This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, docs.sun.com, AnswerBook, AnswerBook2, and Solaris are trademarks or registered trademarks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

U.S. Government Rights – Commercial software. Government users are subject to the Sun Microsystems, Inc. standard license agreement and applicable provisions of the FAR and its supplements.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux États-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, docs.sun.com, AnswerBook, AnswerBook2, et Solaris sont des marques de fabrique ou des marques déposées, de Sun Microsystems, Inc. aux États-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux États-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun™ a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REpondre A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

Index 723

Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.								
SYNOPSIS	<p>This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.</p> <p>The following special characters are used in this section:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">[]</td> <td>Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.</td> </tr> <tr> <td style="padding-right: 10px;">. . .</td> <td>Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".</td> </tr> <tr> <td style="padding-right: 10px;"> </td> <td>Separator. Only one of the arguments separated by this character can be specified at a time.</td> </tr> <tr> <td style="padding-right: 10px;">{ }</td> <td>Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.</td> </tr> </table>	[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.	. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".		Separator. Only one of the arguments separated by this character can be specified at a time.	{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.								
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".								
	Separator. Only one of the arguments separated by this character can be specified at a time.								
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.								

PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the <code>ioctl(2)</code> system call is called <code>ioctl</code> and generates its own heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device). <code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code> .
OPTIONS	This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.
OPERANDS	This section lists the command operands and describes how they affect the actions of the command.
OUTPUT	This section describes the output – standard output, standard error, or output files – generated by the command.
RETURN VALUES	If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.
ERRORS	On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the

	<p>conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.</p>
USAGE	<p>This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:</p> <ul style="list-style-type: none"> Commands Modifiers Variables Expressions Input Grammar
EXAMPLES	<p>This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code>, or if the user must be superuser, <code>example#</code>. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.</p>
ENVIRONMENT VARIABLES	<p>This section lists any environment variables that the command or function affects, followed by a brief description of the effect.</p>
EXIT STATUS	<p>This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.</p>
FILES	<p>This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.</p>
ATTRIBUTES	<p>This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See <code>attributes(5)</code> for more information.</p>
SEE ALSO	<p>This section lists references to other man pages, in-house documentation, and outside publications.</p>

DIAGNOSTICS	This section lists diagnostic messages with a brief explanation of the condition causing the error.
WARNINGS	This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.
NOTES	This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.
BUGS	This section describes known bugs and, wherever possible, suggests workarounds.

Networking Library Functions

accept(3SOCKET)

NAME	accept – accept a connection on a socket										
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h> int accept(int <i>s</i>, struct sockaddr *<i>addr</i>, socklen_t *<i>addrlen</i>);</pre>										
DESCRIPTION	<p>The argument <i>s</i> is a socket that has been created with <code>socket(3SOCKET)</code> and bound to an address with <code>bind(3SOCKET)</code>, and that is listening for connections after a call to <code>listen(3SOCKET)</code>. The <code>accept()</code> function extracts the first connection on the queue of pending connections, creates a new socket with the properties of <i>s</i>, and allocates a new file descriptor, <i>ns</i>, for the socket. If no pending connections are present on the queue and the socket is not marked as non-blocking, <code>accept()</code> blocks the caller until a connection is present. If the socket is marked as non-blocking and no pending connections are present on the queue, <code>accept()</code> returns an error as described below. The <code>accept()</code> function uses the <code>netconfig(4)</code> file to determine the STREAMS device file name associated with <i>s</i>. This is the device on which the connect indication will be accepted. The accepted socket, <i>ns</i>, is used to read and write data to and from the socket that connected to <i>ns</i>. It is not used to accept more connections. The original socket (<i>s</i>) remains open for accepting further connections.</p> <p>The argument <i>addr</i> is a result parameter that is filled in with the address of the connecting entity as it is known to the communications layer. The exact format of the <i>addr</i> parameter is determined by the domain in which the communication occurs.</p> <p>The argument <i>addrlen</i> is a value-result parameter. Initially, it contains the amount of space pointed to by <i>addr</i>; on return it contains the length in bytes of the address returned.</p> <p>The <code>accept()</code> function is used with connection-based socket types, currently with <code>SOCK_STREAM</code>.</p> <p>It is possible to <code>select(3C)</code> or <code>poll(2)</code> a socket for the purpose of an <code>accept()</code> by selecting or polling it for a read. However, this will only indicate when a connect indication is pending; it is still necessary to call <code>accept()</code>.</p>										
RETURN VALUES	The <code>accept()</code> function returns <code>-1</code> on error. If it succeeds, it returns a non-negative integer that is a descriptor for the accepted socket.										
ERRORS	<p><code>accept()</code> will fail if:</p> <table><tr><td>EBADF</td><td>The descriptor is invalid.</td></tr><tr><td>ECONNABORTED</td><td>The remote side aborted the connection before the <code>accept()</code> operation completed.</td></tr><tr><td>EFAULT</td><td>The <i>addr</i> parameter or the <i>addrlen</i> parameter is invalid.</td></tr><tr><td>EINTR</td><td>The <code>accept()</code> attempt was interrupted by the delivery of a signal.</td></tr><tr><td>EMFILE</td><td>The per-process descriptor table is full.</td></tr></table>	EBADF	The descriptor is invalid.	ECONNABORTED	The remote side aborted the connection before the <code>accept()</code> operation completed.	EFAULT	The <i>addr</i> parameter or the <i>addrlen</i> parameter is invalid.	EINTR	The <code>accept()</code> attempt was interrupted by the delivery of a signal.	EMFILE	The per-process descriptor table is full.
EBADF	The descriptor is invalid.										
ECONNABORTED	The remote side aborted the connection before the <code>accept()</code> operation completed.										
EFAULT	The <i>addr</i> parameter or the <i>addrlen</i> parameter is invalid.										
EINTR	The <code>accept()</code> attempt was interrupted by the delivery of a signal.										
EMFILE	The per-process descriptor table is full.										

accept(3SOCKET)

ENODEV	The protocol family and type corresponding to <i>s</i> could not be found in the <code>netconfig</code> file.
ENOMEM	There was insufficient user memory available to complete the operation.
ENOSR	There were insufficient STREAMS resources available to complete the operation.
ENOTSOCK	The descriptor does not reference a socket.
EOPNOTSUPP	The referenced socket is not of type <code>SOCK_STREAM</code> .
EPROTO	A protocol error has occurred; for example, the STREAMS protocol stack has not been initialized or the connection has already been released.
EWOULDBLOCK	The socket is marked as non-blocking and no connections are present to be accepted.

accept(3XNET)

NAME	accept – accept a new connection on a socket						
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h> int accept(int <i>socket</i>, struct sockaddr *restrict <i>address</i>, socklen_t *restrict <i>address_len</i>);</pre>						
DESCRIPTION	<p>The <code>accept()</code> function extracts the first connection on the queue of pending connections, creates a new socket with the same socket type protocol and address family as the specified socket, and allocates a new file descriptor for that socket.</p> <p>The function takes the following arguments:</p> <table><tr><td><i>socket</i></td><td>Specifies a socket that was created with <code>socket(3XNET)</code>, has been bound to an address with <code>bind(3XNET)</code>, and has issued a successful call to <code>listen(3XNET)</code>.</td></tr><tr><td><i>address</i></td><td>Either a null pointer, or a pointer to a <code>sockaddr</code> structure where the address of the connecting socket will be returned.</td></tr><tr><td><i>address_len</i></td><td>Points to a <code>socklen_t</code> which on input specifies the length of the supplied <code>sockaddr</code> structure, and on output specifies the length of the stored address.</td></tr></table> <p>If <i>address</i> is not a null pointer, the address of the peer for the accepted connection is stored in the <code>sockaddr</code> structure pointed to by <i>address</i>, and the length of this address is stored in the object pointed to by <i>address_len</i>.</p> <p>If the actual length of the address is greater than the length of the supplied <code>sockaddr</code> structure, the stored address will be truncated.</p> <p>If the protocol permits connections by unbound clients, and the peer is not bound, then the value stored in the object pointed to by <i>address</i> is unspecified.</p> <p>If the listen queue is empty of connection requests and <code>O_NONBLOCK</code> is not set on the file descriptor for the socket, <code>accept()</code> will block until a connection is present. If the <code>listen(3XNET)</code> queue is empty of connection requests and <code>O_NONBLOCK</code> is set on the file descriptor for the socket, <code>accept()</code> will fail and set <code>errno</code> to <code>EAGAIN</code> or <code>EWOULDBLOCK</code>.</p> <p>The accepted socket cannot itself accept more connections. The original socket remains open and can accept more connections.</p>	<i>socket</i>	Specifies a socket that was created with <code>socket(3XNET)</code> , has been bound to an address with <code>bind(3XNET)</code> , and has issued a successful call to <code>listen(3XNET)</code> .	<i>address</i>	Either a null pointer, or a pointer to a <code>sockaddr</code> structure where the address of the connecting socket will be returned.	<i>address_len</i>	Points to a <code>socklen_t</code> which on input specifies the length of the supplied <code>sockaddr</code> structure, and on output specifies the length of the stored address.
<i>socket</i>	Specifies a socket that was created with <code>socket(3XNET)</code> , has been bound to an address with <code>bind(3XNET)</code> , and has issued a successful call to <code>listen(3XNET)</code> .						
<i>address</i>	Either a null pointer, or a pointer to a <code>sockaddr</code> structure where the address of the connecting socket will be returned.						
<i>address_len</i>	Points to a <code>socklen_t</code> which on input specifies the length of the supplied <code>sockaddr</code> structure, and on output specifies the length of the stored address.						
USAGE	When a connection is available, <code>select(3C)</code> will indicate that the file descriptor for the socket is ready for reading.						
RETURN VALUES	Upon successful completion, <code>accept()</code> returns the nonnegative file descriptor of the accepted socket. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.						
ERRORS	The <code>accept()</code> function will fail if:						

accept(3XNET)

EAGAIN	
EWOULDBLOCK	O_NONBLOCK is set for the socket file descriptor and no connections are present to be accepted.
EBADF	The <i>socket</i> argument is not a valid file descriptor.
ECONNABORTED	A connection has been aborted.
EFAULT	The <i>address</i> or <i>address_len</i> parameter can not be accessed or written.
EINTR	The <code>accept ()</code> function was interrupted by a signal that was caught before a valid connection arrived.
EINVAL	The <i>socket</i> is not accepting connections.
EMFILE	OPEN_MAX file descriptors are currently open in the calling process.
ENFILE	The maximum number of file descriptors in the system are already open.
ENOTSOCK	The <i>socket</i> argument does not refer to a socket.
EOPNOTSUPP	The socket type of the specified socket does not support accepting connections.

The `accept ()` function may fail if:

ENOBUFS	No buffer space is available.
ENOMEM	There was insufficient memory available to complete the operation.
ENOSR	There was insufficient STREAMS resources available to complete the operation.
EPROTO	A protocol error has occurred; for example, the STREAMS protocol stack has not been initialized.

ber_decode(3LDAP)

NAME	ber_decode, ber_alloc_t, ber_free, ber_bvdup, ber_init, ber_flatten, ber_get_next, ber_skip_tag, ber_peek_tag, ber_scanf, ber_get_int, ber_get_stringa, ber_get_stringal, ber_get_stringb, ber_get_null, ber_get_boolean, ber_get_bitstring, ber_first_element, ber_next_element, ber_bvfree, ber_bvecfree – Basic Encoding Rules library decoding functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> BerElement *ber_alloc_t(int options); struct berval *ber_bvdup(struct berval *bv); void ber_free(BerElement *ber, int freebuf); BerElement *ber_init(struct berval *bv); int ber_flatten(BerElement *ber, struct berval **bvPtr); ber_get_next(Socketbuf *sb, unsigned long *len, char *bv_val); ber_skip_tag(BerElement **ber, unsigned long **len); ber_peek_tag(BerElement **ber, unsigned long **len); ber_get_int(BerElement **ber, long **num); ber_get_stringb(BerElement **ber, char **buf, unsigned long **len); ber_get_stringa(BerElement **ber, char ***buf); ber_get_stringal(BerElement **ber, struct berval ***bv); ber_get_null(BerElement **ber); ber_get_boolean(BerElement **ber, int **bool); ber_get_bitstringa(BerElement **ber, char ***buf, unsigned long **blen); ber_first_element(BerElement **ber, unsigned long **len, char ***cookie); ber_next_element(BerElement **ber, unsigned long **len, char **cookie); ber_scanf(BerElement **ber, char **fmt [, arg...]); ber_bvfree(struct berval **bv); ber_bvecfree(struct berval ***bvec);</pre>
DESCRIPTION	<p>These functions provide a subfunction interface to a simplified implementation of the Basic Encoding Rules of ASN.1. The version of BER these functions support is the one defined for the LDAP protocol. The encoding rules are the same as BER, except that only definite form lengths are used, and bitstrings and octet strings are always encoded in primitive form. In addition, these lightweight BER functions restrict tags and class to fit in a single octet (this means the actual tag must be less than 31). When</p>

a "tag" is specified in the descriptions below, it refers to the tag, class, and primitive or constructed bit in the first octet of the encoding. This man page describes the decoding functions in the lber library. See [ber_encode\(3LDAP\)](#) for details on the corresponding encoding functions.

Normally, the only functions that need be called by an application are `ber_get_next()` to get the next BER element and `ber_scanf()` to do the actual decoding. In some cases, `ber_peek_tag()` may also need to be called in normal usage. The other functions are provided for those applications that need more control than `ber_scanf()` provides. In general, these functions return the tag of the element decoded, or `-1` if an error occurred.

The `ber_get_next()` function is used to read the next BER element from the given Sockbuf, *sb*. A Sockbuf consists of the descriptor (usually socket, but a file descriptor works just as well) from which to read, and a BerElement structure used to maintain a buffer. On the first call, the *sb_ber* struct should be zeroed. It strips off and returns the leading tag byte, strips off and returns the length of the entire element in *len*, and sets up *ber* for subsequent calls to `ber_scanf()`, and all to decode the element.

The `ber_scanf()` function is used to decode a BER element in much the same way that `scanf(3C)` works. It reads from *ber*, a pointer to a BerElement such as returned by `ber_get_next()`, interprets the bytes according to the format string *fmt*, and stores the results in its additional arguments. The format string contains conversion specifications which are used to direct the interpretation of the BER element. The format string can contain the following characters.

- a Octet string. A char ** should be supplied. Memory is allocated, filled with the contents of the octet string, null-terminated, and returned in the parameter.
- s Octet string. A char * buffer should be supplied, followed by a pointer to an integer initialized to the size of the buffer. Upon return, the null-terminated octet string is put into the buffer, and the integer is set to the actual size of the octet string.
- O Octet string. A struct ber_val ** should be supplied, which upon return points to a memory allocated struct berval containing the octet string and its length. `ber_bvfree()` can be called to free the allocated memory.
- b Boolean. A pointer to an integer should be supplied.
- i Integer. A pointer to an integer should be supplied.
- B Bitstring. A char ** should be supplied which will point to the memory allocated bits, followed by an unsigned long *, which will point to the length (in bits) of the bitstring returned.
- n Null. No parameter is required. The element is simply skipped if it is recognized.

ber_decode(3LDAP)

- v Sequence of octet strings. A char *** should be supplied, which upon return points to a memory allocated null-terminated array of char *'s containing the octet strings. NULL is returned if the sequence is empty.
- V Sequence of octet strings with lengths. A struct berval *** should be supplied, which upon return points to a memory allocated, null-terminated array of struct berval *'s containing the octet strings and their lengths. NULL is returned if the sequence is empty. `ber_bvecfree()` can be called to free the allocated memory.
- x Skip element. The next element is skipped.
- { Begin sequence. No parameter is required. The initial sequence tag and length are skipped.
- } End sequence. No parameter is required and no action is taken.
-] & Begin set. No parameter is required. The initial set tag and length are skipped.
-] End set. No parameter is required and no action is taken.

The `ber_get_int()` function tries to interpret the next element as an integer, returning the result in *num*. The tag of whatever it finds is returned on success, -1 on failure.

The `ber_get_stringb()` function is used to read an octet string into a preallocated buffer. The *len* parameter should be initialized to the size of the buffer, and will contain the length of the octet string read upon return. The buffer should be big enough to take the octet string value plus a terminating NULL byte.

The `ber_get_stringa()` function is used to allocate memory space into which an octet string is read.

The `ber_get_stringal()` function is used to allocate memory space into which an octet string and its length are read. It takes a struct berval **, and returns the result in this parameter.

The `ber_get_null()` function is used to read a NULL element. It returns the tag of the element it skips over.

The `ber_get_boolean()` function is used to read a boolean value. It is called the same way that `ber_get_int()` is called.

The `ber_get_bitstringa()` function is used to read a bitstring value. It takes a char ** which will hold the allocated memory bits, followed by an unsigned long *, which will point to the length (in bits) of the bitstring returned.

The `ber_first_element()` function is used to return the tag and length of the first element in a set or sequence. It also returns in *cookie* a magic cookie parameter that should be passed to subsequent calls to `ber_next_element()`, which returns similar information.

`ber_alloc_t()` constructs and returns `BerElement`. A null pointer is returned on error. The options field contains a bitwise-or of options which are to be used when generating the encoding of this `BerElement`. One option is defined and must always be supplied:

```
#define LBER_USE_DER 0x01
```

When this option is present, lengths will always be encoded in the minimum number of octets. Note that this option does not cause values of sets and sequences to be rearranged in tag and byte order, so these functions are not suitable for generating DER output as defined in X.509 and X.680

The `ber_init` function constructs a `BerElement` and returns a new `BerElement` containing a copy of the data in the *bv* argument. `ber_init` returns the null pointer on error.

`ber_free()` frees a `BerElement` which is returned from the API calls `ber_alloc_t()` or `ber_init()`. Each `BerElement` must be freed by the caller. The second argument *freebuf* should always be set to 1 to ensure that the internal buffer used by the BER functions is freed as well as the `BerElement` container itself.

`ber_bvdup()` returns a copy of a *berval*. The *bv_val* field in the returned *berval* points to a different area of memory as the *bv_val* field in the argument *berval*. The null pointer is returned on error (that is, is out of memory).

The `ber_flatten` routine allocates a struct *berval* whose contents are BER encoding taken from the *ber* argument. The *bvPtr* pointer points to the returned *berval*, which must be freed using `ber_bvfree()`. This routine returns 0 on success and -1 on error.

EXAMPLES

EXAMPLE 1 Assume the variable *ber* contains a lightweight BER encoding of the following ASN.1 object:

```
AlmostASearchRequest := SEQUENCE {
    baseObject      DistinguishedName,
    scope           ENUMERATED {
        baseObject      (0),
        singleLevel     (1),
        wholeSubtree    (2)
    },
    derefAliases    ENUMERATED {
        neverDerefaliases (0),
        derefInSearching  (1),
        derefFindingBaseObj (2),
        alwaysDerefAliases (3N)
    },
    sizelimit       INTEGER (0 .. 65535),
    timelimit       INTEGER (0 .. 65535),
}
```

ber_decode(3LDAP)

EXAMPLE 1 Assume the variable *ber* contains a lightweight BER encoding of the following ASN.1 object: (Continued)

```
        attrsOnly      BOOLEAN,
        attributes     SEQUENCE OF AttributeType
    }
```

EXAMPLE 2 The element can be decoded using `ber_scanf()` as follows.

```
int    scope, ali, size, time, attrsonly;
char   *dn, **attrs;
if ( ber_scanf( ber, "{aiiiib{v}}", &dn, &scope, &ali,
               &size, &time, &attrsonly, &attrs ) == -1 )
    /* error */
else
    /* success */
```

ERRORS If an error occurs during decoding, generally these functions return -1.

NOTES The return values for all of these functions are declared in the `<lber.h>` header file. Some functions may allocate memory which must be freed by the calling application.

SYNOPSIS	<pre>cc[flag...] file... -lldap[library...] #include <lber.h> BerElement*ber_alloc(); ber_printf(BerElement *ber, char **fmt[, arg...]); ber_put_int(BerElement *ber, long num, char tag); ber_put_ostring(BerElement *ber, char **str, unsigned long len, char tag); ber_put_string(BerElement *ber, char **str, char tag); ber_put_null(BerElement *ber, char tag); ber_put_boolean(BerElement *ber, int bool, char tag); ber_put_bitstring(BerElement *ber, char *str, int blen, char tag); ber_start_seq(BerElement *ber, char tag); ber_start_set(BerElement *ber, char tag); ber_put_seq(BerElement *ber); ber_put_set(BerElement *ber);</pre>
DESCRIPTION	<p>These functions provide a subfunction interface to a simplified implementation of the Basic Encoding Rules of ASN.1. The version of BER these functions support is the one defined for the LDAP protocol. The encoding rules are the same as BER, except that only definite form lengths are used, and bitstrings and octet strings are always encoded in primitive form. In addition, these lightweight BER functions restrict tags and class to fit in a single octet (this means the actual tag must be less than 31). When a "tag" is specified in the descriptions below, it refers to the tag, class, and primitive or constructed bit in the first octet of the encoding. This man page describes the encoding functions in the lber library. See ber_decode(3LDAP) for details on the corresponding decoding functions.</p> <p>Normally, the only functions that need be called by an application are <code>ber_alloc()</code>, to allocate a BER element, and <code>ber_printf()</code> to do the actual encoding. The other functions are provided for those applications that need more control than <code>ber_printf()</code> provides. In general, these functions return the length of the element encoded, or -1 if an error occurred.</p> <p>The <code>ber_alloc()</code> function is used to allocate a new BER element.</p> <p>The <code>ber_printf()</code> function is used to encode a BER element in much the same way that <code>sprintf(3S)</code> works. One important difference, though, is that some state information is kept with the <code>ber</code> parameter so that multiple calls can be made to</p>

ber_encode(3LDAP)

`ber_printf()` to append things to the end of the BER element. `ber_printf()` writes to *ber*, a pointer to a `BerElement` such as returned by `ber_alloc()`. It interprets and formats its arguments according to the format string *fmt*. The format string can contain the following characters:

- b Boolean. An integer parameter should be supplied. A boolean element is output.
- i Integer. An integer parameter should be supplied. An integer element is output.
- B Bitstring. A `char *` pointer to the start of the bitstring is supplied, followed by the number of bits in the bitstring. A bitstring element is output.
- n Null. No parameter is required. A null element is output.
- o Octet string. A `char *` is supplied, followed by the length of the string pointed to. An octet string element is output.
- s Octet string. A null-terminated string is supplied. An octet string element is output, not including the trailing NULL octet.
- t Tag. An `int` specifying the tag to give the next element is provided. This works across calls.
- v Several octet strings. A null-terminated array of `char *`s is supplied. Note that a construct like `'{v}'` is required to get an actual SEQUENCE OF octet strings.
- { Begin sequence. No parameter is required.
- } End sequence. No parameter is required.
-]& Begin set. No parameter is required.
-] End set. No parameter is required.

The `ber_put_int()` function writes the integer element *num* to the BER element *ber*.

The `ber_put_boolean()` function writes the boolean value given by *bool* to the BER element.

The `ber_put_bitstring()` function writes *blen* bits starting at *str* as a bitstring value to the given BER element. Note that *blen* is the length in *bits* of the bitstring.

The `ber_put_ostring()` function writes *len* bytes starting at *str* to the BER element as an octet string.

The `ber_put_string()` function writes the null-terminated string (minus the terminating `"`) to the BER element as an octet string.

The `ber_put_null()` function writes a NULL element to the BER element.

The `ber_start_seq()` function is used to start a sequence in the BER element. The `ber_start_set()` function works similarly. The end of the sequence or set is marked by the nearest matching call to `ber_put_seq()` or `ber_put_set()`, respectively.

The `ber_first_element()` function is used to return the tag and length of the first element in a set or sequence. It also returns in *cookie* a magic cookie parameter that should be passed to subsequent calls to `ber_next_element()`, which returns similar information.

EXAMPLES

EXAMPLE 1 Assuming the following variable declarations, and that the variables have been assigned appropriately, an BER encoding of the following ASN.1 object:

```
AlmostASearchRequest := SEQUENCE {
    baseObject      DistinguishedName,
    scope           ENUMERATED {
        baseObject      (0),
        singleLevel     (1),
        wholeSubtree    (2)
    },
    derefAliases    ENUMERATED {
        neverDerefaliases (0),
        derefInSearching  (1),
        derefFindingBaseObj (2),
        alwaysDerefAliases (3N)
    },
    sizelimit       INTEGER (0 .. 65535),
    timelimit       INTEGER (0 .. 65535),
    attrsOnly       BOOLEAN,
    attributes      SEQUENCE OF AttributeType
}
```

can be achieved like so:

```
int    scope, ali, size, time, attrsonly;
char   *dn, **attrs;

/* ... fill in values ... */
if ( (ber = ber_alloc( )) == NULLBER )
/* error */

if ( ber_printf( ber, "{siiiib{v}}", dn, scope, ali,
    size, time, attrsonly, attrs ) == -1 )
/* error */
else
/* success */
```

RETURN VALUES

If an error occurs during encoding, `ber_alloc()` returns NULL; other functions generally return -1.

ber_encode(3LDAP)

bind(3SOCKET)

EROFS The inode would reside on a read-only file system.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `unlink(2)`, `socket(3SOCKET)`, `attributes(5)`, `privileges(5)`, `socket.h(3HEAD)`

NOTES Binding a name in the UNIX domain creates a socket in the file system that must be deleted by the caller when it is no longer needed by using `unlink(2)`.

The rules used in name binding vary between communication domains.

NAME	bind – bind a name to a socket																
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h> int bind(int <i>socket</i>, const struct sockaddr *<i>address</i>, socklen_t <i>address_len</i>);</pre>																
DESCRIPTION	<p>The <code>bind()</code> function assigns an <i>address</i> to an unnamed socket. Sockets created with <code>socket(3XNET)</code> function are initially unnamed. They are identified only by their address family.</p> <p>The function takes the following arguments:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>socket</i></td> <td>Specifies the file descriptor of the socket to be bound.</td> </tr> <tr> <td><i>address</i></td> <td>Points to a <code>sockaddr</code> structure containing the address to be bound to the socket. The length and format of the address depend on the address family of the socket.</td> </tr> <tr> <td><i>address_len</i></td> <td>Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.</td> </tr> </table> <p>The socket in use may require the process to have appropriate privileges to use the <code>bind()</code> function.</p>	<i>socket</i>	Specifies the file descriptor of the socket to be bound.	<i>address</i>	Points to a <code>sockaddr</code> structure containing the address to be bound to the socket. The length and format of the address depend on the address family of the socket.	<i>address_len</i>	Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.										
<i>socket</i>	Specifies the file descriptor of the socket to be bound.																
<i>address</i>	Points to a <code>sockaddr</code> structure containing the address to be bound to the socket. The length and format of the address depend on the address family of the socket.																
<i>address_len</i>	Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.																
USAGE	An application program can retrieve the assigned socket name with the <code>getsockname(3XNET)</code> function.																
RETURN VALUES	Upon successful completion, <code>bind()</code> returns 0. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.																
ERRORS	<p>The <code>bind()</code> function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EADDRINUSE</td> <td>The specified address is already in use.</td> </tr> <tr> <td>EADDRNOTAVAIL</td> <td>The specified address is not available from the local machine.</td> </tr> <tr> <td>EAFNOSUPPORT</td> <td>The specified address is not a valid address for the address family of the specified socket.</td> </tr> <tr> <td>EBADF</td> <td>The <i>socket</i> argument is not a valid file descriptor.</td> </tr> <tr> <td>EFAULT</td> <td>The <i>address</i> argument can not be accessed.</td> </tr> <tr> <td>EINVAL</td> <td>The socket is already bound to an address, and the protocol does not support binding to a new address; or the socket has been shut down.</td> </tr> <tr> <td>ENOTSOCK</td> <td>The <i>socket</i> argument does not refer to a socket.</td> </tr> <tr> <td>EOPNOTSUPP</td> <td>The socket type of the specified socket does not support binding to an address.</td> </tr> </table>	EADDRINUSE	The specified address is already in use.	EADDRNOTAVAIL	The specified address is not available from the local machine.	EAFNOSUPPORT	The specified address is not a valid address for the address family of the specified socket.	EBADF	The <i>socket</i> argument is not a valid file descriptor.	EFAULT	The <i>address</i> argument can not be accessed.	EINVAL	The socket is already bound to an address, and the protocol does not support binding to a new address; or the socket has been shut down.	ENOTSOCK	The <i>socket</i> argument does not refer to a socket.	EOPNOTSUPP	The socket type of the specified socket does not support binding to an address.
EADDRINUSE	The specified address is already in use.																
EADDRNOTAVAIL	The specified address is not available from the local machine.																
EAFNOSUPPORT	The specified address is not a valid address for the address family of the specified socket.																
EBADF	The <i>socket</i> argument is not a valid file descriptor.																
EFAULT	The <i>address</i> argument can not be accessed.																
EINVAL	The socket is already bound to an address, and the protocol does not support binding to a new address; or the socket has been shut down.																
ENOTSOCK	The <i>socket</i> argument does not refer to a socket.																
EOPNOTSUPP	The socket type of the specified socket does not support binding to an address.																

bind(3XNET)

If the address family of the socket is AF_UNIX, then `bind()` will fail if:

EACCES	A component of the path prefix denies search permission, or the requested name requires writing in a directory with a mode that denies write permission.
EDESTADDRREQ	
EISDIR	The <i>address</i> argument is a null pointer.
EIO	An I/O error occurred.
ELOOP	Too many symbolic links were encountered in translating the pathname in <i>address</i> .
ENAMETOOLONG	A component of a pathname exceeded NAME_MAX characters, or an entire pathname exceeded PATH_MAX characters.
ENOENT	A component of the pathname does not name an existing file or the pathname is an empty string.
ENOTDIR	A component of the path prefix of the pathname in <i>address</i> is not a directory.
EROFS	The name would reside on a read-only filesystem.

