL tree specified by the path given in *ptreepath* into the location *nodeh*.

The syntax of a PICL tree path is:

```
[def_propname:]/[def_propval[match_cond] ...]
```

where *def_propname* prefix is a shorthand notation to specify the name of the property whose value is specified in *def_propval*, and the *match_cond* expression specifies the matching criteria for that node in the form of one or more pairs of property names and values such as

```
[@address] [?prop_name [=prop_val] ...]
```

where '@' is a shorthand notation to refer to the device address, which is followed by the device address value address. The address value is matched with the value of the property "bus-addr" if it exists. If no "bus-addr" property exists, then it is matched with the value of the property "UnitAddress". Use the '?' notation to limit explicitly the comparison to "bus-addr" or "UnitAddress" property. The expression following '?' specifies matching property name and value pairs, where prop_name gives the property name and prop_val gives the property value for non PICL PTYPE VOID properties. The values for properties of type PICL PTYPE TABLE, PICL PTYPE BYTEARRAY, and PICL PTYPE REFERENCE cannot be specified in the *match_cond* expression.

A "_class" property value of "picl" may be used to match nodes of all PICL classes.

All valid paths must start at the root node denoted by '/'.

If no prefix is specified for the path, then the prefix defaults to the "name" property.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL NOTNODE is returned if there is no node corresponding to the specified path.

ERRORS

Invalid argument PICL INVALIDARG

PICL NOTNODE Not a node

NAME | ptree_get_prop_by_name – get a property handle by name

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree get prop by name (picl nodehdl t nodeh, char *name, picl prophdl t *proph);

DESCRIPTION

The ptree_get_prop_by_name() function gets the handle of the property, whose name is specified in *name*, of the node specified by the handle *nodeh*. The property handle is copied into the location specified by *proph*.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL RESERVEDNAME is returned if the name specified is a PICL reserved name property. Reserved name properties do not have an associated property handle. Use ptree get propval by name(3PICLTREE) to get the value of a reserved property.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

```

int ptree get propval(picl prophdl t proph, void *valbuf, size t

int ptree get propval by name (picl nodehdl t nodeh, void *name, void *valbuf, size_t nbytes);

DESCRIPTION

The ptree get propval () function gets the value of the property specified by the handle proph and copies it into the buffer specified by valbuf. The size of the buffer valbuf is specifed in nbytes.

The ptree_get_propval_by_name() function gets the value of the property, whose name is specified by *name*, from the node specified by handle *nodeh*. The value is copied into the buffer specified by *valbuf*. The size of the buffer is specified by *nbytes*.

For volatile properties, the read access function provided by the plug-in publishing the property is invoked.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

NAME | ptree_init_propinfo – initialize ptree_propinfo_t structure

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree init propinfo (ptree propinfo t *infop, int version, int ptype, int pmode, size t psize, char *pname, int (*readfn) (ptree rarg t *, void *), int (*writefn) (ptree warg t *, const void *));

DESCRIPTION

The ptree init propinfo() function initializes a ptree propinfo t property information structure given by location *infop* with the values provided by the arguments.

The *version* argument specifies the version of the ptree propinfo t structure. PTREE PROPINFO VERSION gives the current version. The arguments *ptype*, *pmode*, psize, and pname specify the property's PICL type, access mode, size, and name. The maximum size of a property name is defined by PICL PROPNAMELEN MAX. The arguments readfn and writefn specify a volatile property's read and write access functions. For non-volatile properties, these are set to NULL.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

ERRORS

PICL INVALIDARG Invalid argument

ptree_post_event(3PICLTREE)

NAME | ptree_post_event - post a PICL event

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree post event (const char *ename, const void *earg, size t size, void (*completion_handler) (char *ename, void *earg, size t size));

DESCRIPTION

The ptree post event () function posts the specified event and its arguments to the PICL framework. The argument ename specifies a pointer to a string containing the name of the PICL event. The arguments earg and size specify a pointer to a buffer containing the event arguments and size of that buffer, respectively. The argument completion_handler specifies the completion handler to be called after the event has been dispatched to all handlers. A NULL value for a completion handler indicates that no handler should be called. The PICL framework invokes the completion handler of an event with the ename, earg, and size arguments specified at the time of the posting of the event.

PICL events are dispatched in the order in which they were posted. They are dispatched by executing the handlers registered for that event. The handlers are invoked in the order in which they were registered.

New events will not begin execution until all previous events have finished execution. Specifically, an event posted from an event handler will not begin execution until the current event has finished execution.

The caller may not reuse or reclaim the resources associated with the event name and arguments until the invocation of the completion handler. The completion handlers are normally used to reclaim any resources allocated for the posting of an event.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error, the event is not posted, and the completion handler is not invoked..

ERRORS

PICL INVALIDARG Invalid argument

PICL FAILURE General system failure

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

ptree register handler(3PICLTREE), ptree unregister handler(3PICLTREE), attributes(5)

NAME |

ptree_register_handler - register a handler for the event

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
int ptree register handler (const char *ename, void
     (*evt_handler) (const char *ename, const void *earg, size t size,
```

DESCRIPTION

The ptree register handler () function registers an event handler for a PICL event. The argument ename specifies the name of the PICL event for which to register the handler. The argument evt_handler specifies the event handler function. The argument cookie is a pointer to caller-specific data to be passed as an argument to the event handler when it is invoked.

The event handler function must be defined as

void *cookie), void *cookie);

```
void evt handler(const char *ename, const void *earg, \
        size_t size, void *cookie)
```

where, ename, earg, size, and cookie are the arguments passed to the event handler when it is invoked. The argument ename is the PICL event name for which the handler is invoked. The arguments earg and size gives the pointer to the event argument buffer and its size, respectively. The argument cookie is the pointer to the caller specific data registered with the handler. The arguments *ename* and *earg* point to buffers that are transient and shall not be modified by the event handler or reused after the event handler finishes execution.

The PICL framework invokes the event handlers in the order in which they were registered when dispatching an event. If the event handler execution order is required to be the same as the plug-in dependency order, then a plug-in should register its handlers from its init function. The handlers that do not have any ordering dependencies on other plug-in handlers can be registered at any time.

The registered handler may be called at any time after this function is called.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error and the handler is not registered.

ERRORS

PICL INVALIDARG Invalid argument PICL FAILURE General system failure

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO | ptree unregister handler(3PICLTREE), attributes(5)

ptree_unregister_handler(3PICLTREE)

NAME | ptree_unregister_handler – unregister the event handler for the event

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

```
void ptree register handler (const char *ename, void
     (*evt_handler) (const char *ename, const void *earg, size_t size,
    void *cookie), void *cookie);
```

DESCRIPTION

The ptree unregister handler() function unregisters the event handler for the specified event. The argument ename specifies the name of the PICL event for which to unregister the handler. The argument *evt_handler* specifies the event handler function. The argument cookie is the pointer to the caller-specific data given at the time of registration of the handler.

If the handler being unregistered is currently executing, then this function will block until its completion. Because of this, locks acquired by the handlers should not be held across the call to ptree unregister handler() or a deadlock may result.

The ptree unregister handler() function must not be invoked from the handler that is being unregistered.

RETURN VALUES

This function does not return a value.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ptree_update_propval(3PICLTREE)

NAME | ptree_update_propval, ptree_update_propval_by_name - update a property value

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree update propval (picl prophdl t proph, void *valbuf, size t

int ptree update propval by name (picl nodehdl t nodeh, char *name, void *valbuf, size t nbytes);

DESCRIPTION

The ptree update propval () function updates the value of the property specified by *proph* with the value specified in the buffer *valbuf*. The size of the buffer *valbuf* is specified in nbytes.

The ptree update propval by name() function updates the value of the property, whose name is specified by name, of the node specified by handle nodeh. The new value is specified in the buffer *valbuf*, whose size is specified in *nbytes*.

For volatile properties, the write access function provided by the plug-in publishing the property is invoked.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

PICL STALEHANDLE is returned if the handle is no longer valid. This occurs if the PICL tree was refreshed or reinitialized.

PICL INVALIDHANDLE is returned if the specified handle never existed.

ptree_walk_tree_by_class(3PICLTREE)

NAME | ptree_walk_tree_by_class – walk subtree by class

SYNOPSIS

```
cc [flag ...] file ... -lpicltree [library ...]
#include <picltree.h>
```

int ptree walk tree by class (picl nodehdl t rooth, const char *classname, void *c_args, int (*callback) (picl nodehdl t nodeh, void *c_args));

DESCRIPTION

The ptree walk tree by class() function visits all the nodes of the subtree under the node specified by rooth. The PICL class name of the visited node is compared with the class name specified by classname. If the class names match, the callback function specified by callback is called with the matching node handle and the argument provided in c_args. If the class name specified in classname is NULL, then the callback function is invoked for all the nodes.

The return value from the callback function is used to determine whether to continue or terminate the tree walk. The callback function returns PICL WALK CONTINUE or PICL WALK TERMINATE to continue or terminate the tree walk.

RETURN VALUES

Upon successful completion, 0 is returned. On failure, a non-negative integer is returned to indicate an error.

NAME | read_vtoc, write_vtoc – read and write a disk's VTOC

SYNOPSIS

```
cc [ flag ... ] file ... -ladm [ library ... ]
#include <sys/vtoc.h>
int read vtoc(int fd, struct vtoc *vtoc);
```

int write vtoc(int fd, struct vtoc *vtoc);

DESCRIPTION

The read vtoc() function returns the VTOC (volume table of contents) structure that is stored on the disk associated with the open file descriptor fd.

The write vtoc() function stores the VTOC structure on the disk associated with the open file descriptor fd.

The fd argument refers to any slice on a raw disk.

RETURN VALUES

Upon successful completion, read_vtoc() returns a positive number indicating the slice index associated with the open file descriptor. Otherwise, it returns a negative number indicating one of the following errors:

An I/O error occurred. VT EIO

VT ERROR An unknown error occurred.

Upon successful completion, write vtoc() returns 0. Otherwise, it returns a negative number indicating one of the following errors:

An I/O error occurred. VT EIO

VT ERROR An unknown error occurred.

The VTOC contains an incorrect field. VT EINVAL

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

fmthard(1M), format(1M), prtvtoc(1M), ioctl(2), attributes(5), dkio(7I)

BUGS

The write vtoc() function cannot write a VTOC on an unlabeled disk. Use format(1M) for this purpose.

reg_ci_callback(3DMI)

NAME |

reg_ci_callback - provide a component instrumentation with a transient program number

SYNOPSIS

```
[ library ... ]
cc [ flag ... ] file ... -ldmici
#include <dmi/ci callback svc.hh>
u_long reg_ci_callback();
```

DESCRIPTION

The reg ci callback() function provides a component instrumentation with a transient program number. The instrumentation uses this number to register its RPC service provider. The prognum member of the DmiRegisterInfo structure is populated with the return value of this function

RETURN VALUES

Upon successful completion, the reg ci callback () function returns a transient program number of type u long.

ATTRIBUTES

NAME SYNOPSIS

regexpr, compile, step, advance – regular expression compile and match routines

cc [flag...] [file...] -lgen [library...]

```
#include <regexpr.h>
char *compile(char *instring, char *expbuf, const char *endbuf);
int step(const char *string, const char *expbuf);
int advance(const char *string, const char *expbuf);
extern char *loc1, loc2, locs;
extern int nbra, regerrno, reglength;
extern char *braslist[], *braelist[];
```

DESCRIPTION

These routines are used to compile regular expressions and match the compiled expressions against lines. The regular expressions compiled are in the form used by ed(1).

The parameter *instring* is a null-terminated string representing the regular expression.

The parameter *expbuf* points to the place where the compiled regular expression is to be placed. If *expbuf* is NULL, compile() uses malloc(3C) to allocate the space for the compiled regular expression. If an error occurs, this space is freed. It is the user's responsibility to free unneeded space after the compiled regular expression is no longer needed.

The parameter *endbuf* is one more than the highest address where the compiled regular expression may be placed. This argument is ignored if *expbuf* is NULL. If the compiled expression cannot fit in (*endbuf–expbuf*) bytes, compile() returns NULL and regerrno (see below) is set to 50.

The parameter *string* is a pointer to a string of characters to be checked for a match. This string should be null-terminated.

The parameter *expbuf* is the compiled regular expression obtained by a call of the function <code>compile()</code>.

The function step() returns non-zero if the given string matches the regular expression, and zero if the expressions do not match. If there is a match, two external character pointers are set as a side effect to the call to step(). The variables set in step() are loc1 and loc2. loc1 is a pointer to the first character that matched the regular expression. The variable loc2 points to the character after the last character that matches the regular expression. Thus if the regular expression matches the entire line, loc1 points to the first character of *string* and loc2 points to the null at the end of *string*.

regexpr(3GEN)

The purpose of step() is to step through the *string* argument until a match is found or until the end of *string* is reached. If the regular expression begins with ^, step() tries to match the regular expression at the beginning of the string only.

The advance() function is similar to step(); but, it only sets the variable loc2 and always restricts matches to the beginning of the string.

If one is looking for successive matches in the same string of characters, locs should be set equal to loc2, and step() should be called with *string* equal to loc2. locs is used by commands like ed and sed so that global substitutions like s/y*//g do not loop forever, and is NULL by default.

The external variable nbra is used to determine the number of subexpressions in the compiled regular expression. braslist and braelist are arrays of character pointers that point to the start and end of the nbra subexpressions in the matched string. For example, after calling step() or advance() with string sabcdefg and regular expression \ (abcdef\), braslist[0] will point at a and braelist[0] will point at g. These arrays are used by commands like ed and sed for substitute replacement patterns that contain the \n notation for subexpressions.

Note that it is not necessary to use the external variables regerrno, nbra, loc1, loc2 locs, braelist, and braslist if one is only checking whether or not a string matches a regular expression.

EXAMPLES

EXAMPLE 1 The following is similar to the regular expression code from grep:

```
#include<regexpr.h>
. . .
if(compile(*argv, (char *)0, (char *)0) == (char *)0)
    regerr(regerrno);
. . .
if (step(linebuf, expbuf))
    succeed();
```

RETURN VALUES

If compile() succeeds, it returns a non-NULL pointer whose value depends on *expbuf*. If *expbuf* is non-NULL, compile() returns a pointer to the byte after the last byte in the compiled regular expression. The length of the compiled regular expression is stored in reglength. Otherwise, compile() returns a pointer to the space allocated by malloc(3C).

The functions step () and advance () return non-zero if the given string matches the regular expression, and zero if the expressions do not match.

ERRORS

If an error is detected when compiling the regular expression, a NULL pointer is returned from compile() and regerrno is set to one of the non-zero error numbers indicated below:

regexpr(3GEN)

ERROR	MEANING
11	Range endpoint too large.
16	Bad Number.
25	"\digit" out or range.
36	Illegal or missing delimiter.
41	No remembered string search.
42	\(~\) imbalance.
43	Too many ∖(.
44	More than 2 numbers given in $\ \]$ &~ $\$ }.
45	} expected after \.

ed(1), grep(1), sed(1), malloc(3C), attributes(5), regexp(5)

NOTES

When compiling multi-threaded applications, the $_\texttt{REENTRANT}$ flag must be defined on the compile line. This flag should only be used in multi-threaded applications.

remainder(3M)

NAME

remainder – remainder function

SYNOPSIS

#include <math.h>

double remainder (double x, double y);

DESCRIPTION

The remainder () function returns the floating point remainder r = x - ny when y is non-zero. The value n is the integral value nearest the exact value x/y. When $|n-x/y| = \frac{1}{2}$, the value n is chosen to be even.

The behavior of remainder () is independent of the rounding mode.

RETURN VALUES

The remainder () function returns the floating point remainder r = x - ny when y is non-zero.

When y is 0, remainder () returns NaN. and sets errno to EDOM.

If the value of x is $\pm Inf$, remainder () returns NaN and sets errno to EDOM.

If *x* or *y* is NaN, then the function returns NaN.

ERRORS

The remainder() function will fail if:

EDOM

The y argument is 0 or the x argument is positive or negative

infinity.

USAGE

The remainder () function computes the remainder x REM y required by ANSI/IEEE 754 (IEC 559).

ATTRIBUTES

NAME | rint – round-to-nearest integral value

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double rint(double x);

DESCRIPTION

The rint () function returns the integral value (represented as a double) nearest *x* in the direction of the current IEEE754 rounding mode.

If the current rounding mode rounds toward negative infinity, then rint () is identical to floor(3M). If the current rounding mode rounds toward positive infinity, then rint () is identical to ceil(3M).

RETURN VALUES

Upon successful completion, the rint () function returns the integer (represented as a double precision number) nearest *x* in the direction of the current IEEE754 rounding mode.

When x is $\pm Inf$, rint() returns x.

If the value of *x* is NaN, NaN is returned.

ERRORS

No errors will occur.

rsm_create_localmemory_handle(3RSM)

NAME |

rsm_create_localmemory_handle, rsm_free_localmemory_handle – create or free local memory handle

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

DESCRIPTION

The $rsm_create_localmemory_handle()$ and $rsm_free_localmemory_handle()$ functions are supporting functions for $rsm_memseg_import_putv(3RSM)$ and $rsm_memseg_import_getv(3RSM)$.

The rsm_create_localmemory_handle () function creates a local memory handle to be used in the I/O vector component of a scatter-gather list of subsequent $rsm_memseg_import_putv()$ and $rsm_memseg_import_getv()$ calls. The handle argument specifies the controller handle obtained from $rsm_get_controller(3RSM)$. The l_handle argument is a pointer to the location for the function to return the local memory handle. The $local_vaddr$ argument specifies the local virtual address; it should be aligned at a page boundary. The length argument specifies the length of memory spanned by the handle.

The $rsm_free_localmemory_handle()$ function unlocks the memory range for the local handle specified by l_handle and releases the associated system resources. The handle argument specifies the controller handle. All handles created by a process are freed when the process exits, but the process should call $rsm_free_localmemory_handle()$ as soon as possible to free the system resources.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

rsm free localmemory handle () functions can return the following errors:

ERRORS

The rsm create localmemory handle() and

RSMERR BAD CTLR HNDL Invalid controller handle.

RSMERR BAD LOCALMEM HNDL Invalid local memory handle.

The rsm_create_localmemory_handle() function can return the following errors:

RSMERR_BAD_LENGTH Invalid length.

RSMERR_BAD_ADDRESS Invalid address.

RSMERR INSUFFICIENT MEM Insufficient memory.

 $rsm_create_local memory_handle (3RSM)$

rsm get controller(3RSM)

NAME |

rsm get controller, rsm get controller attr, rsm release controller – get or release a controller handle

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
int rsm get controller (char *name, rsmapi controller handle t
    *controller);
int rsm_get_controller_attr(rsmapi_controller_handle_t chdl,
    rsmapi controller attr t *attr);
```

DESCRIPTION

The controller functions provide mechanisms for obtaining access to a controller, determining the characteristics of the controller, and releasing the controller.

int rsm release controller (rsmapi controller handle t chdl);

The rsm get controller() function acquires a controller handle through the controller argument. The name argument is the specific controller instance (for example, "sci0" or "loopback"). This controller handle is used for subsequent RSMAPI calls.

The rsm get controller attr() function obtains a controller's attributes through the attr argument. The chall argument is the controller handle obtained by the rsm get controller() call. The attribute structure is defined in the <rsmapi> header.

The rsm release controller() function releases the resources associated with the controller identified by the controller handle chdl, obtained by calling rsm get controller(). Each rsm release controller() call must have a corresponding rsm_get_controller() call. It is illegal to access a controller or segments exported or imported using a released controller.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm get controller(), rsm get controller attr(), and rsm release controller() functions can return the following errors:

RSMERR BAD CTLR HNDL Invalid controller handle.

The rsm get controller() and rsm get controller attr() functions can return the following errors:

RSMERR BAD ADDR Bad address.

The rsm get controller() function can return the following errors:

RSMERR CTLR NOT PRESENT Controller not present. RSMERR INSUFFICIENT MEM Insufficient memory. Invalid library version. RSMERR BAD LIBRARY VERSION

rsm_memseg_export_create(3RSM), rsm_memseg_import_connect(3RSM), attributes(5)

$rsm_get_interconnect_topology(3RSM)$

NAME |

rsm_get_interconnect_topology, rsm_free_interconnect_topology – get or free interconnect topology

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

```
int rsm_get_interconnect_topology(rsm_topology_t **topology_data);
void rsm_free_interconnect_topology(rsm_topology_t *topology_data);
```

DESCRIPTION

The rsm get interconnect topology(3RSM) and rsm free interconnect topology(3RSM) functions provide for access to the interconnect controller and connection data. The key interconnect data required for export and import operations includes the respective cluster nodeids and the controller names. To facilitate applications in the establishment of proper and efficient export and import policies, a delineation of the interconnect topology is provided by this interface. The data provided includes local nodeid, local controller name, its hardware address, and remote connection specification for each local controller. An application component exporting memory can thus find the set of existing local controllers and correctly assign controllers for the creation and publishing of segments. Exported segments may also be efficiently distributed over the set of controllers consistent with the hardware interconnect and application software. An application component which is to import memory must be informed of the segment id(s) and controller(s) used in the exporting of memory, this needs to be done using some out-of-band mechanism. The topology data structures are defined in the <rsmapi.h> header.

The rsm_get_interconnect_topology() returns a pointer to the topology data in a location specified by the *topology_data* argument.

The rsm_free_interconnect_topology() frees the resources allocated by rsm get interconnect topology().

RETURN VALUES

Upon successful completion, rsm_get_interconnect_topology() returns 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_get_interconnect_topology() function can return the following errors:

RSMERR BAD TOPOLOGY PTR Invalid topology pointer.

RSMERR_INSUFFICIENT_MEM Insufficient memory.

RSMERR BAD ADDR Bad address.

rsm_get_segmentid_range(3RSM)

NAME |

rsm_get_segmentid_range - get segment ID range

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

```
int rsm_get_segmentid_range(const char *appid, rsm_segment_id_t
    *baseid, uint t *length);
```

DESCRIPTION

RSM segment IDs can be either specified by the application or generated by the system using the <code>rsm_memseg_export_publish(3RSM)</code> function. Applications that specify segment IDs require a reserved range of segment IDs that they can use. This can be achieved by using <code>rsm_get_segmentid_range()</code> and by reserving a range of segment IDs in the segment ID configuration file, <code>/etc/rsm/rsm.segmentid</code>. The <code>rsm_get_segmentid_range()</code> function can be used by applications to obtain the segment ID range reserved for them. The <code>appid</code> argument is a null-terminated string that identifies the application. The <code>baseid</code> argument points to the location where the starting segment ID of the reserved range is returned. The <code>length</code> argument points to the location where the number of reserved segment IDs is returned.

The application can use any value starting at *baseid* and less than *baseid+length*. The application should use an offset within the range of reserved segment IDs to obtain a segment ID such that if the *baseid* or *length* is modified, it will still be within its reserved range.

It is the responsibility of the system administrator to make sure that the segment ID ranges are properly administered (such that they are non-overlapping, the file on various nodes of the cluster have identical entries, and so forth.) Entries in the /etc/rsm/rsm.segmentid file are of the form:

```
#keyword appid baseid length
reserve SUNWfoo 0x600000 1000
```

The fields in the file are separated by tabs or blanks. The first string is a keyword "reserve", followed by the application identifier (a string without spaces), the baseid (the starting segment ID of the reserved range in hexadecimal), and the length (the number of segmentids reserved). Comment lines contain a "#" in the first column. The file should not contain blank or empty lines. Segment IDs reserved for the system are defined in the </usr/include/rsm/rsm_common.h> header and cannot be used by the applications.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm get segmentid range() function can return the following errors:

RSMERR E	BAD ADDR	The address passed	l is inval	lid.
RSMERR E	BAD ADDR	The address passed	l is inval	lid

RSMERR_BAD_APPID The appid is not defined in configuration file.

RSMERR_BAD_CONF The configuration file is not present or not readable, or

the configuration file format is incorrect.

rsm_get_segmentid_range(3RSM)

rsm_intr_signal_post(3RSM)

NAME | rsm intr signal post, rsm intr signal wait – signal or wait for an event

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

int rsm intr signal post(void *memseg, uint t flags); int rsm intr signal wait(void *memseg, int timeout);

DESCRIPTION

The rsm intr signal post() and rsm intr signal wait() functions are event functions that allow synchronization between importer processes and exporter processes. A process may block to wait for an event occurance by calling rsm intr signal wait(). A process can signal a waiting process when an event occurs by calling rsm intr signal post().

The rsm intr signal post() function signals an event occurance. Either an import segment handle (rsm_memseg_import_handle t) or an export segment handle (rsm memseg export handle t) may be type cast to a void pointer for the memseg argument. If memseg refers to an import handle, the exporting process is signalled. If memseg refers to an export handle, all importers of that segment are signalled. The flags argument may be set to RSM SIGPOST NO ACCUMULATE; this will cause this event to be discarded if an event is already pending for the target segment.

The rsm_intr_signal_wait() function allows a process to block and wait for an event occurance. Either an import segment handle (rsm memseg import handle t) or an export segment handle (rsm memseg export handle t) may be type cast to a void pointer for the memseg argument. The process blocks for up to timeout milliseconds for an event to occur; if the timeout value is -1, the process blocks until an event occurs or until interrupted.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm intr signal post() and rsm intr signal wait() functions can return the following error:

Invalid segment handle. RSMERR BAD SEG HNDL

The rsm intr signal post() function can return the following error:

RSMERR REMOTE NODE UNREACHABL Remote node not reachable.

The rsm intr signal wait() function can return the following errors:

RSMERR TIMEOUT Timer expired.

RSMERR INTERRUPTED Wait interrupted.

rsm_memseg_export_create(3RSM)

NAME |

rsm_memseg_export_create, rsm_memseg_export_destroy, rsm_memseg_export_rebind – resource allocation and management functions for export memory segments

SYNOPSIS

DESCRIPTION

The rsm_memseg_export_create(), rsm_memseg_export_destroy(), and rsm_memseg_export_rebind() functions provide for allocation and management of resources supporting export memory segments. Exporting a memory segment involves the application allocating memory in its virtual address space through the System V shared memory interface or normal operating system memory allocation functions. This is followed by the calls to create the export segment and bind physical pages to back to allocated virtual address space.

The rsm_memseg_export_create() creates a new memory segment. Physical memory pages are allocated and are associated with the segment. The segment lifetime is the same as the lifetime of the creating process or until a destroy operation is performed. The <code>controller</code> argument is the controller handle obtained from a prior call to <code>rsm_get_controller(3RSM)</code>. The export memory segment handle is obtained through the <code>memseg</code> argument for use in subsequent operations. The <code>vaddr</code> argument specifies the process virtual address for the segment. It must be aligned according to the controller page size attribute. The <code>length</code> argument specifies the size of the segment in bytes and must be in multiples of the controller page size. The <code>flags</code> argument is a bitmask of flags. The <code>RSM_ALLOW_REBIND</code> flag indicates that unbind and rebind is allowed on the segment during its lifetime. The <code>RSM_LOCK_OPS</code> flag indicates that this segment can be used for lock operations.

The rsm_memseg_export_destroy() function deallocates the physical memory pages associated with the segment and disconnects all importers of the segment. The *memseg* argument is the export memory segment handle obtained by a call to rsm_memseg_export_create().

The rsm_memseg_export_rebind() function releases the current backing pages associated with the segment and allocates new physical memory pages. This operation is transparent to the importers of the segment. It is the responsibility of the application to prevent data access to the export segment until the rebind operation has completed. Segment data access during rebind does not cause a system failure but data content results are undefined. The *memseg* argument is the export segment handle pointer obtained from rsm_memseg_export_create(). The *vaddr* argument must be

aligned with respect to the page size attribute of the controller. The *length* argument modulo controller page size must be 0. The *off* argument is currently unused.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_memseg_export_create(), rsm_memseg_export_destroy(), and rsm_memseg_export_rebind() functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

The rsm_memseg_export_create() and rsm_memseg_export_rebind() functions can return the following errors:

RSMERR_BAD_CTLR_HNDL Invalid controller handle.

RSMERR CTLR NOT PRESENT Controller not present.

RSMERR BAD LENGTH Length zero or length exceeds controller

limits.

RSMERR BAD ADDR Invalid address.

RSMERR_INSUFFICIENT_MEM Insufficient memory.

RSMERR_INSUFFICIENT_RESOURCES Insufficient resources.

RSMERR_PERM_DENIED Permission denied.

RSMERR_NOT_CREATOR Not creator of segment.

RSMERR REBIND NOT ALLOWED Rebind not allowed.

The rsm_memseg_export_create() function can return the following errors:

RSMERR BAD MEM ALIGNMENT The address is not aligned on a page

boundary.

The rsm memseg export rebind() function can return the following errors:

RSMERR_INTERRUPTED The operation was interrupted by a signal.

The rsm memseg export destroy() function can return the following errors:

RSMERR POLLFD IN USE Poll file descriptor in use.

USAGE

Exporting a memory segment involves the application allocating memory in its virtual address space through the System V Shared Memory interface or other normal operating system memory allocation methods such as valloc() (see malloc(3C)) or mmap(2). Memory for a file mapped with mmap() must be mapped MAP_PRIVATE.

NAME

rsm_memseg_export_publish, rsm_memseg_export_unpublish, rsm_memseg_export_republish – allow or disallow a memory segment to be imported by other nodes

SYNOPSIS

DESCRIPTION

The rsm_memseg_export_publish(), rsm_memseg_export_unpublish(), and rsm_memseg_export_republish() functions allow or disallow a memory segment to be imported by other nodes.

The rsm_memseg_export_publish(3RSM) function allows the export segment specified by the *memseg* argument to be imported by other nodes. It also assigns a unique segment identifier to the segment and defines the access control list for the segment. The <code>segment_id</code> argument is a pointer to an identifier which is unique on the publishing node. It is the responsibility of the application to manage the assignment of unique segment identifiers. The identifier can be optionally initialized to 0, in which case the system will return a unique segment identifier value. The <code>access_list</code> argument is composed of pairs of nodeid and access permissions. For each nodeid specified in the list, the associated read/write permissions are provided by three octal digits for owner, group, and other, as for Solaris file permissions. In the access control each octal digit may have the following values:

- 2 write access
- 4 read only access
- 6 read and write access

An access permissions value of 0624 specifies: (1) an importer with the same uid as the exporter has read and write access; (2) an importer with the same gid as the exporter has write access only; and (3) all other importers have read access only. When an access control list is provided, nodes not included in the list will be prevented from importing the segment. However, if the access list is NULL (this will require the length access_list_length to be specified as 0 as well), then no nodes will be excluded from importing and the access permissions on all nodes will equal the owner-group-other file creation permissions of the exporting process. Corresponding to the access_list argument, the access_list_length argument specifies the number of entries in the access_list_array.

rsm_memseg_export_publish(3RSM)

The rsm_memseg_export_unpublish() function disallows the export segment specified by *memseg* from being imported. All the existing import connections are forcibly disconnected.

The rsm_memseg_export_republish() function changes the access control list for the exported and published segment. Although the current import connections remain unaffected by this call, new connections are constrained by the new access list.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_memseg_export_publish(), rsm_memseg_export_unpublish(), and rsm memseg_export_republish() functions can return the following errors:

RSMERR_BAD_SEG_HNDL Invalid segment handle.

RSMERR NOT CREATOR Not creator of segment.

The rsm_memseg_export_publish() and rsm_memseg_export_republish() functions can return the following errors, with the exception that only rsm_memseg_export_publish() can return the errors related to the segment identifier:

RSMERR_SEGID_IN_USE Segment identifier in use.

RSMERR_RESERVED_SEGID Segment identifier reserved.

RSMERR_BAD_SEGID Invalid segment identifier.

RSMERR_BAD_ACL Invalid access control list.

RSMERR_SEG_ALREADY_PUBLISHED Segment already published.

RSMERR_INSUFFICIENT_MEM Insufficient memory.

RSMERR_INSUFFICIENT_RESOURCES Insufficient resources.

RSMERR_LOCKS_NOT_SUPPORTED Locks not supported.

RSMERR BAD ADDR Bad address.

The rsm_memseg_export_republish() and

rsm memseg export unpublish() functions can return the following errors:

RSMERR SEG NOT PUBLISHED Segment not published.

RSMERR_INTERRUPTED The operation was interrupted by a signal.

rsm_memseg_export_create(3RSM), attributes(5)

rsm_memseg_get_pollfd(3RSM)

NAME | rsm memseg get pollfd, rsm memseg release pollfd - get or release a poll descriptor

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

int rsm memseg get pollfd(void *memseg, struct pollfd *fd);

int rsm memseg release pollfd(void *memseg);

DESCRIPTION

The rsm memseg get pollfd() and rsm memseg release pollfd() functions provide an alternative to rsm intr signal wait(3RSM); the waiting process may multiplex event waiting using the poll(2) function after first obtaining a poll descriptor using rsm memseg get pollfd(). The descriptor may subsequently be released using rsm memseg release pollfd().

As a result of a call rsm memseg get pollfd(), the specified pollfd structure is initialized with a descriptor for the specified segment (memseg) and the event generated by rsm intr signal post(3RSM). Either an export segment handle or an import segment handle may be type cast to a void pointer. The *pollfd* argument may subsequently be used with the poll(2) function to wait for the event. If memseg references an export segment, the segment must be currently published. If memseg references an import segment, the segment must be connected.

The rsm memseg reslease pollfd() function decrements the reference count of the pollfd structure associated with the specified segment. A segment unpublish, destroy or unmap operation will fail if the reference count is non-zero.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm memseg get pollfd() and rsm memseg release pollfd() function can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

NAME

rsm_memseg_import_connect, rsm_memseg_import_disconnect – create or break logical commection between import and export segments

SYNOPSIS

DESCRIPTION

The rsm_memseg_import_connect() function provides a means of creating an import segment called <code>memseg</code> and establishing a logical connection with an export segment identified by the <code>segment_id</code> on the node specified by <code>node_id</code>. The controller specified by <code>controller</code> must have a physical connection with the controller (see <code>rsm_get_interconnect_topology(3RSM))</code> used while exporting the segment identified by <code>segment_id</code> on node specified by <code>node_id</code>. The <code>perm</code> argument specifies the mode of access that the importer is requesting for this connection. In the connection process, the mode of access and the importers userid and groupid are compared with the access permissions specified by the exporter. If the request mode is not valid, the connection request is denied. The <code>perm</code> argument is limited to the following octal values:

0400 read mode0200 write mode0600 read/write mode

The rsm_memseg_import_disconnect() function breaks the logical connection between the import segment and the exported segment and deallocates the resources associated with the import segment handle <code>memseg</code>.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_memseg_import_connect() and rsm_memseg_import_disconnect() functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

The rsm_memseg_import_connect() function can return the following errors:

RSMERR_BAD_CTLR_HNDL
Invalid controller handle.

RSMERR_CTLR_NOT_PRESENT
Controller not present.

RSMERR_PERM_DENIED
Permission denied.

rsm_memseg_import_connect(3RSM)

RSMERR_INSUFFICIENT_MEM Insufficient memory.

RSMERR_INSUFFICIENT_RESOURCES Insufficient resources.

RSMERR_SEG_NOT_PUBLISHED_TO_NODE Segment not published to node.

RSMERR_SEG_NOT_PUBLISHED Segment not published at all.

RSMERR_BAD_ADDR Bad address.

RSMERR_REMOTE_NODE_UNREACHABLE Remote not not reachable.

RSMERR_INTERRUPTED
Connection interrupted.

The rsm_memseg_import_disconnect() function can return the following errors:

RSMERR SEG STILL MAPPED Segment still mapped, need to unmap

before disconnect.

RSMERR POLLFD IN USE Poll file descriptor in use.

int rsm memseg import get32 (rsm memseg import handle t im_memseg,
    off t offset, uint32 t *datap, ulong t rep_cnt);
int rsm memseg import get64 (rsm memseg import handle t im_memseg,
    off t offset, uint64 t *datap, ulong t rep_cnt);
```

DESCRIPTION

When using interconnects that allow memory mapping (see rsm memseg import map(3RSM)), standard CPU memory operations may be used for accessing memory of a segment. If a mapping is not provided, then explicitly calling these functions facilitates reading from a segment. Depending on the attributes of the extension library of the specific interconnect, these functions may involve performing an implicit mapping before performing the data transfer. Applications can be made interconnect-independent with respect to segment reads by using these functions. The data access error detection is performed through the use of barriers (see rsm memseg import open barrier(3RSM)). The default barrier operation mode is RSM BARRIER MODE_IMPLICIT, meaning that around every get operation open and close barrier are performed automatically. Alternatively, explicit error handling may be set up for these functions (see rsm memseg import set mode(3RSM)). In either case the barrier should be initialized prior to using these functions using rsm memseg import init barrier(3RSM).

The rsm memseg import get () function copies *length* bytes from the imported segment *im_memseg* beginning at location *offset* from the start of the segment to a local memory buffer pointed to by *dest_addr*.

The rsm memseg import get8() function copies rep cnt number of 8-bit quantities from successive locations starting from offset in the imported segment to successive local memory locations pointed to by datap.

The rsm memseg import get16() functions copies rep_cnt number of 16-bit quantities from successive locations starting from offset in the imported segment to successive local memory locations pointed to by datap. The offset must be aligned at half-word address boundary.

rsm_memseg_import_get(3RSM)

The rsm_memseg_import_get32() function copies *rep_cnt* number of 32-bit quantities from successive locations starting from *offset* in the imported segment to successive local memory locations pointed to by *datap*. The offset must be aligned at word address boundary.

The rsm_memseg_import_get64() function copies *rep_cnt* number of -bit quantities from successive locations starting from *offset* in the imported segment to successive local memory locations pointed to by *datap*. The offset must be aligned at double-word address boundary.

The data transfer functions that transfer small quantities of data (that is, 8-, 16-, 32-, and 64-bit quantities) perform byte swapping prior to the data transfer, in the event that the source and destination have incompatible endian characteristics.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

These functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

RSMERR BAD ADDR Bad address.

RSMERR BAD MEM ALIGNMENT Invalid memory alignment for pointer.

RSMERR_BAD_OFFSET Invalid offset.

RSMERR_BAD_LENGTH Invalid length.

RSMERR_PERM_DENIED Permission denied.

RSMERR_INSUFFICIENT_RESOURCES Insufficient resources.

RSMERR_BARRIER_UNINITIALIZED Barrier not initialized.

RSMERR_BARRIER_FAILURE I/O completion error.

RSMERR CONN ABORTED Connection aborted.

NAME |

rsm_memseg_import_init_barrier, rsm_memseg_import_destroy_barrier – create or destroy barrier for imported segment

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

int rsm_memseg_import_destroy_barrier(rsmapi_barrier_t *barrier);

DESCRIPTION

The rsm_memseg_import_init_barrier() function creates a barrier for the imported segment specified by *memseg*. The barrier type is specified by the *type* argument. Currently, only RSM_BAR_DEFAULT is supported as a barrier type. A handle to the barrier is obtained through the *barrier* argument and is used in subsequent barrier calls.

The ${\tt rsm_memseg_import_destroy_barrier}$ () function deallocates all the resources associated with the barrier.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_memseg_import_init_barrier() and rsm_memseg_import_destroy_barrier() functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

RSMERR BAD BARRIER PTR Invalid barrier pointer.

The rsm_memseg_import_init_barrier() function can return the following errors:

RSMERR INSUFFICIENT MEM

Insufficient memory.

NAME |

rsm memseg import map, rsm memseg import unmap – map or unmap imported segment

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

- int rsm memseg import map(rsm memseg import handle t im_memseg,void **address, rsm_attribute_t attr, rsm permission t perm, off t offset, size t length);
- int rsm memseg import unmap(rsm memseg import handle t im_memseg);

DESCRIPTION

The rsm memseg import map() and rsm memseg import unmap() functions provide for mapping and unmapping operations on imported segments. The mapping operations are only available for native architecture interconnects such as Dolphin-SCI or Wildcat. Mapping a segment allows that segment to be accessed by CPU memory operations, saving the overhead of calling the memory access primitives described on the rsm memseg import get(3RSM) and rsm memseg import put(3RSM) manual pages.

The rsm memseg import map() function maps an import segment into caller's address space for the segment to be accessed by CPU memory operations. The *im_memseg* argument represents the import segment that is being mapped. The location where the process's address space is mapped to the segment is pointed to by the *address* argument. The *attr* argiment can be one fo the following:

The system will choose available virtual address to map and RSM MAP NONE return its value in the address argument.

RSM MAP FIXED The import segment should be mapped at the requested virtual address specified in the address argument.

The perm argument determines whether read, write or a combination of accesses are permitted to the data being mapped. It can be either RSM PERM READ, RSM PERM WRITE, or RSM PERM RDWR.

The *offset* argument is the byte offset location from the base of the segment being mapped to address. The length argument indicates the number of bytes from offset to be mapped.

The rsm memseg import unmap() function unmaps a previously mapped import segment.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm memseg import map() and rsm memseg import unmap() functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

rsm_memseg_import_map(3RSM)

The rsm memseg import map() function can return the following errors:

RSMERR BAD ADDR Invalid address.

RSMERR_BAD_LENGTH Invalid length.

RSMERR_BAD_MEM_ALIGNMENT The address is not aligned on a page

boundary.

RSMERR BAD OFFSET Invalid offset.

RSMERR_BAD_PERMS Invalid permissions.

RSMERR CONN ABORTED Connection aborted.

RSMERR MAP FAILED Map failure.

RSMERR_SEG_ALREADY_MAPPED Segment already mapped.

RSMERR_SEG_NOT_CONNECTED Segment not connected.

rsm_memseg_import_open_barrier(3RSM)

cc [flags...] file... -lrsm [library...]

NAME |

rsm_memseg_import_open_barrier, rsm_memseg_import_order_barrier, rsm_memseg_import_close_barrier – remote memory access error detection functions

SYNOPSIS

```
#include <rsmapi.h>
int rsm_memseg_import_open_barrier(rsmapi_barrier_t *barrier);
int rsm_memseg_import_order_barrier(rsmapi_barrier_t *barrier);
```

int rsm memseg import close barrier (rsmapi barrier t *barrier);

DESCRIPTION

The rsm_memseg_import_open_barrier() and rsm_memseg_import_close_barrier() functions provide a means of remote memory access error detection when the barrier mode is set to RSM_BARRIER_MODE_EXPLICIT. Open and close barrier operations define a span-of-time interval for error detection. A successful close barrier guarantees that remote memory access covered between the open barrier and close barrier have completed successfully. Any individual failures which may have occured between the open barrier and close barrier occur without any notification and the failure is not reported until the close barrier.

The rsm_memseg_import_order_barrier() function imposes the order-of-write completion whereby, with an order barrier, the write operations issued before the order barrier are all completed before the operations after the order barrier. Effectively, with the order barrier call, all writes within one barrier scope are ordered with respect to those in another barrier scope.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_memseg_close_barrier() and rsm_memseg_order_barrier() functions can return the following errors:

RSMERR_BARRIER_UNINITIALIZED Barrier not initialized.

RSMERR_BARRIER_NOT_OPENED Barrier not opened.

RSMERR_BARRIER_FAILURE Memory access error.

RSMERR_CONN_ABORTED Connection aborted.

The rsm memseg import open barrier(),

NAME |

rsm_memseg_import_put, rsm_memseg_import_put8, rsm_memseg_import_put16, rsm_memseg_import_put32, rsm_memseg_import_put64 - write to a segment

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
```

- int rsm memseg import put (rsm memseg import handle t im_memseg, off t offset, void *src_addr, size t length);
- int rsm memseg import put8 (rsm memseg import handle t im_memseg, off t offset, uint8 t datap, ulong t rep_cnt);
- int rsm memseg import put16 (rsm memseg import handle t im_memseg, off t offset, uint16 t datap, ulong t rep_cnt);
- int rsm memseg import put32 (rsm memseg import handle t im_memseg, off t offset, uint32 t datap, ulong t rep_cnt);
- int rsm memseg import put64 (rsm memseg import handle t im_memseg, off t offset, uint64 t datap, ulong t rep_cnt);

DESCRIPTION

When using interconnects that allow memory mapping (see

rsm memseg import map(3RSM)), standard CPU memory operations may be used for accessing memory of a segment. If, however, a mapping is not provided, then explicitly calling these functions facilitates writing to a segment. Depending on the attributes of the extension library for the interconnect, these functions may involve doing an implicit mapping before performing the data transfer. Applications can be made interconnect-independent with respect to segment writes by using these functions. The data access error detection is performed through the use of barriers (see rsm memseg import open barrier(3RSM)). The default barrier operation mode is RSM BARRIER MODE IMPLICIT, which means that around every put operation open and close barrier operations are performed automatically. Explicit error handling may also be set up for these functions (see rsm memseg import set mode(3RSM)).

The rsm memseg import put () function copies length bytes from local memory with start address src_addr to the imported segment im_memseg beginning at location offset from the start of the segment.

The rsm memseg import put8() function copies rep_cnt number of 8-bit quantities from successive local memory locations pointed to by datap to successive locations starting from *offset* in the imported segment.

The rsm memseg import put16() function copies rep_cnt number of 16-bit quantities from successive local memory locations pointed to by datap to successive locations starting from offset in the imported segment. The offset must be aligned at half-word address boundary.

The rsm memseg import put32() function copies rep_cnt number of 32-bit quantities from successive local memory locations pointed to by datap to successive locations starting from offset in the imported segment. The offset must be aligned at word address boundary.

rsm_memseg_import_put(3RSM)

The rsm_memseg_import_put64() function copies *rep_cnt* number of 64-bit quantities from successive local memory locations pointed to by *datap* to successive locations starting from *offset* in the imported segment. The offset must be aligned at double-word address boundary.

The data transfer functions that transfer small quantities of data (that is, 8-, 16-, 32-, and 64-bit quantities) perform byte swapping prior to the data transfer, in the event that the source and destination have incompatible endian characteristics.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

These functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

RSMERR BAD ADDR Bad address.

RSMERR BAD MEM ALIGNMENT Invalid memory alignment for pointer.

RSMERR_BAD_OFFSET Invalid offset.

RSMERR_BAD_LENGTH Invalid length.

RSMERR_PERM_DENIED Permission denied.

RSMERR_INSUFFICIENT_RESOURCES Insufficient resources.

RSMERR_BARRIER_UNINITIALIZED Barrier not initialized.

RSMERR_BARRIER_FAILURE I/O completion error.

RSMERR CONN ABORTED Connection aborted.

rsm_memseg_import_putv(3RSM)

NAME |

rsm_memseg_import_putv, rsm_memseg_import_getv - write to a segment using a list of I/O requests

SYNOPSIS

```
cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>
int rsm_memseg_import_putv(rsm_scat_gath_t *sg_io);
int rsm_memseg_import_getv(rsm_scat_gath_t *sg_io);
```

DESCRIPTION

The $rsm_memseg_import_putv()$ and $rsm_memseg_import_getv()$ functions provide for using a list of I/O requests rather than a single source and destination address as is done for thersm_memseg_import_put(3RSM) and $rsm_memseg_import_get(3RSM)$ functions.

The I/O vector component of the scatter-gather list (*sg_io*), allows specifying local virtual addresses or local_memory_handles. When a local address range is used repeatedly, it is efficient to use a handle because allocated system resources (that is, locked down local memory) are maintained until the handle is freed. The supporting functions for handles are rsm_create_localmemory_handle(3RSM) and rsm_free_localmemory_handle(3RSM).

Virtual addresses or handles may be gathered into the vector for writing to a single remote segment, or a read from a single remote segment may be scattered to the vector of virtual addresses or handles.

Implicit mapping is supported for the scatter-gather type of access. The attributes of the extension library for the specific interconnect are used to determine whether mapping is necessary before any scatter-gather access. If mapping of the imported segment is a prerequisite for scatter-gather access and the mapping has not already been performed, an implicit mapping is performed for the imported segment. The I/O for the vector is then initiated.

I/O for the entire vector is initiated before returning. The barrier mode attribute of the import segment determines if the I/O has completed before the function returns. A barrier mode attribute setting of IMPLICIT guarantees that the transfer of data is completed in the order as entered in the I/O vector. An implicit barrier open and close surrounds each list entry. If an error is detected, I/O for the vector is terminated and the function returns immediately. The residual count indicates the number of entries for which the I/O either did not complete or was not initiated.

Optionally, the scatter-gather list allows support for an implicit signal post after the I/O for the entire vector has completed. This alleviates the need to do an explicit signal post after ever I/O transfer operation. The means of enabling the implicit signal post involves setting the flags field within the scatter-gather list to RSM_IMPLICIT_SIGPOST. The flags field may also be set to RSM_SIG_POST_NO_ACCUMULATE, which will be passed on to the signal post operation when RSM_IMPLICIT_SIGPOST is set.

rsm_memseg_import_putv(3RSM)

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The $rsm_memseg_import_putv()$ and $rsm_memseg_import_getv()$ functions can return the following errors:

RSMERR BAD SGIO Invalid scatter-gather structure pointer.

RSMERR_BAD_SEG_HNDL Invalid segment handle.

RSMERR_BAD_CTLR_HNDL Invalid controller handle.

RSMERR_BAD_OFFSET Invalid offset.

RSMERR_BAD_LENGTH Invalid length.

RSMERR BAD ADDR Bad address.

RSMERR INSUFFICIENT RESOURCES Insufficient resources.

RSMERR_INTERRUPTED The operation was interrupted by a signal.

RSMERR_PERM_DENIED Permission denied.

RSMERR BARRIER FAILURE I/O completion error.

RSMERR REMOTE NODE UNREACHABLE Remote node not reachable.

rsm_memseg_import_set_mode(3RSM)

NAME |

rsm_memseg_import_set_mode, rsm_memseg_import_get_mode – set or get mode for barrier scoping

SYNOPSIS

cc [flags...] file... -lrsm [library...]
#include <rsmapi.h>

int rsm_memseg_import_get_mode(rsm_memseg_import_handle_t memseg,
 rsm barrier mode t *mode);

DESCRIPTION

The rsm_memseg_import_set_mode() function provides support for optional explicit barrier scoping in the functions described on the

rsm_memseg_import_get(3RSM) and rsm_memseg_import_put(3RSM) manual pages. The two valid barrier modes are RSM_BARRIER_MODE_EXPLICIT and RSM_BARRIER_MODE_IMPLICIT. By default, the barrier mode is set to RSM_BARRIER_MODE_IMPLICIT. When the mode is

RSM_BARRIER_MODE_IMPLICIT, an implicit barrier open and barrier close is applied to the put operation. Irrespective of the mode set, the barrier must be initialized using the rsm_memseg_import_init_barrier(3RSM) function before any barrier operations, either implicit or explicit, are used.

The ${\tt rsm_memseg_import_get_mode}$ () function obtains the current value of the mode used for barrier scoping in put functions.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, an error value is returned to indicate the error.

ERRORS

The rsm_memseg_import_set_mode() and rsm_memseg_import_get_mode() functions can return the following errors:

RSMERR BAD SEG HNDL Invalid segment handle.

DESCRIPTION

The librtld db library provides support for monitoring and manipulating runtime linking aspects of a program. There are at least two processes involved, the controlling process and one or more target processes. The controlling process is the librtld db client that links with librtld db and uses librtld db to inspect or modify runtime linking aspects of one or more target processes. See the Linker and Libraries *Guide* for a full description of the runtime linker debugger interface mechanism.

scalb(3M)

NAME |

scalb – load exponent of a radix-independent floating-point number

SYNOPSIS

#include <math.h>

double **scalb** (double x, double n);

DESCRIPTION

The scalb() function computes $x * r^n$, where r is the radix of the machine's floating point arithmetic. When r is 2, scalb() is equivalent to ldexp(3C).

RETURN VALUES

Upon successful completion, the scalb () function returns $x * r^n$.

If the correct value would overflow, scalb() returns $\pm HUGE_VAL$ (according to the sign of x) and sets errno to ERANGE.

If the correct value would underflow to 0.0, $\mathtt{scalb}()$ returns 0 and sets \mathtt{errno} to $\mathtt{ERANGE}.$

The scalb() function returns x when x is \pm Inf.

If x or n is NaN, then scalb() returns NaN.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The scalb() function will fail if:

ERANGE The correct value would overflow or underflow.

USAGE

An application wishing to check for error situations should set errno to 0 before calling scalb(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

sendfile(3EXT)

NAME

sendfile – send files over sockets or copy files to files

SYNOPSIS

cc [flag ...] file ... -lsendfile [library ...]
#include <sys/sendfile.h>

ssize t sendfile(int out_fd, int in_fd, off t *off, size t len);

DESCRIPTION

The <code>sendfile()</code> function copies data from <code>out_fd</code> to <code>in_fd</code> starting at offset <code>off</code> and of length <code>len</code> bytes. The <code>in_fd</code> argument should be a file descriptor to a regular file opened for reading. See <code>open(2)</code>. The <code>out_fd</code> argument should be a file descriptor to a regular file opened for writing or to a connected <code>AF_INET</code> or <code>AF_INET6</code> socket of <code>SOCK_STREAM</code> type. See <code>socket(3SOCKET)</code>. The <code>off</code> argument is a pointer to a variable holding the input file pointer position from which the data will be read. After <code>sendfile()</code> has completed, the variable will be set to the offset of the byte following the last byte that was read. The <code>sendfile()</code> function does not modify the current file pointer of <code>in_fd</code>, but does modify the file pointer for <code>out_fd</code> if it is a regular file.

The sendfile() function can also be used to send buffers by pointing *in_fd* to SFV_FD_SELF.

RETURN VALUES

Upon successful completion, sendfile() returns the total number of bytes written to *out_fd* and also updates the offset to point to the byte that follows the last byte read. Otherwise, it returns –1, and errno is set to indicate an error.

ERRORS

The sendfile() function will fail if:

EAFNOSUPPORT	The implementation does not support	the specified address family
--------------	-------------------------------------	------------------------------

for socket.

EAGAIN Mandatory file or record locking is set on either the file descriptor

or output file descriptor if it points at regular files. O_NDELAY or O_NONBLOCK is set, and there is a blocking record lock. An attempt has been made to write to a stream that cannot accept data with

the O NDELAY or the O NONBLOCK flag set.

EBADF The *out_fd* or *in_fd* argument is either not a valid file descriptor,

out_fd is not opened for writing. or *in_fd* is not opened for reading.

EINVAL The offset cannot be represented by the off_t structure, or the

length is negative when cast to ssize_t.

EIO An I/O error occurred while accessing the file system.

ENOTCONN The socket is not connected.

EOPNOTSUPP The socket type is not supported.

EPIPE The *out_fd* argument is no longer connected to the peer endpoint.

USAGE

The sendfile() function has a transitional interface for 64-bit file offsets. See 1f64(5).

EXAMPLES

EXAMPLE 1 Sending a Buffer Over a Socket

The following example demonstrates how to send the buffer *buf* over a socket. At the end, it prints the number of bytes transferred over the socket from the buffer. It assumes that *addr* will be filled up appropriately, depending upon where to send the buffer.