The `bind()` function may fail if:

EACCES	The specified address is protected, and {PRIV_NET_PRIVADOR} is not asserted in the effective set of the current process.
EINVAL	The <i>address_len</i> argument is not a valid length for the address family.
EISCONN	The socket is already connected.
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.
ENOBUFS	Insufficient resources were available to complete the call.
ENOSR	There were insufficient STREAMS resources for the operation to complete.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

byteorder(3SOCKET)

NAME | byteorder, htonl, htons, ntohl, ntohs – convert values between host and network byte order

SYNOPSIS |

```
cc [ flag... ] file... -lsocket -lnsl [ library... ]
#include <sys/types.h>
#include <netinet/in.h>
#include <inttypes.h>

uint32_t htonl (uint32_t hostlong) ;
uint16_t htons (uint16_t hostshort) ;
uint32_t ntohl (uint32_t netlong) ;
uint16_t ntohs (uint16_t netshort) ;
```

DESCRIPTION | These routines convert 16-bit and 32-bit quantities between network byte order and host byte order. On some architectures these routines are defined as NULL macros in the include file `<netinet/in.h>`. On other architectures, the routines are functional when the host byte order is different from network byte order.

The routines are most often used in conjunction with Internet addresses and ports as returned by `gethostent()` and `getservent()`. See [gethostbyname\(3NSL\)](#) and [getservbyname\(3SOCKET\)](#).

ATTRIBUTES | See [attributes\(5\)](#) for descriptions of the following attributes:

NAME | cldap_close – dispose of connectionless LDAP pointer

SYNOPSIS | `cc [flag...] file... -lldap [library...]`

```
#include <lber.h>
#include <ldap.h>

void clldap_close(LDAP *ld) ;
```

DESCRIPTION | The `clldap_close()` function disposes of memory allocated by `clldap_open(3LDAP)`. It should be called when all CLDAP communication is complete.

PARAMETERS | *ld* The LDAP pointer returned by a previous call to `clldap_open(3LDAP)`.

ATTRIBUTES | See `attributes(5)` for a description of the following attributes:

cldap_open(3LDAP)

NAME	cldap_open – LDAP connectionless communication preparation						
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> LDAP *cldap_open(char *host, int port);</pre>						
PARAMETERS	<p><i>host</i> The name of the host on which the LDAP server is running.</p> <p><i>port</i> The port number to connect.</p>						
DESCRIPTION	<p>The <code>cldap_open()</code> function is called to prepare for connectionless LDAP communication (over <code>udp(7P)</code>). It allocates an LDAP structure which is passed to future search requests.</p> <p>If the default IANA-assigned port of 389 is desired, <code>LDAP_PORT</code> should be specified for <i>port</i>. <i>host</i> can contain a space-separated list of hosts or addresses to try. <code>cldap_open()</code> returns a pointer to an LDAP structure, which should be passed to subsequent calls to <code>cldap_search_s(3LDAP)</code>, <code>cldap_setretryinfo(3LDAP)</code>, and <code>cldap_close(3LDAP)</code>. Certain fields in the LDAP structure can be set to indicate size limit, time limit, and how aliases are handled during operations. See <code>ldap_open(3LDAP)</code> and <code><ldap.h></code> for more details.</p>						
ERRORS	If an error occurs, <code>cldap_open()</code> will return <code>NULL</code> and <code>errno</code> will be set appropriately.						
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:						
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsl (32-bit) SUNWcslx (64-bit)</td></tr><tr><td>Interface Stability</td><td>Evolving</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)	Interface Stability	Evolving

Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)						
Interface Stability	Evolving						
SEE ALSO	<code>ldap(3LDAP)</code> <code>cldap_search_s(3LDAP)</code> , <code>cldap_setretryinfo(3LDAP)</code> , <code>cldap_close(3LDAP)</code> , <code>attributes(5)</code> , <code>udp(7P)</code>						

NAME	cldap_search_s – connectionless LDAP search										
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int cldap_search_s(LDAP *ld, char *base, int scope, char *filter, char *attrs, int attrsonly, LDAPMessage **res, char *logdn);</pre>										
DESCRIPTION	<p>The <code>cldap_search_s()</code> function performs an LDAP search using the Connectionless LDAP (CLDAP) protocol.</p> <p><code>cldap_search_s()</code> has parameters and behavior identical to that of <code>ldap_search_s(3LDAP)</code>, except for the addition of the <code>logdn</code> parameter. <code>logdn</code> should contain a distinguished name to be used only for logging purposed by the LDAP server. It should be in the text format described by RFC 1779, <i>A String Representation of Distinguished Names</i>.</p>										
Retransmission Algorithm	<p><code>cldap_search_s()</code> operates using the CLDAP protocol over <code>udp(7P)</code>. Since UDP is a non-reliable protocol, a retry mechanism is used to increase reliability. The <code>cldap_setretryinfo(3LDAP)</code> function can be used to set two retry parameters: <code>tries</code>, a count of the number of times to send a search request and <code>timeout</code>, an initial timeout that determines how long to wait for a response before re-trying. <code>timeout</code> is specified seconds. These values are stored in the <code>ld_cldaptries</code> and <code>ld_cldaptimeout</code> members of the <code>ld</code> LDAP structure, and the default values set in <code>ldap_open(3LDAP)</code> are 4 and 3 respectively. The retransmission algorithm used is:</p> <table border="0"> <tr> <td style="padding-right: 20px;">Step 1</td> <td>Set the current timeout to <code>ld_cldaptimeout</code> seconds, and the current LDAP server address to the first LDAP server found during the <code>ldap_open(3LDAP)</code> call.</td> </tr> <tr> <td>Step 2</td> <td>Send the search request to the current LDAP server address.</td> </tr> <tr> <td>Step 3</td> <td>Set the wait timeout to the current timeout divided by the number of server addresses found during <code>ldap_open(3LDAP)</code> or to one second, whichever is larger. Wait at most that long for a response; if a response is received, STOP. Note that the wait timeout is always rounded down to the next lowest second.</td> </tr> <tr> <td>Step 4</td> <td>Repeat steps 2 and 3 for each LDAP server address.</td> </tr> <tr> <td>Step 5</td> <td>Set the current timeout to twice its previous value and repeat Steps 2 through 5 a maximum of <code>tries</code> times.</td> </tr> </table>	Step 1	Set the current timeout to <code>ld_cldaptimeout</code> seconds, and the current LDAP server address to the first LDAP server found during the <code>ldap_open(3LDAP)</code> call.	Step 2	Send the search request to the current LDAP server address.	Step 3	Set the wait timeout to the current timeout divided by the number of server addresses found during <code>ldap_open(3LDAP)</code> or to one second, whichever is larger. Wait at most that long for a response; if a response is received, STOP. Note that the wait timeout is always rounded down to the next lowest second.	Step 4	Repeat steps 2 and 3 for each LDAP server address.	Step 5	Set the current timeout to twice its previous value and repeat Steps 2 through 5 a maximum of <code>tries</code> times.
Step 1	Set the current timeout to <code>ld_cldaptimeout</code> seconds, and the current LDAP server address to the first LDAP server found during the <code>ldap_open(3LDAP)</code> call.										
Step 2	Send the search request to the current LDAP server address.										
Step 3	Set the wait timeout to the current timeout divided by the number of server addresses found during <code>ldap_open(3LDAP)</code> or to one second, whichever is larger. Wait at most that long for a response; if a response is received, STOP. Note that the wait timeout is always rounded down to the next lowest second.										
Step 4	Repeat steps 2 and 3 for each LDAP server address.										
Step 5	Set the current timeout to twice its previous value and repeat Steps 2 through 5 a maximum of <code>tries</code> times.										
EXAMPLES	<p>Assume that the default values for <code>tries</code> and <code>timeout</code> of 4 tries and 3 seconds are used. Further, assume that a space-separated list of two hosts, each with one address, was passed to <code>ldap_open(3LDAP)</code>. The pattern of requests sent will be (stopping as soon as a response is received):</p> <pre>Time Search Request Sent To: +0 Host A try 1 +1 (0+3/2) Host B try 1</pre>										

cldap_search_s(3LDAP)

```
+2 (1+3/2)      Host A try 2
+5 (2+6/2)      Host B try 2
+8 (5+6/2)      Host A try 3
+14 (8+12/2)    Host B try 3
+20 (14+12/2)   Host A try 4
+32 (20+24/2)   Host B try 4
+44 (20+24/2)   (give up - no response)
```

ERRORS `cldap_search_s()` returns `LDAP_SUCCESS` if a search was successful and the appropriate LDAP error code otherwise. See [ldap_error\(3LDAP\)](#) for more information.

cldap_setretryinfo(3LDAP)

NAME cldap_setretryinfo – set connectionless LDAP request retransmission parameters

SYNOPSIS cc [*flag...*] *file...* -lldap [*library...*]

```
#include <lber.h>
#include <ldap.h>
```

```
void cldap_setretryinfo(LDAP *ld, int tries, int timeout);
```

PARAMETERS

ld LDAP pointer returned from a previous call to [cldap_open\(3LDAP\)](#).

tries Maximum number of times to send a request.

timeout Initial time, in seconds, to wait before re-sending a request.

DESCRIPTION The `cldap_setretryinfo()` function is used to set the CLDAP request retransmission behavior for future [cldap_search_s\(3LDAP\)](#) calls. The default values (set by [cldap_open\(3LDAP\)](#)) are 4 tries and 3 seconds between tries. See [cldap_search_s\(3LDAP\)](#) for a complete description of the retransmission algorithm used.

connect(3SOCKET)

NAME	connect – initiate a connection on a socket																		
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <sys/types.h> #include <sys/socket.h> int connect(int s, const struct sockaddr *name, int namelen);</pre>																		
DESCRIPTION	<p>The parameter <i>s</i> is a socket. If it is of type <code>SOCK_DGRAM</code>, <code>connect()</code> specifies the peer with which the socket is to be associated. This address is the address to which datagrams are to be sent if a receiver is not explicitly designated. This address is the only address from which datagrams are to be received. If the socket <i>s</i> is of type <code>SOCK_STREAM</code>, <code>connect()</code> attempts to make a connection to another socket. The other socket is specified by <i>name</i>. <i>name</i> is an address in the communication space of the socket. Each communication space interprets the <i>name</i> parameter in its own way. If <i>s</i> is not bound, then <i>s</i> will be bound to an address selected by the underlying transport provider. Generally, stream sockets can successfully <code>connect()</code> only once. Datagram sockets can use <code>connect()</code> multiple times to change their association. Datagram sockets can dissolve the association by connecting to a null address.</p>																		
RETURN VALUES	<p>If the connection or binding succeeds, 0 is returned. Otherwise, -1 is returned and sets <code>errno</code> to indicate the error.</p>																		
ERRORS	<p>The call fails if:</p> <table><tr><td>EACCES</td><td>Search permission is denied for a component of the path prefix of the pathname in <i>name</i>.</td></tr><tr><td>EADDRINUSE</td><td>The address is already in use.</td></tr><tr><td>EADDRNOTAVAIL</td><td>The specified address is not available on the remote machine.</td></tr><tr><td>EAFNOSUPPORT</td><td>Addresses in the specified address family cannot be used with this socket.</td></tr><tr><td>EALREADY</td><td>The socket is non-blocking, and a previous connection attempt has not yet been completed.</td></tr><tr><td>EBADF</td><td><i>s</i> is not a valid descriptor.</td></tr><tr><td>ECONNREFUSED</td><td>The attempt to connect was forcefully rejected. The calling program should <code>close(2)</code> the socket descriptor, and issue another <code>socket(3SOCKET)</code> call to obtain a new descriptor before attempting another <code>connect()</code> call.</td></tr><tr><td>EINPROGRESS</td><td>The socket is non-blocking, and the connection cannot be completed immediately. You can use <code>select(3C)</code> to complete the connection by selecting the socket for writing.</td></tr><tr><td>EINTR</td><td>The connection attempt was interrupted before any data arrived by the delivery of a signal.</td></tr></table>	EACCES	Search permission is denied for a component of the path prefix of the pathname in <i>name</i> .	EADDRINUSE	The address is already in use.	EADDRNOTAVAIL	The specified address is not available on the remote machine.	EAFNOSUPPORT	Addresses in the specified address family cannot be used with this socket.	EALREADY	The socket is non-blocking, and a previous connection attempt has not yet been completed.	EBADF	<i>s</i> is not a valid descriptor.	ECONNREFUSED	The attempt to connect was forcefully rejected. The calling program should <code>close(2)</code> the socket descriptor, and issue another <code>socket(3SOCKET)</code> call to obtain a new descriptor before attempting another <code>connect()</code> call.	EINPROGRESS	The socket is non-blocking, and the connection cannot be completed immediately. You can use <code>select(3C)</code> to complete the connection by selecting the socket for writing.	EINTR	The connection attempt was interrupted before any data arrived by the delivery of a signal.
EACCES	Search permission is denied for a component of the path prefix of the pathname in <i>name</i> .																		
EADDRINUSE	The address is already in use.																		
EADDRNOTAVAIL	The specified address is not available on the remote machine.																		
EAFNOSUPPORT	Addresses in the specified address family cannot be used with this socket.																		
EALREADY	The socket is non-blocking, and a previous connection attempt has not yet been completed.																		
EBADF	<i>s</i> is not a valid descriptor.																		
ECONNREFUSED	The attempt to connect was forcefully rejected. The calling program should <code>close(2)</code> the socket descriptor, and issue another <code>socket(3SOCKET)</code> call to obtain a new descriptor before attempting another <code>connect()</code> call.																		
EINPROGRESS	The socket is non-blocking, and the connection cannot be completed immediately. You can use <code>select(3C)</code> to complete the connection by selecting the socket for writing.																		
EINTR	The connection attempt was interrupted before any data arrived by the delivery of a signal.																		

connect(3SOCKET)

EINVAL	<i>namelen</i> is not the size of a valid address for the specified address family.
EIO	An I/O error occurred while reading from or writing to the file system.
EISCONN	The socket is already connected.
ELOOP	Too many symbolic links were encountered in translating the pathname in <i>name</i> .
ENETUNREACH	The network is not reachable from this host.
EHOSTUNREACH	The remote host is not reachable from this host.
ENOENT	A component of the path prefix of the pathname in <i>name</i> does not exist.
ENOENT	The socket referred to by the pathname in <i>name</i> does not exist.
ENOSR	There were insufficient STREAMS resources available to complete the operation.
ENXIO	The server exited before the connection was complete.
ETIMEDOUT	Connection establishment timed out without establishing a connection.
EWouldBLOCK	The socket is marked as non-blocking, and the requested operation would block.

The following errors are specific to connecting names in the UNIX domain. These errors might not apply in future versions of the UNIX IPC domain.

ENOTDIR	A component of the path prefix of the pathname in <i>name</i> is not a directory.
ENOTSOCK	<i>s</i> is not a socket.
ENOTSOCK	<i>name</i> is not a socket.
EPROTOTYPE	The file that is referred to by <i>name</i> is a socket of a type other than type <i>s</i> . For example, <i>s</i> is a SOCK_DGRAM socket, while <i>name</i> refers to a SOCK_STREAM socket.

connect(3XNET)

NAME	connect – connect a socket						
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h> int connect(int <i>socket</i>, const struct sockaddr *<i>address</i>, socklen_t <i>address_len</i>);</pre>						
DESCRIPTION	<p>The <code>connect()</code> function requests a connection to be made on a socket. The function takes the following arguments:</p> <table><tr><td><i>socket</i></td><td>Specifies the file descriptor associated with the socket.</td></tr><tr><td><i>address</i></td><td>Points to a <code>sockaddr</code> structure containing the peer address. The length and format of the address depend on the address family of the socket.</td></tr><tr><td><i>address_len</i></td><td>Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.</td></tr></table> <p>If the socket has not already been bound to a local address, <code>connect()</code> will bind it to an address which, unless the socket's address family is <code>AF_UNIX</code>, is an unused local address.</p> <p>If the initiating socket is not connection-mode, then <code>connect()</code> sets the socket's peer address, but no connection is made. For <code>SOCK_DGRAM</code> sockets, the peer address identifies where all datagrams are sent on subsequent <code>send(3XNET)</code> calls, and limits the remote sender for subsequent <code>recv(3XNET)</code> calls. If <i>address</i> is a null address for the protocol, the socket's peer address will be reset.</p> <p>If the initiating socket is connection-mode, then <code>connect()</code> attempts to establish a connection to the address specified by the <i>address</i> argument.</p> <p>If the connection cannot be established immediately and <code>O_NONBLOCK</code> is not set for the file descriptor for the socket, <code>connect()</code> will block for up to an unspecified timeout interval until the connection is established. If the timeout interval expires before the connection is established, <code>connect()</code> will fail and the connection attempt will be aborted. If <code>connect()</code> is interrupted by a signal that is caught while blocked waiting to establish a connection, <code>connect()</code> will fail and set <code>errno</code> to <code>EINTR</code>, but the connection request will not be aborted, and the connection will be established asynchronously.</p> <p>If the connection cannot be established immediately and <code>O_NONBLOCK</code> is set for the file descriptor for the socket, <code>connect()</code> will fail and set <code>errno</code> to <code>EINPROGRESS</code>, but the connection request will not be aborted, and the connection will be established asynchronously. Subsequent calls to <code>connect()</code> for the same socket, before the connection is established, will fail and set <code>errno</code> to <code>EALREADY</code>.</p> <p>When the connection has been established asynchronously, <code>select(3C)</code> and <code>poll(2)</code> will indicate that the file descriptor for the socket is ready for writing.</p>	<i>socket</i>	Specifies the file descriptor associated with the socket.	<i>address</i>	Points to a <code>sockaddr</code> structure containing the peer address. The length and format of the address depend on the address family of the socket.	<i>address_len</i>	Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.
<i>socket</i>	Specifies the file descriptor associated with the socket.						
<i>address</i>	Points to a <code>sockaddr</code> structure containing the peer address. The length and format of the address depend on the address family of the socket.						
<i>address_len</i>	Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.						

	The socket in use may require the process to have appropriate privileges to use the <code>connect ()</code> function.
USAGE	If <code>connect ()</code> fails, the state of the socket is unspecified. Portable applications should close the file descriptor and create a new socket before attempting to reconnect.
RETURN VALUES	Upon successful completion, <code>connect ()</code> returns 0. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.
ERRORS	The <code>connect ()</code> function will fail if:
	<code>EADDRNOTAVAIL</code> The specified address is not available from the local machine.
	<code>EAFNOSUPPORT</code> The specified address is not a valid address for the address family of the specified socket.
	<code>EALREADY</code> A connection request is already in progress for the specified socket.
	<code>EBADF</code> The <i>socket</i> argument is not a valid file descriptor.
	<code>ECONNREFUSED</code> The target address was not listening for connections or refused the connection request.
	<code>EFAULT</code> The address parameter can not be accessed.
	<code>EINPROGRESS</code> <code>O_NONBLOCK</code> is set for the file descriptor for the socket and the connection cannot be immediately established; the connection will be established asynchronously.
	<code>EINTR</code> The attempt to establish a connection was interrupted by delivery of a signal that was caught; the connection will be established asynchronously.
	<code>EISCONN</code> The specified socket is connection-mode and is already connected.
	<code>ENETUNREACH</code> No route to the network is present.
	<code>ENOTSOCK</code> The <i>socket</i> argument does not refer to a socket.
	<code>EPROTOTYPE</code> The specified address has a different type than the socket bound to the specified peer address.
	<code>ETIMEDOUT</code> The attempt to connect timed out before a connection was made.
	If the address family of the socket is <code>AF_UNIX</code> , then <code>connect ()</code> will fail if:
	<code>EIO</code> An I/O error occurred while reading from or writing to the file system.

connect(3XNET)

ELOOP	Too many symbolic links were encountered in translating the pathname in <i>address</i> .
ENAMETOOLONG	A component of a pathname exceeded <code>NAME_MAX</code> characters, or an entire pathname exceeded <code>PATH_MAX</code> characters.
ENOENT	A component of the pathname does not name an existing file or the pathname is an empty string.
ENOTDIR	A component of the path prefix of the pathname in <i>address</i> is not a directory.
The <code>connect()</code> function may fail if:	
EACCES	Search permission is denied for a component of the path prefix; or write access to the named socket is denied.
EADDRINUSE	Attempt to establish a connection that uses addresses that are already in use.
ECONNRESET	Remote host reset the connection request.
EHOSTUNREACH	The destination host cannot be reached (probably because the host is down or a remote router cannot reach it).
EINVAL	The <i>address_len</i> argument is not a valid length for the address family; or invalid address family in <code>sockaddr</code> structure.
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .
ENETDOWN	The local interface used to reach the destination is down.
ENOBUFS	No buffer space is available.
ENOSR	There were insufficient STREAMS resources available to complete the operation.
EOPNOTSUPP	The socket is listening and can not be connected.

dial(3NSL)

NAME	dial, undial – establish an outgoing terminal line connection										
SYNOPSIS	<pre>cc [flag...] file... -lnsl [library...] #include <dial.h> int dial (CALL call) ; void undial (int fd) ;</pre>										
DESCRIPTION	<p>The dial () function returns a file-descriptor for a terminal line open for read/write. The argument to dial () is a CALL structure (defined in the header <dial.h>).</p> <p>When finished with the terminal line, the calling program must invoke undial () to release the semaphore that has been set during the allocation of the terminal device.</p> <p>CALL is defined in the header <dial.h> and has the following members:</p> <pre>struct termio *attr; /* pointer to termio attribute struct */ int baud; /* transmission data rate */ int speed; /* 212A modem: low=300, high=1200 */ char *line; /* device name for out-going line */ char *telno; /* pointer to tel-no digits string */ int modem; /* specify modem control for direct lines */ char *device; /* unused */ int dev_len; /* unused */</pre> <p>The CALL element speed is intended only for use with an outgoing dialed call, in which case its value should be the desired transmission baud rate. The CALL element baud is no longer used.</p> <p>If the desired terminal line is a direct line, a string pointer to its device-name should be placed in the line element in the CALL structure. Legal values for such terminal device names are kept in the Devices file. In this case, the value of the baud element should be set to -1. This value will cause dial to determine the correct value from the <Devices> file.</p> <p>The telno element is for a pointer to a character string representing the telephone number to be dialed. Such numbers may consist only of these characters:</p> <table><tr><td>0-9</td><td>dial 0-9</td></tr><tr><td>*</td><td>dail *</td></tr><tr><td>#</td><td>dail #</td></tr><tr><td>=</td><td>wait for secondary dial tone</td></tr><tr><td>-</td><td>delay for approximately 4 seconds</td></tr></table>	0-9	dial 0-9	*	dail *	#	dail #	=	wait for secondary dial tone	-	delay for approximately 4 seconds
0-9	dial 0-9										
*	dail *										
#	dail #										
=	wait for secondary dial tone										
-	delay for approximately 4 seconds										

The `CALL` element `modem` is used to specify modem control for direct lines. This element should be non-zero if modem control is required. The `CALL` element `attr` is a pointer to a `termio` structure, as defined in the header `<termio.h>`. A `NULL` value for this pointer element may be passed to the `dial` function, but if such a structure is included, the elements specified in it will be set for the outgoing terminal line before the connection is established. This setting is often important for certain attributes such as parity and baud-rate.

The `CALL` elements `device` and `dev_len` are no longer used. They are retained in the `CALL` structure for compatibility reasons.

RETURN VALUES On failure, a negative value indicating the reason for the failure will be returned. Mnemonics for these negative indices as listed here are defined in the header `<dial.h>`.

```
INTRPT  -1      /* interrupt occurred */
D_HUNG  -2      /* dialer hung (no return from write) */
NO_ANS  -3      /* no answer within 10 seconds */
ILL_BD  -4      /* illegal baud-rate */
A_PROB  -5      /* acu problem (open( ) failure) */
L_PROB  -6      /* line problem (open( ) failure) */
NO_Ldv  -7      /* can't open Devices file */
DV_NT_A -8      /* requested device not available */
DV_NT_K -9      /* requested device not known */
NO_BD_A -10     /* no device available at requested baud */
NO_BD_K -11     /* no device known at requested baud */
DV_NT_E -12     /* requested speed does not match */
BAD_SYS -13     /* system not in Systems file*/
```

FILES `/etc/uucp/Devices`
`/etc/uucp/Systems`
`/var/spool/uucp/LCK. .tty-device`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `uucp(1C)`, `alarm(2)`, `read(2)`, `write(2)`, `attributes(5)`, `termio(7I)`

NOTES Including the header `<dial.h>` automatically includes the header `<termio.h>`. An `alarm(2)` system call for 3600 seconds is made (and caught) within the `dial` module for the purpose of “touching” the `LCK. .` file and constitutes the device allocation semaphore for the terminal device. Otherwise, `uucp(1C)` may simply delete the `LCK. .` entry on its 90-minute clean-up rounds. The alarm may go off while the user program is in a `read(2)` or `write(2)` function, causing an apparent error return. If the user program expects to be around for an hour or more, error returns from `read()`s should be checked for (`errno==EINTR`), and the `read()` possibly reissued.

dial(3NSL)

This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

NAME	doconfig – execute a configuration script
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lnsl [<i>library</i> ...] # include <sac.h> int doconfig(int <i>fildev</i>, char *<i>script</i>, long <i>rflag</i>);</pre>
DESCRIPTION	<p>doconfig() is a Service Access Facility library function that interprets the configuration scripts contained in the files </etc/saf/<i>pmtag</i>/<i>_config</i>>, </etc/saf/<i>_sysconfig</i>>, and </etc/saf/<i>pmtag</i>/<i>svctag</i>>, where <i>pmtag</i> specifies the tag associated with the port monitor, and <i>svctag</i> specifies the service tag associated with a given service. See pmadm(1M) and sacadm(1M).</p> <p><i>script</i> is the name of the configuration script; <i>fildev</i> is a file descriptor that designates the stream to which stream manipulation operations are to be applied; <i>rflag</i> is a bitmask that indicates the mode in which <i>script</i> is to be interpreted. If <i>rflag</i> is zero, all commands in the configuration script are eligible to be interpreted. If <i>rflag</i> has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If <i>rflag</i> has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns.</p> <p>The configuration language in which <i>script</i> is written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: assign, push, pop, runwait, and run. The comment character is #; when a # occurs on a line, everything from that point to the end of the line is ignored. Blank lines are not significant. No line in a command script may exceed 1024 characters.</p> <p><i>assign variable=value</i></p> <p>Used to define environment variables. <i>variable</i> is the name of the environment variable and <i>value</i> is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. <i>value</i> may be quoted. The quoting rules are those used by the shell for defining environment variables. assign will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.</p> <p><i>push module1[, module2, module3, ...]</i></p> <p>Used to push STREAMS modules onto the stream designated by <i>fildev</i>. <i>module1</i> is the name of the first module to be pushed, <i>module2</i> is the name of the second module to be pushed, etc. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.</p> <p><i>pop [module]</i></p> <p>Used to pop STREAMS modules off the designated stream. If pop is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If <i>module</i> is the special keyword ALL, then all modules on the stream will be popped. Note that only modules above the topmost driver are affected.</p>

doconfig(3NSL)

runwait command

The `runwait` command runs a command and waits for it to complete. `command` is the pathname of the command to be run. The command is run with `/usr/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The `runwait` command will fail if `command` cannot be found or cannot be executed, or if `command` exits with a non-zero status.

run command

The `run` command is identical to `runwait` except that it does not wait for `command` to complete. `command` is the pathname of the command to be run. `run` will not fail unless it is unable to create a child process to execute the command.

Although they are syntactically indistinguishable, some of the commands available to `run` and `runwait` are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The `doconfig()` interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See `sh(1)`. The built-in commands are:

```
cd
ulimit
umask
```

RETURN VALUES

`doconfig()` returns 0 if the script was interpreted successfully. If a command in the script fails, the interpretation of the script ceases at that point and a positive number is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. When a script fails, the process whose environment was being established should *not* be started.

NAME	endhostent, gethostbyaddr, gethostbyname, gethostent, sethostent – network host database functions
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <netdb.h> extern int h_errno; void endhostent(void); struct hostent *gethostbyaddr(const void *<i>addr</i>, socklen_t <i>len</i>, int <i>type</i>); struct hostent *gethostbyname(const char *<i>name</i>); struct hostent *gethostent(void); void sethostent(int <i>stayopen</i>);</pre>
DESCRIPTION	<p>The <code>gethostent()</code>, <code>gethostbyaddr()</code>, and <code>gethostbyname()</code> functions each return a pointer to a <code>hostent</code> structure, the members of which contain the fields of an entry in the network host database.</p> <p>The <code>gethostent()</code> function reads the next entry of the database, opening a connection to the database if necessary.</p> <p>The <code>gethostbyaddr()</code> function searches the database and finds an entry which matches the address family specified by the <code>type</code> argument and which matches the address pointed to by the <code>addr</code> argument, opening a connection to the database if necessary. The <code>addr</code> argument is a pointer to the binary-format (that is, not null-terminated) address in network byte order, whose length is specified by the <code>len</code> argument. The datatype of the address depends on the address family. For an address of type <code>AF_INET</code>, this is an <code>in_addr</code> structure, defined in <code><netinet/in.h></code>. For an address of type <code>AF_INET6</code>, there is an <code>in6_addr</code> structure defined in <code><netinet/in.h></code>.</p> <p>The <code>gethostbyname()</code> function searches the database and finds an entry which matches the host name specified by the <code>name</code> argument, opening a connection to the database if necessary. If <code>name</code> is an alias for a valid host name, the function returns information about the host name to which the alias refers, and <code>name</code> is included in the list of aliases returned.</p> <p>The <code>sethostent()</code> function opens a connection to the network host database, and sets the position of the next entry to the first entry. If the <code>stayopen</code> argument is non-zero, the connection to the host database will not be closed after each call to <code>gethostent()</code> (either directly, or indirectly through one of the other <code>gethost*()</code> functions).</p> <p>The <code>endhostent()</code> function closes the connection to the database.</p>
USAGE	<p>The <code>gethostent()</code>, <code>gethostbyaddr()</code>, and <code>gethostbyname()</code> functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.</p> <p>These functions are generally used with the Internet address family.</p>

endhostent(3XNET)

RETURN VALUES

On successful completion, `gethostbyaddr()`, `gethostbyname()` and `gethostent()` return a pointer to a `hostent` structure if the requested entry was found, and a null pointer if the end of the database was reached or the requested entry was not found. Otherwise, a null pointer is returned.

On unsuccessful completion, `gethostbyaddr()` and `gethostbyname()` functions set `h_errno` to indicate the error.

ERRORS

No errors are defined for `endhostent()`, `gethostent()` and `sethostent()`.

The `gethostbyaddr()` and `gethostbyname()` functions will fail in the following cases, setting `h_errno` to the value shown in the list below. Any changes to `errno` are unspecified.

- HOST_NOT_FOUND No such host is known.
- NO_DATA The server recognised the request and the name but no address is available. Another type of request to the name server for the domain might return an answer.
- NO_RECOVERY An unexpected server failure occurred which can not be recovered.
- TRY_AGAIN A temporary and possibly transient error occurred, such as a failure of a server to respond.

NAME	ethers, ether_ntoa, ether_aton, ether_ntohost, ether_hostton, ether_line – Ethernet address mapping operations				
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <sys/types.h> #include <sys/ethernet.h> char *ether_ntoa(const struct ether_addr *e); struct ether_addr *ether_aton(const char *s); int ether_ntohost(char *hostname, const struct ether_addr *e); int ether_hostton(const char *hostname, struct ether_addr *e); int ether_line(const char *l, struct ether_addr *e, char *hostname);</pre>				
DESCRIPTION	<p>These routines are useful for mapping 48 bit Ethernet numbers to their ASCII representations or their corresponding host names, and vice versa.</p> <p>The function <code>ether_ntoa()</code> converts a 48 bit Ethernet number pointed to by <code>e</code> to its standard ASCII representation; it returns a pointer to the ASCII string. The representation is of the form <code>x:x:x:x:x:x</code> where <code>x</code> is a hexadecimal number between 0 and ff. The function <code>ether_aton()</code> converts an ASCII string in the standard representation back to a 48 bit Ethernet number; the function returns NULL if the string cannot be scanned successfully.</p> <p>The function <code>ether_ntohost()</code> maps an Ethernet number (pointed to by <code>e</code>) to its associated hostname. The string pointed to by <code>hostname</code> must be long enough to hold the hostname and a NULL character. The function returns zero upon success and non-zero upon failure. Inversely, the function <code>ether_hostton()</code> maps a hostname string to its corresponding Ethernet number; the function modifies the Ethernet number pointed to by <code>e</code>. The function also returns zero upon success and non-zero upon failure. In order to do the mapping, both these functions may lookup one or more of the following sources: the ethers file, the NIS maps <code>ethers.byname</code> and <code>ethers.byaddr</code> and the NIS+ table <code>ethers</code>. The sources and their lookup order are specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code> for details.</p> <p>The function <code>ether_line()</code> scans a line, pointed to by <code>l</code>, and sets the hostname and the Ethernet number, pointed to by <code>e</code>. The string pointed to by <code>hostname</code> must be long enough to hold the hostname and a NULL character. The function returns zero upon success and non-zero upon failure. The format of the scanned line is described by <code>ethers(4)</code>.</p>

NAME	freeaddrinfo, getaddrinfo – get address information
SYNOPSIS	<pre>cc [flag ...] file ... -lxnet [library ...] #include <sys/socket.h> #include <netdb.h> void freeaddrinfo(struct addrinfo *ai); int getaddrinfo(const char *restrict <i>nodename</i>, const char *restrict <i>servname</i>, const struct addrinfo *restrict <i>hints</i>, struct addrinfo **restrict <i>res</i>);</pre>
DESCRIPTION	<p>The <code>freeaddrinfo()</code> function frees one or more <code>addrinfo</code> structures returned by <code>getaddrinfo()</code>, along with any additional storage associated with those structures. If the <code>ai_next</code> member of the structure is not null, the entire list of structures is freed. The <code>freeaddrinfo()</code> function supports the freeing of arbitrary sublists of an <code>addrinfo</code> list originally returned by <code>getaddrinfo()</code>.</p> <p>The <code>getaddrinfo()</code> function translates the name of a service location (for example, a host name) and/or a service name and returns a set of socket addresses and associated information to be used in creating a socket with which to address the specified service.</p> <p>The <code>nodename</code> and <code>servname</code> arguments are either null pointers or pointers to null-terminated strings. One or both of these two arguments are supplied by the application as a non-null pointer.</p> <p>The format of a valid name depends on the address family or families. If a specific family is not given and the name could be interpreted as valid within multiple supported families, the implementation attempts to resolve the name in all supported families and, in absence of errors, one or more results are returned.</p> <p>If the <code>nodename</code> argument is not null, it can be a descriptive name or can be an address string. If the specified address family is <code>AF_INET</code>, <code>AF_INET6</code>, or <code>AF_UNSPEC</code>, valid descriptive names include host names. If the specified address family is <code>AF_INET</code> or <code>AF_UNSPEC</code>, address strings using Internet standard dot notation as specified in inet_addr(3XNET) are valid.</p> <p>If the specified address family is <code>AF_INET6</code> or <code>AF_UNSPEC</code>, standard IPv6 text forms described in inet_ntop(3XNET) are valid.</p> <p>If <code>nodename</code> is not null, the requested service location is named by <code>nodename</code>; otherwise, the requested service location is local to the caller.</p> <p>If <code>servname</code> is null, the call returns network-level addresses for the specified <code>nodename</code>. If <code>servname</code> is not null, it is a null-terminated character string identifying the requested service. This string can be either a descriptive name or a numeric representation suitable for use with the address family or families. If the specified address family is <code>AF_INET</code>, <code>AF_INET6</code>, or <code>AF_UNSPEC</code>, the service can be specified as a string specifying a decimal port number.</p>

freeaddrinfo(3XNET)

If the *hints* argument is not null, it refers to a structure containing input values that can direct the operation by providing options and by limiting the returned information to a specific socket type, address family and/or protocol. In this *hints* structure every member other than *ai_flags*, *ai_family*, *ai_socktype*, and *ai_protocol* is set to 0 or a null pointer. A value of `AF_UNSPEC` for *ai_family* means that the caller accepts any address family. A value of 0 for *ai_socktype* means that the caller accepts any socket type. A value of 0 for *ai_protocol* means that the caller accepts any protocol. If *hints* is a null pointer, the behavior is as if it referred to a structure containing the value 0 for the *ai_flags*, *ai_socktype*, and *ai_protocol* members, and `AF_UNSPEC` for the *ai_family* member.

The *ai_flags* member to which the *hints* parameter points is set to 0 or be the bitwise-inclusive OR of one or more of the values `AI_PASSIVE`, `AI_CANONNAME`, `AI_NUMERICHOST`, and `AI_NUMERICSERV`.

If the `AI_PASSIVE` flag is specified, the returned address information is suitable for use in binding a socket for accepting incoming connections for the specified service. In this case, if the *nodename* argument is null, then the IP address portion of the socket address structure is set to `INADDR_ANY` for an IPv4 address or `IN6ADDR_ANY_INIT` for an IPv6 address. If the `AI_PASSIVE` flag is not specified, the returned address information is suitable for a call to `connect(3XNET)` (for a connection-mode protocol) or for a call to `connect()`, `sendto(3XNET)`, or `sendmsg(3XNET)` (for a connectionless protocol). In this case, if the *nodename* argument is null, then the IP address portion of the socket address structure is set to the loopback address.

If the `AI_CANONNAME` flag is specified and the *nodename* argument is not null, the function attempts to determine the canonical name corresponding to *nodename* (for example, if *nodename* is an alias or shorthand notation for a complete name).

If the `AI_NUMERICHOST` flag is specified, then a non-null *nodename* string supplied is a numeric host address string. Otherwise, an `EAI_NONAME` error is returned. This flag prevents any type of name resolution service (for example, the DNS) from being invoked.

If the `AI_NUMERICSERV` flag is specified, then a non-null *servname* string supplied is a numeric port string. Otherwise, an `EAI_NONAME` error is returned. This flag prevents any type of name resolution service (for example, NIS+) from being invoked.

If the `AI_V4MAPPED` flag is specified along with an *ai_family* of `AF_INET6`, then `getaddrinfo()` returns IPv4-mapped IPv6 addresses on finding no matching IPv6 addresses (*ai_addrlen* is 16). The `AI_V4MAPPED` flag is ignored unless *ai_family* equals `AF_INET6`. If the `AI_ALL` flag is used with the `AI_V4MAPPED` flag, then `getaddrinfo()` returns all matching IPv6 and IPv4 addresses. The `AI_ALL` flag without the `AI_V4MAPPED` flag is ignored.

The `ai_socktype` member to which `hints` points specifies the socket type for the service, as defined in `socket(3XNET)`. If a specific socket type is not given (for example, a value of 0) and the service name could be interpreted as valid with multiple supported socket types, the implementation attempts to resolve the service name for all supported socket types and, in the absence of errors, all possible results are returned. A non-zero socket type value limits the returned information to values with the specified socket type.

If the `ai_family` member to which `hints` points has the value `AF_UNSPEC`, addresses are returned for use with any address family that can be used with the specified `nodename` and/or `servname`. Otherwise, addresses are returned for use only with the specified address family. If `ai_family` is not `AF_UNSPEC` and `ai_protocol` is not 0, then addresses are returned for use only with the specified address family and protocol; the value of `ai_protocol` is interpreted as in a call to the `socket()` function with the corresponding values of `ai_family` and `ai_protocol`.

RETURN VALUES

A 0 return value for `getaddrinfo()` indicates successful completion; a non-zero return value indicates failure. The possible values for the failures are listed in the `ERRORS` section.

Upon successful return of `getaddrinfo()`, the location to which `res` points refers to a linked list of `addrinfo` structures, each of which specifies a socket address and information for use in creating a socket with which to use that socket address. The list includes at least one `addrinfo` structure. The `ai_next` member of each structure contains a pointer to the next structure on the list, or a null pointer if it is the last structure on the list. Each structure on the list includes values for use with a call to the `socket` function, and a socket address for use with the `connect` function or, if the `AI_PASSIVE` flag was specified, for use with the `bind(3XNET)` function. The `ai_family`, `ai_socktype`, and `ai_protocol` members are usable as the arguments to the `socket()` function to create a socket suitable for use with the returned address. The `ai_addr` and `ai_addrlen` members are usable as the arguments to the `connect()` or `bind()` functions with such a socket, according to the `AI_PASSIVE` flag.

If `nodename` is not null, and if requested by the `AI_CANONNAME` flag, the `ai_canonname` member of the first returned `addrinfo` structure points to a null-terminated string containing the canonical name corresponding to the input `nodename`. If the canonical name is not available, then `ai_canonname` refers to the `nodename` argument or a string with the same contents. The contents of the `ai_flags` member of the returned structures are undefined.

All members in socket address structures returned by `getaddrinfo()` that are not filled in through an explicit argument (for example, `sin6_flowinfo`) are set to 0, making it easier to compare socket address structures.

ERRORS

The `getaddrinfo()` function will fail if:

<code>EAI_AGAIN</code>	The name could not be resolved at this time. Future attempts might succeed.
------------------------	---

freeaddrinfo(3XNET)

EAI_BADFLAGS	The <code>ai_flags</code> member of the <code>addrinfo</code> structure had an invalid value.
EAI_FAIL	A non-recoverable error occurred when attempting to resolve the name.
EAI_FAMILY	The address family was not recognized.
EAI_MEMORY	There was a memory allocation failure when trying to allocate storage for the return value.
EAI_NONAME	The name does not resolve for the supplied parameters. Neither <code>nodename</code> nor <code>servname</code> were supplied. At least one of these must be supplied.
EAI_SERVICE	The service passed was not recognized for the specified socket type.
EAI_SOCKTYPE	The intended socket type was not recognized.
EAI_SYSTEM	A system error occurred. The error code can be found in <code>errno</code> .
EAI_OVERFLOW	An argument buffer overflowed.

USAGE If the caller handles only TCP and not UDP, for example, then the `ai_protocol` member of the `hints` structure should be set to `IPPROTO_TCP` when `getaddrinfo()` is called.

If the caller handles only IPv4 and not IPv6, then the `ai_family` member of the `hints` structure should be set to `AF_INET` when `getaddrinfo()` is called.

getaddrinfo(3SOCKET)

NAME	getaddrinfo, getnameinfo, freeaddrinfo, gai_strerror – translate between node name and address
SYNOPSIS	<pre>cc [flag ...] file... -lsocket -lnsl [library ...] #include <sys/socket.h> #include <netdb.h> int getaddrinfo(const char *nodename, const char *servname, const struct addrinfo *hints, struct addrinfo **res); int getnameinfo(const struct sockaddr *sa, socklen_t salen, char *host, size_t hostlen, char *serv, size_t servlen, int flags); void freeaddrinfo(struct addrinfo *ai); char *gai_strerror(int errcode);</pre>
DESCRIPTION	<p>These functions perform translations from node name to address and from address to node name in a protocol-independent manner.</p> <p>The <code>getaddrinfo()</code> function performs the node name to address translation. The <code>nodename</code> and <code>servname</code> arguments are pointers to null-terminated strings or NULL. One or both of these arguments must be a non-null pointer. In the normal client scenario, both the <code>nodename</code> and <code>servname</code> are specified. In the normal server scenario, only the <code>servname</code> is specified.</p> <p>A non-null <code>nodename</code> string can be a node name or a numeric host address string. The <code>nodename</code> can also be an IPv6 zone-id in the form:</p> <pre><address>%<zone-id></pre> <p>The address is the literal IPv6 link-local address or host name of the destination. The zone-id is the interface ID of the IPv6 link used to send the packet. The zone-id can either be a numeric value, indicating a literal zone value, or an interface name such as <code>hme0</code>.</p> <p>A non-null <code>servname</code> string can be either a service name or a decimal port number.</p> <p>The caller can optionally pass an <code>addrinfo</code> structure, pointed to by the <code>hints</code> argument, to provide hints concerning the type of socket that the caller supports.</p> <p>The <code>addrinfo</code> structure is defined as:</p> <pre>struct addrinfo { int ai_flags; /* AI_PASSIVE, AI_CANONNAME, AI_NUMERICHOST, AI_NUMERICSERV AI_V4MAPPED, AI_ALL, AI_ADDRCONFIG */ int ai_family; /* PF_xxx */ int ai_socktype; /* SOCK_xxx */ int ai_protocol; /* 0 or IPPROTO_xxx for IPv4 and IPv6 */ socklen_t ai_addrlen; /* length of ai_addr */ char *ai_canonname; /* canonical name for nodename */ struct sockaddr *ai_addr; /* binary address */ struct addrinfo *ai_next; /* next structure in linked list */ };</pre>

getaddrinfo(3SOCKET)

In this *hints* structure, all members other than `ai_flags`, `ai_family`, `ai_socktype`, and `ai_protocol` must be 0 or a null pointer. A value of `PF_UNSPEC` for `ai_family` indicates that the caller will accept any protocol family. A value of 0 for `ai_socktype` indicates that the caller will accept any socket type. A value of 0 for `ai_protocol` indicates that the caller will accept any protocol. For example, if the caller handles only TCP and not UDP, then the `ai_socktype` member of the *hints* structure should be set to `SOCK_STREAM` when `getaddrinfo()` is called. If the caller handles only IPv4 and not IPv6, then the `ai_family` member of the *hints* structure should be set to `PF_INET` when `getaddrinfo()` is called. If the third argument to `getaddrinfo()` is a null pointer, it is as if the caller had filled in an `addrinfo` structure initialized to 0 with `ai_family` set to `PF_UNSPEC`.

Upon success, a pointer to a linked list of one or more `addrinfo` structures is returned through the final argument. The caller can process each `addrinfo` structure in this list by following the `ai_next` pointer, until a null pointer is encountered. In each returned `addrinfo` structure the three members `ai_family`, `ai_socktype`, and `ai_protocol` are the corresponding arguments for a call to the `socket(3SOCKET)` function. In each `addrinfo` structure the `ai_addr` member points to a filled-in socket address structure whose length is specified by the `ai_addrlen` member.

If the `AI_PASSIVE` bit is set in the `ai_flags` member of the *hints* structure, the caller plans to use the returned socket address structure in a call to `bind(3SOCKET)`. In this case, if the *nodename* argument is a null pointer, the IP address portion of the socket address structure will be set to `INADDR_ANY` for an IPv4 address or `IN6ADDR_ANY_INIT` for an IPv6 address.

If the `AI_PASSIVE` bit is not set in the `ai_flags` member of the *hints* structure, then the returned socket address structure will be ready for a call to `connect(3SOCKET)` (for a connection-oriented protocol) or either `connect(3SOCKET)`, `sendto(3SOCKET)`, or `sendmsg(3SOCKET)` (for a connectionless protocol). If the *nodename* argument is a null pointer, the IP address portion of the socket address structure will be set to the loopback address.

If the `AI_CANONNAME` bit is set in the `ai_flags` member of the *hints* structure, then upon successful return the `ai_canonname` member of the first `addrinfo` structure in the linked list will point to a null-terminated string containing the canonical name of the specified *nodename*.

If the `AI_NUMERICHOST` bit is set in the `ai_flags` member of the *hints* structure, then a non-null *nodename* string must be a numeric host address string. Otherwise an error of `EAI_NONAME` is returned. This flag prevents any type of name resolution service (such as DNS) from being called.

If the `AI_NUMERICSERV` flag is specified, then a non-null *servname* string supplied shall be a numeric port string. Otherwise, an `[EAI_NONAME]` error is returned. This flag prevents any type of name resolution service (for example, NIS+) from being invoked.

getaddrinfo(3SOCKET)

If the `AI_V4MAPPED` flag is specified along with an `ai_family` of `AF_INET6`, then `getaddrinfo()` returns IPv4-mapped IPv6 addresses on finding no matching IPv6 addresses (`ai_addrlen` shall be 16). For example, if no AAAA records are found when using DNS, a query is made for A records. Any found records are returned as IPv4-mapped IPv6 addresses.

The `AI_V4MAPPED` flag is ignored unless `ai_family` equals `AF_INET6`.

If the `AI_ALL` flag is used with the `AI_V4MAPPED` flag, then `getaddrinfo()` returns all matching IPv6 and IPv4 addresses. For example, when using the DNS, queries are made for both AAAA records and A records, and `getaddrinfo()` returns the combined results of both queries. Any IPv4 addresses found are returned as IPv4-mapped IPv6 addresses.

The `AI_ALL` flag without the `AI_V4MAPPED` flag is ignored.

When `ai_family` is not specified (`AF_UNSPEC`), `AI_V4MAPPED` and `AI_ALL` flags are used only if `AF_INET6` is supported.

If the `AI_ADDRCONFIG` flag is specified, IPv4 addresses are returned only if an IPv4 address is configured on the local system, and IPv6 addresses are returned only if an IPv6 address is configured on the local system. For this case, the loopback address is not considered to be as valid as a configured address. For example, when using the DNS, a query for AAAA records should occur only if the node has at least one IPv6 address configured (other than IPv6 loopback) and a query for A records should occur only if the node has at least one IPv4 address configured (other than the IPv4 loopback).

All of the information returned by `getaddrinfo()` is dynamically allocated: the `addrinfo` structures as well as the socket address structures and canonical node name strings pointed to by the `addrinfo` structures. The `freeaddrinfo()` function is called to return this information to the system the function. For `freeaddrinfo()`, the `addrinfo` structure pointed to by the `ai` argument is freed, along with any dynamic storage pointed to by the structure. This operation is repeated until a null `ai_next` pointer is encountered.

To aid applications in printing error messages based on the `EAI_*` codes returned by `getaddrinfo()`, the `gai_strerror()` is defined. The argument is one of the `EAI_*` values defined below and the return value points to a string describing the error. If the argument is not one of the `EAI_*` values, the function still returns a pointer to a string whose contents indicate an unknown error.

The `getnameinfo()` function looks up an IP address and port number provided by the caller in the name service database and system-specific database, and returns text strings for both in buffers provided by the caller. The function indicates successful completion by a 0 return value; a non-zero return value indicates failure.

The first argument, `sa`, points to either a `sockaddr_in` structure (for IPv4) or a `sockaddr_in6` structure (for IPv6) that holds the IP address and port number. The `salen` argument gives the length of the `sockaddr_in` or `sockaddr_in6` structure.

getaddrinfo(3SOCKET)

The function returns the node name associated with the IP address in the buffer pointed to by the *host* argument.

The function can also return the IPv6 zone-id in the form:

```
<address>%<zone-id>
```

The caller provides the size of this buffer with the *hostlen* argument. The service name associated with the port number is returned in the buffer pointed to by *serv*, and the *servlen* argument gives the length of this buffer. The caller specifies not to return either string by providing a 0 value for the *hostlen* or *servlen* arguments. Otherwise, the caller must provide buffers large enough to hold the node name and the service name, including the terminating null characters.

To aid the application in allocating buffers for these two returned strings, the following constants are defined in `<netdb.h>`:

```
#define NI_MAXHOST 1025
#define NI_MAXSERV 32
```

The final argument is a flag that changes the default actions of this function. By default, the fully-qualified domain name (FQDN) for the host is looked up in the name service database and returned. If the flag bit `NI_NOFQDN` is set, only the node name portion of the FQDN is returned for local hosts.

If the flag bit `NI_NUMERICHOST` is set, or if the host's name cannot be located in the name service, the numeric form of the host's address is returned instead of its name, for example, by calling `inet_ntop()` (see `inet(3SOCKET)`) instead of `getipnodebyname(3SOCKET)`. If the flag bit `NI_NAMEREQD` is set, an error is returned if the host's name cannot be located in the name service database.

If the flag bit `NI_NUMERICSERV` is set, the numeric form of the service address is returned (for example, its port number) instead of its name. The two `NI_NUMERIC*` flags are required to support the `-n` flag that many commands provide.

A fifth flag bit, `NI_DGRAM`, specifies that the service is a datagram service, and causes `getservbyport(3SOCKET)` to be called with a second argument of `udp` instead of the default `tcp`. This is required for the few ports (for example, 512-514) that have different services for UDP and TCP.

These `NI_*` flags are defined in `<netdb.h>` along with the `AI_*` flags already defined for `getaddrinfo()`.

RETURN VALUES

For `getaddrinfo()`, if the query is successful, a pointer to a linked list of one or more `addrinfo` structures is returned by the fourth argument and the function returns 0. The order of the addresses returned in the fourth argument is discussed in the ADDRESS ORDERING section. If the query fails, a non-zero error code will be returned. For `getnameinfo()`, if successful, the strings *hostname* and *service* are copied into *host* and *serv*, respectively. If unsuccessful, zero values for either *hostlen* or

getaddrinfo(3SOCKET)

servlen will suppress the associated lookup; in this case no data is copied into the applicable buffer. If `gai_strerror()` is successful, a pointer to a string containing an error message appropriate for the `EAI_*` errors is returned. If *errcode* is not one of the `EAI_*` values, a pointer to a string indicating an unknown error is returned.

Address Ordering

AF_INET6 addresses returned by the fourth argument of `getaddrinfo()` are ordered according to the algorithm described in *RFC 3484, Default Address Selection for Internet Protocol version 6 (IPv6)*. The addresses are ordered using a list of pair-wise comparison rules which are applied in order. If a rule determines that one address is better than another, the remaining rules are irrelevant to the comparison of those two addresses. If two addresses are equivalent according to one rule, the remaining rules act as a tie-breaker. The address ordering list of pair-wise comparison rules follow below:

Avoid unusable destinations.	Prefer a destination that is reachable through the IP routing table.
Prefer matching scope.	Prefer a destination whose scope is equal to the scope of its source address. See <code>inet6(7P)</code> for the definition of scope used by this rule.
Avoid link-local source.	Avoid selecting a link-local source address when the destination address is not a link-local address.
Avoid deprecated addresses.	Prefer a destination that is not deprecated (<code>IFF_DEPRECATED</code>).
Prefer matching label. This rule uses labels that are obtained through the IPv6 default address selection policy table. See <code>ipaddrsel(1M)</code> for a description of the default contents of the table and how the table is configured.	Prefer a destination whose label is equal to the label of its source address.
Prefer higher precedence. This rule uses precedence values that are obtained through the IPv6 default address selection policy table. See <code>ipaddrsel(1M)</code> for a description of the default contents of the table and how the table is configured.	Prefer the destination whose precedence is higher than the other destination.
Prefer native transport.	Prefer a destination if the interface that is used for sending packets to that destination is not an IP over IP tunnel.
Prefer smaller scope. See <code>inet6(7P)</code> for the definition of this rule.	Prefer the destination whose scope is smaller than the other destination.

Use longest matching prefix.	When the two destinations belong to the same address family, prefer the destination that has the longer matching prefix with its source address.
------------------------------	--

ERRORS The following names are the error values returned by `getaddrinfo()` and are defined in `<netdb.h>`:

<code>EAI_ADDRFAMILY</code>	Address family for <i>nodename</i> is not supported.
<code>EAI_AGAIN</code>	Temporary failure in name resolution has occurred .
<code>EAI_BADFLAGS</code>	Invalid value specified for <code>ai_flags</code> .
<code>EAI_FAIL</code>	Non-recoverable failure in name resolution has occurred.
<code>EAI_FAMILY</code>	The <code>ai_family</code> is not supported.
<code>EAI_MEMORY</code>	Memory allocation failure has occurred.
<code>EAI_NODATA</code>	No address is associated with <i>nodename</i> .
<code>EAI_NONAME</code>	Neither <i>nodename</i> nor <i>servname</i> is provided or known.
<code>EAI_SERVICE</code>	The <i>servname</i> is not supported for <code>ai_socktype</code> .
<code>EAI_SOCKTYPE</code>	The <code>ai_socktype</code> is not supported.
<code>EAI_OVERFLOW</code>	Argument buffer has overflowed.
<code>EAI_SYSTEM</code>	System error was returned in <code>errno</code> .