```
int tfd;
off_t baddr;
struct sockaddr in sin;
char buf[64 * 1024];
in_addr_t addr;
    tfd = socket(AF_INET, SOCK_STREAM, 0);
   if (tfd == -1) {
       perror("socket");
       exit(1);
    sin.sin_family = AF_INET;
    sin.sin addr = addr; /* Fill in the appropriate address. */
    sin.sin_port = htons(2345);
   if (connect(tfd, (struct sockaddr *)&sin, sizeof(sin))<0) {</pre>
       perror("connect");
        exit(1);
   baddr = (off t)buf;
   len = sendfile(tfd, SFV FD SELF, &baddr, len);
    if (len == -1) {
       perror("sendfile");
       exit(1);
    printf("Transfered %d bytes from buffer to socket0 len);
```

EXAMPLE 2 Transferring Files to Sockets

The following program demonstrates a transfer of files to sockets:

```
int ffd, tfd;
off_t off;
struct sockaddr_in sin;
in_addr_t addr;
int len;
struct stat stat_buf;

ffd = open("file", O_RDONLY);
if (ffd == -1) {
    perror("open");
    exit(1);
}

tfd = socket(AF_INET, SOCK_STREAM, 0);
if (tfd == -1) {
```

sendfile(3EXT)

FILES

/usr/lib/libsendfile.so.1 shared object file

SEE ALSO

open(2), socket(3SOCKET), attributes(5), 1f64(5)

NAME | sendfiley – send a file

SYNOPSIS

```
cc -flag ... file ...-lsendfile [ -library ]
#include <sys/sendfile.h>
ssize t sendfilev(int fildes, const struct sendfilevec *vec, int
     sfvcnt, size t *xferred);
```

DESCRIPTION

The sendfilev() function attempts to write data from the sfvcnt buffers specified by the members of vec array: vec [0], vec [1], ..., vec [sfvcnt-1]. fildes is a file descriptor to a regular file or to a AF NCA, AF INET, or AF INET6 family type SOCK STREAM socket that is open for writing.

This function is analogous to the writev() system call. See writev(2). However, instead of sending out chunks of data, sendfilev() can read input data from data buffers or file descriptors.

The following is the sendfilevec structure:

```
typedef struct sendfilevec {
                                     /* input fd */
         int sfv fd;
                                    /* Flags. see below */
/* offset to start reading from */
/* amount of data */
         uint_t sfv_flag;
         off_t sfv_off;
size_t sfv_len;
} sendfilevec_t;
#define SFV FD SELF
                             (-2)
```

To send a file, open the file for reading. Point sfv_fd to the file descriptor returned as a result. See open(2). sfv off should contain the offset within the file. sfv len should have the length of the file to be transferred.

The *xferred* parameter is updated to record the total number of bytes written to out fd.

The sfv flag field is reserved and should be set to zero.

To send data directly from the address space of the process, set sfv fd to SFV FD SELF. sfv off should point to the data, with sfv len containing the length of the buffer.

PARAMETERS

The sendfilev() function supports the following parameters:

fildes A file descriptor to a regular file or to a AF NCA, AF INET, or AF INET6 family type SOCK STREAM socket that is open for writing. For AF NCA, the protocol type should be zero.

An array of SENDFILEVEC T, as defined in the sendfilevec structure vec above.

The number of members in vec. sfvcnt

xferred The total number of bytes written to out fd.

sendfilev(3EXT)

RETURN VALUES

Upon successful completion, sendfilev() returns total number of bytes written to out_fd. Otherwise, it returns -1, and errno is set to indicate an error. *xferred* contains the amount of data successfuly transferred, which can be used to discover the error vector.

ERRORS

error vector.	
EAFNOSUPPORT	The implementation does not support the specified address family for socket.
EPROTOTYPE	The socket type is not supported.
EBADF	The <i>fildes</i> argument is not a valid descriptor open for writing or an sfv_fd is invalid or not open for reading.
EACCES	The process does not have appropriate privileges or one of the files pointed by sfv_fd does not have appropriate permissions.
EPIPE	The <i>fildes</i> argument is a socket that has been shut down for writing.
EIO	An I/O error occurred while accessing the file system.
EFAULT	The vec argument points to an illegal address.
EFAULT	The <i>xferred</i> argument points to an illegal address.
EINVAL	The <i>sfvcnt</i> argument was less than or equal to 0. One of the sfv_len in <i>vec</i> array was less than or equal to 0, or greater than the file size. An sfv_fd is not seekable.
EAGAIN	Mandatory file or record locking is set on either the file descriptor or output file descriptor if it points at regular files. O_NDELAY or O_NONBLOCK is set, and there is a blocking record lock. An attempt has been made to write to a stream that cannot accept data with the O_NDELAY or the O_NONBLOCK flag set.

USAGE

The sendfilev() function has a transitional interface for 64-bit file offsets. See 1f64(5).

EXAMPLES

The following example sends 2 vectors, one of HEADER data and a file of length 100 over sockfd is in a connected state, that is, socket(), accept(), and bind() operation are complete.

```
#include <sys/sendfile.h>
.
.
int
main (int argc, char eargv[]){
  int sockfd;
  ssize_t ret;
  size_t xfer;
  struct sendfilevec vec[2];
  .
.
```

sendfilev(3EXT)

```
vec[0].sfv_fd = SFV_FD_SELF;
vec[0].sfv_flag = 0;
vec[0].sfv_off = "HEADER_DATA";
vec[0].sfv_len = strlen("HEADER_DATA");
vec[1].sfv_fd = open("input_file",....);
vec[1].sfv_flag = 0;
vec[1].sfv_off = 0;
vec[1].sfv_len = 100;
ret = sendfilev(sockfd, vec, 2, &xfer);
```

setproject(3PROJECT)

NAME |

setproject – place process in new project with attendant resource controls and attributes

SYNOPSIS

```
cc [ flag ... ] file ... - lproject [ library ... ]
#include <project.h>
```

int setproject(const char *project_name, const char *user_name, uint t flags);

DESCRIPTION

The setproject () function provides a simplified method for the association of a user process with a project and its various resource management attributes, as stored in the project(4) name service database.

If user_name is a valid member of the project specified by project_name, as determined by inproj(3PROJECT), then setproject() will create a new task with settaskid(2) and use setrct1(2) to associate various resource controls with the process, task, and project. Controls not explicitly specified in the project entry will be preserved.

RETURN VALUES

Upon successful completion, setproject () returns 0. If any of the attribute assignments failed but the project assignment and task creation succeeded, then an integer value corresponding to the offset into the key-value pair list of the failed attribute assignment is returned. If the project assignment was not successful, setproject () returns –1 and sets errno to indicate the error.

ERRORS

The setproject () function will fail if:

EACCES THE HIVOKING LASK WAS CHEALED WITH THE LASK FINAL HAS	EACCES	The invoking task was	created with the TAS	SK FINAL flag.
--	--------	-----------------------	----------------------	----------------

The project ID associated with the given project is not within the EINVAL

range of valid project IDs.

EPERM The effective user of the calling process is not superuser. The specified user is not a valid user of the given project. ESRCH

If setproject () returns an offset into the key-value pair list, the returned error value is associated with setrct1(2).

USAGE

The setproject () function recognizes a name-structured value pair for the attributes in the project(4) database with the following format:

```
entity.control=(privilege, value, action, action, ...),...
```

where privilege is one of BASIC or PRIVILEGED, value is a numeric value with optional units, and action is one of none, deny, and signal/signum or signal/SIGNAME. For instance, to set a series of progressively more assertive control values on a project's per-process CPU time, specify

```
process.max-cpu-time=(PRIVILEGED, 1000s, signal/SIGXRES), \
(PRIVILEGED, 1250, signal=SIGTERM), (PRIVILEGED, 1500, signal=SIGKILL)
```

To prevent a task from exceeding a total of 128 LWPs, specify a resource control with

task.max-lwps=(PRIVILEGED, 128, deny)

significand(3M)

NAME | significand – significand function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double significand(double x);

DESCRIPTION

The significand() function, along with the logb(3M) and scalb(3M) functions, allows users to verify compliance to ANSI/IEEE Std 754-1985 by running certain test vectors distributed by the University of California.

If x equals $sig * 2^n$ with 1 < sig < 2, then significand (x) returns sig for exercising the fraction-part(F) test vector. significand (x) is not defined when x is either 0, ±Inf or NaN.

RETURN VALUES

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by various Standards.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

NAME | sin – sine function

SYNOPSIS

cc [flag ...] file ... -lm [library ...] #include <math.h>

double sin(double x);

DESCRIPTION

The sin() function computes the sine of its argument x, measured in radians.

RETURN VALUES

Upon successful completion, sin() returns the sine of x.

If x is NaN or \pm Inf, NaN is returned.

ERRORS

No errors will occur.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

asin(3M), isnan(3M), attributes(5)

sinh(3M)

NAME | sinh – hyperbolic sine function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
```

#include <math.h>

double sinh(double x);

DESCRIPTION

The sinh() function computes the hyperbolic sine of x.

RETURN VALUES

Upon successful completion, sinh() returns the hyperbolic sine of x.

If the result would cause an overflow, ±HUGE_VAL is returned and errno is set to

ERANGE.

If *x* is NaN, NaN is returned.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by

Standards other than XPG4.

ERRORS

The sinh() function will fail if:

ERANGE

The result would cause overflow.

USAGE

An application wishing to check for error situations should set errno to 0 before calling sinh(). If errno is non-zero on return, or the return value is NaN, an error

has occurred.

NAME | sqrt – square root function

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
#include <math.h>
```

double sqrt(double x);

DESCRIPTION

The sqrt() function computes the square root of x.

RETURN VALUES

Upon successful completion, sqrt() returns the square root of x.

If *x* is NaN, NaN is returned.

If *x* is negative, NaN is returned and errno is set to EDOM.

ERRORS

The sqrt() function will fail if:

EDOM

The value of *x* is negative.

USAGE

An application wishing to check for error situations should set errno to 0 before calling sqrt(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

SSAAgentIsAlive(3SNMP)

NAME

SSAAgentIsAlive, SSAGetTrapPort, SSARegSubtable, SSARegSubagent, SSARegSubtree, SSASendTrap, SSASubagentOpen – Sun Solstice Enterprise Agent registration and communication helper functions

SYNOPSIS

DESCRIPTION

The SSAAgentIsAlive() function returns TRUE if the master agent is alive, otherwise returns FALSE. The <code>agent_addr</code> parameter is the address of the agent. Specify the security token in the <code>community</code> parameter. You can specify the maximum amount of time to wait for a response with the <code>timeout</code> parameter.

The SSAGetTrapPort () function returns the port number used by the Master Agent to communicate with the subagent.

The SSARegSubagent () function enables a subagent to register and unregister with a Master Agent. The *agent* parameter is a pointer to an Agent structure containing the following members:

```
int
int
int
char *personal_file; /* optional */
char *config_file; /* optional */
char *executable; /* optional */
          *version_string; /* optional */
char
       *protocol; /* optional */
process_id; /* optional */
char
int
char *name; /* optional */
int system_up_time; /* optional */
         watch dog time; /* optional */
int
                              /* required */
Address address; /* required */
struct _Agent; /* reserved */
struct _Subtree; /* reserved */
```

The agent_id member is an integer value returned by the SSASubagentOpen() function. After calling SSASubagentOpen(), you pass the agent_id in the SSARegSubagent() call to register the subagent with the Master Agent.

The following values are supported for agent_status:

```
SSA_OPER_STATUS_ACTIVE
SSA_OPER_STATUS_NOT_IN_SERVICE
SSA_OPER_STATUS_DESTROY
```

You pass SSA_OPER_STATUS_DESTROY as the value in a SSARegSubagent () function call when you want to unregister the agent from the Master Agent.

Address has the same structure as sockaddr_in, that is a common UNIX structure containing the following members:

```
short sin_family;
ushort_t sin_port;
struct in_addr sin_addr;
char sin_zero[8];
```

The SSARegSubtable () function registers a MIB table with the Master Agent. If this function is successful, an index number is returned, otherwise 0 is returned. The *table* parameter is a pointer to a SSA_Table structure containing the following members:

The regTblStatus can have one of the following values:

```
SSA_OPER_STATUS_ACTIVE
SSA OPER STATUS NOT IN SERVICE
```

The SSARegSubtree() function registers a MIB subtree with the master agent. If successful this function returns an index number, otherwise 0 is returned. The *subtree* parameter is a pointer to a SSA_Subtree structure containing the following members:

The regtreeStatus can have one of the following values:

```
SSA_OPER_STATUS_ACTIVE
SSA_OPER_STATUS_NOT_IN_SERVICE
```

The SSASendTrap() function instructs the Master Agent to send a trap notification, based on the keyword passed with *name*. When your subagent MIB is compiled by mibcodegen, it creates a lookup table of the trap notifications defined in the MIB. By passing the name of the trap notification type as *name*, the subagent instructs the Master Agent to construct the type of trap defined in the MIB.

SSAAgentIsAlive(3SNMP)

The SSASubagentOpen() function initializes communication between the subagent and the Master Agent. You must call this function before calling SSARegSubagent() to register the subagent with the Master Agent. The SSASubagentOpen() function returns a unique agent ID that is passed in the SSARegSubagent() call to register the subagent. If 0 is returned as the agent ID, the attempt to initialize communication with the Master Agent was unsuccessful. Since UDP is used to initialize communication with the Master Agent, you may want to set the value of <code>num_of_retry</code> to make multiple attempts.

The value for *agent_name* must be unique within the domain for which the Master Agent is responsible.

NAME |

SSAOidCmp, SSAOidCpy, SSAOidDup, SSAOidFree, SSAOidInit, SSAOidNew, SSAOidString, SSAOidStrToOid, SSAOidZero – Sun Solstice Enterprise Agent OID helper functions

SYNOPSIS

```
cc [ flag ... ] file ... -lssasnmp [ library .. ]
#include <impl.h>
int SSAOidCmp(Oid *oid1, Oid *oid2);
int SSAOidCpy(Oid *oid1, Oid *oid2, char *error_label);
Oid *SSAOidDup(Oid *oid, char *error_label);
void SSAOidFree(Oid *oid);
int SSAOidInit(Oid *oid, Subid *subids, int len, char *error_label);
Oid *SSAOidNew();
char *SSAOidString(Oid *oid);
Oid *SSAOidStrToOid(char* name, char *error_label);
void SSAOidZero(Oid *oid);
```

DESCRIPTION

The ${\tt SSAOidCmp}\,()$ function performs a comparison of the given OIDs. This function returns:

```
o if oid1 is equal to oid2
1 if oid1 is greater than oid2
-1 if oid1 is less than oid2
```

The SSAOidCpy() function makes a deep copy of oid2 to oid1. This function assumes oid1 has been processed by the SSAOidZero() function. Memory is allocated inside oid1 and the contents of oid2, not just the pointer, is copied to oid1. If an error is encountered, an error message is stored in the <code>error_label</code> buffer.

The SSAOidDup() function returns a clone of *oid*, by using the deep copy. Error information is stored in the *error_label* buffer.

The SSAOidFree() function frees the OID instance, with its content.

The SSAOidNew() function returns a new OID.

The SSAOidInit() function copies the Subid array from *subids* to the OID instance with the specified length *len*. This function assumes that the OID instance has been processed by the SSAOidZero() function or no memory is allocated inside the OID instance. If an error is encountered, an error message is stored in the *error_label* buffer.

The SSAOidString() function returns a char pointer for the printable form of the given *oid*.

SSAOidCmp(3SNMP)

The SSAOidStrToOid() function returns a new OID instance from *name*. If an error is encountered, an error message is stored in the *error_label* buffer.

The SSAOidZero() function frees the memory used by the OID object for buffers, but not the OID instance itself.

RETURN VALUES

The SSAOidNew() and SSAOidStrToOid() functions return 0 if an error is detected.

attributes(5)

NAME |

SSAStringCpy, SSAStringInit, SSAStringToChar, SSAStringZero – Sun Solstice Enterprise Agent string helper functions

SYNOPSIS

DESCRIPTION

The SSAStringCpy() function makes a deep copy of *string2* to *string1*. This function assumes that *string1* has been processed by the SSAStringZero() function. Memory is allocated inside the *string1* and the contents of *string2*, not just the pointer, is copied to the *string1*. If an error is encountered, an error message is stored in the *error_label* buffer.

The SSAStringInit() function copies the char array from *chars* to the string instance with the specified length *len*. This function assumes that the string instance has been processed by the SSAStringZero() function or no memory is allocated inside the string instance. If an error is encountered, an error message is stored in the *error label* buffer.

The SSAStringToChar() function returns a temporary char array buffer for printing purposes.

The SSAStringZero() function frees the memory inside of the String instance, but not the string object itself.

RETURN VALUES

The SSAStringInit() and SSAStringCpy() functions return 0 if successful and -1 if error.

strccpy(3GEN)

NAME

strccpy, streadd, strcadd, strecpy – copy strings, compressing or expanding escape codes

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
char *strccpy(char *output, const char *input);
char *strcadd(char *output, const char *input);
char *strecpy(char *output, const char *input, const char *exceptions);
char *streadd(char *output, const char *input, const char *exceptions);
```

DESCRIPTION

strccpy() copies the *input* string, up to a null byte, to the *output* string, compressing the C-language escape sequences (for example, \n, \001) to the equivalent character. A null byte is appended to the output. The *output* argument must point to a space big enough to accommodate the result. If it is as big as the space pointed to by *input* it is guaranteed to be big enough. strccpy() returns the *output* argument.

strcadd() is identical to strccpy(), except that it returns the pointer to the null byte that terminates the output.

strecpy() copies the *input* string, up to a null byte, to the *output* string, expanding non-graphic characters to their equivalent C-language escape sequences (for example, \n, \001). The *output* argument must point to a space big enough to accommodate the result; four times the space pointed to by *input* is guaranteed to be big enough (each character could become \ and 3 digits). Characters in the *exceptions* string are not expanded. The *exceptions* argument may be zero, meaning all non-graphic characters are expanded. strecpy() returns the *output* argument.

streadd() is identical to strecpy(), except that it returns the pointer to the null byte that terminates the output.

EXAMPLES

EXAMPLE 1 Example of expanding and compressing escape codes.

```
/* expand all but newline and tab */
strecpy( output, input, "\n\t" );
/* concatenate and compress several strings */
cp = strcadd( output, input1 );
cp = strcadd( cp, input2 );
cp = strcadd( cp, input3 );
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

string(3C), strfind(3GEN), attributes(5) **SEE ALSO**

When compiling multi-thread applications, the $_\texttt{REENTRANT}$ flag must be defined on the compile line. This flag should only be used in multi-thread applications. **NOTES**

strfind(3GEN)

NAME | strfind, strrspn, strtrns, str – string manipulations

SYNOPSIS

```
cc [ flag ... ] file ... -lgen [ library ... ]
#include <libgen.h>
int strfind(const char *as1, const char *as2);
char *strrspn(const char *string, const char *tc);
char * strtrns (const char *string, const char *old, const char *new,
    char *result);
```

DESCRIPTION

The strfind() function returns the offset of the first occurrence of the second string, as2, if it is a substring of string as1. If the second string is not a substring of the first string strfind() returns -1.

The strrspn() function trims chartacters from a string. It searches from the end of string for the first character that is not contained in tc. If such a character is found, strrspn() returns a pointer to the next character; otherwise, it returns a pointer to string.

The strtrns() function transforms *string* and copies it into *result*. Any character that appears in *old* is replaced with the character in the same position in *new*. The *new* result is returned.

USAGE

When compiling multithreaded applications, the REENTRANT flag must be defined on the compile line. This flag should only be used in multithreaded applications.

EXAMPLES

EXAMPLE 1 An example of the strfind() function.

```
/* find offset to substring "hello" within as1 */
i = strfind(as1, "hello");
/* trim junk from end of string */
s2 = strrspn(s1, "*?#$%");
*s2 = '\0';
/* transform lower case to upper case */
a1[] = "abcdefghijklmnopqrstuvwxyz";
a2[] = "ABCDEFGHIJKLMNOPQRSTUVWXYZ";
s2 = strtrns(s1, a1, a2, s2);
```

Interface Stability	Evolving
MT-Level	MT-Safe

SEE ALSO attributes(5)

sysevent_get_attr_list(3SYSEVENT)

ev

NAME | sysevent_get_attr_list – get attribute list pointer

SYNOPSIS

cc [flag ...] file ... -lsysevent -lnvpair [library ...] #include <libsysevent.h>

#include <libnvpair.h>

int sysevent get attr list(sysevent t *ev, nvlist t **attr_list);

PARAMETERS

handle to a system event

attr_list address of a pointer to attribute list (nvlist t)

DESCRIPTION

The sysevent get attr list() function updates attr_list to point to a searchable name-value pair list associated with the sysevent event, ev. The interface manages the allocation of the attribute list, but it is up to the caller to free the list when it is no longer needed with a call to nvlist free(). See nvlist alloc(3NVPAIR).

RETURN VALUES

The sysevent get attr list() function returns 0 if the attribute list for *ev* is found to be valid. Otherwise it returns -1 and sets errno to indicate the error.

ERRORS

The sysevent get attr list() function will fail if:

ENOMEM Insufficient memory available to allocate an nvlist.

EINVAL Invalid sysevent event attribute list.

NAME |

sysevent_get_class_name, sysevent_get_subclass_name, sysevent_get_event_id, sysevent_get_size – get class name, subclass name, ID or buffer size of event

SYNOPSIS

```
cc [flag...] file ...-lsysevent [library...]
#include <libsysevent.h>
char *sysevent_get_class_name(sysevent_t *ev);
char *sysevent_get_subclass_name(sysevent_t *ev);
void sysevent_get_event_id(sysevent_t *ev, sysevent_id_t *eid);
int sysevent_get_size(sysevent_t *ev);
eid pointer to sysevent_id_t structure
```

PARAMETERS

pointer to sysevent_id_t structure
handle to event

DESCRIPTION

The sysevent_get_class_name() and sysevent_get_subclass_name() functions return, respectively, the class and subclass names for the provided event *ev*.

The sysevent_get_event_id() function returns the unique event identifier associated with the sysevent handle, *ev*. The identifier is composed of a relative timestamp issued at the time the event was generated and a sequence number to ensure uniqueness.