FILES	<code>/etc/inet/hosts</code>	host name database
	<code>/etc/inet/ipnodes</code>	local database that associates names of nodes with IP addresses
	<code>/etc/netconfig</code>	network configuration database
	<code>/etc/nsswitch.conf</code>	configuration file for the name service switch

gethostbyname(3NSL)

NAME	gethostbyname, gethostbyname_r, gethostbyaddr, gethostbyaddr_r, gethostent, gethostent_r, sethostent, endhostent – get network host entry
SYNOPSIS	<pre>cc [flag...] file... -lnsl [library...] #include <netdb.h> struct hostent *gethostbyname(const char *name, int main, int argc, const char **argv); struct hostent *gethostbyname_r(const char *name, struct hostent *result, char *buffer, int buflen, int *h_errnop); struct hostent *gethostbyaddr(const char *addr, int len, int type); struct hostent *gethostbyaddr_r(const char *addr, int length, int type, struct hostent *result, char *buffer, int buflen, int *h_errnop); struct hostent *gethostent(void); struct hostent *gethostent_r(struct hostent *result, char *buffer, int buflen, int *h_errnop); int sethostent(int stayopen); int endhostent(void);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing hosts. An entry can come from any of the sources for hosts specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code>. These functions have been superseded by <code>getipnodebyname(3SOCKET)</code>, <code>getipnodebyaddr(3SOCKET)</code>, and <code>getaddrinfo(3SOCKET)</code>, which provide greater portability to applications when multithreading is performed or technologies such as IPv6 are used. For example, the functions described in the following cannot be used with applications targeted to work with IPv6.</p> <p>The <code>gethostbyname()</code> function searches for information for a host with the hostname specified by the character-string parameter <i>name</i>.</p> <p>The <code>gethostbyaddr()</code> function searches for information for a host with a given host address. The parameter <i>type</i> specifies the family of the address. This should be one of the address families defined in <code><sys/socket.h></code>. See the NOTES section for more information. Also see the EXAMPLES section for information on how to convert an Internet IP address notation that is separated by periods (.) into an <i>addr</i> parameter. The parameter <i>len</i> specifies the length of the buffer indicated by <i>addr</i>.</p> <p>All addresses are returned in network order. In order to interpret the addresses, <code>byteorder(3SOCKET)</code> must be used for byte order conversion.</p> <p>The <code>sethostent()</code>, <code>gethostent()</code>, and <code>endhostent()</code> functions are used to enumerate host entries from the database.</p>

gethostbyname(3NSL)

The `sethostent()` function sets or resets the enumeration to the beginning of the set of host entries. This function should be called before the first call to `gethostent()`. Calls to `gethostbyname()` and `gethostbyaddr()` leave the enumeration position in an indeterminate state. If the *stayopen* flag is non-zero, the system can keep allocated resources such as open file descriptors until a subsequent call to `endhostent()`.

Successive calls to the `gethostent()` function return either successive entries or `NULL`, indicating the end of the enumeration.

The `endhostent()` function can be called to indicate that the caller expects to do no further host entry retrieval operations; the system can then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more host retrieval functions after calling `endhostent()`.

Reentrant Interfaces

The `gethostbyname()`, `gethostbyaddr()`, and `gethostent()` functions use static storage that is reused in each call, making these functions unsafe for use in multithreaded applications.

The `gethostbyname_r()`, `gethostbyaddr_r()`, and `gethostent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results and the interfaces are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct hostent` structure allocated by the caller. On successful completion, the function returns the host entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the host data. All of the pointers within the returned `struct hostent result` point to data stored within this buffer. See the RETURN VALUES section for more information. The buffer must be large enough to hold all of the data associated with the host entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer*. The parameter *h_errnop* should be a pointer to an integer. An integer error status value is stored there on certain error conditions. See the ERRORS section for more information.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `sethostent()` function can be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `gethostent_r()`, the threads will enumerate disjoint subsets of the host database.

Like their non-reentrant counterparts, `gethostbyname_r()` and `gethostbyaddr_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Host entries are represented by the `struct hostent` structure defined in `<netdb.h>`:

gethostbyname(3NSL)

```
struct hostent {
    char    *h_name;           /* canonical name of host */
    char    **h_aliases;      /* alias list */
    int     h_addrtype;       /* host address type */
    int     h_length;         /* length of address */
    char    **h_addr_list;    /* list of addresses */
};
```

See the **EXAMPLES** section for information about how to retrieve a "." separated Internet IP address string from the *h_addr_list* field of struct hostent.

The `gethostbyname()`, `gethostbyname_r()`, `gethostbyaddr()`, and `gethostbyaddr_r()` functions each return a pointer to a struct hostent if they successfully locate the requested entry; otherwise they return NULL.

The `gethostent()` and `gethostent_r()` functions each return a pointer to a struct hostent if they successfully enumerate an entry; otherwise they return NULL, indicating the end of the enumeration.

The `gethostbyname()`, `gethostbyaddr()`, and `gethostent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `gethostbyname_r()`, `gethostbyaddr_r()`, and `gethostent_r()` is not NULL, it is always equal to the *result* pointer that was supplied by the caller.

The `sethostent()` and `endhostent()` functions return 0 on success.

ERRORS

The reentrant functions `gethostbyname_r()`, `gethostbyaddr_r()`, and `gethostent_r()` will return NULL and set *errno* to ERANGE if the length of the buffer supplied by caller is not large enough to store the result. See [Intro\(2\)](#) for the proper usage and interpretation of *errno* in multithreaded applications.

The reentrant functions `gethostbyname_r()` and `gethostbyaddr_r()` set the integer pointed to by *h_errnop* to one of these values in case of error.

On failures, the non-reentrant functions `gethostbyname()` and `gethostbyaddr()` set a global integer *h_errno* to indicate one of these error codes (defined in `<netdb.h>`): `HOST_NOT_FOUND`, `TRY_AGAIN`, `NO_RECOVERY`, `NO_DATA`, and `NO_ADDRESS`.

If a resolver is provided with a malformed address, or if any other error occurs before `gethostbyname()` is resolved, then `gethostbyname()` returns an internal error with a value of -1.

The `gethostbyname()` function will set *h_errno* to `NETDB_INTERNAL` when it returns a NULL value.

EXAMPLES

EXAMPLE 1 Using `gethostbyname()`

Here is a sample program that gets the canonical name, aliases, and "." separated Internet IP addresses for a given "." separated IP address:

EXAMPLE 1 Using `gethostbyname()` (Continued)

```

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>
#include <netdb.h>
int main(int argc, const char **argv)
{
    in_addr_t addr;
    struct hostent *hp;
    char **p;
    if (argc != 2) {
        (void) printf("usage: %s IP-address\
", argv[0]);
        exit (1);
    }
    if ((int)(addr = inet_addr(argv[1])) == -1) {
        (void) printf("IP-address must be of the form a.b.c.d\
");
        exit (2);
    }
    hp = gethostbyaddr((char *)&addr, 4, AF_INET);
    if (hp == NULL) {
        (void) printf("host information for %s not found\
", argv[1]);
        exit (3);
    }
    for (p = hp->h_addr_list; *p != 0; p++) {
        struct in_addr in;
        char **q;
        (void) memcpy(&in.s_addr, *p, sizeof (in.s_addr));
        (void) printf("%s\t%s", inet_ntoa(in), hp->h_name);
        for (q = hp->h_aliases; *q != 0; q++)
            (void) printf(" %s", *q);
        (void) putchar('\
');
    }
    exit (0);
}

```

Note that the preceding sample program is unsafe for use in multithreaded applications.

gethostbyname(3NSL)

ATTRIBUTES See attributes (5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in the DESCRIPTION section.

SEE ALSO Intro(2), Intro(3), [byteorder\(3SOCKET\)](#), [inet\(3SOCKET\)](#), [netdb.h\(3HEAD\)](#), [netdir\(3NSL\)](#), [hosts\(4\)](#), [netconfig\(4\)](#), [nss\(4\)](#), [nsswitch.conf\(4\)](#), [attributes\(5\)](#)

WARNINGS The reentrant interfaces `gethostbyname_r()`, `gethostbyaddr_r()`, and `gethostent_r()` are included in this release on an uncommitted basis only and are subject to change or removal in future minor releases.

NOTES To ensure that they all return consistent results, `gethostbyname()`, `gethostbyname_r()`, and `netdir_getbyname()` are implemented in terms of the same internal library function. This function obtains the system-wide source lookup policy based on the `inet` family entries in [netconfig\(4\)](#) and the `hosts`: entry in [nsswitch.conf\(4\)](#). Similarly, `gethostbyaddr()`, `gethostbyaddr_r()`, and `netdir_getbyaddr()` are implemented in terms of the same internal library function. If the `inet` family entries in [netconfig\(4\)](#) have a "-" in the last column for `nametoaddr` libraries, then the entry for `hosts` in [nsswitch.conf](#) will be used; `nametoaddr` libraries in that column will be used, and [nsswitch.conf](#) will not be consulted.

There is no analogue of `gethostent()` and `gethostent_r()` in the `netdir` functions, so these enumeration functions go straight to the `hosts` entry in [nsswitch.conf](#). Thus enumeration can return results from a different source than that used by `gethostbyname()`, `gethostbyname_r()`, `gethostbyaddr()`, and `gethostbyaddr_r()`.

All the functions that return a `struct hostent` must always return the *canonical name* in the `h_name` field. This name, by definition, is the well-known and official hostname shared between all aliases and all addresses. The underlying source that satisfies the request determines the mapping of the input name or address into the set of names and addresses in `hostent`. Different sources might do that in different ways. If there is more than one alias and more than one address in `hostent`, no pairing is implied between them.

The system attempts to put those addresses that are on the same subnet as the caller before addresses that are on different subnets. However, if address sorting is disabled by setting `SORT_ADDRS` to `FALSE` in the `/etc/default/nss` file, the system does not put the local subnet addresses first. See [nss\(4\)](#) for more information.

When compiling multithreaded applications, see [Intro\(3\)](#), `MULTITHREADED APPLICATIONS`, for information about the use of the `_REENTRANT` flag.

gethostbyname(3NSL)

Use of the enumeration interfaces `gethostent()` and `gethostent_r()` is discouraged; enumeration might not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

The current implementations of these functions only return or accept addresses for the Internet address family (type `AF_INET`).

The form for an address of type `AF_INET` is a `struct in_addr` defined in `<netinet/in.h>`. The functions described in `inet(3SOCKET)`, and illustrated in the `EXAMPLES` section, are helpful in constructing and manipulating addresses in this form.

gethostname(3XNET)

NAME	gethostname – get name of current host						
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <unistd.h> int gethostname(char *<i>name</i>, size_t <i>namelen</i>);</pre>						
DESCRIPTION	<p>The <code>gethostname()</code> function returns the standard host name for the current machine. The <i>namelen</i> argument specifies the size of the array pointed to by the <i>name</i> argument. The returned name is null-terminated, except that if <i>namelen</i> is an insufficient length to hold the host name, then the returned name is truncated and it is unspecified whether the returned name is null-terminated.</p> <p>Host names are limited to 255 bytes.</p>						
RETURN VALUES	On successful completion, 0 is returned. Otherwise, -1 is returned.						
ERRORS	No errors are defined.

<i>af</i>	Address family														
<i>flags</i>	Various flags														
<i>name</i>	Name of host														
<i>error_num</i>	Error storage														
<i>src</i>	Address for lookup														
<i>len</i>	Length of address														
<i>ptr</i>	Pointer to hostent structure														
DESCRIPTION	<p>The <code>getipnodebyname()</code> function searches the ipnodes database from the beginning. The function finds the first <code>h_name</code> member that matches the hostname specified by <code>name</code>. The function takes an <code>af</code> argument that specifies the address family. The address family can be <code>AF_INET</code> for IPv4 addresses or <code>AF_INET6</code> for IPv6 addresses. The <code>flags</code> argument determines what results are returned based on the value of <code>flags</code>. If the <code>flags</code> argument is set to 0 (zero), the default operation of the function is specified as follows:</p> <ul style="list-style-type: none"> ■ If the <code>af</code> argument is <code>AF_INET</code>, a query is made for an IPv4 address. If successful, IPv4 addresses are returned and the <code>h_length</code> member of the <code>hostent</code> structure is 4. Otherwise, the function returns a NULL pointer. ■ If the <code>af</code> argument is <code>AF_INET6</code>, a query is made for an IPv6 address. If successful, IPv6 addresses are returned and the <code>h_length</code> member of the <code>hostent</code> structure is 16. Otherwise, the function returns a NULL pointer. <p>The <code>flags</code> argument changes the default actions of the function. Set the <code>flags</code> argument with a logical OR operation on any of combination of the following values:</p> <pre>AI_V4MAPPED AI_ALL AI_ADDRCONFIG</pre> <p>The special flags value, <code>AI_DEFAULT</code>, should handle most applications. Porting simple applications to use IPv6 replaces the call</p> <pre>hptr = gethostbyname(name);</pre>														

getipnodebyname(3SOCKET)

with

```
hptr = getipnodebyname(name, AF_INET6, AI_DEFAULT, &error_num);
```

The *flags* value 0 (zero) implies a strict interpretation of the *af* argument:

- If *flags* is 0 and *af* is `AF_INET`, the caller wants only IPv4 addresses. A query is made for A records. If successful, IPv4 addresses are returned and the `h_length` member of the `hostent` structure is 4. Otherwise, the function returns a NULL pointer.
- If *flags* is 0 and *af* is `AF_INET6`, the caller wants only IPv6 addresses. A query is made for AAAA records. If successful, IPv6 addresses are returned and the `h_length` member of the `hostent` structure is 16. Otherwise, the function returns a NULL pointer.

Logically OR other constants into the *flags* argument to modify the behavior of the `getipnodebyname()` function.

- If the `AI_V4MAPPED` flag is specified with *af* set to `AF_INET6`, the caller can accept IPv4-mapped IPv6 addresses. If no AAAA records are found, a query is made for A records. Any A records found are returned as IPv4-mapped IPv6 addresses and the `h_length` is 16. The `AI_V4MAPPED` flag is ignored unless *af* equals `AF_INET6`.
- The `AI_ALL` flag is used in conjunction with the `AI_V4MAPPED` flag, exclusively with the IPv6 address family. When `AI_ALL` is logically ORed with `AI_V4MAPPED` flag, the caller wants all addresses: IPv6 and IPv4-mapped IPv6 addresses. A query is first made for AAAA records and, if successful, IPv6 addresses are returned. Another query is then made for A records. Any A records found are returned as IPv4-mapped IPv6 addresses and the `h_length` is 16. Only when both queries fail does the function return a NULL pointer. The `AI_ALL` flag is ignored unless *af* is set to `AF_INET6`.
- The `AI_ADDRCONFIG` flag specifies that a query for AAAA records should occur only when the node is configured with at least one IPv6 source address. A query for A records should occur only when the node is configured with at least one IPv4 source address. For example, if a node is configured with no IPv6 source addresses, *af* equals `AF_INET6`, and the node name queried has both AAAA and A records, then:
 - A NULL pointer is returned when only the `AI_ADDRCONFIG` value is specified.
 - The A records are returned as IPv4-mapped IPv6 addresses when the `AI_ADDRCONFIG` and `AI_V4MAPPED` values are specified.

The special flags value, `AI_DEFAULT`, is defined as

```
#define AI_DEFAULT (AI_V4MAPPED | AI_ADDRCONFIG)
```

The `getipnodebyname()` function allows the *name* argument to be a node name or a literal address string: a dotted-decimal IPv4 address or an IPv6 hex address. Applications do not have to call `inet_pton(3SOCKET)` to handle literal address strings.

Four scenarios arise based on the type of literal address string and the value of the *af* argument. The two simple cases occur when *name* is a dotted-decimal IPv4 address and *af* equals AF_INET and when *name* is an IPv6 hex address and *af* equals AF_INET6. The members of the returned `hostent` structure are:

<code>h_name</code>	Pointer to a copy of the name argument
<code>h_aliases</code>	NULL pointer.
<code>h_addrtype</code>	Copy of the <i>af</i> argument.
<code>h_length</code>	4 for AF_INET or 16 for AF_INET6.
<code>h_addr_list</code>	Array of pointers to 4-byte or 16-byte binary addresses. The array is terminated by a NULL pointer.

RETURN VALUES

Upon successful completion, `getipnodebyname()` and `getipnodebyaddr()` return a `hostent` structure. Otherwise they return NULL.

The `hostent` structure does not change from the existing definition when used with `gethostbyname(3NSL)`. For example, host entries are represented by the `struct hostent` structure defined in `<netdb.h>`:

```
struct hostent {
    char    *h_name;          /* canonical name of host */
    char    **h_aliases;     /* alias list */
    int     h_addrtype;      /* host address type */
    int     h_length;        /* length of address */
    char    **h_addr_list;   /* list of addresses */
};
```

An error occurs when *name* is an IPv6 hex address and *af* equals AF_INET. The return value of the function is a NULL pointer and `error_num` equals `HOST_NOT_FOUND`.

The `getipnodebyaddr()` function has the same arguments as the existing `gethostbyaddr(3NSL)` function, but adds an error number. As with `getipnodebyname()`, `getipnodebyaddr()` is thread-safe. The `error_num` value is returned to the caller with the appropriate error code to support thread-safe error code returns. The following error conditions can be returned for `error_num`:

<code>HOST_NOT_FOUND</code>	Host is unknown.
<code>NO_DATA</code>	No address is available for the <i>name</i> specified in the server request. This error is not a soft error. Another type of <i>name</i> server request might be successful.
<code>NO_RECOVERY</code>	An unexpected server failure occurred, which is a non-recoverable error.
<code>TRY_AGAIN</code>	This error is a soft error that indicates that the local server did not receive a response from an authoritative server. A retry at some later time might be successful.

getipnodebyname(3SOCKET)

One possible source of confusion is the handling of IPv4-mapped IPv6 addresses and IPv4-compatible IPv6 addresses, but the following logic should apply:

1. If *af* is `AF_INET6`, and if *len* equals 16, and if the IPv6 address is an IPv4-mapped IPv6 address or an IPv4-compatible IPv6 address, then skip over the first 12 bytes of the IPv6 address, set *af* to `AF_INET`, and set *len* to 4.
2. If *af* is `AF_INET`, lookup the *name* for the given IPv4 address.
3. If *af* is `AF_INET6`, lookup the *name* for the given IPv6 address.
4. If the function is returning success, then the single address that is returned in the `hostent` structure is a copy of the first argument to the function with the same address family that was passed as an argument to this function.

All four steps listed are performed in order.

This structure, and the information pointed to by this structure, are dynamically allocated by `getipnodebyname()` and `getipnodebyaddr()`. The `freehostent()` function frees this memory.

EXAMPLES

EXAMPLE 1 Getting the Canonical Name, Aliases, and Internet IP Addresses for a Given Hostname

The following is a sample program that retrieves the canonical name, aliases, and all Internet IP addresses, both version 6 and version 4, for a given hostname.

```
#include <stdio.h>
#include <string.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>
#include <netdb.h>

main(int argc, const char **argv)
{
    char abuf[INET6_ADDRSTRLEN];
    int error_num;
    struct hostent *hp;
    char **p;

    if (argc != 2) {
        (void) printf("usage: %s hostname\
", argv[0]);
        exit (1);
    }

    /* argv[1] can be a pointer to a hostname or literal IP address */
    hp = getipnodebyname(argv[1], AF_INET6, AI_ALL | AI_ADDRCONFIG |
        AI_V4MAPPED, &error_num);
    if (hp == NULL) {
        if (error_num == TRY_AGAIN) {
            printf("%s: unknown host or invalid literal address "
                "(try again later)\
", argv[1]);
```

EXAMPLE 1 Getting the Canonical Name, Aliases, and Internet IP Addresses for a Given Hostname (Continued)

```

        } else {
            printf("%s: unknown host or invalid literal address\
",
                argv[1]);
        }
        exit (1);
    }
    for (p = hp->h_addr_list; *p != 0; p++) {
        struct in6_addr in6;
        char **q;

        bcopy(*p, (caddr_t)&in6, hp->h_length);
        (void) printf("%s\\t%s", inet_ntop(AF_INET6, (void *)&in6,
            abuf, sizeof(abuf)), hp->h_name);
        for (q = hp->h_aliases; *q != 0; q++)
            (void) printf(" %s", *q);
        (void) putchar('\
');
    }
    freehostent (hp);
    exit (0);
}

```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT-Level	Safe

SEE ALSO [getaddrinfo\(3SOCKET\)](#), [gethostbyname\(3NSL\)](#), [htonl\(3SOCKET\)](#), [inet\(3SOCKET\)](#), [netdb.h\(3HEAD\)](#), [hosts\(4\)](#), [ipnodes\(4\)](#), [nsswitch.conf\(4\)](#), [attributes\(5\)](#)

NOTES No enumeration functions are provided for IPv6. Existing enumeration functions such as [sethostent\(3NSL\)](#) do not work in combination with the [getipnodebyname\(\)](#) and [getipnodebyaddr\(\)](#) functions.

All the functions that return a `struct hostent` must always return the canonical in the `h_name` field. This name, by definition, is the well-known and official hostname shared between all aliases and all addresses. The underlying source that satisfies the request determines the mapping of the input name or address into the set of names and addresses in `hostent`. Different sources might make such as determination in different ways. If more than one alias and more than one address in `hostent` exist, no pairing is implied between the alias and address.

The current implementations of these functions return or accept only addresses for the Internet address family (type `AF_INET`) or the Internet address family Version 6 (type `AF_INET6`).

getipnodebyname(3SOCKET)

The form for an address of type `AF_INET` is a struct `in_addr` defined in `<netinet/in.h>`. The form for an address of type `AF_INET6` is a struct `in6_addr`, also defined in `<netinet/in.h>`. The functions described in [inet_ntop\(3SOCKET\)](#) and [inet_pton\(3SOCKET\)](#) that are illustrated in the `EXAMPLES` section are helpful in constructing and manipulating addresses in either of these forms.

NAME	getipsecalgbyname, getipsecalgbynum, freeipsecalgent – query algorithm mapping entries				
SYNOPSIS	<pre>cc -flag ... file...-lnsl [-library ...] #include <netdb.h> struct ipsecalgent *getipsecalgbyname(const char *alg_name, int protocol_num, int *errnop); struct ipsecalgent *getipsecalgbynum(int alg_num, int protocol_num, int *errnop); void freeipsecalgent(struct ipsecalgent *ptr);</pre>				
DESCRIPTION	<p>Use the <code>getipsecalgbyname()</code>, <code>getipsecalgbynum()</code>, <code>freeipsecalgent()</code> functions to obtain the IPsec algorithm mappings that are defined by <code>ipsecalgs(1M)</code>. The IPsec algorithms and associated protocol name spaces are defined by <i>RFC 2407</i>.</p> <p><code>getipsecalgbyname()</code> and <code>getipsecalgbynum()</code> return a structure that describes the algorithm entry found. This structure is described in the RETURN VALUES section below.</p> <p><code>freeipsecalgent()</code> must be used by the caller to free the structures returned by <code>getipsecalgbyname()</code> and <code>getipsecalgbynum()</code> when they are no longer needed.</p> <p>Both <code>getipsecalgbyname()</code> and <code>getipsecalgbynum()</code> take as parameter the protocol identifier in which the algorithm is defined. See getipsecprotobyname(3NSL) and getipsecprotobynum(3NSL).</p> <p>The following protocol numbers are pre-defined:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">IPSEC_PROTO_ESP</td> <td>Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.</td> </tr> <tr> <td>IPSEC_PROTO_AH</td> <td>Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.</td> </tr> </table> <p><code>getipsecalgbyname()</code> looks up the algorithm by its name, while <code>getipsecalgbynum()</code> looks up the algorithm by its assigned number.</p>	IPSEC_PROTO_ESP	Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.	IPSEC_PROTO_AH	Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.
IPSEC_PROTO_ESP	Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.				
IPSEC_PROTO_AH	Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.				
PARAMETERS	<p><i>errnop</i> A pointer to an integer used to return an error status value on certain error conditions. See ERRORS.</p>				
RETURN VALUES	<p>The <code>getipsecalgbyname()</code> and <code>getipsecalgbynum()</code> functions return a pointer to the structure <code>ipsecalgent_t</code>, defined in <code><netdb.h></code>. If the requested algorithm cannot be found, these functions return <code>NULL</code>.</p> <p>The structure <code>ipsecalgent_t</code> is defined as follows:</p> <pre>typedef struct ipsecalgent { char **a_names; /* algorithm names */ int a_proto_num; /* protocol number */</pre>				

getipsecalgbyname(3NSL)

```

    int a_alg_num;          /* algorithm number */
    char *a_mech_name;     /* mechanism name */
    int *a_block_sizes;    /* supported block sizes */
    int *a_key_sizes;      /* supported key sizes */
    int a_key_increment;   /* key size increment */
} ipsecalgent_t;

```

If `a_key_increment` is non-zero, `a_key_sizes[0]` contains the default key size for the algorithm. `a_key_sizes[1]` and `a_key_sizes[2]` specify the smallest and biggest key sizes support by the algorithm, and `a_key_increment` specifies the valid key size increments in that range.

If `a_key_increment` is zero, the array `a_key_sizes` contains the set of key sizes, in bits, supported by the algorithm. The last key length in the array is followed by an element of value 0. The first element of this array is used as the default key size for the algorithm.

`a_name` is an array of algorithm names, terminated by an element containing a NULL pointer. `a_name[0]` is the primary name for the algorithm.

`a_proto_num` is the protocol identifier of this algorithm. `a_alg_num` is the algorithm number. `a_mech_name` contains the mechanism name associated with the algorithm.

`a_block_sizes` is an array containing the supported block lengths or MAC lengths, in bytes, supported by the algorithm. The last valid value in the array is followed by an element containing the value 0.

ERRORS When the specified algorithm cannot be returned to the caller, `getipsecalgbyname()` and `getipsecalgbyname()` return a value of NULL and set the integer pointed to by the `errno` parameter to one of the following values:

ENOMEM	Not enough memory
ENOENT	Specified algorithm not found
EINVAL	Specified protocol number not found

getipsecprotobyname(3NSL)

NAME	getipsecprotobyname, getipsecprotobynum – query IPsec protocols entries						
SYNOPSIS	<pre>cc -flag ... file...-lnsl [-library ...] #include <netdb.h> int getipsecprotobyname(const char *proto_name); char *getipsecprotobynum(int proto_num);</pre>						
DESCRIPTION	<p>Use the <code>getipsecprotobyname()</code> and <code>getipsecprotobynum()</code> functions to obtain the IPsec algorithm mappings that are defined by <code>ipsecalgs(1M)</code>. You can also use the <code>getipsecprotobyname()</code> and <code>getipsecprotobynum()</code> functions in conjunction with <code>getipsecalgbyname(3NSL)</code> and <code>getipsecalgbynum(3NSL)</code> to obtain information about the supported IPsec algorithms. The IPsec algorithms and associated protocol name spaces are defined by <i>RFC 2407</i>.</p> <p><code>getipsecprotobyname()</code> takes as an argument the name of an IPsec protocol and returns its assigned protocol number. The character string returned by the <code>getipsecprotobyname()</code> function must be freed by the called when it is no longer needed.</p> <p><code>getipsecprotobynum()</code> takes as an argument a protocol number and returns the corresponding protocol name.</p> <p>The following protocol numbers are pre-defined:</p> <table><tr><td>IPSEC_PROTO_ESP</td><td>Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.</td></tr><tr><td>IPSEC_PROTO_AH</td><td>Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.</td></tr></table>	IPSEC_PROTO_ESP	Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.	IPSEC_PROTO_AH	Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.		
IPSEC_PROTO_ESP	Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.						
IPSEC_PROTO_AH	Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.						
PARAMETERS	<p><i>proto_name</i> A pointer to the name of an IPsec protocol.</p> <p><i>proto_num</i> A pointer to a protocol number. conditions.</p>						
RETURN VALUES	<p>The <code>getipsecprotobyname()</code> function returns a protocol number upon success, or -1 if the protocol specified does not exist.</p> <p>The <code>getipsecprotobynum()</code> function returns a protocol name upon success, or the NULL value if the protocol number specified does not exist.</p>

getnameinfo(3XNET)

NAME	getnameinfo – get name information
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lxnet [<i>library</i> ...] #include <sys/socket.h> #include <netdb.h> int getnameinfo(const struct sockaddr *restrict <i>sa</i>, socklen_t <i>salen</i>, char *restrict <i>node</i>, socklen_t <i>nodelen</i>, char *restrict <i>service</i>, socklen_t <i>servicelen</i>, unsigned <i>flags</i>);</pre>
DESCRIPTION	<p>The <code>getnameinfo()</code> function translates a socket address to a node name and service location, all of which are defined as in <code>getaddrinfo(3XNET)</code>.</p> <p>The <i>sa</i> argument points to a socket address structure to be translated. If the socket address structure contains an IPv4-mapped IPv6 address or an IPv4-compatible IPv6 address, the implementation extracts the embedded IPv4 address and lookup the node name for that IPv4 address.</p> <p>If the <i>node</i> argument is non-NULL and the <i>nodelen</i> argument is non-zero, then the <i>node</i> argument points to a buffer able to contain up to <i>nodelen</i> characters that receives the node name as a null-terminated string. If the <i>node</i> argument is NULL or the <i>nodelen</i> argument is zero, the node name is not returned. If the node's name cannot be located, the numeric form of the node's address is returned instead of its name.</p> <p>If the <i>service</i> argument is non-NULL and the <i>servicelen</i> argument is non-zero, then the <i>service</i> argument points to a buffer able to contain up to <i>servicelen</i> bytes that receives the service name as a null-terminated string. If the <i>service</i> argument is NULL or the <i>servicelen</i> argument is zero, the service name is not returned. If the service's name cannot be located, the numeric form of the service address (for example, its port number) is returned instead of its name.</p> <p>The <i>flags</i> argument is a flag that changes the default actions of the function. By default the fully-qualified domain name (FQDN) for the host is returned, but:</p> <ul style="list-style-type: none">■ If the flag bit <code>NI_NOFQDN</code> is set, only the node name portion of the FQDN is returned for local hosts.■ If the flag bit <code>NI_NUMERICHOST</code> is set, the numeric form of the host's address is returned instead of its name, under all circumstances.■ If the flag bit <code>NI_NAMEREQD</code> is set, an error is returned if the host's name cannot be located.■ If the flag bit <code>NI_NUMERICSERV</code> is set, the numeric form of the service address is returned (for example, its port number) instead of its name, under all circumstances.■ If the flag bit <code>NI_DGRAM</code> is set, this indicates that the service is a datagram service (<code>SOCK_DGRAM</code>). The default behavior assumes that the service is a stream service (<code>SOCK_STREAM</code>).
RETURN VALUES	A 0 return value for <code>getnameinfo()</code> indicates successful completion; a non-zero return value indicates failure. The possible values for the failures are listed in the <code>ERRORS</code> section.

Upon successful completion, `getnameinfo()` returns the node and service names, if requested, in the buffers provided. The returned names are always null-terminated strings.

ERRORS The `getnameinfo()` function will fail if:

<code>EAI_AGAIN</code>	The name could not be resolved at this time. Future attempts might succeed.
<code>EAI_BADFLAGS</code>	The <i>flags</i> argument had an invalid value.
<code>EAI_FAIL</code>	A non-recoverable error occurred.
<code>EAI_FAMILY</code>	The address family was not recognized or the address length was invalid for the specified family.
<code>EAI_MEMORY</code>	There was a memory allocation failure.
<code>EAI_NONAME</code>	The name does not resolve for the supplied parameters. <code>NI_NAMEREQD</code> is set and the host's name cannot be located, or both <i>nodename</i> and <i>servname</i> were <code>NULL</code> .
<code>EAI_SYSTEM</code>	A system error occurred. The error code can be found in <code>errno</code> .

USAGE If the returned values are to be used as part of any further name resolution (for example, passed to `getaddrinfo()`), applications should provide buffers large enough to store any result possible on the system.

Given the IPv4-mapped IPv6 address `::ffff:1.2.3.4`, the implementation performs a lookup as if the socket address structure contains the IPv4 address `"1.2.3.4"`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard
MT-Level	MT-Safe

SEE ALSO [gai_strerror\(3XNET\)](#), [getaddrinfo\(3XNET\)](#), [getservbyname\(3XNET\)](#), [socket\(3XNET\)](#), [attributes\(5\)](#), [standards\(5\)](#)

NOTES The IPv6 unspecified address (`:::`) and the IPv6 loopback address (`:::1`) are not IPv4-compatible addresses. If the address is the IPv6 unspecified address (`:::`), a lookup is not performed, and the `EAI_NONAME` error is returned.

The two `NI_NUMERICxxx` flags are required to support the `-n` flag that many commands provide.

The `NI_DGRAM` flag is required for the few `AF_INET` and `AF_INET6` port numbers (for example, [512,514]) that represent different services for UDP and TCP.

getnetbyname(3SOCKET)

NAME	getnetbyname, getnetbyname_r, getnetbyaddr, getnetbyaddr_r, getnetent, getnetent_r, setnetent, endnetent – get network entry								
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <netdb.h> struct netent *getnetbyname(const char *name); struct netent *getnetbyname_r(const char *name, struct netent *result, char *buffer, int buflen); struct netent *getnetbyaddr(long net, int type); struct netent *getnetbyaddr_r(long net, int type, struct netent *result, char *buffer, int buflen); struct netent *getnetent(void); struct netent *getnetent_r(struct netent *result, char *buffer, int buflen); int setnetent(int stayopen); int endnetent(void);</pre>								
DESCRIPTION	<p>These functions are used to obtain entries for networks. An entry may come from any of the sources for networks specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code>.</p> <p><code>getnetbyname()</code> searches for a network entry with the network name specified by the character string parameter <i>name</i>.</p> <p><code>getnetbyaddr()</code> searches for a network entry with the network address specified by <i>net</i>. The parameter <i>type</i> specifies the family of the address. This should be one of the address families defined in <code><sys/socket.h></code>. See the NOTES section below for more information.</p> <p>Network numbers and local address parts are returned as machine format integer values, that is, in host byte order. See also inet(3SOCKET).</p> <p>The <code>netent.n_net</code> member in the <code>netent</code> structure pointed to by the return value of the above functions is calculated by <code>inet_network()</code>. The <code>inet_network()</code> function returns a value in host byte order that is aligned based upon the input string. For example:</p> <table><thead><tr><th>Text</th><th>Value</th></tr></thead><tbody><tr><td>"10"</td><td>0x0000000a</td></tr><tr><td>"10.0"</td><td>0x00000a00</td></tr><tr><td>"10.0.1"</td><td>0a000a0001</td></tr></tbody></table>	Text	Value	"10"	0x0000000a	"10.0"	0x00000a00	"10.0.1"	0a000a0001
Text	Value								
"10"	0x0000000a								
"10.0"	0x00000a00								
"10.0.1"	0a000a0001								

getnetbyname(3SOCKET)

Text	Value
"10.0.1.28"	0x0a000180

Commonly, the alignment of the returned value is used as a crude approximate of pre-CIDR (Classless Inter-Domain Routing) subnet mask. For example:

```
in_addr_t addr, mask;

addr = inet_network(net_name);
mask = ~(in_addr_t)0;
if ((addr & IN_CLASSA_NET) == 0)
    addr <<= 8, mask <<= 8;
if ((addr & IN_CLASSB_NET) == 0)
    addr <<= 8, mask <<= 8;
if ((addr & IN_CLASSC_NET) == 0)
    addr <<= 8, mask <<= 8;
```

This usage is deprecated by the CIDR requirements. See Fuller, V., Li, T., Yu, J., and Varadhan, K. *RFC 1519, Classless Inter-Domain Routing (CIDR): an Address Assignment and Aggregation Strategy*. Network Working Group. September 1993.

The functions `setnetent()`, `getnetent()`, and `endnetent()` are used to enumerate network entries from the database.

`setnetent()` sets (or resets) the enumeration to the beginning of the set of network entries. This function should be called before the first call to `getnetent()`. Calls to `getnetbyname()` and `getnetbyaddr()` leave the enumeration position in an indeterminate state. If the *stayopen* flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to `endnetent()`.

Successive calls to `getnetent()` return either successive entries or `NULL`, indicating the end of the enumeration.

`endnetent()` may be called to indicate that the caller expects to do no further network entry retrieval operations; the system may then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more network entry retrieval functions after calling `endnetent()`.

Reentrant Interfaces

The functions `getnetbyname()`, `getnetbyaddr()`, and `getnetent()` use static storage that is reused in each call, making these routines unsafe for use in multi-threaded applications.

The functions `getnetbyname_r()`, `getnetbyaddr_r()`, and `getnetent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multi-threaded applications.

getnetbyname(3SOCKET)

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct netent` structure allocated by the caller. On successful completion, the function returns the network entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the network entry data. All of the pointers within the returned `struct netent result` point to data stored within this buffer. See RETURN VALUES. The buffer must be large enough to hold all of the data associated with the network entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multi-threaded applications, the position within the enumeration is a process-wide property shared by all threads. `setnetent()` may be used in a multi-threaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getnetent_r()`, the threads will enumerate disjointed subsets of the network database.

Like their non-reentrant counterparts, `getnetbyname_r()` and `getnetbyaddr_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Network entries are represented by the `struct netent` structure defined in `<netdb.h>`.

The functions `getnetbyname()`, `getnetbyname_r()`, `getnetbyaddr()`, and `getnetbyaddr_r()` each return a pointer to a `struct netent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions `getnetent()` and `getnetent_r()` each return a pointer to a `struct netent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions `getnetbyname()`, `getnetbyaddr()`, and `getnetent()` use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getnetbyname_r()`, `getnetbyaddr_r()`, and `getnetent_r()` is non-`NULL`, it is always equal to the *result* pointer that was supplied by the caller.

The functions `setnetent()` and `endnetent()` return 0 on success.

ERRORS

The reentrant functions `getnetbyname_r()`, `getnetbyaddr_r()` and `getnetent_r()` will return `NULL` and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multi-threaded applications.

FILES

<code>/etc/networks</code>	network name database
<code>/etc/nsswitch.conf</code>	configuration file for the name service switch

getnetbyname(3SOCKET)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `Intro(2)`, `Intro(3)`, `byteorder(3SOCKET)`, `inet(3SOCKET)`, `netdb.h(3HEAD)`, `networks(4)`, `nsswitch.conf(4)`, `attributes(5)`

Fuller, V., Li, T., Yu, J., and Varadhan, K. *RFC 1519, Classless Inter-Domain Routing (CIDR): an Address Assignment and Aggregation Strategy*. Network Working Group. September 1993.

WARNINGS The reentrant interfaces `getnetbyname_r()`, `getnetbyaddr_r()`, and `getnetent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES The current implementation of these functions only return or accept network numbers for the Internet address family (type `AF_INET`). The functions described in `inet(3SOCKET)` may be helpful in constructing and manipulating addresses and network numbers in this form.

When compiling multi-threaded applications, see `Intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getnetent()` and `getnetent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

getnetconfig(3NSL)

NAME	getnetconfig, setnetconfig, endnetconfig, getnetconfigent, freenetconfigent, nc_perror, nc_sperror – get network configuration database entry
SYNOPSIS	<pre>#include <netconfig.h> struct netconfig *getnetconfig(void *handlep); void *setnetconfig(void); int endnetconfig(void *handlep); struct netconfig *getnetconfigent(const char *netid); void freenetconfigent(struct netconfig *netconfigp); void nc_perror(const char *msg); char *nc_sperror(void);</pre>
DESCRIPTION	<p>The library routines described on this page are part of the Network Selection component. They provide the application access to the system network configuration database, <code>/etc/netconfig</code>. In addition to the routines for accessing the <code>netconfig</code> database, Network Selection includes the environment variable <code>NETPATH</code> (see <code>environ(5)</code>) and the <code>NETPATH</code> access routines described in getnetpath(3NSL).</p> <p><code>getnetconfig()</code> returns a pointer to the current entry in the <code>netconfig</code> database, formatted as a <code>struct netconfig</code>. Successive calls will return successive <code>netconfig</code> entries in the <code>netconfig</code> database. <code>getnetconfig()</code> can be used to search the entire <code>netconfig</code> file. <code>getnetconfig()</code> returns <code>NULL</code> at the end of the file. <code>handlep</code> is the handle obtained through <code>setnetconfig()</code>.</p> <p>A call to <code>setnetconfig()</code> has the effect of “binding” to or “rewinding” the <code>netconfig</code> database. <code>setnetconfig()</code> must be called before the first call to <code>getnetconfig()</code> and may be called at any other time. <code>setnetconfig()</code> need <i>not</i> be called before a call to <code>getnetconfigent()</code>. <code>setnetconfig()</code> returns a unique handle to be used by <code>getnetconfig()</code>.</p> <p><code>endnetconfig()</code> should be called when processing is complete to release resources for reuse. <code>handlep</code> is the handle obtained through <code>setnetconfig()</code>. Programmers should be aware, however, that the last call to <code>endnetconfig()</code> frees all memory allocated by <code>getnetconfig()</code> for the <code>struct netconfig</code> data structure. <code>endnetconfig()</code> may not be called before <code>setnetconfig()</code>.</p> <p><code>getnetconfigent()</code> returns a pointer to the <code>struct netconfig</code> structure corresponding to <code>netid</code>. It returns <code>NULL</code> if <code>netid</code> is invalid (that is, does not name an entry in the <code>netconfig</code> database).</p> <p><code>freenetconfigent()</code> frees the <code>netconfig</code> structure pointed to by <code>netconfigp</code> (previously returned by <code>getnetconfigent()</code>).</p> <p><code>nc_perror()</code> prints a message to the standard error indicating why any of the above routines failed. The message is prepended with the string <code>msg</code> and a colon. A <code>NEWLINE</code> is appended at the end of the message.</p>

`nc_spperror()` is similar to `nc_perror()` but instead of sending the message to the standard error, will return a pointer to a string that contains the error message.

`nc_perror()` and `nc_spperror()` can also be used with the NETPATH access routines defined in [getnetpath\(3NSL\)](#).

RETURN VALUES

`setnetconfig()` returns a unique handle to be used by `getnetconfig()`. In the case of an error, `setnetconfig()` returns NULL and `nc_perror()` or `nc_spperror()` can be used to print the reason for failure.

`getnetconfig()` returns a pointer to the current entry in the `netconfig()` database, formatted as a `struct netconfig`. `getnetconfig()` returns NULL at the end of the file, or upon failure.

`endnetconfig()` returns 0 on success and -1 on failure (for example, if `setnetconfig()` was not called previously).

On success, `getnetconfig()` returns a pointer to the `struct netconfig` structure corresponding to *netid*; otherwise it returns NULL.

`nc_spperror()` returns a pointer to a buffer which contains the error message string. This buffer is overwritten on each call. In multithreaded applications, this buffer is implemented as thread-specific data.

getnetpath(3NSL)

NAME	getnetpath, setnetpath, endnetpath – get /etc/netconfig entry corresponding to NETPATH component
SYNOPSIS	<pre>#include <netconfig.h> struct netconfig *getnetpath(void *handlep) ; void *setnetpath(void) ; int endnetpath(void *handlep) ;</pre>
DESCRIPTION	<p>The routines described on this page are part of the Network Selection component. They provide the application access to the system network configuration database, /etc/netconfig, as it is "filtered" by the NETPATH environment variable. See environ(5). See getnetconfig(3NSL) for other routines that also access the network configuration database directly. The NETPATH variable is a list of colon-separated network identifiers.</p> <p>getnetpath() returns a pointer to the netconfig database entry corresponding to the first valid NETPATH component. The netconfig entry is formatted as a struct netconfig. On each subsequent call, getnetpath() returns a pointer to the netconfig entry that corresponds to the next valid NETPATH component. getnetpath() can thus be used to search the netconfig database for all networks included in the NETPATH variable. When NETPATH has been exhausted, getnetpath() returns NULL.</p> <p>A call to setnetpath() "binds" to or "rewinds" NETPATH. setnetpath() must be called before the first call to getnetpath() and may be called at any other time. It returns a handle that is used by getnetpath().</p> <p>getnetpath() silently ignores invalid NETPATH components. A NETPATH component is invalid if there is no corresponding entry in the netconfig database.</p> <p>If the NETPATH variable is unset, getnetpath() behaves as if NETPATH were set to the sequence of "default" or "visible" networks in the netconfig database, in the order in which they are listed.</p> <p>endnetpath() may be called to "unbind" from NETPATH when processing is complete, releasing resources for reuse. Programmers should be aware, however, that endnetpath() frees all memory allocated by getnetpath() for the struct netconfig data structure. endnetpath() returns 0 on success and -1 on failure (for example, if setnetpath() was not called previously).</p>
RETURN VALUES	<p>setnetpath() returns a handle that is used by getnetpath(). In case of an error, setnetpath() returns NULL. nc_perror() or nc_spperror() can be used to print out the reason for failure. See getnetconfig(3NSL).</p> <p>When first called, getnetpath() returns a pointer to the netconfig database entry corresponding to the first valid NETPATH component. When NETPATH has been exhausted, getnetpath() returns NULL.</p> <p>endnetpath() returns 0 on success and -1 on failure (for example, if setnetpath() was not called previously).</p>

getnetpath(3NSL)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO [getnetconfig\(3NSL\)](#), `netconfig(4)`, `attributes(5)`, `environ(5)`

getpeername(3SOCKET)

NAME	getpeername – get name of connected peer										
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h> int getpeername(int <i>s</i>, struct sockaddr *<i>name</i>, socklen_t *<i>namelen</i>);</pre>										
DESCRIPTION	getpeername() returns the name of the peer connected to socket <i>s</i> . The <i>int</i> pointed to by the <i>namelen</i> parameter should be initialized to indicate the amount of space pointed to by <i>name</i> . On return it contains the actual size of the name returned (in bytes), prior to any truncation. The name is truncated if the buffer provided is too small.										
RETURN VALUES	If successful, getpeername() returns 0; otherwise it returns -1 and sets errno to indicate the error.										
ERRORS	The call succeeds unless: <table><tr><td>EBADF</td><td>The argument <i>s</i> is not a valid descriptor.</td></tr><tr><td>ENOMEM</td><td>There was insufficient user memory for the operation to complete.</td></tr><tr><td>ENOSR</td><td>There were insufficient STREAMS resources available for the operation to complete.</td></tr><tr><td>ENOTCONN</td><td>The socket is not connected.</td></tr><tr><td>ENOTSOCK</td><td>The argument <i>s</i> is not a socket.</td></tr></table>	EBADF	The argument <i>s</i> is not a valid descriptor.	ENOMEM	There was insufficient user memory for the operation to complete.	ENOSR	There were insufficient STREAMS resources available for the operation to complete.	ENOTCONN	The socket is not connected.	ENOTSOCK	The argument <i>s</i> is not a socket.
EBADF	The argument <i>s</i> is not a valid descriptor.										
ENOMEM	There was insufficient user memory for the operation to complete.										
ENOSR	There were insufficient STREAMS resources available for the operation to complete.

getprotobyname(3SOCKET)

NAME	getprotobyname, getprotobyname_r, getprotobynumber, getprotobynumber_r, getprotoent, getprotoent_r, setprotoent, endprotoent – get protocol entry
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <netdb.h> struct protoent *getprotobyname(const char *name); struct protoent *getprotobyname_r(const char *name, struct protoent *result, char *buffer, int buflen); struct protoent *getprotobynumber(int proto); struct protoent *getprotobynumber_r(int proto, struct protoent *result, char *buffer, int buflen); struct protoent *getprotoent(void); struct protoent *getprotoent_r(struct protoent *result, char *buffer, int buflen); int setprotoent(int stayopen); int endprotoent(void);</pre>
DESCRIPTION	<p>These functions return a protocol entry. Two types of interfaces are supported: reentrant (getprotobyname_r(), getprotobynumber_r(), and getprotoent_r()) and non-reentrant (getprotobyname(), getprotobynumber(), and getprotoent()). The reentrant functions can be used in single-threaded applications and are safe for multithreaded applications, making them the preferred interfaces.</p> <p>The reentrant routines require additional parameters which are used to return results data. <i>result</i> is a pointer to a struct protoent structure and will be where the returned results will be stored. <i>buffer</i> is used as storage space for elements of the returned results. <i>buflen</i> is the size of <i>buffer</i> and should be large enough to contain all returned data. <i>buflen</i> must be at least 1024 bytes.</p> <p>getprotobyname_r(), getprotobynumber_r(), and getprotoent_r() each return a protocol entry.</p> <p>The entry may come from one of the following sources: the protocols file (see protocols(4)), the NIS maps “protocols.byname” and “protocols.bynumber”, and the NIS+ table “protocols”. The sources and their lookup order are specified in the /etc/nsswitch.conf file (see nsswitch.conf(4) for details). Some name services such as NIS will return only one name for a host, whereas others such as NIS+ or DNS will return all aliases.</p> <p>The getprotobyname_r() and getprotobynumber_r() functions sequentially search from the beginning of the file until a matching protocol name or protocol number is found, or until an EOF is encountered.</p>

getprotobyname(3SOCKET)

`getprotobyname()` and `getprotobynumber()` have the same functionality as `getprotobyname_r()` and `getprotobynumber_r()` except that a static buffer is used to store returned results. These functions are *Unsafe* in a multithreaded application.

`getprotoent_r()` enumerates protocol entries: successive calls to `getprotoent_r()` will return either successive protocol entries or `NULL`. Enumeration might not be supported by some sources. If multiple threads call `getprotoent_r()`, each will retrieve a subset of the protocol database.

`getprotent()` has the same functionality as `getprotent_r()` except that a static buffer is used to store returned results. This routine is *unsafe* in a multithreaded application.

`setprotoent()` “rewinds” to the beginning of the enumeration of protocol entries. If the *stayopen* flag is non-zero, resources such as open file descriptors are not deallocated after each call to `getprotobynumber_r()` and `getprotobyname_r()`. Calls to `getprotobyname_r()`, `getprotobyname()`, `getprotobynumber_r()`, and `getprotobynumber()` functions might leave the enumeration in an indeterminate state, so `setprotoent()` should be called before the first call to `getprotoent_r()` or `getprotoent()`. The `setprotoent()` function has process-wide scope, and “rewinds” the protocol entries for all threads calling `getprotoent_r()` as well as main-thread calls to `getprotoent()`.

The `endprotoent()` function can be called to indicate that protocol processing is complete; the system may then close any open protocols file, deallocate storage, and so forth. It is legitimate, but possibly less efficient, to call more protocol functions after `endprotoent()`.

The internal representation of a protocol entry is a `protoent` structure defined in `<netdb.h>` with the following members:

```
char *p_name;
char **p_aliases;
int p_proto;
```

RETURN VALUES

The `getprotobyname_r()`, `getprotobyname()`, `getprotobynumber_r()`, and `getprotobynumber()` functions return a pointer to a struct `protoent` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getprotoent_r()` and `getprotoent()` functions return a pointer to a struct `protoent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

ERRORS

The `getprotobyname_r()`, `getprotobynumber_r()`, and `getprotoent_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

FILES

`/etc/protocols`
`/etc/nsswitch.conf`

getprotobyname(3SOCKET)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `intro(3)`, `nsswitch.conf(4)`, `protocols(4)`, `attributes(5)`, `netdb.h(3HEAD)`

NOTES Although `getprotobyname_r()`, `getprotobyname_r()`, and `getprotoent_r()` are not mentioned by POSIX 1003.1:2001, they were added to complete the functionality provided by similar thread-safe functions.

When compiling multithreaded applications, see `intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

The `getprotobyname_r()`, `getprotobyname_r()`, and `getprotoent_r()` functions are reentrant and multithread safe. The reentrant interfaces can be used in single-threaded as well as multithreaded applications and are therefore the preferred interfaces.

The `getprotobyname()`, `getprotobyaddr()`, and `getprotoent()` functions use static storage, so returned data must be copied if it is to be saved. Because of their use of static storage for returned data, these functions are not safe for multithreaded applications.

The `setprotoent()` and `endprotoent()` functions have process-wide scope, and are therefore not safe in multi-threaded applications.

Use of `getprotoent_r()` and `getprotoent()` is discouraged; enumeration is well-defined for the `protocols` file and is supported (albeit inefficiently) for NIS and NIS+, but in general may not be well-defined. The semantics of enumeration are discussed in `nsswitch.conf(4)`.

BUGS Only the Internet protocols are currently understood.

NAME	getpublickey, getsecretkey, publickey – retrieve public or secret key				
SYNOPSIS	<pre>#include <rpc/rpc.h> #include <rpc/key_prot.h> int getpublickey(const char <i>netname</i>[MAXNETNAMELEN], char <i>publickey</i>[HEXKEYBYTES+1]); int getsecretkey(const char <i>netname</i>[MAXNETNAMELEN], char <i>secretkey</i>[HEXKEYBYTES+1], const char *<i>passwd</i>);</pre>				
DESCRIPTION	<p>getpublickey() and getsecretkey() get public and secret keys for <i>netname</i>. The key may come from one of the following sources:</p> <ul style="list-style-type: none"> ■ the /etc/publickey file. See publickey(4). ■ the NIS map “publickey.byname” or the NIS+ table “cred.org_dir”. The sources and their lookup order are specified in the /etc/nsswitch.conf file. See nsswitch.conf(4). <p>getsecretkey() has an extra argument, <i>passwd</i>, which is used to decrypt the encrypted secret key stored in the database.</p>				
RETURN VALUES	Both routines return 1 if they are successful in finding the key. Otherwise, the routines return 0. The keys are returned as null-terminated, hexadecimal strings. If the password supplied to getsecretkey() fails to decrypt the secret key, the routine will return 1 but the <i>secretkey</i> [0] will be set to NULL.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	Safe				
SEE ALSO	secure_rpc(3NSL) , nsswitch.conf(4) , publickey(4) , attributes(5)				
WARNINGS	If getpublickey() gets the public key from any source other than NIS+, all authenticated NIS+ operations may fail. To ensure that this does not happen, edit the nsswitch.conf(4) file to make sure that the public key is obtained from NIS+.				
NOTES	NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit http://www.sun.com/directory/nisplus/transition.html .				

getrpcbyname(3NSL)

NAME	getrpcbyname, getrpcbyname_r, getrpcbynumber, getrpcbynumber_r, getrpcent, getrpcent_r, setrpcent, endrpcent – get RPC entry
SYNOPSIS	<pre>cc [flag ...] file ... -lnsl [library ...] #include <rpc/rpcent.h> struct rpcent *getrpcbyname(const char *name); struct rpcent *getrpcbyname_r(const char *name, struct rpcent *result, char *buffer, int buflen); struct rpcent *getrpcbynumber(const int number); struct rpcent *getrpcbynumber_r(const int number, struct rpcent *result, char *buffer, int buflen); struct rpcent *getrpcent(void); struct rpcent *getrpcent_r(struct rpcent *result, char *buffer, int buflen); void setrpcent(const int stayopen); void endrpcent(void);</pre>
DESCRIPTION	<p>These functions are used to obtain entries for RPC (Remote Procedure Call) services. An entry may come from any of the sources for <code>rpc</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p><code>getrpcbyname()</code> searches for an entry with the RPC service name specified by the parameter <code>name</code>.</p> <p><code>getrpcbynumber()</code> searches for an entry with the RPC program number <code>number</code>.</p> <p>The functions <code>setrpcent()</code>, <code>getrpcent()</code>, and <code>endrpcent()</code> are used to enumerate RPC entries from the database.</p> <p><code>setrpcent()</code> sets (or resets) the enumeration to the beginning of the set of RPC entries. This function should be called before the first call to <code>getrpcent()</code>. Calls to <code>getrpcbyname()</code> and <code>getrpcbynumber()</code> leave the enumeration position in an indeterminate state. If the <code>stayopen</code> flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to <code>endrpcent()</code>.</p> <p>Successive calls to <code>getrpcent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p> <p><code>endrpcent()</code> may be called to indicate that the caller expects to do no further RPC entry retrieval operations; the system may then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more RPC entry retrieval functions after calling <code>endrpcent()</code>.</p>
Reentrant Interfaces	The functions <code>getrpcbyname()</code> , <code>getrpcbynumber()</code> , and <code>getrpcent()</code> use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The functions `getrpcbyname_r()`, `getrpcbynumber_r()`, and `getrpccent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct rpcent` structure allocated by the caller. On successful completion, the function returns the RPC entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the RPC entry data. All of the pointers within the returned `struct rpcent result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the RPC entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setrpccent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getrpccent_r()`, the threads will enumerate disjoint subsets of the RPC entry database.