```
typedef struct sysevent_id {
      uint64_t eid_seq;
      hrtime_t eid_ts;
} sysevent_id_t;
```

The $sysevent_get_size()$ function returns the size of the event buffer, ev.

EXAMPLES

EXAMPLE 1 Parse sysevent header information.

The following example parses sysevent header information from an application's event handler.

sysevent_get_class_name(3SYSEVENT)

EXAMPLE 1 Parse sysevent header information. (Continued)

```
* Check for replayed sysevent, time must
          * be greater than previously recorded.
          */
         sysevent get event id(ev, &eid);
         if (eid.eid_ts < last_ev_time ||</pre>
             (eid.eid_ts == last_ev_time && eid.eid_seq <=</pre>
             last ev seq)) {
                 return;
         last_ev_time = eid.eid_ts;
         last_ev_seq = eid.eid_seq;
         /* Store event for later processing */
         ev_sz = sysevent_get_size(ev):
         new_ev (sysevent_t *)malloc(ev_sz);
         bcopy(ev, new_ev, ev_sz);
         queue_event(new_ev);
}
```

NAME

sysevent_get_vendor_name, sysevent_get_pub_name, sysevent_get_pid - get vendor name, publisher name or processor ID of event

SYNOPSIS

```
cc [flag ...] file ...-lsysevent [library ...]
#include <libsysevent.h>
char *sysevent get vendor name(sysevent t *ev);
char *sysevent get pub name(sysevent t *ev);
pid t sysevent get pid(sysevent t *ev);
                handle to a system event object
```

PARAMETERS DESCRIPTION

The sysevent get pub name () function returns the publisher name for the sysevent handle, ev. The publisher name identifies the name of the publishing application or kernel subsystem of the sysevent.

The sysevent get pid() function returns the process ID for the publishing application or SE KERN PID for sysevents originating in the kernel. The publisher name and PID are useful for implementing event acknowledgement.

The sysevent get vendor name () function returns the vendor string for the publishing application or kernel subsystem. A vendor string is the company's stock symbol that provided the application or kernel subsystem that generated the system event. This information is useful for filtering sysevents for one or more vendors.

The interface manages the allocation of the vendor and publisher name strings, but it is up to the caller to free the strings when they are no longer needed with a call to free(). See malloc(3MALLOC).

EXAMPLES

EXAMPLE 1 Parse sysevent header information.

The following example parses sysevent header information from an application's event handler.

```
char *vendor;
char *pub;
void
event handler(sysevent t *ev)
        if (strcmp(EC PRIV, sysevent get class name(ev)) != 0) {
                return;
        vendor = sysevent_get_vendor_name(ev);
        if (strcmp("SUNW", vendor) != 0) {
               free (vendor);
                return;
        pub = sysevent_get_pub_name(ev);
        if (strcmp("test daemon", pub) != 0) {
                free (vendor);
```

sysevent_get_vendor_name(3SYSEVENT)

EXAMPLE 1 Parse sysevent header information. (Continued)

```
free(pub);
       return;
(void) kill(sysevent_get_pid(ev), SIGUSR1);
free(vendor);
free(pub);
```

NAME

sysevent_post_event – post system event for applications

SYNOPSIS

```
cc [flag...] file...-lsysevent -lnvpair [library...]
#include <libsysevent.h>
#include <libnvpair.h>
```

int sysevent_post_event(char *class, char *subclass, char *vendor, char
 *publisher, nvlist t *attr_list, sysevent id t *eid);

PARAMETERS

attr_list pointer to an nvlist t, listing the name-value attributes

associated with the event, or NULL if there are no such attributes

for this event

class pointer to a string defining the event class eid pointer to a system unique identifier

publisher pointer to a string defining the event's publisher nam

subclass pointer to a string defining the event subclass

vendor pointer to a string defining the vendor

DESCRIPTION

The sysevent_post_event() function causes a system event of the specified class, subclass, vendor, and publisher to be generated on behalf of the caller and queued for delivery to the sysevent daemon syseventd(1M).

The vendor must be the company stock symbol of the event posting application. The publisher should be the name of the application generating the event.

For example, all events posted by Sun applications begin with the company's stock symbol, "SUNW". The publisher is usually the name of the application generating the system event. A system event generated by devfsadm(1M) has a publisher string of devfsadm.

The publisher information is used by sysevent consumers to filter unwanted event publishers.

Upon successful queuing of the system event, a unique identifier is assigned to eid.

RETURN VALUES

The sysevent_post_event() function returns 0 if the system event has been queued successfully for delivery. Otherwise it returns -1 and sets errno to indicate the error.

ERRORS

The sysevent_post_event() function will fail if:

ENOMEM Insufficient resources to queue the system event.

EIO The syseventd daemon is not responding and events cannot be

queued or delivered at this time.

EINVAL Invalid argument.

EPERM Permission denied.

sysevent_post_event(3SYSEVENT)

EFAULT

A copy error occurred.

EXAMPLES

EXAMPLE 1 Post a system event event with no attributes.

The following example posts a system event event with no attributes.

```
if (sysevent post event(EC PRIV, "ESC MYSUBCLASS", "SUNW", argv[0],
   NULL) != 0) {
       fprintf(stdout, "error logging system event\n");
}
```

EXAMPLE 2 Post a system event with two name-value pair attributes.

The following example posts a system event event with two name-value pair attributes, an integer value and a string.

```
nvlist_t
               *attr_list;
uint32_t
               uint32_val = 0XFFFFFFF;
char
               *string val = "string value data";
if (nvlist_alloc(&attr_list, 0, 0) == 0) {
        err = nvlist_add_uint32(attr_list, "uint32 data", uint32_val);
       if (err == 0)
               err = nvlist add string(attr list, "str data",
                  str_value);
       if (err == 0)
               err = sysevent_post_event("EC_PRIV", "ESC_MYSUBCLASS",
                   "SUNW", argv[0], attr_list);
        if (err != 0)
               fprintf(stdout, "error logging system event\n");
       nvlist free(attr list);
}
```

NAME | tan – tangent function

SYNOPSIS

cc [flag ...] file ... -lm [library ...]

#include <math.h>

double tan(double x);

DESCRIPTION

The tan() function computes the tangent of its argument x, measured in radians.

RETURN VALUES

Upon successful completion, tan() returns the tangent of x.

If x is NaN or \pm Inf, NaN is returned.

ERRORS

No errors will occur.

NAME | tnfctl buffer alloc, tnfctl buffer dealloc – allocate or deallocate a buffer for trace data

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
```

tnfctl errcode t tnfctl buffer alloc(tnfctl handle t *hndl, const char *trace_file_name, size t trace_buffer_size);

tnfctl buffer dealloc(tnfctl handle t *hndl);

DESCRIPTION

tnfctl buffer alloc() allocates a buffer to which trace events are logged. When tracing a process using a tnfctl handle returned by tnfctl pid open(3TNF), tnfctl_exec_open(3TNF), tnfctl_indirect open(3TNF), and tnfctl internal open(3TNF)), trace_file_name is the name of the trace file to which trace events should be logged. It can be an absolute path specification or a relative path specification. If it is relative, the current working directory of the process that is calling tnfctl buffer alloc() is prefixed to trace_file_name. If the named trace file already exists, it is overwritten. For kernel tracing, that is, for a tnfctl handle returned by tnfctl kernel open(3TNF), trace events are logged to a trace buffer in memory; therefore, trace_file_name is ignored. Use tnfxtract(1) to extract a kernel buffer into a file.

trace buffer size is the size in bytes of the trace buffer that should be allocated. An error is returned if an attempt is made to allocate a buffer when one already exists. tnfctl buffer alloc() affects the trace attributes; use tnfctl trace attrs qet(3TNF) to get the latest trace attributes after a buffer is allocated.

tnfctl buffer dealloc() is used to deallocate a kernel trace buffer that is no longer needed. hndl must be a kernel handle, returned by tnfctl kernel open(3TNF). A process's trace file cannot be deallocated using tnfctl buffer dealloc(). Instead, once the trace file is no longer needed for analysis and after the process being traced exits, use rm(1) to remove the trace file. Do not remove the trace file while the process being traced is still alive. tnfctl buffer dealloc () affects the trace attributes; use tnfctl trace attrs get(3TNF) to get the latest trace attributes after a buffer is deallocated.

For a complete discussion of tnf tracing, see tracing(3TNF).

RETURN VALUES

tnfctl buffer alloc() and tnfctl buffer dealloc() return TNFCTL ERR NONE upon success.

ERRORS

The following error codes apply to tnfctl_buffer_alloc():

TNFCTL ERR BUFEXISTS A buffer already exists.

Permission denied; could not create a trace TNFCTL ERR ACCES file.

tnfctl_buffer_alloc(3TNF)

TNFCTL ERR SIZETOOSMALL The trace_buffer_size requ
--

than the minimum trace buffer size needed. Use trace_min_size of trace attributes in tnfctl_trace_attrs_get(3TNF) to determine the minimum size of the buffer.

TNFCTL ERR SIZETOOBIG The requested trace file size is too big.

TNFCTL ERR BADARG trace_file_name is NULL or the absolute path

name is longer than MAXPATHLEN.

TNFCTL ERR ALLOCFAIL A memory allocation failure occurred.

TNFCTL_ERR_INTERNAL An internal error occurred.

The following error codes apply to tnfctl_buffer_dealloc():

TNFCTL ERR BADARG hndl is not a kernel handle.

TNFCTL ERR NOBUF No buffer exists to deallocate.

TNFCTL ERR BADDEALLOC Cannot deallocate a trace buffer unless

tracing is stopped. Use

tnfctl_trace_state_set(3TNF) to stop

tracing.

TNFCTL ERR INTERNAL An internal error occurred.

NAME | tnfctl_close – close a tnfctl handle

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
tnfctl errcode t tnfctl close(tnfctl handle t *hndl,
     tnfctl targ op t action);
```

DESCRIPTION

tnfctl close () is used to close a tnfctl handle and to free up the memory associated with the handle. When the handle is closed, the tracing state and the states of the probes are not changed. tnfctl close() can be used to close handles in any mode, that is, whether they were created by tnfctl internal open(3TNF), tnfctl pid open(3TNF), tnfctl exec open(3TNF), tnfctl indirect open(3TNF), or tnfctl kernel open(3TNF).

The action argument is only used in direct mode, that is, if hndl was created by tnfctl exec open(3TNF) or tnfctl pid open(3TNF). In direct mode, action specifies whether the process will proceed, be killed, or remain suspended. action may have the following values:

TNFCTL_TARG_DEFAULT	Kills the target process if hndl was created

with tnfctl exec open(3TNF), but lets it continue if it was created with

tnfctl pid open(3TNF).

TNFCTL TARG KILL Kills the target process.

TNFCTL TARG RESUME Allows the target process to continue.

TNFCTL TARG SUSPEND Leaves the target process suspended. This is

> not a job control suspend. It is possible to attach to the process again with a debugger or with the tnfctl pid open(3TNF) interface. The target process can also be

continued with prun(1).

RETURN VALUES

tnfctl close() returns TNFCTL ERR NONE upon success.

ERRORS

The following error codes apply to tnfctl close():

A bad argument was sent in action. TNFCTL ERR BADARG

TNFCTL ERR INTERNAL An internal error occurred.

NAME |

tnfctl indirect open, tnfctl check libs – control probes of another process where caller provides /proc functionality

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
tnfctl errcode t tnfctl indirect open (void *prochandle,
    tnfctl ind config t *config, tnfctl handle t **ret_val);
tnfctl errcode t tnfctl check libs(tnfctl handle t *hndl);
```

DESCRIPTION

The interfaces tnfctl indirect open() and tnfctl check libs() are used to control probes in another process where the libtnfctl(3TNF) client has already opened proc(4) on the target process. An example of this is when the client is a debugger. Since these clients already use /proc on the target, libtnfctl(3TNF) cannot use /proc directly. Therefore, these clients must provide callback functions that can be used to inspect and to update the target process. The target process must load libtnfprobe.so.1 (defined in <tnf/tnfctl.h> as macro TNFCTL LIBTNFPROBE).

The first argument *prochandle* is a pointer to an opaque structure that is used in the callback functions that inspect and update the target process. This structure should encapsulate the state that the caller needs to use /proc on the target process (the /proc file descriptor). The second argument, *config*, is a pointer to

```
typedef
struct tnfctl ind config {
   int (*p_read)(void *prochandle, paddr_t addr, char *buf,
                   size t size);
    int (*p write) (void *prochandle, paddr t addr, char *buf,
                   size_t size);
    pid t (*p getpid) (void *prochandle);
    int (*p_obj_iter)(void *prochandle, tnfctl_ind_obj_f *func,
                   void *client data);
} tnfctl ind config t;
```

The first field *p_read* is the address of a function that can read size bytes at address *addr* in the target image into the buffer *buf*. The function should return 0 upon success.. The second field *p_write* is the address of a function that can write size bytes at address addr in the target image from the buffer buf. The function should return 0 upon success. The third field *p_getpid* is the address of a function that should return the process id of the target process (*prochandle*). The fourth field *p_obj_iter* is the address of a function that iterates over all load objects and the executable by calling the callback function *func* with *client_data*. If *func* returns 0, *p_obj_iter* should continue processing link objects. If *func* returns any other value, *p_obj_iter* should stop calling the callback function and return that value. *p_obj_iter* should return 0 if it iterates over all load objects.

If a failure is returned by any of the functions in *config*, the error is propagated back as PREX ERR INTERNAL by the libtnfctl interface that called it.

The definition of tnfctl ind obj f is:

tnfctl_indirect_open(3TNF)

```
tnfctl ind obj f(void *prochandle,
    const struct tnfctl_ind_obj_info *obj
    void *client_data);
typedef struct tnfctl_ind_obj_info {
          objfd;
                             /* -1 indicates fd not available */
   int
                              /* virtual addr of text segment */
    paddr_t text_base;
paddr_t data_base;
    paddr_t data_base; /* virtual addr of data segment */
const char *objname; /* null-term ---'
                               /* null-term. pathname to loadobj */
} tnfctl ind obj info t;
```

objfd should be the file descriptor of the load object or executable. If it is −1, then objname should be an absolute pathname to the load object or executable. If objfd is not closed by libtnfctl, it should be closed by the load object iterator function. text_base and data_base are the addresses where the text and data segments of the load object are mapped in the target process.

Whenever the target process opens or closes a dynamic object, the set of available probes may change. See dlopen(3DL) and dlclose(3DL). In indirect mode, call tnfctl check libs() when such events occur to make libtnfctl aware of any changes. In other modes this is unnecessary but harmless. It is also harmless to call tnfctl check libs() when no such events have occurred.

RETURN VALUES

tnfctl indirect open() and tnfctl check libs() return TNFCTL ERR NONE upon success.

ERRORS

The following error codes apply to tnfctl indirect open():

TNFCTL ERR ALLOCFAIL A memory allocation failure occurred.

Internal tracing is being used. TNFCTL ERR BUSY

libtnfprobe.so.1 is not loaded in the TNFCTL ERR NOLIBTNFPROBE

target process.

TNFCTL ERR INTERNAL An internal error occurred.

The following error codes apply to tnfctl check libs():

TNFCTL ERR ALLOCFAIL A memory allocation failure occurred.

TNFCTL ERR INTERNAL An internal error occurred.

Linker and Libraries Guide

NOTES

tnfctl indirect open() should only be called after the dynamic linker has mapped in all the libraries (rtld sync point) and called only after the process is stopped. Indirect process probe control assumes the target process is stopped whenever any libtnfctl interface is used on it. For example, when used for indirect process probe control, tnfctl probe enable(3TNF) and tnfctl probe trace(3TNF) should be called only for a process that is stopped.

tnfctl_internal_open(3TNF)

NAME | tnfctl internal open - create handle for internal process probe control

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
```

tnfctl errcode t tnfctl internal open(tnfctl handle t **ret_val);

DESCRIPTION

tnfctl internal open() returns in ret_val a pointer to an opaque handle that can be used to control probes in the same process as the caller (internal process probe control). The process must have libtnfprobe.so.1 loaded. Probes in libraries that are brought in by dlopen(3DL) will be visible after the library has been opened. Probes in libraries closed by a dlclose(3DL) will not be visible after the library has been disassociated. See the NOTES section for more details.

RETURN VALUES

tnfctl internal open() returns TNFCTL ERR NONE upon success.

ERRORS

TNFCTL ERR ALLOCFAIL A memory allocation failure occurred.

Another client is already tracing this TNFCTL ERR BUSY

program (internally or externally).

TNFCTL ERR NOLIBTNFPROBE libtnfprobe.so.1 is not linked in the

target process.

TNFCTL ERR INTERNAL An internal error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

MT Level	MT-Safe

SEE ALSO

ld(1), prex(1), TNF PROBE(3TNF), dlopen(3DL), dlclose(3DL), libtnfctl(3TNF), tracing(3TNF), attributes(5)

Linker and Libraries Guide

NOTES

libtnfctl interposes on dlopen(3DL) and dlclose(3DL) in order to be notified of libraries being dynamically opened and closed. This interposition is necessary for internal process probe control to update its list of probes. In these interposition functions, a lock is acquired to synchronize on traversal of the library list maintained by the runtime linker. To avoid deadlocking on this lock,

tnfctl internal open() should not be called from within the init section of a library that can be opened by dlopen(3DL).

Since interposition does not work as expected when a library is opened dynamically, tnfctl internal open() should not be used if the client opened libtnfctl through dlopen(3DL). In this case, the client program should be built with a static

tnfctl_internal_open(3TNF)

dependency on libtnfctl. Also, if the client program is explicitly linking in -ldl, it should link -ltnfctl before -ldl .

Probes in filtered libraries (see 1d(1)) will not be seen because the filtee (backing library) is loaded lazily on the first symbol reference and not at process startup or dlopen(3DL) time. A workaround is to call tnfctl_check_libs(3TNF) once the caller is sure that the filtee has been loaded.

tnfctl_kernel_open(3TNF)

NAME | tnfctl_kernel_open - create handle for kernel probe control

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
```

tnfctl errcode t tnfctl kernel open(tnfctl handle t **ret_val);

DESCRIPTION

tnfctl kernel open() starts a kernel tracing session and returns in ret val an opaque handle that can be used to control tracing and probes in the kernel. Only one kernel tracing session is possible at a time on a given machine. An error code of TNFCTL ERR BUSY is returned if there is another process using kernel tracing. Use the command

fuser -f /dev/tnfctlto print the process id of the process currently using kernel tracing. Only a superuser may use tnfctl_kernel_open(). An error code of TNFCTL ERR ACCES is returned if the caller does not have the necessary privileges.

RETURN VALUES

tnfctl_kernel_open returns TNFCTL_ERR NONE upon success.

ERRORS

TNFCTL ERR ACCES Permission denied. Superuser privileges are

needed for kernel tracing.

TNFCTL ERR BUSY Another client is currently using kernel

tracing.

TNFCTL ERR ALLOCFAIL Memory allocation failed.

TNFCTL ERR FILENOTFOUND /dev/tnfctl not found.

TNFCTL ERR INTERNAL Some other failure occurred.

NAME | tnfctl pid open, tnfctl exec open, tnfctl continue – interfaces for direct probe and process control for another process

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
tnfctl errcode t tnfctl pid open(pid t pid, tnfctl handle t
    **ret_val);
tnfctl_errcode_t tnfctl_exec_open(const char *pgm_name, char *
    const *argv, char * const *envp, const char *libnfprobe_path, const
    char *ld_preload, tnfctl handle t **ret_val);
tnfctl errcode t tnfctl continue(tnfctl handle t *hndl,
    tnfctl event t *evt, tnfctl handle t **child hndl);
```

DESCRIPTION

tnfctl pid open(), tnfctl exec open(), and tnfctl continue() are the interfaces used to create handles to control probes in another process (direct process probe control). Either tnfctl pid open() or tnfctl exec open() will return a handle in *ret_val* that can be used for probe control. On return of these calls, the process is stopped. tnfctl continue() allows the process specified by hndl to continue execution.

tnfctl pid open() attaches to a running process with process id of pid. The process is stopped on return of this call. tnfctl_pid_open() returns an error message if pid is the same as the calling process. See tnfctl internal open(3TNF) for information on internal process probe control. A pointer to an opaque handle is returned in ret_val, which can be used to control the process and the probes in the process. The target process must have libtnfprobe.so.1 (defined in <tnf/tnfctl.h> as macro TNFCTL LIBTNFPROBE) linked in for probe control to work.

tnfctl exec open() is used to exec(2) a program and obtain a probe control handle. For probe control to work, the process image to be exec'd must load libtnfprobe.so.1. The interface tnfctl exec open() makes it simple for the library to be loaded at process start up time. pgm_name is the command to exec. If pgm_name is not an absolute path, then the \$PATH environment variable is used to find the pgm_name. argv is a null-terminated argument pointer, that is, it is a null-terminated array of pointers to null-terminated strings. These strings constitute the argument list available to the new process image. argv must have at least one member, and it should point to a string that is the same as pgm_name. See execve(2). libnfprobe_path is an optional argument, and if set, it should be the path to the directory that contains libtnfprobe.so.1. There is no need for a trailing "/" in this argument. This argument is useful if libtnfprobe.so.1 is not installed in /usr/lib. *ld_preload* is a space-separated list of libraries to preload into the target program. This string should follow the syntax guidelines of the LD PRELOAD environment variable. See ld. so. 1(1). The following illustrates how strings are concatenated to form the LD PRELOAD environment variable in the new process image:

```
<current value of $LD_PRELOAD> + <space> +
libtnfprobe_path + "/libtnfprobe.so.1" +<space> +
ld preload
```

This option is useful for preloading interposition libraries that have probes in them.

<code>envp</code> is an optional argument, and if set, it is used for the environment of the target program. It is a null-terminated array of pointers to null-terminated strings. These strings constitute the environment of the new process image. See <code>execve(2)</code>. If <code>envp</code> is set, it overrides <code>ld_preload</code>. In this case, it is the caller's responsibility to ensure that <code>libtnfprobe.so.1</code> is loaded into the target program. If <code>envp</code> is not set, the new process image inherits the environment of the calling process, except for <code>LD_PRELOAD</code>.

<code>ret_val</code> is the return argument which is the handle that can be used to control the process and the probes within the process. Upon return, the process is stopped before any user code, including <code>.init</code> sections, has been executed.

tnfctl_continue() is a blocking call and lets the target process referenced by <code>hndl</code> continue running. It can only be used on handles returned by <code>tnfctl_pid_open()</code> and <code>tnfctl_exec_open()</code> (direct process probe control). It returns when the target stops; the reason that the process stopped is returned in <code>evt</code>. This call is interruptible by signals. If it is interrupted, the process is stopped, and <code>TNFCTL_EVENT_EINTR</code> is returned in <code>evt</code>. The client of this library will have to decide which signal implies a stop to the target and catch that signal. Since a signal interrupts <code>tnfctl_continue()</code>, it will return, and the caller can decide whether or not to call <code>tnfctl_continue()</code> again.

tnfctl continue() returns with an event of TNFCTL EVENT DLOPEN, TNFCTL EVENT DLCLOSE, TNFCTL EVENT EXEC, TNFCTL EVENT FORK, TNFCTL EVENT EXIT, or TNFCTL EVENT TARGGONE, respectively, when the target program does a dlopen(3DL), dlclose(3DL), any flavor of exec(2), fork(2) (or fork1(2)), exit(2), or terminates unexpectedly. If the target program did an exec(2), then the client needs to call tnfctl close(3TNF) on the current handle leaving the target resumed, suspended, or killed (second argument to tnfctl close(3TNF)). No other libtnfctl interface call can be used on the existing handle. If the client wants to control the exec'ed image, it should leave the old handle suspended, and use tnfctl pid open() to reattach to the same process. This new handle can then be used to control the exec'ed image. See EXAMPLES below for sample code. If the target process did a fork(2) or fork1(2), and if control of the child process is not needed, then *child_hndl* should be NULL. If control of the child process is needed, then child_hndl should be set. If it is set, a pointer to a handle that can be used to control the child process is returned in *child_lndl*. The child process is stopped at the end of the fork() system call. See EXAMPLES for an example of this event.

RETURN VALUES

```
tnfctl_pid_open( ), tnfctl_exec_open( ), and tnfctl_continue()
return TNFCTL ERR NONE upon success.
```

ERRORS

The following error codes apply to tnfctl pid open():

tnfctl_pid_open(3TNF)

TNFCTL_ERR_BADARG Bad input argument. hndl is not a direct

process probe control handle.

TNFCTL_ERR_INTERNAL An internal error occurred.

TNFCTL_ERR_NOPROCESS No such target process exists.

EXAMPLES

```
EXAMPLE 1 Using tnfctl pid open()
```

These examples do not include any error-handling code. Only the initial example includes the declaration of the variables that are used in all of the examples.

The following example shows how to preload libtnfprobe.so.1 from the normal location and inherit the parent's environment.

```
const char *pgm;
char * const *argv;
tnfctl_handle_t *hndl, *new_hndl, *child_hndl;
tnfctl errcode t err;
```

```
EXAMPLE 1 Using tnfctl pid open() (Continued)
```

This example shows how to preload two user-supplied libraries libc_probe.so.1 and libthread_probe.so.1. They interpose on the corresponding libc.so and libthread.so interfaces and have probes for function entry and exit. libtnfprobe.so.1 is preloaded from the normal location and the parent's environment is inherited.

This example preloads an interposition library libc_probe.so.1, and specifies a different location from which to preload libtnfprobe.so.1.

To set up the environment explicitly for probe control to work, the target process must link libtnfprobe.so.1. If using *envp*, it is the caller's responsibility to do so.

```
/* assuming argv has been allocated */
argv[0] = pgm;
/* set up rest of argument vector here */
/* envptr set up to caller's needs */
err = tnfctl_exec_open(pgm, argv, envptr, NULL, NULL, &hndl);
```

Use this example to resume a process that does an exec(2) without controlling it.

```
err = tnfctl_continue(hndl, &evt, NULL);
switch (evt) {
case TNFCTL_EVENT_EXEC:
    /* let target process continue without control */
    err = tnfctl_close(hndl, TNFCTL_TARG_RESUME);
    ...
    break;
}
```

Alternatively, use the next example to control a process that does an exec(2).

```
* assume the pid variable has been set by calling
 * tnfctl_trace_attrs_get()
*/
err = tnfctl_continue(hndl, &evt, NULL);
switch (evt) {
case TNFCTL EVENT EXEC:
    /* suspend the target process */
    err = tnfctl close(hndl, TNFCTL TARG SUSPEND);
    /* re-open the exec'ed image */
    err = tnfctl_pid_open(pid, &new_hndl);
    /* new hndl now controls the exec'ed image */
    break;
}
To let fork'ed children continue without control, use NULL as the last argument to
tnfctl continue().
err = tnfctl continue(hndl, &evt, NULL);
The next example is how to control child processes that fork(2) or fork1(2) create.
err = tnfctl_continue(hndl, &evt, &child_hndl);
switch (evt) {
case TNFCTL EVENT FORK:
```

NOTES

After a tnfctl_continue() returns, a client should use tnfctl_trace_attrs_get(3TNF) to check the trace_buf_state member of the trace attributes and make sure that there is no internal error in the target.

tnfctl_probe_apply(3TNF)

NAME | tnfctl_probe_apply, tnfctl_probe_apply_ids – iterate over probes

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
tnfctl errcode t tnfctl probe apply(tnfctl handle t *hndl,
     tnfctl probe op t probe_op, void *clientdata);
tnfctl errcode t tnfctl probe apply ids(tnfctl handle t *hndl,
    ulong t probe_count, ulong t *probe_ids, tnfctl probe op t probe_op,
    void *clientdata);
```

DESCRIPTION

tnfctl probe apply () is used to iterate over the probes controlled by hndl. For every probe, the *probe_op* function is called:

```
typedef tnfctl_errcode_t (*tnfctl_probe_op_t)(
   tnfctl handle t *hndl,
   tnfctl probe t *probe hndl,
   void *clientdata);
```

Several predefined functions are available for use as *probe_op*. These functions are described in tnfctl probe state get(3TNF).