Like their non-reentrant counterparts, `getrpcbyname_r()` and `getrpcbynumber_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

RPC entries are represented by the `struct rpcent` structure defined in `<rpc/rpcent.h>`:

```
struct rpcent {
    char *r_name;           /* name of this rpc service
    char **r_aliases;      /* zero-terminated list of alternate names */
    int r_number;          /* rpc program number */
};
```

The functions `getrpcbyname()`, `getrpcbyname_r()`, `getrpcbynumber()`, and `getrpcbynumber_r()` each return a pointer to a `struct rpcent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions `getrpccent()` and `getrpccent_r()` each return a pointer to a `struct rpcent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions `getrpcbyname()`, `getrpcbynumber()`, and `getrpccent()` use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getrpcbyname_r()`, `getrpcbynumber_r()`, and `getrpccent_r()` is non-`NULL`, it is always equal to the *result* pointer that was supplied by the caller.

getrpcbyname(3NSL)

ERRORS The reentrant functions `getrpcbyname_r()`, `getrpcbynumber_r()` and `getrpccent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

FILES `/etc/rpc`
`/etc/nsswitch.conf`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `rpcinfo(1M)`, `rpc(3NSL)`, `nsswitch.conf(4)`, `rpc(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getrpcbyname_r()`, `getrpcbynumber_r()`, and `getrpccent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getrpccent()` and `getrpccent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

NAME	getservbyname, getservbyname_r, getservbyport, getservbyport_r, getservent, getservent_r, setservent, endservent – get service entry
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library ...] #include <netdb.h> struct servent *getservbyname(const char *name, const char *proto); struct servent *getservbyname_r(const char *name, const char *proto, struct servent *result, char *buffer, int buflen); struct servent *getservbyport(int port, const char *proto); struct servent *getservbyport_r(int port, const char *proto, struct servent *result, char *buffer, int buflen); struct servent *getservent(void); struct servent *getservent_r(struct servent *result, char *buffer, int buflen); int setservent(int stayopen); int endservent(void);</pre>
DESCRIPTION	<p>These functions are used to obtain entries for Internet services. An entry may come from any of the sources for services specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code>.</p> <p>The <code>getservbyname()</code> and <code>getservbyport()</code> functions sequentially search from the beginning of the file until a matching protocol name or port number is found, or until end-of-file is encountered. If a protocol name is also supplied (non-null), searches must also match the protocol.</p> <p>The <code>getservbyname()</code> function searches for an entry with the Internet service name specified by the <i>name</i> parameter.</p> <p>The <code>getservbyport()</code> function searches for an entry with the Internet port number <i>port</i>.</p> <p>All addresses are returned in network order. In order to interpret the addresses, <code>byteorder(3SOCKET)</code></p> <p>must be used for byte order conversion. The string <i>proto</i> is used by both <code>getservbyname()</code> and <code>getservbyport()</code> to restrict the search to entries with the specified protocol. If <i>proto</i> is NULL, entries with any protocol can be returned.</p> <p>The functions <code>setservent()</code>, <code>getservent()</code>, and <code>endservent()</code> are used to enumerate entries from the services database.</p>

getservbyname(3SOCKET)

The `setservent()` function sets (or resets) the enumeration to the beginning of the set of service entries. This function should be called before the first call to `getservent()`. Calls to the functions `getservbyname()` and `getservbyport()` leave the enumeration position in an indeterminate state. If the *stayopen* flag is non-zero, the system may keep allocated resources such as open file descriptors until a subsequent call to `endservent()`.

The `getservent()` function reads the next line of the file, opening the file if necessary. `getservent()` opens and rewinds the file. If the *stayopen* flag is non-zero, the net data base will not be closed after each call to `getservent()` (either directly, or indirectly through one of the other "getserv" calls).

Successive calls to `getservent()` return either successive entries or `NULL`, indicating the end of the enumeration.

The `endservent()` function closes the file. The `endservent()` function can be called to indicate that the caller expects to do no further service entry retrieval operations; the system can then deallocate resources it was using. It is still allowed, but possibly less efficient, for the process to call more service entry retrieval functions after calling `endservent()`.

Reentrant Interfaces

The functions `getservbyname()`, `getservbyport()`, and `getservent()` use static storage that is re-used in each call, making these functions unsafe for use in multithreaded applications.

The functions `getservbyname_r()`, `getservbyport_r()`, and `getservent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the "_r" suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter *result* must be a pointer to a `struct servent` structure allocated by the caller. On successful completion, the function returns the service entry in this structure. The parameter *buffer* must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the service entry data. All of the pointers within the returned `struct servent result` point to data stored within this buffer. See the RETURN VALUES section of this manual page. The buffer must be large enough to hold all of the data associated with the service entry. The parameter *buflen* should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setservent()` function can be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getservent_r()`, the threads will enumerate disjoint subsets of the service database.

Like their non-reentrant counterparts, `getservbyname_r()` and `getservbyport_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Service entries are represented by the `struct servent` structure defined in `<netdb.h>`:

```
struct servent {
    char    *s_name;           /* official name of service */
    char    **s_aliases;      /* alias list */
    int     s_port;           /* port service resides at */
    char    *s_proto;         /* protocol to use */
};
```

The members of this structure are:

<code>s_name</code>	The official name of the service.
<code>s_aliases</code>	A zero terminated list of alternate names for the service.
<code>s_port</code>	The port number at which the service resides. Port numbers are returned in network byte order.
<code>s_proto</code>	The name of the protocol to use when contacting the service

The functions `getservbyname()`, `getservbyname_r()`, `getservbyport()`, and `getservbyport_r()` each return a pointer to a `struct servent` if they successfully locate the requested entry; otherwise they return `NULL`.

The functions `getservent()` and `getservent_r()` each return a pointer to a `struct servent` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The functions `getservbyname()`, `getservbyport()`, and `getservent()` use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getservbyname_r()`, `getservbyport_r()`, and `getservent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS

The reentrant functions `getservbyname_r()`, `getservbyport_r()`, and `getservent_r()` return `NULL` and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

FILES

<code>/etc/services</code>	Internet network services
<code>/etc/netconfig</code>	network configuration file
<code>/etc/nsswitch.conf</code>	configuration file for the name-service switch

getservbyname(3SOCKET)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `intro(2)`, `intro(3)`, `byteorder(3SOCKET)`, `netdir(3NSL)`, `netconfig(4)`, `nsswitch.conf(4)`, `services(4)`, `attributes(5)`, `netdb.h(3HEAD)`

WARNINGS The reentrant interfaces `getservbyname_r()`, `getservbyport_r()`, and `getservent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES The functions that return `struct servent` return the least significant 16-bits of the `s_port` field in *network byte order*. `getservbyport()` and `getservbyport_r()` also expect the input parameter `port` in the *network byte order*. See `htons(3SOCKET)` for more details on converting between host and network byte orders.

To ensure that they all return consistent results, `getservbyname()`, `getservbyname_r()`, and `netdir_getbyname()` are implemented in terms of the same internal library function. This function obtains the system-wide source lookup policy based on the `inet` family entries in `netconfig(4)` and the `services` entry in `nsswitch.conf(4)`. Similarly, `getservbyport()`, `getservbyport_r()`, and `netdir_getbyaddr()` are implemented in terms of the same internal library function. If the `inet` family entries in `netconfig(4)` have a "-" in the last column for `nametoaddr` libraries, then the entry for `services` in `nsswitch.conf` will be used; otherwise the `nametoaddr` libraries in that column will be used, and `nsswitch.conf` will not be consulted.

There is no analogue of `getservent()` and `getservent_r()` in the `netdir` functions, so these enumeration functions go straight to the `services` entry in `nsswitch.conf`. Thus enumeration may return results from a different source than that used by `getservbyname()`, `getservbyname_r()`, `getservbyport()`, and `getservbyport_r()`.

When compiling multithreaded applications, see `intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getservent()` and `getservent_r()` is discouraged; enumeration may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

NAME getsockname – get socket name

SYNOPSIS

```
cc [ flag ... ] file ... -lsocket -lnsl [ library ... ]
#include <sys/types.h>
#include <sys/socket.h>

int getsockname(int s, struct sockaddr *name, socklen_t *namelen);
```

DESCRIPTION getsockname() returns the current *name* for socket *s*. The *namelen* parameter should be initialized to indicate the amount of space pointed to by *name*. On return it contains the actual size in bytes of the name returned.

RETURN VALUES If successful, getsockname() returns 0; otherwise it returns -1 and sets *errno* to indicate the error.

ERRORS The call succeeds unless:

EBADF	The argument <i>s</i> is not a valid file descriptor.
ENOMEM	There was insufficient memory available for the operation to complete.
ENOSR	There were insufficient STREAMS resources available for the operation to complete.
ENOTSOCK	The argument <i>s</i> is not a socket.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NAME	getsockopt, setsockopt – get and set options on sockets												
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lsocket -lnsl [<i>library</i> ...] #include <sys/types.h> #include <sys/socket.h> int getsockopt(int <i>s</i>, int <i>level</i>, int <i>optname</i>, void *<i>optval</i>, int *<i>optlen</i>); int setsockopt(int <i>s</i>, int <i>level</i>, int <i>optname</i>, const void *<i>optval</i>, int <i>optlen</i>);</pre>												
DESCRIPTION	<p>getsockopt () and setsockopt () manipulate options associated with a socket. Options may exist at multiple protocol levels; they are always present at the uppermost “socket” level.</p> <p>When manipulating socket options, the level at which the option resides and the name of the option must be specified. To manipulate options at the “socket” level, <i>level</i> is specified as SOL_SOCKET. To manipulate options at any other level, <i>level</i> is the protocol number of the protocol that controls the option. For example, to indicate that an option is to be interpreted by the TCP protocol, <i>level</i> is set to the TCP protocol number. See getprotobyname(3SOCKET).</p> <p>The parameters <i>optval</i> and <i>optlen</i> are used to access option values for setsockopt (). For getsockopt (), they identify a buffer in which the value(s) for the requested option(s) are to be returned. For getsockopt (), <i>optlen</i> is a value-result parameter, initially containing the size of the buffer pointed to by <i>optval</i>, and modified on return to indicate the actual size of the value returned. Use a 0 <i>optval</i> if no option value is to be supplied or returned.</p> <p><i>optname</i> and any specified options are passed uninterpreted to the appropriate protocol module for interpretation. The include file <sys/socket.h> contains definitions for the socket-level options described below. Options at other protocol levels vary in format and name.</p> <p>Most socket-level options take an int for <i>optval</i>. For setsockopt (), the <i>optval</i> parameter should be non-zero to enable a boolean option, or zero if the option is to be disabled. SO_LINGER uses a struct linger parameter that specifies the desired state of the option and the linger interval. struct linger is defined in <sys/socket.h>. struct linger contains the following members:</p> <table border="0" style="margin-left: 20px;"> <tr> <td>l_onoff</td> <td>on = 1/off = 0</td> </tr> <tr> <td>l_linger</td> <td>linger time, in seconds</td> </tr> </table> <p>The following options are recognized at the socket level. Except as noted, each may be examined with getsockopt () and set with setsockopt ().</p> <table border="0" style="margin-left: 20px;"> <tr> <td>SO_DEBUG</td> <td>enable/disable recording of debugging information</td> </tr> <tr> <td>SO_REUSEADDR</td> <td>enable/disable local address reuse</td> </tr> <tr> <td>SO_KEEPALIVE</td> <td>enable/disable keep connections alive</td> </tr> <tr> <td>SO_DONTROUTE</td> <td>enable/disable routing bypass for outgoing messages</td> </tr> </table>	l_onoff	on = 1/off = 0	l_linger	linger time, in seconds	SO_DEBUG	enable/disable recording of debugging information	SO_REUSEADDR	enable/disable local address reuse	SO_KEEPALIVE	enable/disable keep connections alive	SO_DONTROUTE	enable/disable routing bypass for outgoing messages
l_onoff	on = 1/off = 0												
l_linger	linger time, in seconds												
SO_DEBUG	enable/disable recording of debugging information												
SO_REUSEADDR	enable/disable local address reuse												
SO_KEEPALIVE	enable/disable keep connections alive												
SO_DONTROUTE	enable/disable routing bypass for outgoing messages												

getsockopt(3SOCKET)

SO_LINGER	linger on close if data is present
SO_BROADCAST	enable/disable permission to transmit broadcast messages
SO_OOBINLINE	enable/disable reception of out-of-band data in band
SO_SNDBUF	set buffer size for output
SO_RCVBUF	set buffer size for input
SO_DGRAM_ERRIND	application wants delayed error
SO_TYPE	get the type of the socket (get only)
SO_ERROR	get and clear error on the socket (get only)

SO_DEBUG enables debugging in the underlying protocol modules. SO_REUSEADDR indicates that the rules used in validating addresses supplied in a `bind(3SOCKET)` call should allow reuse of local addresses. SO_KEEPAIVE enables the periodic transmission of messages on a connected socket. If the connected party fails to respond to these messages, the connection is considered broken and threads using the socket are notified using a SIGPIPE signal. SO_DONTROUTE indicates that outgoing messages should bypass the standard routing facilities. Instead, messages are directed to the appropriate network interface according to the network portion of the destination address.

SO_LINGER controls the action taken when unsent messages are queued on a socket and a `close(2)` is performed. If the socket promises reliable delivery of data and SO_LINGER is set, the system will block the thread on the `close()` attempt until it is able to transmit the data or until it decides it is unable to deliver the information (a timeout period, termed the linger interval, is specified in the `setsockopt()` call when SO_LINGER is requested). If SO_LINGER is disabled and a `close()` is issued, the system will process the `close()` in a manner that allows the thread to continue as quickly as possible.

The option SO_BROADCAST requests permission to send broadcast datagrams on the socket. With protocols that support out-of-band data, the SO_OOBINLINE option requests that out-of-band data be placed in the normal data input queue as received; it will then be accessible with `recv()` or `read()` calls without the MSG_OOB flag.

SO_SNDBUF and SO_RCVBUF are options that adjust the normal buffer sizes allocated for output and input buffers, respectively. The buffer size may be increased for high-volume connections or may be decreased to limit the possible backlog of incoming data. The maximum buffer size for UDP is determined by the value of the ndd variable `udp_max_buf`. The maximum buffer size for TCP is determined the value of the ndd variable `tcp_max_buf`. Use the `ndd(1M)` utility to determine the current default values. See the *Solaris Tunable Parameters Reference Manual* for information on setting the values of `udp_max_buf` and `tcp_max_buf`.

getsockopt(3SOCKET)

By default, delayed errors (such as ICMP port unreachable packets) are returned only for connected datagram sockets. `SO_DGRAM_ERRIND` makes it possible to receive errors for datagram sockets that are not connected. When this option is set, certain delayed errors received after completion of a `sendto()` or `sendmsg()` operation will cause a subsequent `sendto()` or `sendmsg()` operation using the same destination address (*to* parameter) to fail with the appropriate error. See `send(3SOCKET)`.

Finally, `SO_TYPE` and `SO_ERROR` are options used only with `getsockopt()`. `SO_TYPE` returns the type of the socket, for example, `SOCK_STREAM`. It is useful for servers that inherit sockets on startup. `SO_ERROR` returns any pending error on the socket and clears the error status. It may be used to check for asynchronous errors on connected datagram sockets or for other asynchronous errors.

RETURN VALUES If successful, `getsockopt()` and `setsockopt()` return 0; otherwise, the functions return -1 and set `errno` to indicate the error.

ERRORS The `getsockopt()` and `setsockopt()` calls succeed unless:

<code>EBADF</code>	The argument <i>s</i> is not a valid file descriptor.
<code>ENOMEM</code>	There was insufficient memory available for the operation to complete.
<code>ENOPROTOOPT</code>	The option is unknown at the level indicated.
<code>ENOSR</code>	There were insufficient STREAMS resources available for the operation to complete.
<code>ENOTSOCK</code>	The argument <i>s</i> is not a socket.
<code>ENOBUFS</code>	<code>SO_SNDBUF</code> or <code>SO_RCVBUF</code> exceeds a system limit.
<code>EINVAL</code>	Invalid length for <code>IP_OPTIONS</code> .
<code>EHOSTUNREACH</code>	Invalid address for <code>IP_MULTICAST_IF</code> .
<code>EINVAL</code>	Not a multicast address for <code>IP_ADD_MEMBERSHIP</code> and <code>IP_DROP_MEMBERSHIP</code> .
<code>EADDRNOTAVAIL</code>	Bad interface address for <code>IP_ADD_MEMBERSHIP</code> and <code>IP_DROP_MEMBERSHIP</code> .
<code>EADDRINUSE</code>	Address already joined for <code>IP_ADD_MEMBERSHIP</code> .
<code>ENOENT</code>	Address not joined for <code>IP_DROP_MEMBERSHIP</code> .
<code>EPERM</code>	No permissions.
<code>EINVAL</code>	The specified option is invalid at the specified socket level, or the socket has been shut down.

Solaris Tunable Parameters Reference Manual

NAME	getsockopt – get the socket options										
SYNOPSIS	<pre>cc [flag...] file... -lXnet [library...] #include <sys/socket.h> int getsockopt(int <i>socket</i>, int <i>level</i>, int <i>option_name</i>, void *restrict <i>option_value</i>, socklen_t *restrict <i>option_len</i>);</pre>										
DESCRIPTION	<p>The <code>getsockopt()</code> function retrieves the value for the option specified by the <code>option_name</code> argument for the socket specified by the <code>socket</code> argument. If the size of the option value is greater than <code>option_len</code>, the value stored in the object pointed to by the <code>option_value</code> argument will be silently truncated. Otherwise, the object pointed to by the <code>option_len</code> argument will be modified to indicate the actual length of the value.</p> <p>The <code>level</code> argument specifies the protocol level at which the option resides. To retrieve options at the socket level, specify the <code>level</code> argument as <code>SOL_SOCKET</code>. To retrieve options at other levels, supply the appropriate protocol number for the protocol controlling the option. For example, to indicate that an option will be interpreted by the TCP (Transport Control Protocol), set <code>level</code> to the protocol number of TCP, as defined in the <code><netinet/in.h></code> header, or as determined by using <code>getprotobyname(3XNET)</code> function.</p> <p>The socket in use might require the process to have appropriate privileges to use the <code>getsockopt()</code> function.</p> <p>The <code>option_name</code> argument specifies a single option to be retrieved. It can be one of the following values defined in <code><sys/socket.h></code>:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>SO_DEBUG</code></td> <td>Reports whether debugging information is being recorded. This option stores an <code>int</code> value. This is a boolean option.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>SO_ACCEPTCONN</code></td> <td>Reports whether socket listening is enabled. This option stores an <code>int</code> value.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>SO_BROADCAST</code></td> <td>Reports whether transmission of broadcast messages is supported, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>SO_REUSEADDR</code></td> <td>Reports whether the rules used in validating addresses supplied to <code>bind(3XNET)</code> should allow reuse of local addresses, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>SO_KEEPALIVE</code></td> <td>Reports whether connections are kept active with periodic transmission of messages, if this is supported by the protocol.</td> </tr> </table> <p>If the connected socket fails to respond to these messages, the connection is broken and threads writing to that socket are notified with a <code>SIGPIPE</code> signal. This option stores an <code>int</code> value.</p>	<code>SO_DEBUG</code>	Reports whether debugging information is being recorded. This option stores an <code>int</code> value. This is a boolean option.	<code>SO_ACCEPTCONN</code>	Reports whether socket listening is enabled. This option stores an <code>int</code> value.	<code>SO_BROADCAST</code>	Reports whether transmission of broadcast messages is supported, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.	<code>SO_REUSEADDR</code>	Reports whether the rules used in validating addresses supplied to <code>bind(3XNET)</code> should allow reuse of local addresses, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.	<code>SO_KEEPALIVE</code>	Reports whether connections are kept active with periodic transmission of messages, if this is supported by the protocol.
<code>SO_DEBUG</code>	Reports whether debugging information is being recorded. This option stores an <code>int</code> value. This is a boolean option.										
<code>SO_ACCEPTCONN</code>	Reports whether socket listening is enabled. This option stores an <code>int</code> value.										
<code>SO_BROADCAST</code>	Reports whether transmission of broadcast messages is supported, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.										
<code>SO_REUSEADDR</code>	Reports whether the rules used in validating addresses supplied to <code>bind(3XNET)</code> should allow reuse of local addresses, if this is supported by the protocol. This option stores an <code>int</code> value. This is a boolean option.										
<code>SO_KEEPALIVE</code>	Reports whether connections are kept active with periodic transmission of messages, if this is supported by the protocol.										

getsockopt(3XNET)

	This is a boolean option.
SO_LINGER	Reports whether the socket lingers on <code>close(2)</code> if data is present. If <code>SO_LINGER</code> is set, the system blocks the process during <code>close(2)</code> until it can transmit the data or until the end of the interval indicated by the <code>l_linger</code> member, whichever comes first. If <code>SO_LINGER</code> is not specified, and <code>close(2)</code> is issued, the system handles the call in a way that allows the process to continue as quickly as possible. This option stores a <code>linger</code> structure.
SO_OOBINLINE	Reports whether the socket leaves received out-of-band data (data marked urgent) in line. This option stores an <code>int</code> value. This is a boolean option.
SO_SNDBUF	Reports send buffer size information. This option stores an <code>int</code> value.
SO_RCVBUF	Reports receive buffer size information. This option stores an <code>int</code> value.
SO_ERROR	Reports information about error status and clears it. This option stores an <code>int</code> value.
SO_TYPE	Reports the socket type. This option stores an <code>int</code> value.
SO_DONTROUTE	Reports whether outgoing messages bypass the standard routing facilities. The destination must be on a directly-connected network, and messages are directed to the appropriate network interface according to the destination address. The effect, if any, of this option depends on what protocol is in use. This option stores an <code>int</code> value. This is a boolean option.

For boolean options, a zero value indicates that the option is disabled and a non-zero value indicates that the option is enabled.

Options at other protocol levels vary in format and name.

The socket in use may require the process to have appropriate privileges to use the `getsockopt()` function.

RETURN VALUES Upon successful completion, `getsockopt()` returns 0. Otherwise, `-1` is returned and `errno` is set to indicate the error.

ERRORS The `getsockopt()` function will fail if:

`EBADF` The *socket* argument is not a valid file descriptor.

getsockopt(3XNET)

- EFAULT The *option_value* or *option_len* parameter can not be accessed or written.
- EINVAL The specified option is invalid at the specified socket level.
- ENOPROTOOPT The option is not supported by the protocol.
- ENOTSOCK The *socket* argument does not refer to a socket.

The `getsockopt()` function may fail if:

- EACCES The calling process does not have the appropriate privileges.
- EINVAL The socket has been shut down.
- ENOBUFS Insufficient resources are available in the system to complete the call.
- ENOSR There were insufficient STREAMS resources available for the operation to complete.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard

gss_accept_sec_context(3GSS)

NAME	gss_accept_sec_context – accept a security context initiated by a peer application
SYNOPSIS	<pre>cc -flag ... file ...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_accept_sec_context(OM_uint32 *minor_status, gss_ctx_id_t *context_handle, const gss_cred_id_t acceptor_cred_handle, const gss_buffer_t input_token, const gss_channel_bindings_t input_chan_bindings, const gss_name_t *src_name, gss_OID *mech_type, gss_buffer_t output_token, OM_uint32 *ret_flags, OM_uint32 *time_rec, gss_cred_id_t *delegated_cred_handle);</pre>
DESCRIPTION	<p>The <code>gss_accept_sec_context()</code> function allows a remotely initiated security context between the application and a remote peer to be established. The routine may return an <i>output_token</i>, which should be transferred to the peer application, where the peer application will present it to <code>gss_init_sec_context()</code>. See <code>gss_init_sec_context(3GSS)</code>. If no token need be sent, <code>gss_accept_sec_context()</code> will indicate this by setting the length field of the <i>output_token</i> argument to zero. To complete the context establishment, one or more reply tokens may be required from the peer application; if so, <code>gss_accept_sec_context()</code> will return a status flag of <code>GSS_S_CONTINUE_NEEDED</code>, in which case it should be called again when the reply token is received from the peer application, passing the token to <code>gss_accept_sec_context()</code> by means of the <i>input_token</i> parameters.</p> <p>Portable applications should be constructed to use the token length and return status to determine whether to send or to wait for a token.</p> <p>Whenever <code>gss_accept_sec_context()</code> returns a major status that includes the value <code>GSS_S_CONTINUE_NEEDED</code>, the context is not fully established, and the following restrictions apply to the output parameters:</p> <ul style="list-style-type: none">■ The value returned by means of the <i>time_rec</i> parameter is undefined.■ Unless the accompanying <i>ret_flags</i> parameter contains the bit <code>GSS_C_PROT_READY_FLAG</code>, which indicates that per-message services may be applied in advance of a successful completion status, the value returned by the <i>mech_type</i> parameter may be undefined until <code>gss_accept_sec_context()</code> returns a major status value of <code>GSS_S_COMPLETE</code>. <p>The values of the <code>GSS_C_DELEG_FLAG</code>, <code>GSS_C_MUTUAL_FLAG</code>, <code>GSS_C_REPLAY_FLAG</code>, <code>GSS_C_SEQUENCE_FLAG</code>, <code>GSS_C_CONF_FLAG</code>, <code>GSS_C_INTEG_FLAG</code> and <code>GSS_C_ANON_FLAG</code> bits returned by means of the <i>ret_flags</i> parameter are values that would be valid if context establishment were to succeed.</p> <p>The values of the <code>GSS_C_PROT_READY_FLAG</code> and <code>GSS_C_TRANS_FLAG</code> bits within <i>ret_flags</i> indicate the actual state at the time <code>gss_accept_sec_context()</code> returns, whether or not the context is fully established. However, applications should not rely on this behavior, as <code>GSS_C_PROT_READY_FLAG</code> was not defined in Version 1 of the GSS-API. Instead, applications should be prepared to use per-message services after a successful context establishment, based upon the <code>GSS_C_INTEG_FLAG</code> and <code>GSS_C_CONF_FLAG</code> values.</p>

All other bits within the *ret_flags* argument are set to zero.

While `gss_accept_sec_context()` returns `GSS_S_CONTINUE_NEEDED`, the values returned by means of the *ret_flags* argument indicate the services available from the established context. If the initial call of `gss_accept_sec_context()` fails, no context object is created, and the value of the *context_handle* parameter is set to `GSS_C_NO_CONTEXT`. In the event of a failure on a subsequent call, the security context and the *context_handle* parameter are left untouched for the application to delete using `gss_delete_sec_context(3GSS)`. During context establishment, the informational status bits `GSS_S_OLD_TOKEN` and `GSS_S_DUPLICATE_TOKEN` indicate fatal errors; GSS-API mechanisms always return them in association with a routine error of `GSS_S_FAILURE`. This pairing requirement did not exist in version 1 of the GSS-API specification, so applications that wish to run over version 1 implementations must special-case these codes.

PARAMETERS

The parameter descriptions for `gss_accept_sec_context()` follow:

<i>minor_status</i>	The status code returned by the underlying mechanism.
<i>context_handle</i>	The context handle to return to the initiator. This should be set to <code>GSS_C_NO_CONTEXT</code> before the loop begins.
<i>acceptor_cred_handle</i>	The handle for the credentials acquired by the acceptor, typically through <code>gss_acquire_cred()</code> . It may be initialized to <code>GSS_C_NO_CREDENTIAL</code> to indicate a default credential to use. If no default credential is defined, the function returns <code>GSS_C_NO_CRED</code> .
<i>input_token_buffer</i>	Token received from the context initiative.
<i>input_chan_bindings</i>	Optional application-specified bindings. Allows application to securely bind channel identification information to the security context. Set to <code>GSS_C_NO_CHANNEL_BINDINGS</code> if you do not want to use channel bindings.
<i>src_name</i>	The authenticated name of the context initiator. After use, this name should be deallocated by passing it to <code>gss_release_name()</code> . See gss_release_name(3GSS) . If not required, specify <code>NULL</code> .
<i>mech_type</i>	The security mechanism used. Set to <code>NULL</code> if it does not matter which mechanism is used.
<i>output_token</i>	The token to send to the acceptor. Initialize it to <code>GSS_C_NO_BUFFER</code> before the function is called (or its length field set to zero). If the length is zero, no token need be sent.

`gss_accept_sec_context(3GSS)`

`ret_flags`

Contains various independent flags, each of which indicates that the context supports a specific service option. If not needed, specify `NULL`. Test the returned bit-mask `ret_flags` value against its symbolic name to determine if the given option is supported by the context. `ret_flags` may contain one of the following values:

`GSS_C_DELEG_FLAG`

If true, delegated credentials are available by means of the `delegated_cred_handle` parameter. If false, no credentials were delegated.

`GSS_C_MUTUAL_FLAG`

If true, a remote peer asked for mutual authentication. If false, no remote peer asked for mutual authentication.

`GSS_C_REPLY_FLAG`

If true, replay of protected messages will be detected. If false, replayed messages will not be detected.

`GSS_C_SEQUENCE_FLAG`

If true, out of sequence protected messages will be detected. If false, they will not be detected.

`GSS_C_CONF_FLAG`

If true, confidentiality service may be invoked by calling the `gss_wrap()` routine. If false, no confidentiality service is available by means of `gss_wrap()`. `gss_wrap()` will provide message encapsulation, data-origin authentication and integrity services only.

`GSS_C_INTEG_FLAG`

If true, integrity service may be invoked by calling either the `gss_get_mic(3GSS)` or the `gss_wrap(3GSS)` routine. If false, per-message integrity service is not available.

`GSS_C_ANON_FLAG`

If true, the initiator does not wish to be authenticated. The `src_name` parameter, if requested, contains an anonymous internal name. If false, the initiator has been authenticated normally.

`GSS_C_PROT_READY_FLAG`

If true, the protection services specified by the states of `GSS_C_CONF_FLAG` and `GSS_C_INTEG_FLAG` are available if the accompanying major status return value is either `GSS_S_COMPLETE` or

`gss_accept_sec_context(3GSS)`

`GSS_S_CONTINUE_NEEDED`. If false, the protection services are available only if the accompanying major status return value is `GSS_S_COMPLETE`.

`GSS_C_TRANS_FLAG`

If true, the resultant security context may be transferred to other processes by means of a call to `gss_export_sec_context(3GSS)`. If false, the security context cannot be transferred.

time_rec

The number of sections for which the context will remain value Specify NULL if not required.

delegated_cred_handle

The credential value for credentials received from the context's initiator. It is valid only if the initiator has requested that the acceptor act as a proxy: that is, if the *ret_flag* argument resolves to `GSS_C_DELEG_FLAG`.

ERRORS

`gss_accept_sec_context()` may return the following status codes:

`GSS_S_COMPLETE`

Successful completion.

`GSS_S_CONTINUE_NEEDED`

A token from the peer application is required to complete the context, and that `gss_accept_sec_context()` must be called again with that token.

`GSS_S_DEFECTIVE_TOKEN`

Consistency checks performed on the *input_token* failed.

`GSS_S_DEFECTIVE_CREDENTIAL`

Consistency checks performed on the credential failed.

`GSS_S_NO_CRED`

The supplied credentials were not valid for context acceptance, or the credential handle did not reference any credentials.

`GSS_S_CREDENTIALS_EXPIRED`

The referenced credentials have expired.

`GSS_S_BAD_BINDINGS`

The *input_token* contains different channel bindings than those specified by means of the *input_chan_bindings* parameter.

`GSS_S_NO_CONTEXT`

The supplied context handle did not refer to a valid context.

`GSS_S_BAD_SIG`

The *input_token* contains an invalid MIC.

`GSS_S_OLD_TOKEN`

The *input_token* was too old. This is a fatal error while establishing context.

`GSS_S_DUPLICATE_TOKEN`

The *input_token* is valid, but it is duplicate of a token already processed. This is a fatal error while establishing context.

gss_accept_sec_context(3GSS)

GSS_S_BAD_MECH	The token received specified a mechanism that is not supported by the implementation or the provided credential.
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

EXAMPLES **EXAMPLE 1** Invoking `gss_accept_sec_context()` Within a Loop

A typical portable caller should always invoke `gss_accept_sec_context()` within a loop:

```
gss_ctx_id_t context_hdl = GSS_C_NO_CONTEXT;

do {
    receive_token_from_peer(input_token);
    maj_stat = gss_accept_sec_context(&min_stat,
                                     &context_hdl,
                                     cred_hdl,
                                     input_token,
                                     input_bindings,
                                     &client_name,
                                     &mech_type,
                                     output_token,
                                     &ret_flags,
                                     &time_rec,
                                     &deleg_cred);

    if (GSS_ERROR(maj_stat)) {
        report_error(maj_stat, min_stat);
    };
    if (output_token->length != 0) {
        send_token_to_peer(output_token);
        gss_release_buffer(&min_stat, output_token);
    };
    if (GSS_ERROR(maj_stat)) {
        if (context_hdl != GSS_C_NO_CONTEXT)
            gss_delete_sec_context(&min_stat,
                                   &context_hdl,
                                   GSS_C_NO_BUFFER);

        break;
    };
} while (maj_stat & GSS_S_CONTINUE_NEEDED);
```

Solaris Security for Developers Guide

gss_acquire_cred(3GSS)

NAME	<code>gss_acquire_cred</code> – acquire a handle for a pre-existing credential by name				
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_acquire_cred(OM_uint32 *minor_status, const gss_name_t *desired_name, OM_uint32 time_req, const gss_OID_set desired_mech, gss_cred_usage_t cred_usage, gss_cred_id_t *output_cred_handle, gss_OID_set *actual_mechs, OM_uint32 *time_rec);</pre>				
DESCRIPTION	<p>The <code>gss_acquire_cred()</code> function allows an application to acquire a handle for a pre-existing credential by name. This routine is not intended as a function to login to the network; a function for login to the network would involve creating new credentials rather than merely acquiring a handle to existing credentials.</p> <p>If <i>desired_name</i> is <code>GSS_C_NO_NAME</code>, the call is interpreted as a request for a credential handle that will invoke default behavior when passed to <code>gss_init_sec_context(3GSS)</code> (if <i>cred_usage</i> is <code>GSS_C_INITIATE</code> or <code>GSS_C_BOTH</code>) or <code>gss_accept_sec_context(3GSS)</code> (if <i>cred_usage</i> is <code>GSS_C_ACCEPT</code> or <code>GSS_C_BOTH</code>).</p> <p>Normally <code>gss_acquire_cred()</code> returns a credential that is valid only for the mechanisms requested by the <i>desired_mechs</i> argument. However, if multiple mechanisms can share a single credential element, the function returns all the mechanisms for which the credential is valid in the <i>actual_mechs</i> argument.</p> <p><code>gss_acquire_cred()</code> is intended to be used primarily by context acceptors, since the GSS-API routines obtain initiator credentials through the system login process. Accordingly, you may not acquire <code>GSS_C_INITIATE</code> or <code>GSS_C_BOTH</code> credentials by means of <code>gss_acquire_cred()</code> for any name other than <code>GSS_C_NO_NAME</code>. Alternatively, you may acquire <code>GSS_C_INITIATE</code> or <code>GSS_C_BOTH</code> credentials for a name produced when <code>gss_inquire_cred(3GSS)</code> is applied to a valid credential, or when <code>gss_inquire_context(3GSS)</code> is applied to an active context.</p> <p>If credential acquisition is time-consuming for a mechanism, the mechanism may choose to delay the actual acquisition until the credential is required, for example, by <code>gss_init_sec_context(3GSS)</code> or by <code>gss_accept_sec_context(3GSS)</code>. Such mechanism-specific implementations are, however, invisible to the calling application; thus a call of <code>gss_inquire_cred(3GSS)</code> immediately following the call of <code>gss_acquire_cred()</code> will return valid credential data and incur the overhead of a deferred credential acquisition.</p>				
PARAMETERS	<p>The parameter descriptions for <code>gss_acquire_cred()</code> follow:</p> <table><tr><td><i>desired_name</i></td><td>The name of the principal for which a credential should be acquired.</td></tr><tr><td><i>time_req</i></td><td>The number of seconds that credentials remain valid. Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted lifetime</td></tr></table>	<i>desired_name</i>	The name of the principal for which a credential should be acquired.	<i>time_req</i>	The number of seconds that credentials remain valid. Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted lifetime
<i>desired_name</i>	The name of the principal for which a credential should be acquired.				
<i>time_req</i>	The number of seconds that credentials remain valid. Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted lifetime				

gss_acquire_cred(3GSS)

<i>desired_mechs</i>	The set of underlying security mechanisms that may be used. <code>GSS_C_NO_OID_SET</code> may be used to obtain a default.
<i>cred_usage</i>	A flag that indicates how this credential should be used. If the flag is <code>GSS_C_ACCEPT</code> , then credentials will be used only to accept security credentials. <code>GSS_C_INITIATE</code> indicates that credentials will be used only to initiate security credentials. If the flag is <code>GSS_C_BOTH</code> , then credentials may be used either to initiate or accept security contexts.
<i>output_cred_handle</i>	The returned credential handle. Resources associated with this credential handle must be released by the application after use with a call to <code>gss_release_cred(3GSS)</code>
<i>actual_mechs</i>	The set of mechanisms for which the credential is valid. Storage associated with the returned OID-set must be released by the application after use with a call to <code>gss_release_oid_set(3GSS)</code> . Specify <code>NULL</code> if not required.
<i>time_rec</i>	Actual number of seconds for which the returned credentials will remain valid. Specify <code>NULL</code> if not required.
<i>minor_status</i>	Mechanism specific status code.

ERRORS

<code>gss_acquire_cred()</code> may return the following status code:	
<code>GSS_S_COMPLETE</code>	Successful completion.
<code>GSS_S_BAD_MECH</code>	An unavailable mechanism has been requested.
<code>GSS_S_BAD_NAME</code>	The type contained within the <i>desired_name</i> parameter is not supported.
<code>GSS_S_BAD_NAME_TYPE</code>	The value supplied for <i>desired_name</i> parameter is ill formed.
<code>GSS_S_CREDENTIALS_EXPIRED</code>	The credentials could not be acquired because they have expired.
<code>GSS_S_NO_CRED</code>	No credentials were found for the specified name.
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted initiator lifetime.</td> </tr> </table>	<i>minor_status</i>	Mechanism specific status code.	<i>input_cred_handle</i>	Credential to which the credential-element is added. If <code>GSS_C_NO_CREDENTIAL</code> is specified, the function composes the new credential based on default behavior. While the credential-handle is not modified by <code>gss_add_cred()</code> , the underlying credential is modified if <i>output_credential_handle</i> is NULL.	<i>desired_name</i>	Name of the principal for which a credential should be acquired.	<i>desired_mech</i>	Flag that indicates how a credential is used to initiate or accept security contexts. If the value of <i>desired_mech</i> is <code>GSS_C_BOTH</code> , the credential can be used either to initiate or to accept security contexts. If the value of <i>desired_mech</i> is <code>GSS_C_INITIATE</code> , the credential is used only to initiate security contexts. If the value of <i>desired_mech</i> is <code>GSS_C_ACCEPT</code> , the credential is used only to accept security contexts.	<i>cred_usage</i>	Flag that indicates how a credential is used to initiate or accept security credentials. If the flag is <code>GSS_C_ACCEPT</code> , the credentials are used only to accept security credentials. If the flag is <code>GSS_C_INITIATE</code> , the credentials are used only to initiate security credentials. If the flag is <code>GSS_C_BOTH</code> , the credentials can be used to either initiate or accept security contexts.	<i>initiator_time_req</i>	Number of seconds that the credential may remain valid for initiating security contexts. This argument is ignored if the composed credentials are of the <code>GSS_C_ACCEPT</code> type. Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted initiator lifetime.
<i>minor_status</i>	Mechanism specific status code.												
<i>input_cred_handle</i>	Credential to which the credential-element is added. If <code>GSS_C_NO_CREDENTIAL</code> is specified, the function composes the new credential based on default behavior. While the credential-handle is not modified by <code>gss_add_cred()</code> , the underlying credential is modified if <i>output_credential_handle</i> is NULL.												
<i>desired_name</i>	Name of the principal for which a credential should be acquired.												
<i>desired_mech</i>	Flag that indicates how a credential is used to initiate or accept security contexts. If the value of <i>desired_mech</i> is <code>GSS_C_BOTH</code> , the credential can be used either to initiate or to accept security contexts. If the value of <i>desired_mech</i> is <code>GSS_C_INITIATE</code> , the credential is used only to initiate security contexts. If the value of <i>desired_mech</i> is <code>GSS_C_ACCEPT</code> , the credential is used only to accept security contexts.												
<i>cred_usage</i>	Flag that indicates how a credential is used to initiate or accept security credentials. If the flag is <code>GSS_C_ACCEPT</code> , the credentials are used only to accept security credentials. If the flag is <code>GSS_C_INITIATE</code> , the credentials are used only to initiate security credentials. If the flag is <code>GSS_C_BOTH</code> , the credentials can be used to either initiate or accept security contexts.												
<i>initiator_time_req</i>	Number of seconds that the credential may remain valid for initiating security contexts. This argument is ignored if the composed credentials are of the <code>GSS_C_ACCEPT</code> type. Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted initiator lifetime.												

gss_add_cred(3GSS)

<i>acceptor_time_req</i>	Number of seconds that the credential may remain valid for accepting security contexts. This argument is ignored if the composed credentials are of the <code>GSS_C_INITIATE</code> type. Specify <code>GSS_C_INDEFINITE</code> to request that the credentials have the maximum permitted initiator lifetime.
<i>output_cred_handle</i>	Returned credential handle that contains the new credential-element and all the credential-elements from <i>input_cred_handle</i> . If a valid pointer to a <code>gss_cred_id_t</code> is supplied for this parameter, <code>gss_add_cred()</code> creates a new credential handle that contains all credential-elements from <i>input_cred_handle</i> and the newly acquired credential-element. If <code>NULL</code> is specified for this parameter, the newly acquired credential-element is added to the credential identified by <i>input_cred_handle</i> . The resources associated with any credential handle returned by means of this parameter must be released by the application after use by a call to <code>gss_release_cred(3GSS)</code> .
<i>actual_mechs</i>	Complete set of mechanisms for which the new credential is valid. Storage for the returned OID-set must be freed by the application after use by a call to <code>gss_release_oid_set(3GSS)</code> . Specify <code>NULL</code> if this parameter is not required.
<i>initiator_time_rec</i>	Actual number of seconds for which the returned credentials remain valid for initiating contexts using the specified mechanism. If a mechanism does not support expiration of credentials, the value <code>GSS_C_INDEFINITE</code> is returned. Specify <code>NULL</code> if this parameter is not required.
<i>acceptor_time_rec</i>	Actual number of seconds for which the returned credentials remain valid for accepting security contexts using the specified mechanism. If a mechanism does not support expiration of credentials, the value <code>GSS_C_INDEFINITE</code> is returned. Specify <code>NULL</code> if this parameter is not required.

DESCRIPTION

The `gss_add_cred()` function adds a credential-element to a credential. The credential-element is identified by the name of the principal to which it refers. This function is not intended as a function to login to the network. A function for login to the network would involve creating new mechanism-specific authentication data, rather than acquiring a handle to existing data.

gss_add_cred(3GSS)

If the value of *desired_name* is `GSS_C_NO_NAME`, the call is interpreted as a request to add a credential-element to invoke default behavior when passed to `gss_init_sec_context(3GSS)` if the value of *cred_usage* is `GSS_C_INITIATE` or `GSS_C_BOTH`. The call is also interpreted as a request to add a credential-element to the invoke default behavior when passed to `gss_accept_sec_context(3GSS)` if the value of *cred_usage* is `GSS_C_ACCEPT` or `GSS_C_BOTH`.

The `gss_add_cred()` function is expected to be used primarily by context acceptors. The GSS-API provides mechanism-specific ways to obtain GSS-API initiator credentials through the system login process. Consequently, the GSS-API does not support acquiring `GSS_C_INITIATE` or `GSS_C_BOTH` credentials by means of `gss_acquire_cred(3GSS)` for any name other than the following:

- `GSS_C_NO_NAME`
- Name produced by `gss_inquire_cred(3GSS)` applied to a valid credential
- Name produced by `gss_inquire_context(3GSS)` applied to an active context

If credential acquisition is time consuming for a mechanism, the mechanism can choose to delay the actual acquisition until the credential is required by `gss_init_sec_context(3GSS)`, for example, or by `gss_accept_sec_context(3GSS)`. Such mechanism-specific implementation decisions are invisible to the calling application. A call to `gss_inquire_cred(3GSS)` immediately following the call `gss_add_cred()` returns valid credential data as well as incurring the overhead of deferred credential acquisition.

The `gss_add_cred()` function can be used either to compose a new credential that contains all credential-elements of the original in addition to the newly-acquired credential-element. The function can also be used to add the new credential-element to an existing credential. If the value of the *output_cred_handle* parameter is `NULL`, the new credential-element is added to the credential identified by *input_cred_handle*. If a valid pointer is specified for the *output_cred_handle* parameter, a new credential handle is created.

If the value of *input_cred_handle* is `GSS_C_NO_CREDENTIAL`, the `gss_add_cred()` function composes a credential and sets the *output_cred_handle* parameter based on the default behavior. The call has the same effect as a call first made by the application to `gss_acquire_cred(3GSS)` to specify the same usage and to pass `GSS_C_NO_NAME` as the *desired_name* parameter. Such an application call obtains an explicit credential handle that incorporates the default behaviors, then passes the credential handle to `gss_add_cred()`, and finally calls `gss_release_cred(3GSS)` on the first credential handle.

If the value of the *input_cred_handle* parameter is `GSS_C_NO_CREDENTIAL`, a non-`NULL` value must be supplied for the *output_cred_handle* parameter.

RETURN VALUES

The `gss_add_cred()` function can return the following status codes:

`GSS_S_COMPLETE` Successful completion.

gss_add_cred(3GSS)

GSS_S_BAD_MECH	An unavailable mechanism has been requested.
GSS_S_BAD_NAME	The value supplied for <i>desired_name</i> parameter is ill formed.
GSS_S_BAD_NAMETYPE	The type contained within the <i>desired_name</i> parameter is not supported.
GSS_S_DUPLICATE_ELEMENT	The credential already contains an element for the requested mechanism that has overlapping usage and validity period.
GSS_S_CREDENTIALS_EXPIRED	The credentials could not be added because they have expired.
GSS_S_NO_CRED	No credentials were found for the specified name.
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

Solaris Security for Developers Guide

NAME	gss_add_oid_set_member – add an object identifier to an object identifier set								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_add_oid_set_member(OM_uint32 *minor_status, const gss_OID member_oid, gss_OID_set *oid_set);</pre>								
DESCRIPTION	<p>The <code>gss_add_oid_set_member()</code> function adds an object identifier to an object identifier set. You should use this function in conjunction with <code>gss_create_empty_oid_set(3GSS)</code> when constructing a set of mechanism OIDs for input to <code>gss_acquire_cred(3GSS)</code>. The <code>oid_set</code> parameter must refer to an OID-set created by GSS-API, that is, a set returned by <code>gss_create_empty_oid_set(3GSS)</code>.</p> <p>The GSS-API creates a copy of the <code>member_oid</code> and inserts this copy into the set, expanding the storage allocated to the OID-set elements array, if necessary. The function may add the new member OID anywhere within the elements array, and the GSS-API verifies that the new <code>member_oid</code> is not already contained within the elements array. If the <code>member_oid</code> is already present, the <code>oid_set</code> should remain unchanged.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_add_oid_set_member()</code> follow:</p> <p><code>minor_status</code> A mechanism specific status code.</p> <p><code>member_oid</code> Object identifier to be copied into the set.</p> <p><code>oid_set</code> Set in which the object identifier should be inserted.</p>								
ERRORS	<p>The <code>gss_add_oid_set_member()</code> function may return the following status codes:</p> <p><code>GSS_S_COMPLETE</code> Successful completion.</p> <p><code>GSS_S_FAILURE</code> The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <code>minor_status</code> parameter details the error condition.</p>								
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWgss (32-bit)</td> </tr> <tr> <td></td> <td>SUNWgssx (64-bit)</td> </tr> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWgss (32-bit)		SUNWgssx (64-bit)	MT-Level	Safe

gss_canonicalize_name(3GSS)

NAME	gss_canonicalize_name – convert an internal name to a mechanism name
SYNOPSIS	<pre>cc [flag ...] file... -lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_canonicalize_name(OM_uint32 *minor_status, const gss_name_t input_name, const gss_OID mech_type, gss_name_t *output_name) ;</pre>
DESCRIPTION	<p>The <code>gss_canonicalize_name()</code> function generates a canonical mechanism name from an arbitrary internal name. The mechanism name is the name that would be returned to a context acceptor on successful authentication of a context where the initiator used the <code>input_name</code> in a successful call to <code>gss_acquire_cred(3GSS)</code>, specifying an OID set containing <code>mech_type</code> as its only member, followed by a call to <code>gss_init_sec_context(3GSS)</code>, specifying <code>mech_type</code> as the authentication mechanism.</p>
PARAMETERS	<p>The parameter descriptions for <code>gss_canonicalize_name()</code> follow:</p> <p><i>minor_status</i> Mechanism-specific status code.</p> <p><i>input_name</i> The name for which a canonical form is desired.</p> <p><i>mech_type</i> The authentication mechanism for which the canonical form of the name is desired. The desired mechanism must be specified explicitly; no default is provided.</p> <p><i>output_name</i> The resultant canonical name. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name(3GSS)</code>.</p>
ERRORS	<p>The <code>gss_canonicalize_name()</code> function may return the status codes:</p> <p>GSS_S_COMPLETE Successful completion.</p> <p>GSS_S_BAD_MECH The identified mechanism is not supported.</p> <p>GSS_S_BAD_NAME The provided internal name contains no elements that could be processed by the specified mechanism.</p> <p>GSS_S_BAD_NAME The provided internal name was ill-formed.</p> <p>GSS_S_FAILURE The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <code>minor_status</code> parameter details the error condition.</p>

gss_compare_name(3GSS)

NAME	gss_compare_name – compare two internal-form names								
SYNOPSIS	<pre>cc [flag ...] file... -lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_compare_name(OM_uint32 *minor_status, const gss_name_t name1, const gss_name_t name2, int *name_equal);</pre>								
DESCRIPTION	<p>The <code>gss_compare_name()</code> function allows an application to compare two internal-form names to determine whether they refer to the same entity.</p> <p>If either name presented to <code>gss_compare_name()</code> denotes an anonymous principal, the routines indicate that the two names do not refer to the same identity.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_compare_name()</code> follow:</p> <table><tr><td><i>minor_status</i></td><td>Mechanism-specific status code.</td></tr><tr><td><i>name1</i></td><td>Internal-form name.</td></tr><tr><td><i>name2</i></td><td>Internal-form name.</td></tr><tr><td><i>name_equal</i></td><td>If non-zero, the names refer to same entity. If 0, the names refer to different entities. Strictly, the names are not known to refer to the same identity.</td></tr></table>	<i>minor_status</i>	Mechanism-specific status code.	<i>name1</i>	Internal-form name.	<i>name2</i>	Internal-form name.	<i>name_equal</i>	If non-zero, the names refer to same entity. If 0, the names refer to different entities. Strictly, the names are not known to refer to the same identity.
<i>minor_status</i>	Mechanism-specific status code.								
<i>name1</i>	Internal-form name.								
<i>name2</i>	Internal-form name.								
<i>name_equal</i>	If non-zero, the names refer to same entity. If 0, the names refer to different entities. Strictly, the names are not known to refer to the same identity.								
ERRORS	<p>The <code>gss_compare_name()</code> function may return the following status codes:</p> <table><tr><td>GSS_S_COMPLETE</td><td>Successful completion.</td></tr><tr><td>GSS_S_BAD_NAME_TYPE</td><td>The two names were of incomparable types.</td></tr><tr><td>GSS_S_BAD_NAME</td><td>One or both of <i>name1</i> or <i>name2</i> was ill-formed.</td></tr><tr><td>GSS_S_FAILURE</td><td>The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</td></tr></table>	GSS_S_COMPLETE	Successful completion.	GSS_S_BAD_NAME_TYPE	The two names were of incomparable types.	GSS_S_BAD_NAME	One or both of <i>name1</i> or <i>name2</i> was ill-formed.	GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.
GSS_S_COMPLETE	Successful completion.								
GSS_S_BAD_NAME_TYPE	The two names were of incomparable types.								
GSS_S_BAD_NAME	One or both of <i>name1</i> or <i>name2</i> was ill-formed.								
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

NAME	gss_context_time – determine how long a context will remain valid								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_context_time(OM_uint32 *minor_status, gss_ctx_id_t *context_handle, OM_uint32 *time_rec);</pre>								
DESCRIPTION	The gss_context_time() function determines the number of seconds for which the specified context will remain valid.								
PARAMETERS	<p>The parameter descriptions for gss_context_time() are as follows:</p> <p><i>minor_status</i> A mechanism-specific status code.</p> <p><i>context_handle</i> A read-only value. Identifies the context to be interrogated.</p> <p><i>time_rec</i> Modifies the number of seconds that the context remains valid. If the context has already expired, returns zero.</p>								
ERRORS	<p>The gss_context_time() function returns one of the following status codes:</p> <p>GSS_S_COMPLETE Successful completion.</p> <p>GSS_S_CONTEXT_EXPIRED The context has already expired.</p> <p>GSS_S_NO_CONTEXT The <i>context_handle</i> parameter did not identify a valid context.</p> <p>GSS_S_FAILURE The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</p>

gss_create_empty_oid_set(3GSS)

NAME	<code>gss_create_empty_oid_set</code> – create an object-identifier set containing no object identifiers								
SYNOPSIS	<pre>cc -flag ... file ...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_create_empty_oid_set(OM_uint32 *minor_status, gss_OID_set *oid_set);</pre>								
DESCRIPTION	The <code>gss_create_empty_oid_set()</code> function creates an object-identifier set containing no object identifiers to which members may be subsequently added using the <code>gss_add_oid_set_member(3GSS)</code> function. These functions can be used to construct sets of mechanism object identifiers for input to <code>gss_acquire_cred(3GSS)</code> .								
PARAMETERS	The parameter descriptions for <code>gss_create_empty_oid_set()</code> follow: <table><tr><td><i>minor_status</i></td><td>Mechanism-specific status code</td></tr><tr><td><i>oid_set</i></td><td>Empty object identifier set. The function will allocate the <code>gss_OID_set_desc</code> object, which the application must free after use with a call to <code>gss_release_oid_set(3GSS)</code>.</td></tr></table>	<i>minor_status</i>	Mechanism-specific status code	<i>oid_set</i>	Empty object identifier set. The function will allocate the <code>gss_OID_set_desc</code> object, which the application must free after use with a call to <code>gss_release_oid_set(3GSS)</code> .				
<i>minor_status</i>	Mechanism-specific status code								
<i>oid_set</i>	Empty object identifier set. The function will allocate the <code>gss_OID_set_desc</code> object, which the application must free after use with a call to <code>gss_release_oid_set(3GSS)</code> .								
ERRORS	The <code>gss_create_empty_oid_set()</code> function may return the following status codes: <table><tr><td><code>GSS_S_COMPLETE</code></td><td>Successful completion</td></tr><tr><td><code>GSS_S_FAILURE</code></td><td>The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</td></tr></table>	<code>GSS_S_COMPLETE</code>	Successful completion	<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.				
<code>GSS_S_COMPLETE</code>	Successful completion								
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.								
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWgss (32-bit)</td></tr><tr><td></td><td>SUNWgssx (64-bit)</td></tr><tr><td>MT-Level</td><td>Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWgss (32-bit)		SUNWgssx (64-bit)	MT-Level	Safe

NAME	gss_delete_sec_context – delete a GSS-API security context
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_delete_sec_context(OM_uint32 *minor_status, gss_ctx_id_t *context_handle, gss_buffer_t output_token);</pre>
DESCRIPTION	<p>Use the <code>gss_delete_sec_context()</code> function to delete a security context. The <code>gss_delete_sec_context()</code> function will delete the local data structures associated with the specified security context. You may not obtain further security services that use the context specified by <code>context_handle</code>.</p> <p>In addition to deleting established security contexts, <code>gss_delete_sec_context()</code> will delete any half-built security contexts that result from incomplete sequences of calls to <code>gss_init_sec_context(3GSS)</code> and <code>gss_accept_sec_context(3GSS)</code>.</p> <p>The Solaris implementation of the GSS-API retains the <code>output_token</code> parameter for compatibility with version 1 of the GSS-API. Both peer applications should invoke <code>gss_delete_sec_context()</code>, passing the value <code>GSS_C_NO_BUFFER</code> to the <code>output_token</code> parameter; this indicates that no token is required. If the application passes a valid buffer to <code>gss_delete_sec_context()</code>, it will return a zero-length token, indicating that no token should be transferred by the application.</p>
PARAMETERS	<p>The parameter descriptions for <code>gss_delete_sec_context()</code> follow:</p> <p><i>minor_status</i> A mechanism specific status code.</p> <p><i>context_handle</i> Context handle identifying specific context to delete. After deleting the context, the GSS-API will set <code>context_handle</code> to <code>GSS_C_NO_CONTEXT</code>.</p> <p><i>output_token</i> A token to be sent to remote applications that instructs them to delete the context.</p>
ERRORS	<p><code>gss_delete_sec_context()</code> may return the following status codes:</p> <p><code>GSS_S_COMPLETE</code> Successful completion.</p> <p><code>GSS_S_NO_CONTEXT</code> No valid context was supplied.</p> <p><code>GSS_S_FAILURE</code> The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <code>minor_status</code> parameter details the error condition.</p>