The clientdata supplied in tnfctl probe apply() is passed in as the last argument of probe_op. The probe_hndl in the probe operation function can be used to query or change the state of the probe. See tnfctl probe state get(3TNF). The probe_op function should return TNFCTL ERR NONE upon success. It can also return an error code, which will cause tnfctl probe apply() to stop processing the rest of the probes and return with the same error code. Note that there are five (5) error codes reserved that the client can use for its own semantics. See ERRORS.

The lifetime of *probe hndl* is the same as the lifetime of *hndl*. It is good until *hndl* is closed by tnfctl close(3TNF). Do not confuse a probe_hndl with hndl. The probe_hndl refers to a particular probe, while hndl refers to a process or the kernel. If probe_hndl is used in another libtnfctl(3TNF) interface, and it references a probe in a library that has been dynamically closed (see dlclose(3DL)), then the error code TNFCTL ERR INVALIDPROBE will be returned by that interface.

tnfctl_probe_apply_ids() is very similar to tnfctl_probe apply(). The difference is that probe_op is called only for probes that match a probe id specified in the array of integers referenced by *probe_ids*. The number of probe ids in the array should be specified in *probe_count*. Use tnfctl probe state get() to get the *probe_id* that corresponds to the *probe_handl*.

RETURN VALUES

```
tnfctl probe apply() and tnfctl probe apply ids() return
TNFCTL ERR NONE upon success.
```

ERRORS

```
The following errors apply to both tnfctl probe apply() and
tnfctl probe apply ids():
TNFCTL ERR INTERNAL
                                    An internal error occurred.
```

tnfctl_probe_apply(3TNF)

TNFCTL_ERR_USR1	Error code reserved for user.
TNFCTL_ERR_USR2	Error code reserved for user.
TNFCTL_ERR_USR3	Error code reserved for user.
TNFCTL_ERR_USR4	Error code reserved for user.
TNFCTL_ERR_USR5	Error code reserved for user.

tnfctl_probe_apply() and tnfctl_probe_apply_ids() also return any error
returned by the callback function probe_op.

The following errors apply only to tnfctl_probe_apply_ids():

TNFCTL ERR INVALIDPROBE The probe handle is no longer valid. For

example, the probe is in a library that has

been closed by dlclose(3DL).

EXAMPLES

EXAMPLE 1 Enabling Probes

To enable all probes:

```
tnfctl_probe_apply(hndl, tnfctl_probe_enable, NULL);
```

EXAMPLE 2 Disabling Probes

To disable the probes that match a certain pattern in the probe attribute string:

```
/* To disable all probes that contain the string "vm" */
tnfctl_probe_apply(hndl, select_disable, "vm");
static tnfctl_errcode_t
select_disable(tnfctl_handle_t *hndl, tnfctl_probe_t *probe_hndl,
void *client_data)
{
    char *pattern = client_data;
    tnfctl_probe_state_t probe_state;
    tnfctl_probe_state_get(hndl, probe_hndl, &probe_state);
    if (strstr(probe_state.attr_string, pattern)) {
        tnfctl_probe_disable(hndl, probe_hndl, NULL);
    }
}
```

    tnfctl probe t *probe_hndl, void *ignored);
tnfctl errcode t tnfctl probe disconnect all(tnfctl handle t
    *hndl, tnfctl probe t *probe_hndl, void *ignored);
tnfctl errcode t tnfctl probe connect(tnfctl handle t *hndl,
    tnfctl probe t *probe_hndl, const char *lib_base_name, const char
    *func_name);
```

DESCRIPTION

tnfctl_probe_state_get() returns the state of the probe specified by *probe_hndl* in the process or kernel specified by *hndl*. The user will pass these in to an apply iterator. The caller must also allocate *state* and pass in a pointer to it. The semantics of the individual members of *state* are:

id	The unique integer assigned to this probe. This number does not change over the lifetime of this probe. A <code>probe_hndl</code> can be obtained by using the calls <code>tnfctl_apply(),tanfctl_apply_ids(),ortnfctl_register_funcs()</code> .
attr_string	A string that consists of <i>attribute value</i> pairs separated by semicolons. For the syntax of this string, see the syntax of the detail argument of the TNF_PROBE(3TNF) macro. The attributes <i>name</i> , <i>slots</i> , <i>keys</i> , file, and line are defined for every probe. Additional user-defined attributes can be added by using the <i>detail</i> argument of the TNF_PROBE(3TNF) macro. An example of <i>attr_string</i> follows:

"name pageout;slots vnode pages_pageout ;
keys vm pageio io;file vm.c;line 25;"

tnfctl_probe_state_get(3TNF)

-8	ei(31NF)	
	enabled	B_TRUE if the probe is enabled, or B_FALSE if the probe is disabled. Probes are disabled by default. Use tnfctl_probe_enable() or tnfctl_probe_disable() to change this state.
	traced	B_TRUE if the probe is traced, or B_FALSE if the probe is not traced. Probes in user processes are traced by default. Kernel probes are untraced by default. Use tnfctl_probe_trace() or tnfctl_probe_untrace() to change this state.
	new_probe	B_TRUE if this is a new probe brought in since the last change in libraries. See dlopen(3DL) or dlclose(3DL). Otherwise, the value of new_probe will be B_FALSE. This field is not meaningful for kernel probe control.
	obj_name	The name of the shared object or executable in which the probe is located. This string can be freed, so the client should make a copy of the string if it needs to be saved for use by other libtnfctl interfaces. In kernel mode, this string is always NULL.
	func_names	A null-terminated array of pointers to strings that contain the names of functions connected to this probe. Whenever an enabled probe is encountered at runtime, these functions are executed. This array also will be freed by the library when the state of the probe changes. Use tnfctl_probe_connect() or tnfctl_probe_disconnect_all() to change this state.
	func_addrs	A null-terminated array of pointers to addresses of functions in the target image connected to this probe. This array also will be freed by the library when the state of the probe changes.
	client_registered_data	Data that was registered by the client for this probe by the creator function in tnfctl_register_funcs(3TNF).
	tnfctl_probe_trace(), tnfctl_probe_disconnect feature permits these functions tnfctl_probe_apply(3TNF tnfctl_probe_enable() e master switch on a probe. A pro-	thfctl_probe_disable(), thfctl_probe_untrace(), and t_all() ignore the last argument. This convenient to be used in the <i>probe_op</i> field of and thfctl_probe_apply_ids(3TNF). nables the probe specified by <i>probe_hndl</i> . This is the robe does not perform any action until it is enabled.
	<pre>tnicti_probe_disable()</pre>	disables the probe specified by <i>probe_hndl</i> .

tnfctl_probe_trace() turns on tracing for the probe specified by *probe_hndl*. Probes emit a trace record only if the probe is traced.

tnfctl_probe_untrace() turns off tracing for the probe specified by *probe_hndl*. This is useful if you want to connect probe functions to a probe without tracing it.

tnfctl_probe_connect() connects the function *func_name* which exists in the library *lib_base_name*, to the probe specified by *probe_hndl*.

tnfctl_probe_connect() returns an error code if used on a kernel tnfctl handle. <code>lib_base_name</code> is the base name (not a path) of the library. If it is NULL, and multiple functions in the target process match <code>func_name</code>, one of the matching functions is chosen arbitrarily. A probe function is a function that is in the target's address space and is written to a certain specification. The specification is not currently published.

tnf_probe_debug() is one function exported by libtnfprobe.so.1 and is the debug function that prex(1) uses. When the debug function is executed, it prints out the probe arguments and the value of the sunw%debug attribute of the probe to stderr.

tnfctl_probe_disconnect_all() disconnects all probe functions from the probe specified by *probe_lundl*.

Note that no libtnfctl call returns a probe handle (tnfctl_probe_t), yet each of the routines described here takes a *probe_hndl* as an argument. These routines may be used by passing them to one of the tnfctl_probe_apply(3TNF) iterators as the "op" argument. Alternatively, probe handles may be obtained and saved by a user's "op" function, and they can be passed later as the *probe_hndl* argument when using any of the functions described here.

RETURN VALUES

```
tnfctl_probe_state_get(), tnfctl_probe_enable(),
tnfctl_probe_disable(), tnfctl_probe_trace(),
tnfctl_probe_untrace(), tnfctl_probe_disconnect_all() and
tnfctl_probe_connect() return TNFCTL_ERR_NONE upon success.
```

ERRORS

The following error codes apply to tnfctl_probe_state_get():

TNFCTL_ERR_INVALIDPROBE probe_hndl is no longer valid. The library that the probe was in could have been dynamically closed by dlclose(3DL).

NAME | tnfctl register funcs – register callbacks for probe creation and destruction

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
```

tnfctl errcode t tnfctl register funcs(tnfctl handle t *hndl, void * (*create_func) (tnfctl handle t *, tnfctl probe t *), void (*destroy_func) (void *));

DESCRIPTION

The function tnfctl register funcs() is used to store client-specific data on a per-probe basis. It registers a creator and a destructor function with hndl, either of which can be NULL. The creator function is called for every probe that currently exists in hndl. Every time a new probe is discovered, that is brought in by dlopen(3DL), *create_func* is called.

The return value of the creator function is stored as part of the probe state and can be retrieved by tnfctl probe state get(3TNF) in the member field client_registered_data.

destroy func is called for every probe handle that is freed. This does not necessarily happen at the time dlclose(3DL) frees the shared object. The probe handles are freed only when hndl is closed by tnfctl close(3TNF). If tnfctl register funcs() is called a second time for the same *hndl*, then the previously registered destructor function is called first for all of the probes.

RETURN VALUES

tnfctl register funcs() returns TNFCTL ERR NONE upon success.

ERRORS

TNFCTL ERR INTERNAL

An internal error occurred.

Linker and Libraries Guide

tnfctl_strerror(3TNF)

NAME | tnfctl_strerror – map a tnfctl error code to a string

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
```

#include <tnf/tnfctl.h>

const char * tnfctl_strerror(tnfctl_errcode_t errcode);

DESCRIPTION

tnfctl strerror() maps the error number in errode to an error message string, and it returns a pointer to that string. The returned string should not be overwritten or freed.

ERRORS

tnfctl_strerror() returns the string "unknown libtnfctl.so error code" if the error number is not within the legal range.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO | prex(1), TNF PROBE(3TNF), libtnfctl(3TNF), tracing(3TNF), attributes(5)

NAME | tnfctl_trace_attrs_get - get the trace attributes from a tnfctl handle

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
tnfctl_errcode_t tnfctl_trace_attrs_get(tnfctl_handle_t *hndl,
     tnfctl trace attrs t *attrs);
```

DESCRIPTION

tnfctl trace attrs get() returns the trace attributes associated with hndl in attrs. The trace attributes can be changed by some of the other interfaces in libtnfctl(3TNF). It is the client's responsibility to use tnfctl_trace_attrs_get() to get the new trace attributes after use of interfaces

that change them. Typically, a client will use tnfctl_trace_attrs_get() after a call to tnfctl_continue(3TNF) in order to make sure that tracing is still working. See the discussion of trace buf state that follows.

Trace attributes are represented by the struct tnfctl trace attrs structure defined in <tnf/tnfctl.h>:

```
struct tnfctl_trace_attrs {
    pid_t targ_pid; /* not kernel mode */
const char *trace_file_name; /* not kernel mode */
size_t trace_buf_size;
size_t trace_min_size;
    tnfctl_bufstate_t
              trace_buf_state;
     boolean_t trace_state;
boolean_t filter_state; /* kernel mode only */
     long
};
```

The semantics of the individual members of attrs are:

targ_pid	The process id of the target process. This is not valid for kernel tracing.
trace_file_name	The name of the trace file to which the target writes. trace_file_name will be NULL if no trace file exists or if kernel tracing is implemented. This pointer should not be used after calling other libtnfctl interfaces. The client should copy this string if it should be saved for the use of other libtnfctl interfaces.
trace_buf_size	The size of the trace buffer or file in bytes.
trace_min_size	The minimum size in bytes of the trace buffer that can be allocated by using the tnfctl_buffer_alloc(3TNF) interface.
trace_buf_state	The state of the trace buffer. TNFCTL_BUF_OK indicates that a trace buffer has been allocated. TNFCTL_BUF_NONE indicates that no buffer has been

tnfctl_trace_attrs_get(3TNF)

trace state

allocated. TNFCTL BUF BROKEN indicates that there is an internal error in the target for tracing. The target will continue to run correctly, but no trace records will be written. To fix tracing, restart the process. For kernel tracing, deallocate the existing buffer with tnfctl buffer dealloc(3TNF) and allocate a new

one with tnfctl buffer alloc(3TNF).

The global tracing state of the target. Probes that are enabled will not write out data unless this state is on. This state is off by default for the kernel and can be changed by tnfctl trace state set(3TNF). For a process, this state is on by default and can only be changed by tnf process disable(3TNF) and

tnf process enable(3TNF).

The state of process filtering. For kernel probe control, filter state

it is possible to select a set of processes for which

probes are enabled. See

tnfctl filter list get(3TNF), tnfctl filter list add(3TNF), and tnfctl filter list delete(3TNF). No trace

output will be written when other processes traverse these probe points. By default process filtering is off, and all processes cause the generation of trace records

when they hit an enabled probe. Use

tnfctl filter state set(3TNF) to change the

filter state.

RETURN VALUES tnfctl trace attrs get() returns TNFCTL ERR NONE upon success.

> **ERRORS** The following error codes apply to tnfctl trace attrs get()

> > TNFCTL ERR INTERNAL An internal error occurred.

NAME |

tnfctl trace state set, tnfctl filter state set, tnfctl filter list get, tnfctl filter list add, tnfctl_filter_list_delete - control kernel tracing and process filtering

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfctl [ library ... ]
#include <tnf/tnfctl.h>
tnfctl errcode t tnfctl trace state set(tnfctl handle t *hndl,
    boolean t trace_state);
tnfctl errcode t tnfctl filter state set (tnfctl handle t *hndl,
    boolean t filter_state);
tnfctl errcode t tnfctl filter list get(tnfctl handle t *hndl,
    pid t **pid_list, int *pid_count);
tnfctl errcode t tnfctl filter list add(tnfctl handle t *hndl,
    pid t pid_to_add);
tnfctl errcode t tnfctl filter list delete(tnfctl handle t *hndl,
    pid t pid_to_delete);
```

DESCRIPTION

The interfaces to control kernel tracing and process filtering are used only with kernel handles, handles created by tnfctl kernel open(3TNF). These interfaces are used to change the tracing and filter states for kernel tracing.

tnfctl trace state set() sets the kernel global tracing state to "on" if trace_state is B TRUE, or to "off" if trace state is B FALSE. For the kernel, trace state is off by default. Probes that are enabled will not write out data unless this state is on. Use tnfctl trace attrs get(3TNF) to retrieve the current tracing state.

tnfctl filter state set() sets the kernel process filtering state to "on" if filter_state is B TRUE, or to "off" if filter_state is B FALSE. filter_state is off by default. If it is on, only probe points encountered by processes in the process filter set by tnfctl filter list add() will generate trace points. Use tnfctl trace attrs get(3TNF) to retrieve the current process filtering state.

tnfctl filter list get() returns the process filter list as an array in pid_list. The count of elements in the process filter list is returned in pid count. The caller should use free(3C) to free memory allocated for the array pid_list.

tnfctl filter list add() adds pid_to_add to the process filter list. The process filter list is maintained even when the process filtering state is off, but it has no effect unless the process filtering state is on.

tnfctl filter list delete() deletes pid_to_delete from the process filter list. It returns an error if the process does not exist or is not in the filter list.

RETURN VALUES

The interfaces tnfctl trace state set(), tnfctl filter state set(), tnfctl filter list add(),tnfctl filter list delete(),and tnfctl filter list get() return TNFCTL ERR NONE upon success.

ERRORS | The following error codes apply to tnfctl trace state set:

tnfctl_trace_state_set(3TNF)

TNFCTL ERR BADARG The handle is not a kernel handle.

TNFCTL ERR NOBUF

Cannot turn on tracing without a buffer

being allocated.

TNFCTL ERR BUFBROKEN Tracing is broken in the target.

TNFCTL ERR INTERNAL An internal error occurred.

     tnf_member_type_2, c_member_name_2, tnf_member_type_3, c_member_name_3,
     tnf_member_type_4, c_member_name_4);
TNF DEFINE RECORD 5 (c_type, tnf_type, tnf_member_type_1, c_member_name_1,
```

DESCRIPTION

This macro interface is used to extend the TNF (Trace Normal Form) types that can be used in TNF PROBE(3TNF).

tnf_member_type_4, c_member_name_4, tnf_member_type_5,

c member name 5);

tnf member type 2, c member name 2, tnf member type 3, c member name 3,

There should be only one TNF DECLARE RECORD and one TNF DEFINE RECORD per new type being defined. The TNF DECLARE RECORD should precede the TNF DEFINE RECORD. It can be in a header file that multiple source files share if those source files need to use the tnf_type being defined. The TNF DEFINE RECORD should only appear in one of the source files.

The TNF DEFINE RECORD macro interface defines a function as well as a couple of data structures. Hence, this interface has to be used in a source file (.c or .cc file) at file scope and not inside a function.

Note that there is no semicolon after the TNF DEFINE RECORD interface. Having one will generate a compiler warning.

Compiling with the preprocessor option -DNPROBE (see cc(1B)), or with the preprocessor control statement #define NPROBE ahead of the #include <tnf/probe.h> statement, will stop the TNF type extension code from being compiled into the program.

c_type

c_type must be a C struct type. It is the template from which the new *tnf_type* is being created. Not all elements of the C struct need be provided in the TNF type being defined.

TNF DECLARE RECORD(3TNF)

tnf_type is the name being given to the newly created type. Use of this interface uses the name space prefixed by tnf_type. So, if a new type called "xxx_type" is defined by a library, then the library should not use "xxx_type" as a prefix in any other symbols it defines. The policy on managing the type name space is the same as managing any other name space in a library i.e., prefix any new TNF types by the unique prefix that the rest of the symbols in the library use. This would prevent name space collisions when linking multiple libraries that define new TNF types. For example, if a library libpalloc.so uses the prefix "pal" for all symbols it defines, then it should also use the prefix "pal" for all new TNF types being defined.

tnf_member_type_n | *tnf_member_type_n* is the TNF type of the *n*th provided member of the C structure.

tnf_member_name_n *tnf_member_name_n* is the name of the *n*th provided member of the C structure.

EXAMPLES

EXAMPLE 1 Defining and using a TNF type.

This example shows how a new TNF type is defined and used in a probe. This code is assumed to be part of a fictitious library called "libpalloc.so" which uses the prefix "pal" for all it's symbols.

```
#include <tnf/probe.h>
typedef struct pal_header {
       long size;
       char * descriptor;
       struct pal_header *next;
} pal_header_t;
TNF_DECLARE_RECORD(pal_header_t, pal_tnf_header);
TNF_DEFINE_RECORD_2(pal_header_t, pal_tnf_header,
                       tnf_long, size,
                       tnf_string, descriptor)
* Note: name space prefixed by pal tnf header should not be used by this
       client anymore.
*/
void
pal free(pal header t *header p)
       int state;
       TNF PROBE 2 (pal free start, "palloc pal free",
               "sunw%debug entering pal_free",
               tnf_long, state_var, state,
               pal tnf header, header var, header p);
}
```

NOTES

It is possible to make a *tnf_type* definition be recursive or mutually recursive e.g. a structure that uses the "next" field to point to itself (a linked list). If such a structure is sent in to a TNF_PROBE(3TNF), then the entire linked list will be logged to the trace file (until the "next" field is NULL) . But, if the list is circular, it will result in an infinite loop. To break the recursion, either don't include the "next" field in the *tnf_type*, or define the type of the "next" member as tnf opaque.

DESCRIPTION

This macro interface is used to insert probes into C or C++ code for tracing. See tracing(3TNF) for a discussion of the Solaris tracing architecture, including example source code that uses it.

You can place probes anywhere in C and C++ programs including .init sections, .fini sections, multi-threaded code, shared objects, and shared objects opened by dlopen(3DL). Use probes to generate trace data for performance analysis or to write debugging output to stderr. Probes are controlled at runtime by prex(1).

The trace data is logged to a trace file in Trace Normal Form (TNF). The interface for the user to specify the name and size of the trace file is described in prex(1). Think of the trace file as the least recently used circular buffer. Once the file has been filled, newer events will overwrite the older ones.

Use TNF_PROBE_0 through TNF_PROBE_5 to create production probes. These probes are compiled in by default. Developers are encouraged to embed such probes strategically, and to leave them compiled within production software. Such probes facilitate on-site analysis of the software.

Use TNF_PROBE_0_DEBUG through TNF_PROBE_5_DEBUG to create debug probes. These probes are compiled out by default. If you compile the program with the preprocessor option -DTNF_DEBUG (see cc(1B)), or with the preprocessor control statement #define TNF_DEBUG ahead of the #include < tnf/probe.h> statement, the debug probes will be compiled into the program. When compiled in, debug probes differ in only one way from the equivalent production probes. They contain an additional "debug" attribute which may be used to distinguish them from production probes at runtime, for example, when using prex(). Developers are encouraged to embed any number of probes for debugging purposes. Disabled probes have such a small runtime overhead that even large numbers of them do not make a significant impact.

If you compile with the preprocessor option -DNPROBE (see cc(1B)), or place the preprocessor control statement #define NPROBE ahead of the #include <tnf/probe.h> statement, no probes will be compiled into the program.

name

The *name* of the probe should follow the syntax guidelines for identifiers in ANSI C. The use of *name* declares it, hence no separate declaration is necessary. This is a block scope declaration, so it does not affect the name space of the program.

keys

keys is a string of space-separated keywords that specify the groups that the probe belongs to. Semicolons, single quotation marks, and the equal character (=) are not allowed in this string. If any of the groups are enabled, the probe is enabled. *keys* cannot be a variable. It must be a string constant.

detail

detail is a string that consists of <attribute> <value> pairs that are each separated by a semicolon. The first word (up to the space) is considered to be the attribute and the rest of the string (up to the semicolon) is considered the value. Single quotation marks are used to denote a string value. Besides quotation marks, spaces separate multiple values. The value is optional. Although semicolons or single quotation marks generally are not allowed within either the attribute or the value, when text with embedded spaces is meant to denote a single value, use single quotes surrounding this text.

Use *detail* for one of two reasons. First, use *detail* to supply an attribute that a user can type into prex(1) to select probes. For example, if a user defines an attribute called color, then prex(1) can select probes based on the value of color. Second, use *detail* to annotate a probe with a string that is written out to a trace file only once. prex(1) uses

TNF_PROBE(3TNF)

spaces to tokenize the value when searching for a match. Spaces around the semicolon delimiter are allowed. *detail* cannot be a variable; it must be a string constant. For example, the *detail* string:

```
"XYZ%debug 'entering function A'; XYZ%exception 'no file'; XYZ%func_entry; XYZ%color red blue"
```

consists of 4 units:

Attribute	Value	Values that prex matches on
XYZ%debug	'entering function A'	'entering function A'
XYZ%exception	'no file'	'no file'
XYZ%func_entry	/.*/	(regular expression)
XYZ%color	red blue	red <or> blue</or>

Attribute names must be prefixed by the vendor stock symbol followed by the '%' character. This avoids conflicts in the attribute name space. All attributes that do not have a '%' character are reserved. The following attributes are predefined:

Attribute	Semantics
name	name of probe
keys	keys of the probe (value is space– separated tokens)
file	file name of the probe
line	line number of the probe
slots	slot names of the probe event (arg_name_n)
object	the executable or shared object that this probe is in.
debug	distinguishes debug probes from production probes

arg_type_n

This is the type of the *n*th argument. The following are predefined TNF types:

tnf Type	Associated C type (and semantics)
tnf_int	int
tnf_uint	unsigned int

tnf Type	Associated C type (and semantics)
tnf_long	long
tnf_ulong	unsigned long
tnf_longlong	long long (if implemented in compilation system)
tnf_ulonglong	unsigned long long (if implemented in compilation system)
tnf_float	float
tnf_double	double
tnf_string	char *
tnf_opaque	void *

To define new TNF types that are records consisting of the predefined TNF types or references to other user defined types, use the interface specified in TNF DECLARE RECORD(3TNF).

arg_name_n

<code>arg_name_n</code> is the name that the user associates with the <code>n</code>th argument. Do not place quotation marks around <code>arg_name_n</code>. Follow the syntax guidelines for identifiers in ANSI C. The string version of <code>arg_name_n</code> is stored for every probe and can be accessed as the attribute "slots".

arg_value_n

<code>arg_value_n</code> is evaluated to yield a value to be included in the trace file. A read access is done on any variables that are in mentioned in <code>arg_value_n</code>. In a multi-threaded program, it is the user's responsibility to place locks around the <code>TNF_PROBE</code> macro if <code>arg_value_n</code> contains a variable that should be read protected.

EXAMPLES

EXAMPLE 1 tracing(3TNF).

See tracing(3TNF) for complete examples showing debug and production probes in source code.

NOTES

If attaching to a running program with prex(1) to control the probes, compile the program with -ltnfprobe or start the program with the environment variable LD_PRELOAD set to libtnfprobe.so.1. See ld(1). If libtnfprobe is explicitly linked into the program, it must be before libthread on the link line.

tnf process disable(3TNF)

NAME |

tnf process disable, tnf process enable, tnf thread disable, tnf thread enable - probe control internal interface

SYNOPSIS

```
cc [ flag ... ] file ... -ltnfprobe [ library ... ]
#include <tnf/probe.h>
void tnf process disable(void);
void tnf process enable(void);
void tnf thread disable(void);
void tnf thread enable(void);
```

DESCRIPTION

There are three levels of granularity for controlling tracing and probe functions (called probing from here on) — probing for the entire process, a particular thread, and the probe itself can be disabled/enabled. The first two (process and thread) are controlled by this interface. The probe is controlled via the application prex(1).

tnf process disable() turns off probing for the process. The default process state is to have probing enabled. tnf process enable() turns on probing for the process.

tnf thread disable() turns off probing for the currently running thread. Threads are "born" or created with this state enabled. tnf thread enable() turns on probing for the currently running thread. If the program is a non-threaded program, these two thread interfaces disable or enable probing for the process.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnfd
MT-Level	MT-Safe

SEE ALSO

prex(1), tnfdump(1), TNF DECLARE RECORD(3TNF), TNF PROBE(3TNF), attributes(5)

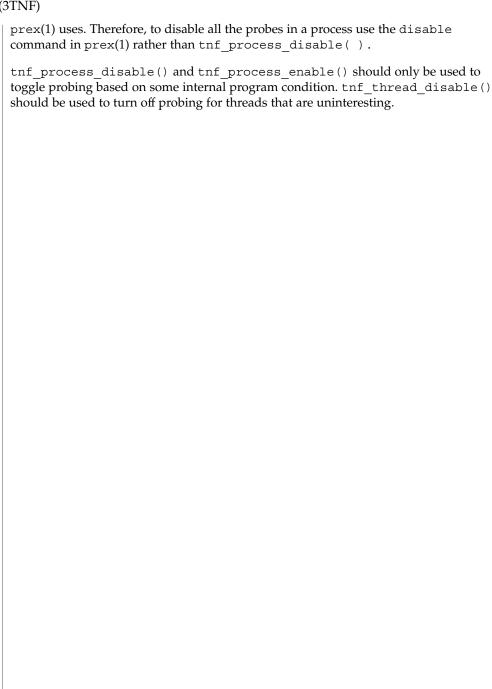

NOTES

A probe is considered enabled only if:

- prex(1) has enabled the probe AND
- the process has probing enabled which is the default or could be set via tnf process enable() AND
- the thread that hits the probe has probing enabled which is every thread's default or could be set via tnf thread enable().

There is a run time cost associated with determining that the probe is disabled. To reduce the performance effect of probes, this cost should be minimized. The quickest way that a probe can be determined to be disabled is by the enable control that

tnf_process_disable(3TNF)

NAME

tracing – overview of tnf tracing system

DESCRIPTION

tnf tracing is a set of programs and API's that can be used to present a high-level view of the performance of an executable, a library, or part of the kernel. tracing is used to analyze a program's performance and identify the conditions that produced a bug.

The core elements of tracing are:

The core elements of cracing are.		
TNF_PROBE_*()	The TNF_PROBE_* () macros define "probes" to be placed in code which, when enabled and executed, cause information to be added to a trace file. See TNF_PROBE(3TNF). If there are insufficient TNF_PROBE_* macros to store all the data of interest for a probe, data may be grouped into records. See TNF_DECLARE_RECORD(3TNF).	
prex	Displays and controls probes in running software. See prex(1).	
kernel probes	A set of probes built into the Solaris kernel which capture information about system calls, multithreading, page faults, swapping, memory management, and I/O. You can use these probes to obtain detailed traces of kernel activity under your application workloads. See tnf_kernel_probes(4).	
tnfxtract	A program that extracts the trace data from the kernel's in-memory buffer into a file. See tnfxtract(1).	
tnfdump	A program that displays the information from a trace file. See tnfdump(1).	
libtnfctl	A library of interfaces that controls probes in a process. See libtnfctl(3TNF). prex(1) also utilizes this library. Other tools and processes use the libtnfctl interfaces to exercise fine control over their own probes.	
<pre>tnf_process_enable()</pre>	A routine called by a process to turn on tracing and probe functions for the current process. See tnf_process_enable(3TNF).	
<pre>tnf_process_disable()</pre>	A routine called by a process to turn off tracing and probe functions for the current process. See tnf_process_disable(3TNF).	
<pre>tnf_thread_enable()</pre>	A routine called by a process to turn on tracing and probe functions for the currently running thread. See tnf_thread_enable(3TNF).	

tnf_thread_disable() A routine called by a process to turn off tracing and probe functions for the currently running thread. See tnf_thread_disable(3TNF).

EXAMPLES

EXAMPLE 1 Tracing a Process

The following function in some daemon process accepts job requests of various types, queueing them for later execution. There are two "debug probes" and one "production probe." Note that probes which are intended for debugging will not be compiled into the final version of the code; however, production probes are compiled into the final product.

```
\mbox{\ensuremath{\star}} To compile in all probes (for development):
      cc -DTNF DEBUG ...
  * To compile in only production probes (for release):
 * To compile in no probes at all:
      cc -DNPROBE ...
 * /
#include <tnf/probe.h>
void work(long, char *);
enum work request type { READ, WRITE, ERASE, UPDATE };
static char *work request name[] = {"read", "write", "erase", "update"};
main()
 long i:
 for (i = READ; i <= UPDATE; i++)
    work(i, work request name[i]);
void work(long request_type, char *request_name)
    static long g length;
    TNF PROBE 2 DEBUG(work start, "work",
        "XYZ%debug 'in function work'",
       tnf_long, request_type_arg, request_type,
       tnf_string, request_name_arg, request_name);
    /* assume work request is queued for later processing */
    q_length++;
    TNF_PROBE_1(work_queue, "work queue",
        "XYZ%work load heavy",
        tnf_long, queue_length, q_length);
    TNF PROBE 0 DEBUG(work end, "work", "");
```

The production probe "work_queue," which remains compiled in the code, will, when enabled, log the length of the work queue each time a request is received.

The debug probes "work_start" and "work_end," which are compiled only during the development phase, track entry to and exit from the work() function and measure how much time is spent executing it. Additionally, the debug probe "work_start" logs the value of the two incoming arguments request type and request name. The

EXAMPLE 1 Tracing a Process (Continued)

runtime overhead for disabled probes is low enough that one can liberally embed them in the code with little impact on performance.

For debugging, the developer would compile with -DTNF_DEBUG, run the program under control of prex(1), enable the probes of interest (in this case, all probes), continue the program until exit, and dump the trace file:

For the production version of the system, the developer simply compiles without -DTNF DEBUG.

EXAMPLE 2 Tracing the Kernel

Kernel tracing is similar to tracing a process; however, there are some differences. For instance, to trace the kernel, you need superuser privileges. The following example uses prex(1) and traces the probes in the kernel that capture system call information.

```
Allocate kernel
trace buffer and capture trace data:
root# prex -k
Type "help" for help ...
prex> buffer alloc 2m # allocate kernel trace buffer
Buffer of size 2097152 bytes allocated
# (keys=syscall)
<syscall probes list output here>
prex> enable syscall
                         # enable only syscall probes
prex> ktrace on
                        # turn on kernel tracing
<Run your application in another window at this point>
Extract the kernel's trace buffer into a file:
root# tnfxtract /tmp/ktrace # extract kernel trace buffer
Reset kernel tracing:
root# prex -k
```

tracing(3TNF)

EXAMPLE 2 Tracing the Kernel (Continued)

CAUTION: Do not deallocate the trace buffer until you have extracted it into a trace file. Otherwise, you will lose the trace data that you collected from your experiment!

Examine the kernel trace file:

prex can also attach to a running process, list probes, and perform a variety of other tasks.

NAME | volmgt_acquire – reserve removable media device

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <sys/types.h>
#include <volmgt.h>
int volmgt acquire (char *dev, char *id, int ovr, char **err, pid t
```

DESCRIPTION

The volmgt acquire() routine reserves the removable media device specified as dev. volmqt acquire() operates in two different modes, depending on whether or not Volume Management is running. See vold(1M).

If Volume Management is running, volmgt acquire() attempts to reserve the removable media device specified as dev. Specify dev as either a symbolic device name (for example, floppy0) or a physical device pathname (for example, /vol/dsk/unnamed floppy).

If Volume Management is not running, volmgt acquire() requires callers to specify a physical device pathname for dev. Specifying dev as a symbolic device name is not acceptable. In this mode, volmgt acquire() relies entirely on the major and minor numbers of the device to determine whether or not the device is reserved.

If dev is free, volmgt acquire() updates the internal device reservation database with the caller's process id (pid) and the specified id string.

If dev is reserved by another process, the reservation attempt fails and volmgt acquire():

- sets errno to EBUSY
- fills the caller's id value in the array pointed to by err
- fills in the pid to which the pointer pidp points with the pid of the process which holds the reservation, if the supplied *pidp* is non-zero

If the override *ovr* is non-zero, the call overrides the device reservation.

RETURN VALUES

Upon successful completion, volmgt acquire() returns a non-zero value.

Upon failure, volmgt acquire() returns 0. If the return value is 0, and errno is set to EBUSY, the address pointed to by err contains the string that was specified as id (when the device was reserved by the process holding the reservation).

ERRORS

The volmgt acquire () routine fails if one or more of the following are true:

EINVAL One of the specified arguments is invalid or missing.

dev is already reserved by another process (and ovr was not set to a **EBUSY**

non-zero value)

volmgt_acquire(3VOLMGT)

EXAMPLES

EXAMPLE 1 Using volmgt acquire()

In the following example, Volume Management is running and the first floppy drive is reserved, accessed and released.

EXAMPLE 2 Using volmgt_acquire() To Override A Lock On Another Process

The following example shows how callers can override a lock on another process using volmqt acquire().

```
char *errp, buf[20];
int override = 0;
pid_t pid;
if (!volmgt acquire("floppy0", "FileMgr", 0, &errp,
    &pid)) {
     if (errno == EBUSY) {
            (void) printf("override %s (pid=%ld)?\n",
              errp, pid); {
             (void) fgets(buf, 20, stdin);
            if (buf[0] == 'y') {
                  override++;
       } else {
            /* handle other errors */
if (override) {
     if (!volmgt_acquire("floppy0", "FileMgr", 1,
         &errp, NULL)) {
           /* really give up this time! */
     }
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

vold(1M), free(3C), malloc(3C), volmgt release(3VOLMGT), attributes(5)

NOTES

When returning a string through *err*, volmgt acquire() allocates a memory area using malloc(3C). Use free(3C) to release the memory area when no longer needed.

The *ovr* argument is intended to allow callers to override the current device reservation. It is assumed that the calling application has determined that the current reservation can safely be cleared. See EXAMPLES.

volmgt_check(3VOLMGT)

NAME |

volmgt_check - have Volume Management check for media

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
int volmgt check(char *pathname);
```

DESCRIPTION

This routine asks Volume Management to check the specified *pathname* and determine if new media has been inserted in that drive.

If a null pointer is passed in, then Volume Management will check each device it is managing that can be checked.

If new media is found, volmgt_check() tells Volume Management to initiate any "actions" specified in /etc/vold.conf (see vold.conf(4)).

RETURN VALUES

This routine returns 0 if no media was found, and a non-zero value if any media was found.

ERRORS

This routine can fail, returning 0, if a stat(2) or open(2) of the supplied *pathname* fails, or if any of the following is true:

ENXIO Volume Management is not running.

EINTR An interrupt signal was detected while checking for media.

EXAMPLES

EXAMPLE 1 Checking If Any New Media Is Inserted

To check if any drive managed by Volume Management has any new media inserted in it:

```
if (volmgt_check(NULL)) {
          (void) printf("Volume Management found media\n");
}
```

This would also request Volume Management to take whatever action was specified in /etc/vold.conf for any media found.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

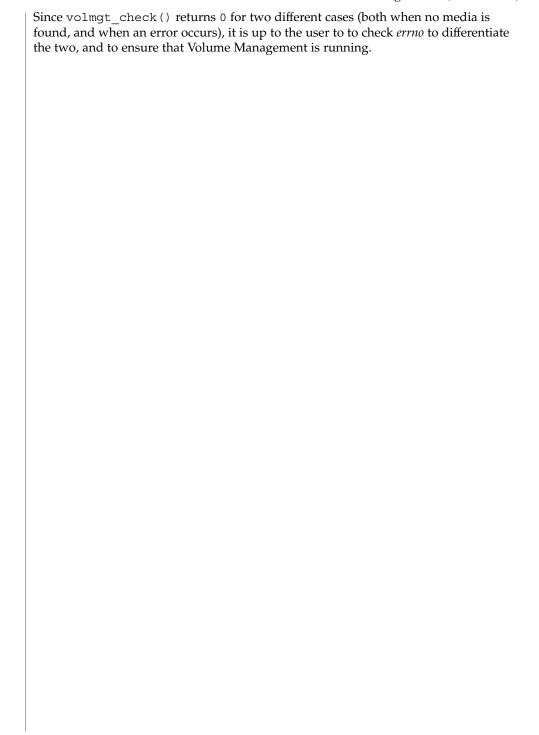

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

cc(1B), volcheck(1), vold(1M), open(2), stat(2), volmgt_inuse(3VOLMGT), volmgt_running(3VOLMGT), vold.conf(4), attributes(5), volfs(7FS)

NOTES

Volume Management must be running for this routine to work.

volmgt_feature_enabled(3VOLMGT)

NAME |

volmgt_feature_enabled – check whether specific Volume Management features are enabled

SYNOPSIS

```
cc [ flag ... ] file ... -1 volmgt [ library ... ]
#include <volmgt.h>
int volmgt feature enabled(char *feat_str);
```

DESCRIPTION

The <code>volmgt_feature_enabled()</code> routine checks whether specific Volume Management features are enabled. <code>volmgt_feature_enabled()</code> checks for the Volume Management features passed in to it by the <code>feat_str</code> parameter.

Currently, the only supported feature string that volmgt_feature_enabled() checks for is floppy-summit-interfaces. The floppy-summit-interfaces feature string checks for the presence of the libvolmgt routines volmgt acquire() and volmgt release().

The list of features that volmgt_feature_enabled() checks for is expected to expand in the future.

RETURN VALUES

0 is returned if the specified feature is not currently available. A non-zero value indicates that the specified feature is currently available.

EXAMPLES

EXAMPLE 1 A sample of the volmgt_feature_enabled() function.

In the following example, volmgt_feature_enabled() checks whether the floppy-summit-interfaces feature is enabled.

```
if (volmgt_feature_enabled("floppy-summit-interfaces")) {
          (void) printf("Media Sharing Routines ARE present\n");
} else {
          (void) printf("Media Sharing Routines are NOT present\n");
}
```

ATTRIBUTES

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

volmgt acquire(3VOLMGT), volmgt release(3VOLMGT), attributes(5)

NAME

volmgt_inuse - check whether or not Volume Management is managing a pathname

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
```

int volmgt inuse(char *pathname);

DESCRIPTION

volmgt_inuse() checks whether Volume Management is managing the specified
pathname.

RETURN VALUES

A non-zero value is returned if Volume Management is managing the specified *pathname*, otherwise 0 is returned.

ERRORS

This routine can fail, returning 0, if a stat(2) of the supplied *pathname* or an open(2) of /dev/volctl fails, or if any of the following is true:

ENXIO Volume Management is not running.

EINTR An interrupt signal was detected while checking for the supplied

pathname for use.

EXAMPLES

EXAMPLE 1 Using volmgt_inuse()

To see if Volume Management is managing the first floppy disk:

```
if (volmgt_inuse("/dev/rdiskette0") != 0) {
          (void) printf("volmgt is managing diskette 0\n");
} else {
          (void) printf("volmgt is NOT managing diskette 0\n");
}
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

cc(1B), vold(1M), open(2), stat(2), errno(3C), $volmgt_check(3VOLMGT)$, $volmgt_running(3VOLMGT)$, attributes(5), volfs(7FS)

NOTES

This routine requires Volume Management to be running.

Since <code>volmgt_inuse()</code> returns 0 for two different cases (both when a volume is not in use, and when an error occurs), it is up to the user to check <code>errno</code> to differentiate the two, and to ensure that Volume Management is running.

volmgt_ownspath(3VOLMGT)

NAME |

volmgt_ownspath - check Volume Management name space for path

SYNOPSIS

```
cc [flag ...] file ...-lvolgmt [library ...]
#include <volmgt.h>
```

int volmgt_ownspath(char *path);

DESCRIPTION

volmgt_ownspath() checks to see if a given path is contained in the Volume Management name space. This is achieved by comparing the beginning of the supplied path name with the output from volmgt root(3VOLMGT)

PARAMETERS

path A string containing the path.

RETURN VALUES

non-zero The *path* is owned by Volume Management.

o volgmt () does not have *path* in its name space, or Volume

Management is not running.

EXAMPLES

EXAMPLE 1 Using volmgt ownspath()

The following example first checks if volmgt () is running, then checks the Volume Management name space for *path*, and then returns the *id* for the piece of media.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT Level	Safe
Commitment Level	Public

SEE ALSO

NAME | volmgt_release - release removable media device reservation

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
int volmgt release(char *dev);
```

DESCRIPTION

The volmqt release () routine releases the removable media device reservation specified as dev. See volmgt acquire(3VOLMGT) for a description of dev.

If dev is reserved by the caller, volmqt release() updates the internal device reservation database to indicate that the device is no longer reserved. If the requested device is reserved by another process, the release attempt fails and errno is set to 0.

RETURN VALUES

Upon successful completion, volmgt release returns a non-zero value. Upon failure, 0 is returned.

ERRORS

On failure, volmgt release () returns 0, and sets errno for one of the following conditions:

EINVAL dev was invalid or missing.

EBUSY dev was not reserved by the caller.

EXAMPLES

EXAMPLE 1 Using volmgt release()

In the following example, Volume Management is running, and the first floppy drive is reserved, accessed and released.

```
#include <volmgt.h>
char *errp;
if (!volmgt_acquire("floppy0", "FileMgr", 0, &errp,
   NULL)) {
    /* handle error case */
/* floppy acquired - now access it */
if (!volmgt release("floppy0")) {
   /* handle error case */
```

volmgt_root(3VOLMGT)

NAME |

volmgt_root – return the Volume Management root directory

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
const char *volmgt root(void);
```

DESCRIPTION

The volmgt_root() function returns the current Volume Management root directory, which by default is /vol but can be configured to be in a different location.

RETURN VALUES

The volmgt_root () function returns pointer to a static string containing the root directory for Volume Management.

ERRORS

This function may fail if an open () of /dev/volctl fails. If this occurs a pointer to the default Volume Management root directory is returned.

EXAMPLES

EXAMPLE 1 Finding the Volume Management root directory.

To find out where the Volume Management root directory is:

```
if ((path = volmgt_root()) != NULL) {
          (void) printf("Volume Management root dir=%s\n", path);
} else {
          (void) printf("can't find Volume Management root dir\n");
}
```

FILES

/vol

default location for the Volume Management root directory

NOTES

This function returns the default root directory location even when Volume Management is not running.

NAME

volmgt_running - return whether or not Volume Management is running

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
int volmgt running(void);
```

DESCRIPTION

volmgt running() tells whether or not Volume Management is running.

RETURN VALUES

A non-zero value is returned if Volume Management is running, else 0 is returned.

ERRORS

 $volmgt_running()$ will fail, returning 0, if a stat(2) or open(2) of dev/volctl fails, or if any of the following is true:

ENXIO Volume Management is not running.

EINTR An interrupt signal was detected while checking to see if Volume

Management was running.

EXAMPLES

EXAMPLE 1 Using volmgt running()

To see if Volume Management is running:

```
if (volmgt_running() != 0) {
          (void) printf("Volume Management is running\n");
} else {
          (void) printf("Volume Management is NOT running\n");
}
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

cc(1B), vold(1M), open(2), stat(2), $volmgt_check(3VOLMGT)$, $volmgt_inuse(3VOLMGT)$, attributes(5), volfs(7FS)

NOTES

Volume Management must be running for many of the Volume Management library routines to work.

volmgt_symname(3VOLMGT)

NAME |

volmgt_symname, volmgt_symdev – convert between Volume Management symbolic names, and the devices that correspond to them

SYNOPSIS

```
cc [ flag ... ] file ... -lvolmgt [ library ... ]
#include <volmgt.h>
char *volmgt_symname(char *pathname);
char *volmgt symdev(char *symname);
```

DESCRIPTION

These two routines compliment each other, translating between Volume Management's symbolic name for a device, called a *symname*, and the /dev *pathname* for that same device.

volmgt_symname() converts a supplied /dev pathname to a symname, Volume Management's idea of that device's symbolic name (see volfs(7FS) for a description of Volume Management symbolic names).

volmgt_symdev() does the opposite conversion, converting between a *symname*, Volume Management's idea of a device's symbolic name for a volume, to the /dev *pathname* for that device.

RETURN VALUES

volmgt_symname() returns the symbolic name for the device pathname supplied,
and volmgt_symdev() returns the device pathname for the supplied symbolic name.

These strings are allocated upon success, and therefore must be freed by the caller when they are no longer needed (see free(3C)).

ERRORS

volmgt_symname() can fail, returning a null string pointer, if a stat(2) of the supplied pathname fails, or if an open(2) of /dev/volctl fails, or if any of the following is true:

ENXIO Volume Management is not running.

EINTR An interrupt signal was detected while trying to convert the

supplied *pathname* to a *symname*.

 $volmgt_symdev()$ can fail if an open(2) of /dev/volctl fails, or if any of the following is true:

ENXIO Volume Management is not running.

EINTR An interrupt signal was detected while trying to convert the

supplied symname to a /dev pathname.

EXAMPLES

EXAMPLE 1 Testing Floppies

The following tests how many floppies Volume Management currently sees in floppy drives (up to 10):

```
for (i=0; i < 10; i++) {
    (void) sprintf(path, "floppy%d", i);
    if (volmgt_symdev(path) != NULL) {</pre>
```

EXAMPLE 1 Testing Floppies (Continued)

```
(void) printf("volume %s is in drive d\n",
                   path, i);
}
```

EXAMPLE 2 Finding The Symbolic Name

This code finds out what symbolic name (if any) Volume Management has for /dev/rdsk/c0t6d0s2:

```
if ((nm = volmgt_symname("/dev/rdsk/c0t6d0s2")) == NULL) \{
        (void) printf("path not managed\n");
} else {
        (void) printf("path managed as %s\n", nm);
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

```
cc(1B), vold(1M), open(2), stat(2), free(3C), malloc(3C),
volmgt_check(3VOLMGT), volmgt inuse(3VOLMGT),
volmgt running(3VOLMGT), attributes(5), volfs(7FS)
```

NOTES

These routines only work when Volume Management is running.

BUGS

There should be a straightforward way to query Volume Management for a list of all media types it's managing, and how many of each type are being managed.

wsreg_add_child_component(3WSREG)

NAME |

wsreg add child component, wsreg remove child component, wsreg_get_child_components - add or remove a child component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

int wsreg add child component (Wsreg component *comp, const Wsreq component *childComp);

int wsreg_remove_child_component(Wsreg_component *comp, const Wsreg component *childComp);

Wsreg component **wsreg get child components(const Wsreq component *comp);

DESCRIPTION

The wsreg add child component() function adds the component specified by childComp to the list of child components contained in the component specified by comp.

The wsreg remove child component () function removes the component specified by childComp from the list of child components contained in the component specified by *comp*.

The wsreg get child components() function returns the list of child components contained in the component specified by comp.

RETURN VALUES

The wsreg add child component () function returns a non-zero value if the specified child component was successfully added; otherwise, 0 is returned.

The wsreg remove child component() function returns a non-zero value if the specified child component was successfully removed; otherwise, 0 is returned.

The wsreq get child components() function returns a null-terminated array of Wareq component pointers that represents the specified component's list of child components. If the specified component has no child components, NULL is returned. The resulting array must be released by the caller through a call to wsreg free component array(). See wsreg create component(3WSREG).

USAGE

The parent-child relationship between components in the product install registry is used to record a product's structure. Product structure is the arrangement of features and components that make up a product. The structure of installed products can be displayed with the prodreg GUI.

The child component must be installed and registered before the parent component can be. The registration of a parent component that has child components results in each of the child components being updated to reflect their parent component.

Read access to the product install registry is required in order to use these functions because these relationships are held with lightweight component references that can only be fully resolved using the registry contents.

wsreg_add_child_component(3WSREG)

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

wsreg_add_compatible_version(3WSREG)

NAME |

wsreg_add_compatible_version, wsreg_remove_compatible_version, wsreg_get_compatible_versions – add or remove a backward-compatible version

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

char **wsreg_get_compatible_versions(const Wsreg_component
 *comp);

DESCRIPTION

The wsreg_add_compatible_version() function adds the version string specified by *version* to the list of backward-compatible versions contained in the component specified by *comp*.

The wsreg_remove_compatible_version() function removes the version string specified by *version* from the list of backward-compatible versions contained in the component specified by *comp*.

The wsreg_get_compatible_versions() function returns the list of backward-compatible versions contained in the component specified by *comp*.

RETURN VALUES

The wsreg_add_compatible_version() function returns a non-zero value if the specified backward-compatible version was successfully added; otherwise, 0 is returned.

The wsreg_remove_compatible_version() function returns a non-zero value if the specified backward-compatible version was successfully removed; otherwise, 0 is returned.

The wsreg_get_compatible_versions() function returns a null-terminated array of char pointers that represents the specified component's list of backward-compatible versions. If the specified component has no such versions, NULL is returned. The resulting array and its contents must be released by the caller.

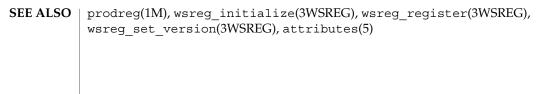

USAGE

The list of backward compatible versions is used to allow components that are used by multiple products to upgrade successfully without compromising any of its dependent products. The installer that installs such an update can check the list of backward-compatible versions and look at what versions are required by all of the dependent components to ensure that the upgrade will not result in a broken product.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

wsreg_add_dependent_component(3WSREG)

NAME |

wsreg_add_dependent_component, wsreg_remove_dependent_component, wsreg_get_dependent_components – add or remove a dependent component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

- int wsreg_add_dependent_component(Wsreg_component *comp, const
 Wsreg_component *dependentComp);
- int wsreg_remove_dependent_component (Wsreg_component *comp, const
 Wsreg_component *dependentComp);

DESCRIPTION

The wsreg_add_dependent_component() function adds the component specified by *dependentComp* to the list of dependent components contained in the component specified by *comp*.

The wsreg_remove_dependent_component() function removes the component specified by *dependentComp* from the list of dependent components contained in the component specified by *comp*.

The wsreg_get_dependent_components() function returns the list of dependent components contained in the component specified by *comp*.

RETURN VALUES

The wsreg_add_dependent_component() function returns a non-zero value if the specified dependent component was successfully added; otherwise, 0 is returned.

The wsreg_remove_dependent_component () function returns a non-zero value if the specified dependent component was successfully removed; otherwise, 0 is returned.

The wsreg_get_dependent_components() function returns a null-terminated array of Wsreg_component pointers that represents the specified component's list of dependent components. If the specified component has no dependent components, NULL is returned. The resulting array must be released by the caller through a call to wsreg free component array(). See wsreg create component(3WSREG).

USAGE

The relationship between two components in which one must be installed for the other to be complete is a dependent/required relationship. The component that is required by the other component is the required component. The component that requires the other is the dependent component.

The required component must be installed and registered before the dependent component can be. Uninstaller applications should check the registry before uninstalling and unregistering components so a successful uninstallation of one product will not result in another product being compromised.

wsreg_add_dependent_component(3WSREG)

Read access to the product install registry is required to use these functions because these relationships are held with lightweight component references that can only be fully resolved using the registry contents.

The act of registering a component having required components results in the converse dependent relationships being established automatically.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

wsreg_add_display_name(3WSREG)

NAME |

wsreg_add_display_name, wsreg_remove_display_name, wsreg_get_display_name, wsreg_get_display_languages – add, remove, or return a localized display name

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

- int wsreg_add_display_name(Wsreg_component *comp, const char
 *language, const char *display_name);
- int wsreg_remove_display_name(Wsreg_component *comp, const char
 *language);
- char **wsreg_get_display languages(const Wsreg component *comp);

DESCRIPTION

For each of these functions, the *comp* argument specifies the component on which these functions operate. The *language* argument is the ISO 639 language code identifying a particular display name associated with the specified component.

The wsreg_add_display_name() function adds the display name specified by *display_name* to the component specified by *comp*.

The wsreg_remove_display_name() function removes a display name from the component specified by *comp*.

The wsreg_get_display_name() function returns a display name from the component specified by *comp*.

The wsreg_get_display_languages () returns the ISO 639 language codes for which display names are available from the component specified by *comp*.

RETURN VALUES

The wsreg_add_display_name() function returns a non-zero value if the display name was set correctly; otherwise 0 is returned.

The wsreg_remove_display_name() function returns a non-zero value if the display name was removed; otherwise 0 is returned.

The wsreg_get_display_name() function returns the display name from the specified component if the component has a display name for the specified language code. Otherwise, NULL is returned. The caller must not free the resulting display name.

The wsreg_get_display_languages() function returns a null-terminated array of ISO 639 language codes for which display names have been set into the specified component. If no display names have been set, NULL is returned. It is the caller's responsibility to release the resulting array, but not the contents of the array.

ATTRIBUTES

```

- int wsreg_add_required_component(Wsreg_component *comp, const
 Wsreg_component *requiredComp);
- int wsreg_remove_required_component(Wsreg_component *comp, const
 Wsreg_component *requiredComp);

DESCRIPTION

The wsreg_add_required_component() function adds the component specified by *requiredComp* to the list of required components contained in the component specified by *comp*.

The wsreg_remove_required_component() function removes the component specified by *requiredComp* from the list of required components contained in the component specified by *comp*.

The wsreg_get_required_components() function returns the list of required components contained in the component specified by *comp*.

RETURN VALUES

The wsreg_add_required_component() function returns a non-zero value if the specified required component was successfully added. Otherwise, 0 is returned.

The wsreg_remove_required_component() function returns a non-zero value if the specified required component was successfully removed. Otherwise, 0 is returned.

The wsreg_get_required_components() function returns a null-terminated array of Wsreg_component pointers that represents the specified component's list of required components. If the specified component has no required components, NULL is returned. The resulting array must be released by the caller through a call to wsreg_free_component_array(). See wsreg_create_component(3WSREG).

USAGE

The relationship between two components in which one must be installed for the other to be complete is a dependent/required relationship. The component that is required by the other component is the required component. The component that requires the other is the dependent component.

The required component must be installed and registered before the dependent component can be. Uninstaller applications should check the registry before uninstalling and unregistering components so a successful uninstallation of one product will not result in another product being compromised.

Read access to the product install registry is required in order to use these functions because these relationships are held with lightweight component references that can only be fully resolved using the registry contents.

wsreg_can_access_registry(3WSREG)

NAME | wsreg can access registry – determine access to product install registry

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <fcntl.h>
#include <wsreq.h>
int wsreg can access registry (int access_flag);
```

DESCRIPTION

The wsreg can access registry() function is used to determine what access, if any, an application has to the product install registry.

The access_flag argument can be one of the following:

Inquire about read only access to the registry. O RDONLY

O RDWR Inquire about modify (read and write) access to the registry.

RETURN VALUES

The wsreg can access registry () function returns non-zero if the specified access level is permitted. A return value of 0 indicates the specified access level is not permitted.

EXAMPLES

EXAMPLE 1 Initialize the registry and determine if access to the registry is permitted.

```
#include <fcntl.h>
#include <wsreq.h>
int main(int argc, char **argv)
    int result;
    if (wsreg initialize(WSREG INIT NORMAL, NULL)) {
       printf("conversion recommended, sufficient access denied\n");
    if (wsreg_can_access_registry(O_RDONLY)) {
       printf("registry read access granted\n");
    } else {
       printf("registry read access denied\n");
    if (wsreg can access registry(O RDWR)) {
       printf("registry read/write access granted\n");
    } else {
       printf("registry read/write access denied\n");
}
```

USAGE

The wsreg initialize(3WSREG) function must be called before calls to wsreg can access registry() can be made.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

wsreg_clone_component(3WSREG)

NAME | wsreg_clone_component – clone a component

SYNOPSIS

cc [flag ...] file ...-lwsreg [library ...]

#include <wsreg.h>

Wsreg component *wsreg clone component (const Wsreg component

DESCRIPTION

The wsreg clone component () function clones the component specified by *comp*.

RETURN VALUES

The wsreq clone component () returns a pointer to a component that is

configured exactly the same as the component specified by comp.

USAGE

The resulting component must be released through a call to

wsreg free component () by the caller. See

wsreg create component(3WSREG).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

NAME | wsreg_components_equal – determine equality of two components

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

int wsreg components equal(const Wsreg component *comp1, const Wsreg component *comp2);

DESCRIPTION

The wsreg components equal () function determines if the component specified by the *comp1* argument is equal to the component specified by the *comp2* argument. Equality is evaluated based only on the content of the two components, not the order in which data was set into the components.

RETURN VALUES

The wsreg components equal () function returns a non-zero value if the component specified by the comp1 argument is equal to the component specified by the *comp*2 argument. Otherwise, 0 is returned.

ATTRIBUTES

wsreg_create_component(3WSREG)

NAME |

wsreg_create_component, wsreg_free_component, wsreg_free_component_array – create or release a component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

Wsreg component *wsreg create component(const char *uuid);

void wsreg free component(Wsreg component *comp);

int wsreg free component array(Wsreg component **complist);

DESCRIPTION

The wsreg_create_component() function allocates a new component and assigns the uuid (universal unique identifier) specified by *uuid* to the resulting component.

The wsreg_free_component() function releases the memory associated with the component specified by *comp*.

The wsreg_free_component_array() function frees the null-terminated array of component pointers specified by *complist*. This function can be used to free the results of a call to wsreg_get_all(). See wsreg_get(3WSREG).

RETURN VALUES

The wsreg_create_component() function returns a pointer to the newly allocated Wsreg component structure.

The wsreg_free_component_array() function returns a non-zero value if the specified Wsreg_component array was freed successfully. Otherwise, 0 is returned.

USAGE

A minimal registerable Wsreg_component configuration must include a version, unique name, display name, and an install location.

ATTRIBUTES

NAME | wsreg_get, wsreg_get_all – query product install registry

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

Wsreg component *wsreg get(const Wsreg query *query);

Wsreg component **wsreg get all(void);

DESCRIPTION

The wsreg_get() function queries the product install registry for a component that matches the query specified by *query*.

The wsreg get all() function returns all components currently registered in the product install registry.

RETURN VALUES

The wsreg get () function returns a pointer to a Wsreg component structure representing the registered component. If no component matching the specified query is currently registered, wsreq get () returns NULL.

The wsreg get all() function returns a null-terminated array of Wsreg component pointers. Each element in the resulting array represents one registered component.

USAGE

The wsreg library must be initialized by a call to wsreg initialize(3WSREG) before any call to wsreg get () or wsreg get all().

The Wsreg component pointer returned from wsreg get () should be released through a call to wsreq free component (). See wsreg create component(3WSREG).

The Wsreq component pointer array returned from wsreq get all() should be released through a call to wsreg_free_component_array(). See wsreg create component(3WSREG).

ATTRIBUTES

 *alternate root);

DESCRIPTION

The wsreg initialize() function initializes the wsreg library.

The *level* argument can be one of the following:

WSREG INIT NORMAL If an old registry file is present, attempt to

perform a conversion.

WSREG_INIT_NO_CONVERSION If an old conversion file is present, do not

perform the conversion, but indicate that

the conversion is recommended.

The *alternate_root* argument can be used to specify a root prefix. If NULL is specified, no root prefix is used.

RETURN VALUES

The wsreq initialize() function can return one of the following:

WSREG SUCCESS The initialization was successful and no

registry conversion is necessary.

WSREG CONVERSION RECOMMENDED An old registry file exists and should be

converted.

A conversion is attempted if the <code>init_level</code> argument is <code>WSREG_INIT_NORMAL</code> and a registry file from a previous version of the product install registry exists. If the <code>wsreg_initialize()</code> function returns <code>WSREG_CONVERSION_RECOMMENDED</code>, the user either does not have permission to update the product install registry or does not have read/write access to the previous registry file.

USAGE

The wsreg_initialize() function must be called before any other wsreg library functions.

The registry conversion can take some time to complete. The registry conversion can also be performed using the graphical registry viewer /usr/bin/prodreg or by the registry converter /usr/bin/regconvert.

NAME | wsreg_query_create, wsreg_query_free – create a new query

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

Wsreg query *wsreg query create(void);

void wsreg query free(Wsreg query *query);

DESCRIPTION

The wsreg query create () function allocates a new query that can retrieve components from the product install registry.

The wsreg query free() function releases the memory associated with the query specified by *query*.

RETURN VALUES

The wsreg query create () function returns a pointer to the newly allocated query. The resulting query is completely empty and must be filled in to describe the desired component.

USAGE

The query identifies fields used to search for a specific component in the product install registry. The query must be configured and then passed to the wsreg get(3WSREG) function to perform the registry query.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

wsreg_query_set_id(3WSREG)

NAME | wsreg_query_set_id, wsreg_query_get_id – set or get the uuid of a query

SYNOPSIS

cc [flag ...] file ...-lwsreg [library ...]

#include <wsreg.h>

int wsreg_query_set_id(Wsreg query *query, const char *uuid);

char *wsreg query get id(const Wsreg query *query);

DESCRIPTION

The wsreg query set id() function sets the uuid (universal unique identifier) specified by *uuid* in the query specified by *query*. If a uuid has already been set in the specified query, the resources associated with the previously set uuid are released.

The wsreq guery get id() function returns the uuid associated with the guery specified by query. The resulting string is not a copy and must not be released by the caller.

RETURN VALUES

The wsreg query set id() function returns non-zero if the uuid was set correctly; otherwise 0 is returned.

The wsreg_query_get_id() function returns the uuid associated with the specified query.

USAGE

The query identifies fields used to search for a specific component in the product install registry. By specifying the uuid, the component search is narrowed to all components in the product install registry that have the specified uuid.

Other fields can be specified in the same query to further narrow the search.

ATTRIBUTES

wsreg_query_set_instance(3WSREG)

NAME

wsreg_query_set_instance, wsreg_query_get_instance – set or get the instance of a query

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

int wsreg_query_set_instance(Wsreg_query *query, int instance);

int wsreg query get instance(Wsreg query *comp);

DESCRIPTION

The wsreg_query_set_instance() function sets the instance number specified by *instance* in the query specified by *query*.

The wsreg_query_get_instance() function retrieves the instance from the query specified by *query*.

RETURN VALUES

The wsreg_query_set_instance() function returns a non-zero value if the instance was set correctly; otherwise 0 is returned.

The wsreg_query_get_instance() function returns the instance number from the specified query. It returns 0 if the instance number has not been set.

USAGE

The query identifies fields used to search for a specific component in the product install registry. By specifying the instance, the component search is narrowed to all components in the product install registry that have the specified instance.

Other fields can be specified in the same query to further narrow down the search.

SYNOPSIS

cc [flag ...] file ...-lwsreg [library ...] #include <wsreq.h>

int wsreg query set location (Wsreg query *query, const char *location);

char *wsreg_query_get_location(Wsreg_query *query);

DESCRIPTION

The wsreg guery set location() function sets the location specified by location in the query specified by query. If a location has already been set in the specified query, the resources associated with the previously set location are released.

The wsreg query get location() function gets the location string from the query specified by query.

RETURN VALUES

The wsreg query set location() function returns a non-zero value if the location was set correctly; otherwise 0 is returned.

The wsreg_query_get_location() function returns the location from the specified query structure. The resulting location string is not a copy, so it must not be released by the caller.

USAGE

The query identifies fields used to search for a specific component in the product install registry. By specifying the install location, the component search is narrowed to all components in the product install registry that are installed in the same location.

Other fields can be specified in the same query to further narrow the search.

NAME

wsreg_query_set_unique_name, wsreg_query_get_unique_name – set or get the unique name of a query

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

int wsreg_query_set_unique_name(Wsreg_query *query, const char
 *unique_name);

char *wsreg_query_get_unique_name(const Wsreg query *query);

DESCRIPTION

The wsreg_query_set_unique_name() function sets the unique name specified by *unique_name* in the query specified by *query*. If a unique name has already been set in the specified query, the resources associated with the previously set unique name are released.

The wsreg_query_get_unique_name() function gets the unique name string from the query specified by *query*. The resulting string is not a copy and must not be released by the caller.

RETURN VALUES

The wsreg_query_set_unique_name() function returns a non-zero value if the unique_name was set correctly; otherwise 0 is returned.

The wsreg_query_get_unique_name() function returns a copy of the *unique_name* from the specified query.

USAGE

The query identifies fields used to search for a specific component in the product install registry. By specifying the unique name, the component search is narrowed to all components in the product install registry that have the specified unique name.

Other fields can be specified in the same query to further narrow the search.

NAME | wsreg_query_set_version, wsreg_query_get_version - set or get the version of a query

SYNOPSIS

```
cc [flag ...] file ... -lwsreg [library ...]
#include <wsreg.h>
```

int wsreg query set version (Wsreg query *query, const char

char *wsreg query get version(const Wsreg query *query);

DESCRIPTION

The wsreg query set version() function sets the version specified by version in the query specified by query. If a version has already been set in the specified query, the resources associated with the previously set version are released.

The wsreq query get version() function gets the version string from the query specified by query. The resulting string is not a copy and must not be released by the caller.

RETURN VALUES

The wsreg query set version() function returns a non-zero value if the version was set correctly; otherwise 0 is returned.

The wsreg guery get version() function returns the version from the specified query. If no version has been set, NULLt is returned. The resulting version string is not a copy and must not be released by the caller.

USAGE

The query identifies fields used to search for a specific component in the product install registry. By specifying the version, the component search is narrowed to all components in the product install registry that have the specified version.

Other fields can be specified in the same query to further narrow the search.

NAME

wsreg_register – register a component in the product install registry

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
int wsreq reqister(Wsreq component *comp);
```

DESCRIPTION

The wsreg_register() function updates a component in the product install registry.

If *comp* is already in the product install registry, the call to wsreg_register() results in the currently registered component being updated. Otherwise, *comp* is added to the product install registry.

An instance is assigned to the component upon registration. Subsequent component updates retain the same component instance.

If *comp* has required components, each required component is updated to reflect the required component relationship.

If *comp* has child components, each child component that does not already have a parent is updated to reflect specified component as its parent.

RETURN VALUES

Upon successful completion, a non-zero value is returned. If the component could not be updated in the product install registry, 0 is returned.

EXAMPLES

EXAMPLE 1 Create and register a component.

The following example creates and registers a component.

```
#include <wsreg.h>
int main (int argc, char **argv)
    char *uuid = "d6cf2869-1dd1-11b2-9fcb-080020b69971";
         Wsreg component *comp = NULL;
         /* Initialize the registry */
         wsreg_initialize(WSREG_INIT_NORMAL, NULL);
         /* Create the component */
         comp = wsreg_create_component(uuid);
         wsreg set unique name(comp, "wsreg example 1");
         wsreg set version(comp, "1.0");
         wsreg_add_display_name(comp, "en", "Example 1 component");
         wsreg_set_type(comp, WSREG_COMPONENT);
         wsreg set location(comp, "/usr/local/example1 component");
         /* Register the component */
         wsreg register(comp);
         wsreg_free_component(comp);
         return 0:
}
```

wsreg_register(3WSREG)

USAGE |

A product's structure can be recorded in the product install registry by registering a component for each element and container in the product definition. The product and each of its features would be registered in the same way as a package that represents installed files.

Components should be registered only after they are successfully installed. If an entire product is being registered, the product should be registered after all components and features are installed and registered.

In order to register correctly, the component must be given a uuid, unique name, version, display name, and a location. The location assgined to product structure components should generally be the location in which the user chose to install the product.

NAME |

wsreg_set_data, wsreg_get_data, wsreg_get_data_pairs – add or retrieve a key-value pair

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

char *wsreg get data pairs(const Wsreg component *comp);

DESCRIPTION

The wsreg_set_data() function adds the key-value pair specified by *key* and *value* to the component specified by *comp*. If *value* is NULL, the key and current value is removed from the specified component.

The wsreg_get_data() function retrieves the value associated with the key specified by *key* from the component specified by *comp*.

The wsreg_get_data_pairs() function returns the list of key-value pairs from the component specified by *comp*.

RETURN VALUES

The wsreg_set_data() function returns a non-zero value if the specified key-value pair was successfully added. It returns 0 if the addition failed. If NULL is passed as the value, the current key-value pair are removed from the specified component.

The wsreg_get_data() function returns the value associated with the specified key. It returns NULL if there is no value associated with the specified key. The char pointer that is returned is not a clone, so it must not be freed by the caller.

The wsreg_get_data_pairs() function returns a null-terminated array of char pointers that represents the specified component's list of data pairs. The even indexes of the resulting array represent the key names. The odd indexes of the array represent the values. If the specified component has no data pairs, NULL is returned. The resulting array (not its contents) must be released by the caller.

USAGE

Any string data can be associated with a component. Because this information can be viewed in the prodreg registry viewer, it is a good place to store support contact information.

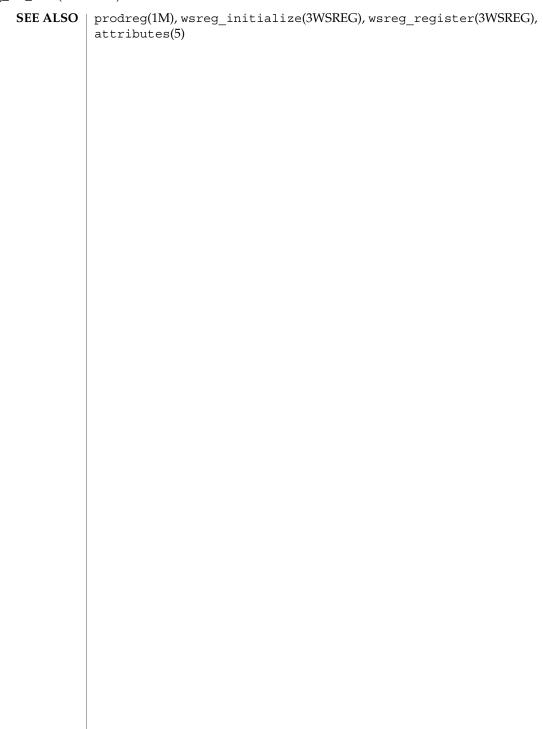

After the data pairs are added or removed, the component must be updated with a call to wsreg_register(3WSREG) for the modifications to be persistent.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

wsreg_set_data(3WSREG)

NAME | wsreg_set_id, wsreg_get_id – set or get the uuid of a component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

int wsreg set id(Wsreg component *comp, const char *uuid);

char *wsreg get id(const Wsreg component *comp);

DESCRIPTION

The wsreg set id() function sets the uuid (universal unique identifier) specified by *uuid* into the component specified by *comp*. If a uuid has already been set into the specified component, the resources associated with the previously set uuid are released.

The wsreq get id() function returns a copy of the uuid of the component specified by comp. The resulting string must be released by the caller.

RETURN VALUES

The wsreg set id() function returns non-zero if the uuid was set correctly; otherwise 0 is returned.

The wsreg get id() function returns a copy of the specified component's uuid.

USAGE

Generally, the uuid will be set into a component by the

wsreg create component(3WSREG) function, so a call to the wsreg set id() is not necessary.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

wsreg create component(3WSREG), wsreg initialize(3WSREG), attributes(5)attributes(5)

wsreg set instance(3WSREG)

NAME | wsreg_set_instance, wsreg_get_instance – set or get the instance of a component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
int wsreg set instance (Wsreg component *comp, int instance);
int wsreg get instance(Wsreg component *comp);
```

DESCRIPTION

The wsreg set instance() function sets the instance number specified by instance of the component specified by comp. The instance number and uuid are used to uniquely identify any component in the product install registry.

The wsreq get instance() function determines the instance number associated with the component specified by *comp*.

RETURN VALUES

The wsreq set instance() function returns a non-zero value if the instance was set correctly; otherwise 0 is returned.

The wsreg get instance() function returns the instance number associated with the specified component.

EXAMPLES

EXAMPLE 1 Get the instance value of a registered component.

The following example demonstrates how how to get the instance value of a registered component.

```
#include <fcntl.h>
#include <wsreq.h>
int main (int argc, char **argv)
    char *uuid = "d6cf2869-1dd1-11b2-9fcb-080020b69971";
    Wsreg component *comp = NULL;
    /* Initialize the registry */
    wsreg initialize(WSREG INIT NORMAL, NULL);
    if (!wsreg_can_access_registry(O_RDWR)) {
       printf("No permission to modify the registry.\
");
       return 1;
    /* Create a component */
    comp = wsreg_create_component(uuid);
    wsreg_set_unique_name(comp, "wsreg_example_1");
    wsreg set version(comp, "1.0");
    wsreg add display name(comp, "en", "Example 1 component");
    wsreg set type(comp, WSREG COMPONENT);
    wsreg set location(comp, "/usr/local/example1 component");
    /* Register */
    wsreg_register(comp);
    printf("Instance %d was assigned\
```

EXAMPLE 1 Get the instance value of a registered component. (*Continued*)

```
", wsreg_get_instance(comp));
    wsreg_free_component(comp);
    return 0;
}
```

USAGE

Upon component registration with the wsreg_register(3WSREG) function, the instance number is set automatically. The instance number of 0 (the default) indicates to the wsreg_register() function that an instance number should be looked up and assigned during registration. If a component with the same uuid and location is already registered in the product install registry, that component's instance number will be used during registration.

After registration of a component, the wsreg_get_instance() function can be used to determine what instance value was assigned.

wsreg_set_location(3WSREG)

NAME | wsreg_set_location, wsreg_get_location - set or get the location of a component

SYNOPSIS

cc [flag ...] file ...-lwsreg [library ...]

#include <wsreg.h>

int wsreg_set_location(Wsreg component *comp, const char *location);

char *wsreg get location(const Wsreg component *comp);

DESCRIPTION

The wsreg set location() function sets the location specified by *location* into the component specified by comp. Every component must have a location before being registered. If a location has already been set into the specified component, the resources associated with the previously set location are released.

The wsreq get location() function gets the location string from the component specified by *comp*. The resulting string must be released by the caller.

RETURN VALUES

The wsreg set location() function returns a non-zero value if the location was set correctly; otherwise 0 is returned.

The wsreg get location() function returns a copy of the location from the specified component.

NAME | wsreg set parent, wsreg get parent - set or get the parent of a component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

void wsreg set parent (Wsreg component *comp, const Wsreg component *parent);

Wsreg component *wsreg get parent(const Wsreg component *comp);

DESCRIPTION

The wsreg set parent () function sets the parent specified by parent of the component specified by comp.

The wsreq get parent () function gets the parent of the component specified by comp.

RETURN VALUES

The wsreq get parent () function returns a pointer to a Wsreq component structure that represents the parent of the specified component. If the specified component does not have a parent, NULL is returned. If a non-null value is returned, it the caller's responsibility to release the memory associated with the resulting Wsreg component pointer with a call to wsreg free component (). See wsreg create component(3WSREG).

USAGE

The parent of a component is set as a result of registering the parent component. When a component that has children is registered, all of the child components are updated to reflect the newly registered component as their parent. This update only occurs if the child component does not already have a parent component set.

The specified parent component is reduced to a lightweight component reference that uniquely identifies the parent in the product install registry. This lightweight reference includes the parent's uuid and instance number.

The parent must be registered before a call to wsreg set parent () can be made, since the parent's instance number must be known at the time the wsreg set parent() function is called.

A process needing to call wsreq set parent() or wsreq get parent() must have read access to the product install registry.

wsreg_set_type(3WSREG)

NAME |

wsreg_set_type, wsreg_get_type – set or get the type of a component

SYNOPSIS

 $\texttt{cc} \hspace{0.2cm} \textit{[flag...]} \hspace{0.2cm} \textit{file...-lwsreg} \hspace{0.2cm} \textit{[library...]}$

#include <wsreg.h>

int wsreg_set_type(Wsreg_component *comp, Wsreg_component_type
 tune):

Wsreg_component_type wsreg_get_type(const Wsreg_component *comp);

DESCRIPTION

The wsreg_set_type() function sets the type specified by *type* in the component specified by *comp*.

The wsreg_get_type() function retrieves the type from the component specified by *comp*.

RETURN VALUES

The wsreg_set_type() function returns a non-zero value if the type is set successfully; otherwise 0 is returned.

The wsreg_get_type() function returns the type currently set in the component specified by *comp*.

USAGE

The component type is used to indicate whether a Wsreg_component structure represents a product, feature, or component. The *type* argument can be one of the following:

WSREG PRODUCT Indicates the Wsreg component represents a product.

A product is a collection of features and/or

components.

WSREG FEATURE Indicates the Wsreg component represents a feature.

A feature is a collection of components.

WSREG COMPONENT Indicates the Wsreg component represents a

component. A component is a collection of files that

may be installed.

NAME |

wsreg_set_uninstaller, wsreg_get_uninstaller – set or get the uninstaller of a component

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreq.h>
```

char *wsreg set uninstaller(const Wsreg component *comp);

DESCRIPTION

The wsreg_set_uninstaller() function sets the uninstaller specified by *uninstaller* in the component specified by *comp*. If an uninstaller has already been set in the specified component, the resources associated with the previously set uninstaller are released.

The wsreg_get_uninstaller() function gets the uninstaller string from the component specified by *comp*. The resulting string must be released by the caller.

RETURN VALUES

The wsreg_set_uninstaller() function returns a non-zero value if the uninstaller was set correctly; otherwise 0 is returned.

The wsreg_get_uninstaller() function returns a copy of the uninstaller from the specified component.

USAGE

An uninstaller is usually only associated with a product, not with every component that comprises a product. The uninstaller string is a command that can be passed to the shell to launch the uninstaller.

If an uninstaller is set in a registered component, the prodreg(1M) registry viewer will provide an uninstall button that will invoke the uninstaller.

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

char *wsreg_get_unique name(const Wsreg component *comp);

DESCRIPTION

The wsreg_set_unique_name() function sets the unique name specified by *unique_name* in the component specified by *comp*. Every component must have a unique name before being registered. If a unique name has already been set in the specified component, the resources associated with the previously set unique name are released.

The wsreg_get_unique_name() function gets the unique name string from the component specified by *comp*. The resulting string must be released by the caller.

RETURN VALUES

The wsreg_set_unique_name() function returns a non-zero value if the unique name was set correctly; otherwise it returns 0.

The wsreg_get_unique_name() function returns a copy of the unique name from the specified component.

NAME | wsreg_set_vendor, wsreg_get_vendor - set or get the vendor of a componentt

SYNOPSIS

```
cc [flag ...] file ...-lwsreg [library ...]
#include <wsreg.h>
```

int wsreg set vendor(Wsreg component *comp, const char *vendor);

char *wsreg get vendor(const Wsreg component *comp);

DESCRIPTION

The wsreg set vendor () function sets the vendor specified by *vendor* in the component specified by comp. The vendor argument is a string that identifies the vendor of the component. If a vendor has already been set in the specified component, the resources associated with the previously set vendor are released.

The wsreq get vendor() function gets the vendor string from the component specified by *comp*. The resulting string must be released by the caller.

RETURN VALUES

The wsreg set vendor () function returns a non-zero value if the vendor was set correctly; otherwise it returns 0.

The wsreg get vendor () function returns a copy of the vendor from the specified component.

NAME

wsreg_unregister - remove a component from the product install registry

SYNOPSIS

```
cc [flag...] file ...-lwsreg [library...]
#include <wsreg.h>
int wsreg unregister(const Wsreg component *comp);
```

DESCRIPTION

The wsreg_unregister() function removes the component specified by *comp* from the product install registry. The component will only be removed if the *comp* argument has a matching uuid, instance, and version.

Usually, the component retrieved through a call to wsreg_get(3WSREG) before being passed to the wsreg_unregister() function.

If the component has required components, the respective dependent components will be updated to reflect the change.

A component that has dependent components cannot be unregistered until the dependent components are uninstalled and unregistered.

RETURN VALUES

Upon successful completion, a non-zero return value is returned. If the component could not be unregistered, 0 is returned.

EXAMPLES

EXAMPLE 1 Unregister a component.

The following example demonstrates how to unregister a component.

```
#include <stdio.h>
#include <wsreg.h>
int main(int argc, char **argv)
    char *uuid = "d6cf2869-1dd1-11b2-9fcb-080020b69971";
        char *location = "/usr/local/example1 component";
         Wsreg query *query = NULL;
        Wsreg_component *comp = NULL;
         /* Initialize the registry */
         wsreg initialize (WSREG INIT NORMAL, NULL);
         /* Query for the component */
         query = wsreq query create();
         wsreg_query_set_id(query, uuid);
         wsreg_query_set_location(query, location);
         comp = wsreg get(query);
         if (comp != NULL) {
             /* The query succeeded. The component has been found. */
             Wsreg_component **dependent_comps;
             dependent comps = wsreg get dependent components(comp);
            if (dependent_comps != NULL) {
             * The component has dependent components. The
              * component cannot be unregistered.
```

EXAMPLE 1 Unregister a component. (*Continued*)

```
wsreg_free_component_array(dependent_comps);
    printf("The component cannot be uninstalled because "
        "it has dependent components\n");
    } else {
        * The component does not have dependent components.
         * It can be unregistered.
        if (wsreg_unregister(comp) != 0) {
           printf("wsreg unregister succeeded\n");
        } else {
           printf("unregister failed\n");
    /* Be sure to free the component */
    wsreg free component (comp);
} else {
    /* The component is not currently registered. */
    printf("The component was not found in the registry\n");
wsreg query free (query);
```

USAGE

Components should be unregistered before uninstallation. If the component cannot be unregistered, uninstallation should not be performed.

A component cannot be unregistered if other registered components require it. A call to wsreg_get_dependent_components() can be used to determine if this situation exists. See wsreg_add_dependent_component(3WSREG).

A successful unregistration of a component will result in all components required by the unregistered component being updated in the product install registry to remove the dependency. Also, child components will be updated so the unregistered component is no longer registered as their parent.

When unregistering a product, the product should first be unregistered, followed by the unregistration of its first feature and then the unregistration and uninstallation of the components that comprise that feature. Be sure to use this top-down approach to avoid removing a component that belongs to a product or feature that is required by a separate product.

y0(3M)

NAME | v0, v1, vn – Bessel functions of the second kind

SYNOPSIS

```
cc [ flag ... ] file ... -lm [ library ... ]
```

double y0 (double x);

double y1 (double x);

double yn(int n, double x);

DESCRIPTION

The y0(), y1() and yn() functions compute Bessel functions of x of the second kind of orders 0, 1 and n respectively. The value of x must be positive.

RETURN VALUES

Upon successful completion, y0(), y1() and yn() will return the relevant Bessel value of *x* of the second kind.

If x is NaN. NaN is returned.

If the x argument to y0(), y1() or yn() is negative, -HUGE VAL or NaN is returned, and errno may be set to EDOM.

If x is 0.0, -HUGE VAL is returned and errno may be set to ERANGE or EDOM.

If the correct result would cause overflow, -HUGE VAL is returned and errno may be set to ERANGE.

For exceptional cases, matherr(3M) tabulates the values to be returned as dictated by Standards other than XPG4.

ERRORS

The y0(), y1() and yn() functions may fail if:

EDOM The value of x is negative.

ERANGE The value of x is too large in magnitude, or x is 0.0, or the correct

result would cause overflow.

USAGE

An application wishing to check for error situations should set errno to 0 before calling y0(), y1() or yn(). If errno is non-zero on return, or the return value is NaN, an error has occurred.

pam — Pluggable Authentication Module Administrative Interface, 344
Interface Overview, 342
Stacking Multiple Schemes, 343
Stateful Interface, 343
PAM error messages get string — pam_strerror, 382

PAM routines to maintain module specific state — pam_get_data, 360 - pam_set_data, 360 PAM Service Module APIs — PAM, 364 pam_acct_mgmt — perform PAM account validation procedures, 345 pam_authenticate — perform authentication within the PAM framework, 346 pam_chauthtok — perform password related functions within the PAM framework, 348 pam_close_session — perform PAM session creation and termination operations, 354 pam_end — authentication transaction routines for PAM, 379 pam_get_data — PAM routines to maintain module specific state, 360 pam_getenv — returns the value for a PAM environment name, 350 pam_getenvlist — returns a list of all the PAM environment variables, 351 pam_get_item — authentication information routines for PAM, 362 pam_open_session — perform PAM session creation and termination operations, 354 pam_putenv — change or add a value to the PAM environment, 356 pam_setcred — modify/delete user credentials for an authentication service, 358 pam_set_data — PAM routines to maintain module specific state, 360 pam_set_item — authentication information routines for PAM, 362 pam_sm — PAM Service Module APIs Interaction with the User, 365 Interface Overview, 364 Stateful Interface, 364 pam_sm_acct_mgmt — service provider implementation for pam_acct_mgmt, 368 pam_sm_authenticate — service provider implementation for pam_authenticate, 370 pam_sm_chauthtok — service provider implementation for pam_chauthtok, 372 pam_sm_close_session — Service provider implementation for pam_open_session and

pam_close_session, 375

```
pam_sm_open_session — Service provider
  implementation for pam_open_session and
  pam_close_session, 375
pam_sm_setcred — service provider
  implementation for pam_setcred, 377
pam_start — authentication transaction routines
  for PAM, 379
pathfind — search for named file in named
  directories, 383
pctx_capture — process context library, 385
pctx_create — process context library, 385
pctx_release — process context library, 385
pctx_run — process context library, 385
pctx_set_events — associate callbacks with
  process events, 387
perform authentication within the PAM
  framework — pam_authenticate, 346
perform PAM account validation procedures —
  pam_acct_mgmt, 345
perform PAM session creation and termination
  operations
  — pam_close_session, 354
  - pam_open_session, 354
perform password related functions within the
  PAM framework — pam_chauthtok, 348
Perl tied hash interface to the kstat facility —
  Sun::Solaris::Kstat, 241
PICL interface library — libpicl, 270
picld_log — log a message in system log, 390
picld_plugin_register — register plug-in with
  the daemon, 391
picl_get_first_prop — get a property handle of a
  node, 393
picl_get_next_by_col — access a table
  property, 395
picl_get_next_by_row — access a table
  property, 395
picl_get_next_prop — get a property handle of
  a node, 393
picl_get_prop_by_name — get the handle of the
  property by name, 397
picl_get_propinfo — get the information about
  a property, 398
picl_get_propinfo_by_name — get property
  information and handle of named
```

property, 399

```
picl_get_propval — get the value of a
  property, 400
picl_get_propval_by_name — get the value of a
  property, 400
picl_get_root — get the root handle of the PICL
  tree, 402
picl_initialize — initiate a session with the PICL
  daemon, 403
picl_set_propval — set the value of a property
  to the specified value, 404
picl_set_propval_by_name — set the value of a
  property to the specified value, 404
picl_shutdown — shutdown the session with
  the PICL daemon, 406
picl_strerror — get error message string, 407
picl_wait — wait for PICL tree to refresh, 408
picl_walk_tree_by_class — walk subtree by
  class, 409
pipes
  open, close to and from a command —
     p2open, p2close, 340
Pluggable Authentication Module
  — PAM, 342
post a PICL event — ptree_post_event, 438
pow — power function, 410
power function — pow, 410
print a DmiString
   printDmiString, 414
print data in DmiAttributeValues list
   printDmiAttributeValues, 412
print data in input data union
  — printDmiDataUnion, 413
print error in string form
  — dmi_error, 123
printDmiAttributeValues— print data in
  DmiAttributeValues list, 412
printDmiDataUnion— print data in input data
  union, 413
printDmiString—print a DmiString, 414
probe insertion interface

- service provider implementation for pam_acct_mgmt pam_sm_acct_mgmt, 368

service provider implementation for pam_authenticate — pam_sm_authenticate, 370 service provider implementation for pam_chauthtok — pam_sm_chauthtok, 372 Service provider implementation for pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setddmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
pam_sm_authenticate, 370 service provider implementation for pam_chauthtok — pam_sm_chauthtok, 372 Service provider implementation for pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 220 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
service provider implementation for pam_chauthtok — pam_sm_chauthtok, 372 Service provider implementation for pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 220 setdmapfile — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
pam_chauthtok — pam_sm_chauthtok, 372 Service provider implementation for pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 220 setdmapfile — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
Service provider implementation for pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
pam_open_session and pam_close_session — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
 — pam_sm_close_session, 375 — pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_maps entry, 220 setdmapent — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
 pam_sm_open_session, 375 service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_maps entry, 220 setdmapent — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
service provider implementation for pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
pam_setcred — pam_sm_setcred, 377 set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
set the value of a property to the specified value — picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_maps entry, 220 setdmapent — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
 picl_set_propval, 404, 480, 590, 591, 592, 593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get device_deallocate entry, 218 setddent — get device_deallocate entry, 218 setddfile — get device_maps entry, 220 setdmapent — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
593, 594, 599, 600, 602, 603, 604, 605, 606, 607, 608 set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
set layout values of a LayoutObject — m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
m_setvalues_layout, 308 setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setac — get audit control file information, 206 setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setauclass — rewind audit_class database file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setemapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
file, 208 setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setauuser — rewind audit_event database file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
file, 211 setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setauthattr — get authorization database entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
entry, 213 setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setauuser — get audit_user database entry, 216 setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setddent — get device_deallocate entry, 218 setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setddfile — get device_deallocate entry, 218 setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setdmapent — get device_maps entry, 220 setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setdmapfile — get device_maps entry, 220 setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setexecattr — get execution profile entry, 222 setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
setprofattr — get profile description and attributes, 227 setprojent — project database entry functions, 229
attributes, 227 setprojent — project database entry functions, 229
setprojent — project database entry functions, 229
functions, 229
functions, 229
setuserattr — get user_attr entry, 233
shell global pattern matching — gmatch, 235
shutdown the session with the PICL daemon —
picl_shutdown, 406
signal or wait for an event —
rsm_intr_signal_post, 458
significand — significand function, 494
significand function — significand, 494
simple difference and accumulate operations —
cpc_event_diff, 71
sin — sine function, 495

sort an ACL — aclsort, 22 sqrt — square root function, 497 square root function — sqrt, 497 SSAAgentIsAlive — Sun Solstice Enterprise Agent registration and communication helper functions, 498 SSAGetTrapPort — Sun Solstice Enterprise Agent registration and communication helper functions, 498 SSAOidCmp — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidCpy — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidDup — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidFree — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidInit — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidNew — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidString — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidStrToOid — Sun Solstice Enterprise Agent OID helper functions, 501 SSAOidZero — Sun Solstice Enterprise Agent OID helper functions, 501 SSARegSubagent — Sun Solstice Enterprise Agent registration and communication helper functions, 498 SSARegSubtable — Sun Solstice Enterprise Agent registration and communication helper functions, 498 SSARegSubtree — Sun Solstice Enterprise Agent registration and communication helper functions, 498 SSASendTrap — Sun Solstice Enterprise Agent registration and communication helper functions, 498 SSAStringCpy — Sun Solstice Enterprise Agent string helper functions, 503 SSAStringInit — Sun Solstice Enterprise Agent string helper functions, 503 SSAStringToChar — Sun Solstice Enterprise Agent string helper functions, 503 SSAStringZero — Sun Solstice Enterprise Agent

string helper functions, 503

SSASubagentOpen — Sun Solstice Enterprise	Sun Solstice Enterprise Agent registration and
Agent registration and communication	communication helper functions
helper functions, 498	— SSAAgentIsAlive, 498
step — regular expression compile and match	— SSAGetTrapPort, 498
routines, 445	— SSARegSubagent, 498
strfind — string manipulations, 506	— SSARegSubtable, 498
strcadd — copy strings, compressing or	— SSARegSubtree, 498
expanding C language escape codes, 504	— SSASendTrap, 498
strccpy — copy strings, compressing or	— SSASubagentOpen, 498
expanding C language escape codes, 504	Sun Solstice Enterprise Agent string helper
streadd — copy strings, compressing or	functions
expanding C language escape codes, 504	— SSAStringCpy, 503
STREAMS	— SSAStringInit, 503
determine whether a buffer of characters is	— SSAStringToChar, 503
encrypted — isencrypt, 238	— SSAStringZero, 503
read stream up to next delimiter —	Sun::Solaris::Kstat — Perl tied hash interface to
bgets, 39	the kstat facility, 241
split buffer into fields — bufsplit, 41	sysevent_free — free memory for sysevent
streepy — copy strings, compressing or	handle, 507
expanding C language escape codes, 504	sysevent_get_attr_list — get attribute list
strfind — string manipulations, 506	pointer, 508
string manipulations — strfind, 506	sysevent_get_class_name — get class name,
strrspn, 506	subclass name, ID or buffer size of
strtrns, 506	event, 509
string manipulations	sysevent_get_event_id — get class name,
— strfind, 506	subclass name, ID or buffer size of
— strrspn, 506	event, 509
— strtrns, 506	
	sysevent_get_pid — get vendor name,
string operation	publisher name or processor ID of event, 511
get PAM error message string —	·
pam_strerror, 382	sysevent_get_pub_name — get vendor name,
strings	publisher name or processor ID of event, 511
copy, compressing or expanding C language	
escape codes, 504	sysevent_get_size — get class name, subclass
strfind — string manipulations, 506	name, ID or buffer size of event, 509
Sun Solstice Enterprise Agent OID helper	sysevent_get_subclass_name — get class name,
functions 501	subclass name, ID or buffer size of
— SSAOidCmp, 501	event, 509
— SSAOidCpy, 501	sysevent_get_vendor_name — get vendor
— SSAOidDup, 501	name, publisher name or processor ID of
— SSAOidFree, 501	event, 511
— SSAOidInit, 501	
— SSAOidNew, 501	
— SSAOidString, 501	т
— SSAOidStrToOid, 501	T
— SSAOidZero, 501	tan — tangent function, 515
	tangent function — tan, 515

tanh — hyperbolic tangent function, 516 tnfctl_probe_trace — interfaces to guery and to test access CPU performance counters change the state of a probe, 535 cpc_access, 60 tnfctl_probe_untrace — interfaces to query and test for NaN — isnan, 239 to change the state of a probe, 535 tnfctl_buffer_alloc — allocate or deallocate a tnfctl_register_funcs — register callbacks for buffer for trace data, 517 probe creation and destruction, 539 tnfctl_buffer_dealloc — allocate or deallocate a tnfctl_strerror — map a tnfctl error code to a buffer for trace data, 517 string, 540 tnfctl_check_libs — control probes of another tnfctl_trace_attrs_get — get the trace attributes process where caller provides /proc from a tnfctl handle, 541 functionality, 521 tnfctl_trace_state_set — control kernel tracing tnfctl_close — close a tnfctl handle, 519 and process filtering, 543 tnfctl_continue — interfaces for direct probe TNF_DEBUG — probe insertion interface, 548 and process control for another process, TNF_PROBE — probe insertion interface tnfctl_exec_open — interfaces for direct probe arg_name_n, 551 and process control for another process, 527 arg_type_n, 550 tnfctl_filter_list_add — control kernel tracing arg_value_n, 551 and process filtering, 543 detail, 549 tnfctl_filter_list_delete — control kernel tracing keys, 549 and process filtering, 543 name, 549 tnfctl_filter_list_get — control kernel tracing TNF_PROBE_0 — probe insertion and process filtering, 543 interface, 548 tnfctl_filter_state_set — control kernel tracing TNF_PROBE_0_DEBUG — probe insertion and process filtering, 543 interface, 548 tnfctl_indirect_open — control probes of TNF_PROBE_1 — probe insertion interface, 548 another process where caller provides /proc TNF_PROBE_1_DEBUG — probe insertion functionality, 521 tnfctl_internal_open — create handle for interface, 548 internal process probe control, 524 TNF_PROBE_2 — probe insertion tnfctl_kernel_open — create handle for kernel interface, 548 probe control, 526 TNF_PROBE_2_DEBUG — probe insertion tnfctl_pid_open — interfaces for direct probe interface, 548 and process control for another process, 527 TNF_PROBE_3 — probe insertion tnfctl_probe_apply — iterate over probes, 532 interface, 548 tnfctl_probe_apply_ids — iterate over TNF_PROBE_3_DEBUG — probe insertion probes, 532 interface, 548 TNF_PROBE_4 — probe insertion tnfctl_probe_connect — interfaces to query and to change the state of a probe, 535 interface, 548 tnfctl_probe_disable — interfaces to query and TNF_PROBE_4_DEBUG — probe insertion to change the state of a probe, 535 interface, 548 tnfctl_probe_disconnect_all — interfaces to TNF_PROBE_5 — probe insertion query and to change the state of a interface, 548

probe, 535

tnfctl_probe_enable — interfaces to guery and

to change the state of a probe, 535

tnfctl_probe_state_get — interfaces to query

and to change the state of a probe, 535

TNF_PROBE_5_DEBUG — probe insertion

tnf_process_disable() — disables probing for the

interface, 548

process, 553

- tnf_process_enable() enables probing for the process, 553
- tnf_thread_disable() disables probing for the calling thread, 553
- tnf_thread_enable() enables probing for the calling thread, 553
- touchlock functions to manage lockfile(s) for user's mailbox, 285
- translate strings to and from events cpc_strtoevent, 81

U

unregister the event handler for the event — ptree_unregister_handler, 440 update a property value — ptree_update_propval, 441 use CPU performance counters on lwps — cpc_bind_event, 61

V

- visit active project IDs on current system project_walk, 417
- volmgt_acquire reserve removable media device, 559
- volmgt_check have Volume Management check for media, 562
- volmgt_feature_enabled check whether specific Volume Management features are enabled, 564
- volmgt_inuse check whether or not Volume Management is managing a pathname, 565
- volmgt_release release removable media device reservation, 567
- volmgt_root return the Volume Management root directory, 568
- volmgt_running return whether or not Volume Management is running, 569
- volmgt_symdev convert between Volume Management symbolic names, and the devices that correspond to them, 570
- volmgt_symname convert between Volume Management symbolic names, and the devices that correspond to them, 570

VTOC, disk's read a disk's VTOC — read_vtoc, 443 write a disk's VTOC — write_vtoc, 443

W

wait for PICL tree to refresh — picl_wait, 408 walk subtree by class — picl_walk_tree_by_class, 409, 442 write to a segment — rsm_memseg_import_put, 476, 478 write_vtoc — read and write a disk's VTOC, 443

wsreg_add_child_component — add or remove a child component, 572

wsreg_add_compatible_version — add or remove a backward compatible version, 574 wsreg_add_dependent_component — add or

remove a dependent component, 576 wsreg_add_display_name — add, remove, or

return a localized display name, 578 wsreg_add_required_component — add or

remove a required component, 580 wsreg_can_access_registry — determine access

to product install registry, 582 wsreg_clone_component — clone a component, 584

wsreg_components_equal — determine equality of two components, 585

wsreg_create_component — create or release a component, 586

wsreg_free_component — create or release a component, 586

wsreg_free_component_array — create or release a component, 586

wsreg_get_child_components — add or remove a child component, 572

wsreg_get_compatible_versions — add or remove a backward compatible version, 574 wsreg_get_data — add or retrieve a key-value

wsreg_get_data — add or retrieve a key-value pair, 597

wsreg_get_data_pairs — add or retrieve a key-value pair, 597

wsreg_get_dependent_components — add or remove a dependent component, 576

or return a localized display name, 578 wsreg_get_display_name — add, remove, or return a localized display name, 578 wsreg_get_id — set or get the uuid of a component, 599 wsreg_get_instance — set or get the instance of a component, 600 wsreg_get_location — set or get the location of a component, 602 wsreg_get_parent — set or get the parent of a component, 603 wsreg_get_required_components — add or remove a required component, 580 wsreg_get_type — set or get the type of a component, 604 wsreg_get_uninstaller — set or get the uninstaller of a component, 605 wsreg_get_unique_name — set or get the unique name of a component, 606 wsreg_get_vendor — set or get the vendor of a componentt, 607 wsreg_get_version — set or get the version of a component, 608 wsreg_initialize — initialize wsreg library, wsreg_query_create — create a new query, 589 wsreg_query_free — create a new query, 589 wsreg_query_get_id — set or get the uuid of a query, 590 wsreg_query_get_instance — set or get the instance of a query, 591 wsreg_query_get_location — set or get the location of a query, 592 wsreg_query_get_unique_name — set or get the unique name of a query, 593 wsreg_query_get_version — set or get the version of a query, 594 wsreg_query_set_id — set or get the uuid of a

query, 590

wsreg_query_set_instance — set or get the

wsreg_query_set_location — set or get the

wsreg_query_set_unique_name — set or get the

instance of a query, 591

location of a query, 592

version of a query, 594

unique name of a query, 593 wsreg_query_set_version — set or get the

wsreg_get_display_languages — add, remove,

wsreg_register — register a component in the product install registry, 595 wsreg_remove_child_component — add or remove a child component, 572 wsreg_remove_compatible_version — add or remove a backward compatible version, 574 wsreg_remove_dependent_component — add or remove a dependent component, 576 wsreg_remove_display_name — add, remove, or return a localized display name, 578 wsreg_remove_required_component — add or remove a required component, 580 wsreg_set_data — add or retrieve a key-value pair, 597 wsreg_set_id — set or get the uuid of a component, 599 wsreg_set_instance — set or get the instance of a component, 600 wsreg_set_location — set or get the location of a component, 602 wsreg_set_parent — set or get the parent of a component, 603 wsreg_set_type — set or get the type of a component, 604 wsreg_set_uninstaller — set or get the uninstaller of a component, 605 wsreg_set_unique_name — set or get the unique name of a component, 606 wsreg_set_vendor — set or get the vendor of a componentt, 607 wsreg_set_version — set or get the version of a component, 608 wsreg_unregister — remove a component from the product install registry, 609

Υ

y0 — Bessel functions of the second kind, 612 y1 — Bessel functions of the second kind, 612 yn — Bessel functions of the second kind, 612