Solaris Security for Developers Guide

NAME	gss_display_status – convert a GSS-API status code to text												
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_display_status(OM_uint32 *minor_status, OM_uint32 status_value, int status_type, const gss_OID mech_type, OM_uint32 *message_context, gss_buffer_t status_string);</pre>												
DESCRIPTION	<p>The <code>gss_display_status()</code> function enables an application to obtain a textual representation of a GSS-API status code for display to the user or for logging purposes. Because some status values may indicate multiple conditions, applications may need to call <code>gss_display_status()</code> multiple times, with each call generating a single text string.</p> <p>The <code>message_context</code> parameter is used by <code>gss_acquire_cred()</code> to store state information on error messages that are extracted from a given <code>status_value</code>. The <code>message_context</code> parameter must be initialized to 0 by the application prior to the first call, and <code>gss_display_status()</code> will return a non-zero value in this parameter if there are further messages to extract.</p> <p>The <code>message_context</code> parameter contains all state information required by <code>gss_display_status()</code> to extract further messages from the <code>status_value</code>. If a non-zero value is returned in this parameter, the application is not required to call <code>gss_display_status()</code> again unless subsequent messages are desired.</p>												
PARAMETERS	<p>The parameter descriptions for <code>gss_display_status()</code> follow:</p> <table border="0"> <tr> <td style="vertical-align: top;"><i>minor_status</i></td> <td>Status code returned by the underlying mechanism.</td> </tr> <tr> <td style="vertical-align: top;"><i>status_value</i></td> <td>Status value to be converted.</td> </tr> <tr> <td style="vertical-align: top;"><i>status_type</i></td> <td>If the value is <code>GSS_C_GSS_CODE</code>, <i>status_value</i> is a GSS-API status code. If the value is <code>GSS_C_MECH_CODE</code>, then <i>status_value</i> is a mechanism status code.</td> </tr> <tr> <td style="vertical-align: top;"><i>mech_type</i></td> <td>Underlying mechanism that is used to interpret a minor status value. Supply <code>GSS_C_NO_OID</code> to obtain the system default.</td> </tr> <tr> <td style="vertical-align: top;"><i>message_context</i></td> <td>Should be initialized to zero prior to the first call. On return from <code>gss_display_status()</code>, a non-zero <i>status_value</i> parameter indicates that additional messages may be extracted from the status code by means of subsequent calls to <code>gss_display_status()</code>, passing the same <i>status_value</i>, <i>status_type</i>, <i>mech_type</i>, and <i>message_context</i> parameters.</td> </tr> <tr> <td style="vertical-align: top;"><i>status_string</i></td> <td>Textual representation of the <i>status_value</i>. Storage associated with this parameter must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code>.</td> </tr> </table>	<i>minor_status</i>	Status code returned by the underlying mechanism.	<i>status_value</i>	Status value to be converted.	<i>status_type</i>	If the value is <code>GSS_C_GSS_CODE</code> , <i>status_value</i> is a GSS-API status code. If the value is <code>GSS_C_MECH_CODE</code> , then <i>status_value</i> is a mechanism status code.	<i>mech_type</i>	Underlying mechanism that is used to interpret a minor status value. Supply <code>GSS_C_NO_OID</code> to obtain the system default.	<i>message_context</i>	Should be initialized to zero prior to the first call. On return from <code>gss_display_status()</code> , a non-zero <i>status_value</i> parameter indicates that additional messages may be extracted from the status code by means of subsequent calls to <code>gss_display_status()</code> , passing the same <i>status_value</i> , <i>status_type</i> , <i>mech_type</i> , and <i>message_context</i> parameters.	<i>status_string</i>	Textual representation of the <i>status_value</i> . Storage associated with this parameter must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .
<i>minor_status</i>	Status code returned by the underlying mechanism.												
<i>status_value</i>	Status value to be converted.												
<i>status_type</i>	If the value is <code>GSS_C_GSS_CODE</code> , <i>status_value</i> is a GSS-API status code. If the value is <code>GSS_C_MECH_CODE</code> , then <i>status_value</i> is a mechanism status code.												
<i>mech_type</i>	Underlying mechanism that is used to interpret a minor status value. Supply <code>GSS_C_NO_OID</code> to obtain the system default.												
<i>message_context</i>	Should be initialized to zero prior to the first call. On return from <code>gss_display_status()</code> , a non-zero <i>status_value</i> parameter indicates that additional messages may be extracted from the status code by means of subsequent calls to <code>gss_display_status()</code> , passing the same <i>status_value</i> , <i>status_type</i> , <i>mech_type</i> , and <i>message_context</i> parameters.												
<i>status_string</i>	Textual representation of the <i>status_value</i> . Storage associated with this parameter must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .												

gss_display_status(3GSS)

ERRORS | The `gss_display_status()` function may return the following status codes:

GSS_S_COMPLETE	Successful completion.
GSS_S_BAD_MECH	Indicates that translation in accordance with an unsupported mechanism type was requested.
GSS_S_BAD_STATUS	The status value was not recognized, or the status type was neither <code>GSS_C_GSS_CODE</code> nor <code>GSS_C_MECH_CODE</code> .
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <code>minor_status</code> parameter details the error condition.

gss_export_name(3GSS)

NAME	gss_export_name – convert a mechanism name to export form								
SYNOPSIS	<pre>cc [flag...] file... -lgss [library...] #include <gssapi/gssapi.h> OM_uint32 gss_export_name(OM_uint32 *minor_status, const gss_name_t input_name, gss_buffer_t exported_name);</pre>								
DESCRIPTION	<p>The <code>gss_export_name()</code> function allows a GSS-API internal name to be converted into a mechanism-specific name. The function produces a canonical contiguous string representation of a mechanism name, suitable for direct comparison, with <code>memcmp(3C)</code>, or for use in authorization functions, matching entries in an access-control list. The <code>input_name</code> parameter must specify a valid mechanism name, that is, an internal name generated by <code>gss_accept_sec_context(3GSS)</code> or by <code>gss_canonicalize_name(3GSS)</code>.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_export_name()</code> follow:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>minor_status</i></td> <td>A mechanism-specific status code.</td> </tr> <tr> <td><i>input_name</i></td> <td>The mechanism name to be exported.</td> </tr> <tr> <td><i>exported_name</i></td> <td>The canonical contiguous string form of <i>input_name</i>. Storage associated with this string must freed by the application after use with <code>gss_release_buffer(3GSS)</code>.</td> </tr> </table>	<i>minor_status</i>	A mechanism-specific status code.	<i>input_name</i>	The mechanism name to be exported.	<i>exported_name</i>	The canonical contiguous string form of <i>input_name</i> . Storage associated with this string must freed by the application after use with <code>gss_release_buffer(3GSS)</code> .		
<i>minor_status</i>	A mechanism-specific status code.								
<i>input_name</i>	The mechanism name to be exported.								
<i>exported_name</i>	The canonical contiguous string form of <i>input_name</i> . Storage associated with this string must freed by the application after use with <code>gss_release_buffer(3GSS)</code> .								
ERRORS	<p>The <code>gss_export_name()</code> function may return the following status codes:</p> <table border="0"> <tr> <td style="padding-right: 20px;">GSS_S_COMPLETE</td> <td>Successful completion.</td> </tr> <tr> <td>GSS_S_NAME_NOT_MN</td> <td>The provided internal name was not a mechanism name.</td> </tr> <tr> <td>GSS_S_FAILURE</td> <td>The underlying mechanism detected an error for which no specific GSS status code is defined. NAME	gss_export_sec_context – transfer a security context to another process						
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_export_sec_context(OM_uint32 *minor_status, gss_ctx_id_t *context_handle, gss_buffer_t interprocess_token);</pre>						
DESCRIPTION	<p>The <code>gss_export_sec_context()</code> function generates an interprocess token for transfer to another process within an end system. <code>gss_export_sec_context()</code> and <code>gss_import_sec_context()</code> allow a security context to be transferred between processes on a single machine.</p> <p>The <code>gss_export_sec_context()</code> function supports the sharing of work between multiple processes. This routine is typically used by the context-acceptor, in an application where a single process receives incoming connection requests and accepts security contexts over them, then passes the established context to one or more other processes for message exchange. <code>gss_export_sec_context()</code> deactivates the security context for the calling process and creates an interprocess token which, when passed to <code>gss_import_sec_context()</code> in another process, reactivates the context in the second process. Only a single instantiation of a given context can be active at any one time; a subsequent attempt by a context exporter to access the exported security context will fail.</p> <p>The interprocess token may contain security-sensitive information, for example cryptographic keys. While mechanisms are encouraged to either avoid placing such sensitive information within interprocess tokens or to encrypt the token before returning it to the application, in a typical object-library GSS-API implementation, this might not be possible. Thus, the application must take care to protect the interprocess token and ensure that any process to which the token is transferred is trustworthy. If creation of the interprocess token is successful, the GSS-API deallocates all process-wide resources associated with the security context and sets the <code>context_handle</code> to <code>GSS_C_NO_CONTEXT</code>. In the event of an error that makes it impossible to complete the export of the security context, the function does not return an interprocess token and leaves the security context referenced by the <code>context_handle</code> parameter untouched.</p> <p>Sun's implementation of <code>gss_export_sec_context()</code> does not encrypt the interprocess token. The interprocess token is serialized before it is transferred to another process.</p>						
PARAMETERS	<p>The parameter descriptions for <code>gss_export_sec_context()</code> are as follows:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>minor_status</i></td> <td>A mechanism-specific status code.</td> </tr> <tr> <td><i>context_handle</i></td> <td>Context handle identifying the context to transfer.</td> </tr> <tr> <td><i>interprocess_token</i></td> <td>Token to be transferred to target process. Storage associated with this token must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code>.</td> </tr> </table>	<i>minor_status</i>	A mechanism-specific status code.	<i>context_handle</i>	Context handle identifying the context to transfer.	<i>interprocess_token</i>	Token to be transferred to target process. Storage associated with this token must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .
<i>minor_status</i>	A mechanism-specific status code.						
<i>context_handle</i>	Context handle identifying the context to transfer.						
<i>interprocess_token</i>	Token to be transferred to target process. Storage associated with this token must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .						

gss_export_sec_context(3GSS)

ERRORS | `gss_export_sec_context()` returns one of the following status codes:

<code>GSS_S_COMPLETE</code>	Successful completion.
<code>GSS_S_CONTEXT_EXPIRED</code>	The context has expired.
<code>GSS_S_NO_CONTEXT</code>	The context was invalid.
<code>GSS_S_UNAVAILABLE</code>	The operation is not supported.
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

Solaris Security for Developers Guide

NAME	gss_get_mic – calculate a cryptographic message										
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_get_mic(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, gss_qop_t qop_req, const gss_buffer_t message_buffer, gss_buffer_t msg_token);</pre>										
DESCRIPTION	<p>The <code>gss_get_mic()</code> function generates a cryptographic MIC for the supplied message, and places the MIC in a token for transfer to the peer application. The <code>qop_req</code> parameter allows a choice between several cryptographic algorithms, if supported by the chosen mechanism.</p> <p>Since some application-level protocols may wish to use tokens emitted by <code>gss_wrap(3GSS)</code> to provide secure framing, the GSS-API allows MICs to be derived from zero-length messages.</p>										
PARAMETERS	<p>The parameter descriptions for <code>gss_get_mic()</code> follow:</p> <table border="0"> <tr> <td style="vertical-align: top;"><i>minor_status</i></td> <td>The status code returned by the underlying mechanism.</td> </tr> <tr> <td style="vertical-align: top;"><i>context_handle</i></td> <td>Identifies the context on which the message will be sent.</td> </tr> <tr> <td style="vertical-align: top;"><i>qop_req</i></td> <td>Specifies the requested quality of protection. Callers are encouraged, on portability grounds, to accept the default quality of protection offered by the chosen mechanism, which may be requested by specifying <code>GSS_C_QOP_DEFAULT</code> for this parameter. If an unsupported protection strength is requested, <code>gss_get_mic()</code> will return a <i>major_status</i> of <code>GSS_S_BAD_QOP</code>.</td> </tr> <tr> <td style="vertical-align: top;"><i>message_buffer</i></td> <td>The message to be protected.</td> </tr> <tr> <td style="vertical-align: top;"><i>msg_token</i></td> <td>The buffer to receive the token. Storage associated with this message must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code>.</td> </tr> </table>	<i>minor_status</i>	The status code returned by the underlying mechanism.	<i>context_handle</i>	Identifies the context on which the message will be sent.	<i>qop_req</i>	Specifies the requested quality of protection. Callers are encouraged, on portability grounds, to accept the default quality of protection offered by the chosen mechanism, which may be requested by specifying <code>GSS_C_QOP_DEFAULT</code> for this parameter. If an unsupported protection strength is requested, <code>gss_get_mic()</code> will return a <i>major_status</i> of <code>GSS_S_BAD_QOP</code> .	<i>message_buffer</i>	The message to be protected.	<i>msg_token</i>	The buffer to receive the token. Storage associated with this message must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .
<i>minor_status</i>	The status code returned by the underlying mechanism.										
<i>context_handle</i>	Identifies the context on which the message will be sent.										
<i>qop_req</i>	Specifies the requested quality of protection. Callers are encouraged, on portability grounds, to accept the default quality of protection offered by the chosen mechanism, which may be requested by specifying <code>GSS_C_QOP_DEFAULT</code> for this parameter. If an unsupported protection strength is requested, <code>gss_get_mic()</code> will return a <i>major_status</i> of <code>GSS_S_BAD_QOP</code> .										
<i>message_buffer</i>	The message to be protected.										
<i>msg_token</i>	The buffer to receive the token. Storage associated with this message must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .										
ERRORS	<p><code>gss_get_mic()</code> may return the following status codes:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>GSS_S_COMPLETE</code></td> <td>Successful completion.</td> </tr> <tr> <td style="vertical-align: top;"><code>GSS_S_CONTEXT_EXPIRED</code></td> <td>The context has already expired.</td> </tr> <tr> <td style="vertical-align: top;"><code>GSS_S_NO_CONTEXT</code></td> <td>The <i>context_handle</i> parameter did not identify a valid context.</td> </tr> <tr> <td style="vertical-align: top;"><code>GSS_S_BAD_QOP</code></td> <td>The specified QOP is not supported by the mechanism.</td> </tr> </table>	<code>GSS_S_COMPLETE</code>	Successful completion.	<code>GSS_S_CONTEXT_EXPIRED</code>	The context has already expired.	<code>GSS_S_NO_CONTEXT</code>	The <i>context_handle</i> parameter did not identify a valid context.	<code>GSS_S_BAD_QOP</code>	The specified QOP is not supported by the mechanism.		
<code>GSS_S_COMPLETE</code>	Successful completion.										
<code>GSS_S_CONTEXT_EXPIRED</code>	The context has already expired.										
<code>GSS_S_NO_CONTEXT</code>	The <i>context_handle</i> parameter did not identify a valid context.										
<code>GSS_S_BAD_QOP</code>	The specified QOP is not supported by the mechanism.										

gss_get_mic(3GSS)

GSS_S_FAILURE

The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the *minor_status* parameter details the error condition.

Solaris Security for Developers Guide

NAME	gss_import_name – convert a contiguous string name to GSS_API internal format										
SYNOPSIS	<pre>cc [flag...] file... -lgss [library...] #include <gssapi/gssapi.h> OM_uint32 gss_import_name(OM_uint32 * minor_status, const gss_buffer_t input_name_buffer, const gss_OID input_name_type, gss_name_t *output_name);</pre>										
DESCRIPTION	The <code>gss_import_name()</code> function converts a contiguous string name to internal form. In general, the internal name returned by means of the <code>output_name</code> parameter will not be a mechanism name; the exception to this is if the <code>input_name_type</code> indicates that the contiguous string provided by means of the <code>input_name_buffer</code> parameter is of type <code>GSS_C_NT_EXPORT_NAME</code> , in which case, the returned internal name will be a mechanism name for the mechanism that exported the name.										
PARAMETERS	<p>The parameter descriptions for <code>gss_import_name()</code> follow:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>minor_status</i></td> <td>Status code returned by the underlying mechanism.</td> </tr> <tr> <td><i>input_name_buffer</i></td> <td>The <code>gss_buffer_desc</code> structure containing the name to be imported. The application must allocate this explicitly. This argument must be deallocated with <code>gss_release_buffer(3GSS)</code> when the application is done with it.</td> </tr> <tr> <td><i>input_name_type</i></td> <td>A <code>gss_OID</code> that specifies the format that the <code>input_name_buffer</code> is in.</td> </tr> <tr> <td><i>output_name</i></td> <td>The <code>gss_name_t</code> structure to receive the name.</td> </tr> </table>	<i>minor_status</i>	Status code returned by the underlying mechanism.	<i>input_name_buffer</i>	The <code>gss_buffer_desc</code> structure containing the name to be imported. The application must allocate this explicitly. gss_import_sec_context(3GSS)

NAME | gss_import_sec_context – import security context established by another process

SYNOPSIS |

```
cc -flag ... file...-lgss [library ...]
#include <gssapi/gssapi.h>

OM_uint32 gss_import_sec_context(OM_uint32 *minor_status, const
    gss_buffer_t interprocess_token, gss_ctx_id_t *context_handle);
```

DESCRIPTION | The `gss_import_sec_context()` function allows a process to import a security context established by another process. A given interprocess token can be imported only once. See [gss_export_sec_context\(3GSS\)](#).

PARAMETERS | The parameter descriptions for `gss_import_sec_context()` are as follows:

<i>minor_status</i>	A mechanism-specific status code.
<i>interprocess_token</i>	Token received from exporting process.
<i>context_handle</i>	Context handle of newly reactivated context. Resources associated with this context handle must be released by the application after use with a call to gss_delete_sec_context(3GSS) .

ERRORS | `gss_import_sec_context()` returns one of the following status codes:

GSS_S_COMPLETE	Successful completion.
GSS_S_NO_CONTEXT	The token did not contain a valid context reference.
GSS_S_DEFECTIVE_TOKEN	The token was invalid.
GSS_S_UNAVAILABLE	The operation is unavailable.
GSS_S_UNAUTHORIZED	Local policy prevents the import of this context by the current process.
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

ATTRIBUTES | See [attributes\(5\)](#) for descriptions of the following attributes:

gss_init_sec_context(3GSS)

NAME	<code>gss_init_sec_context</code> – initiate a GSS-API security context with a peer application
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_init_sec_context(OM_uint32 *minor_status, const gss_cred_id_t initiator_cred_handle, gss_ctx_id_t *context_handle, const gss_name_t *target_name, const gss_OID mech_type, OM_uint32 req_flags, OM_uint32 time_req, const gss_channel_bindings_t input_chan_bindings, const gss_buffer_t input_token, gss_OID *actual_mech_type, gss_buffer_t output_token, OM_uint32 *ret_flags, OM_uint32 *time_rec);</pre>
DESCRIPTION	<p>The <code>gss_init_sec_context()</code> function initiates the establishment of a security context between the application and a remote peer. Initially, the <code>input_token</code> parameter should be specified either as <code>GSS_C_NO_BUFFER</code>, or as a pointer to a <code>gss_buffer_desc</code> object with a length field that contains a zero value. The routine may return a <code>output_token</code>, which should be transferred to the peer application, which will present it to <code>gss_accept_sec_context(3GSS)</code>. If no token need be sent, <code>gss_init_sec_context()</code> will indicate this by setting the length field of the <code>output_token</code> argument to zero. To complete context establishment, one or more reply tokens may be required from the peer application; if so, <code>gss_init_sec_context()</code> will return a status code that contains the supplementary information bit <code>GSS_S_CONTINUE_NEEDED</code>. In this case, make another call to <code>gss_init_sec_context()</code> when the reply token is received from the peer application and pass the reply token to <code>gss_init_sec_context()</code> by means of the <code>input_token</code> parameter.</p> <p>Construct portable applications to use the token length and return status to determine whether to send or wait for a token.</p> <p>Whenever the routine returns a major status that includes the value <code>GSS_S_CONTINUE_NEEDED</code>, the context is not fully established, and the following restrictions apply to the output parameters:</p> <ul style="list-style-type: none">■ The value returned by means of the <code>time_rec</code> parameter is undefined. Unless the accompanying <code>ret_flags</code> parameter contains the bit <code>GSS_C_PROT_READY_FLAG</code>, which indicates that per-message services may be applied in advance of a successful completion status, the value returned by means of the <code>actual_mech_type</code> parameter is undefined until the routine returns a major status value of <code>GSS_S_COMPLETE</code>.■ The values of the <code>GSS_C_DELEG_FLAG</code>, <code>GSS_C_MUTUAL_FLAG</code>, <code>GSS_C_REPLAY_FLAG</code>, <code>GSS_C_SEQUENCE_FLAG</code>, <code>GSS_C_CONF_FLAG</code>, <code>GSS_C_INTEG_FLAG</code> and <code>GSS_C_ANON_FLAG</code> bits returned by the <code>ret_flags</code> parameter contain values that will be valid if context establishment succeeds. For example, if the application requests a service such as delegation or anonymous authentication by means of the <code>req_flags</code> argument, and the service is unavailable from the underlying mechanism, <code>gss_init_sec_context()</code> generates a token that will not provide the service, and it indicate by means of the <code>ret_flags</code> argument that the service will not be supported. The application may choose to abort context

`gss_init_sec_context(3GSS)`

establishment by calling `gss_delete_sec_context(3GSS)` if it cannot continue without the service, or if the service was merely desired but not mandatory, it may transmit the token and continue context establishment.

- The values of the `GSS_C_PROT_READY_FLAG` and `GSS_C_TRANS_FLAG` bits within `ret_flags` indicate the actual state at the time `gss_init_sec_context()` returns, whether or not the context is fully established.
- The GSS-API sets the `GSS_C_PROT_READY_FLAG` in the final `ret_flags` returned to a caller, for example, when accompanied by a `GSS_S_COMPLETE` status code. However, applications should not rely on this behavior, as the flag was not defined in Version 1 of the GSS-API. Instead, applications should determine what per-message services are available after a successful context establishment according to the `GSS_C_INTEG_FLAG` and `GSS_C_CONF_FLAG` values.
- All other bits within the `ret_flags` argument are set to zero.

If the initial call of `gss_init_sec_context()` fails, the GSS-API does not create a context object; it leaves the value of the `context_handle` parameter set to `GSS_C_NO_CONTEXT` to indicate this. In the event of failure on a subsequent call, the GSS-API leaves the security context untouched for the application to delete using `gss_delete_sec_context(3GSS)`.

During context establishment, the informational status bits `GSS_S_OLD_TOKEN` and `GSS_S_DUPLICATE_TOKEN` indicate fatal errors, and GSS-API mechanisms should always return them in association with a status code of `GSS_S_FAILURE`. This pairing requirement was not part of Version 1 of the GSS-API specification, so applications that wish to run on Version 1 implementations must special-case these codes.

PARAMETERS

The parameter descriptions for `gss_init_sec_context()` follow:

<i>minor_status</i>	A mechanism specific status code.
<i>initiator_cred_handle</i>	The handle for the credentials claimed. Supply <code>GSS_C_NO_CREDENTIAL</code> to act as a default initiator principal. If no default initiator is defined, the function returns <code>GSS_S_NO_CRED</code> .
<i>context_handle</i>	The context handle for a new context. Supply the value <code>GSS_C_NO_CONTEXT</code> for the first call, and use the value returned in any continuation calls. The resources associated with <code>context_handle</code> must be released by the application after use by a call to <code>gss_delete_sec_context(3GSS)</code> .
<i>target_name</i>	The name of the target.
<i>mech_type</i>	The object ID of the desired mechanism. To obtain a specific default, supply the value <code>GSS_C_NO_ID</code> .
<i>req_flags</i>	Contains independent flags, each of which will request that the context support a specific service option. A symbolic name is provided for each flag. Logically-OR

gss_init_sec_context(3GSS)

	<p>the symbolic name to the corresponding required flag to form the bit-mask value. <i>req_flags</i> may contain one of the following values:</p> <p>GSS_C_DELEG_FLAG If true, delegate credentials to a remote peer. Do not delegate the credentials if the value is false.</p> <p>GSS_C_MUTUAL_FLAG If true, request that the peer authenticate itself. If false, authenticate to the remote peer only.</p> <p>GSS_C_REPLAY_FLAG If true, enable replay detection for messages protected with <code>gss_wrap(3GSS)</code> or <code>gss_get_mic(3GSS)</code>. Do not attempt to detect replayed messages if false.</p> <p>GSS_C_SEQUENCE_FLAG If true, enable detection of out-of-sequence protected messages. Do not attempt to detect out-of-sequence messages if false.</p> <p>GSS_C_CONF_FLAG If true, request that confidential service be made available by means of <code>gss_wrap(3GSS)</code>. If false, no per-message confidential service is required.</p> <p>GSS_C_INTEG_FLAG If true, request that integrity service be made available by means of <code>gss_wrap(3GSS)</code> or <code>gss_get_mic(3GSS)</code>. If false, no per-message integrity service is required.</p> <p>GSS_C_ANON_FLAG If true, do not reveal the initiator's identify to the acceptor. If false, authenticate normally.</p>
<i>time_req</i>	<p>The number of seconds for which the context will remain valid. Supply a zero value to <i>time_req</i> to request a default validity period.</p>
<i>input_chan_bindings</i>	<p>Optional application-specified bindings. Allows application to securely bind channel identification information to the security context. Set to <code>GSS_C_NO_CHANNEL_BINDINGS</code> if you do not want to use channel bindings.</p>
<i>input_token</i>	<p>Token received from the peer application. On the initial call, supply <code>GSS_C_NO_BUFFER</code> or a pointer to a buffer containing the value <code>GSS_C_EMPTY_BUFFER</code>.</p>

`gss_init_sec_context(3GSS)`

<i>actual_mech_type</i>	The actual mechanism used. The OID returned by means of this parameter will be pointer to static storage that should be treated as read-only. The application should not attempt to free it. To obtain a specific default, supply the value <code>GSS_C_NO_ID</code> . Specify <code>NULL</code> if the parameter is not required.
<i>output_token</i>	The token to send to the peer application. If the length field of the returned buffer is zero, no token need be sent to the peer application. After use storage associated with this buffer must be freed by the application by a call to <code>gss_release_buffer(3GSS)</code> .
<i>ret_flags</i>	<p>Contains various independent flags, each of which indicates that the context supports a specific service option. If not needed, specify <code>NULL</code>. Test the returned bit-mask <i>ret_flags</i> value against its symbolic name to determine if the given option is supported by the context. <i>ret_flags</i> may contain one of the following values:</p> <p><code>GSS_C_DELEG_FLAG</code> If true, credentials were delegated to the remote peer. If false, no credentials were delegated.</p> <p><code>GSS_C_MUTUAL_FLAG</code> If true, the remote peer authenticated itself. If false, the remote peer did not authenticate itself.</p> <p><code>GSS_C_REPLY_FLAG</code> If true, replay of protected messages will be detected. If false, replayed messages will not be detected.</p> <p><code>GSS_C_SEQUENCE_FLAG</code> If true, out of sequence protected messages will be detected. If false, they will not be detected.</p> <p><code>GSS_C_CONF_FLAG</code> If true, confidential service may be invoked by calling the <code>gss_wrap()</code> routine. If false, no confidentiality service is available by means of <code>gss_wrap(3GSS)</code>. <code>gss_wrap()</code> will provide message encapsulation, data-origin authentication and integrity services only.</p> <p><code>GSS_C_INTEG_FLAG</code> If true, integrity service may be invoked by calling either the <code>gss_wrap(3GSS)</code> or <code>gss_get_mic(3GSS)</code> routine. If false, per-message integrity service is not available.</p>

gss_init_sec_context(3GSS)

GSS_C_ANON_FLAG

If true, the initiator's identity has not been revealed; it will not be revealed if any emitted token is passed to the acceptor. If false, the initiator has been or will be authenticated normally.

GSS_C_PROT_READY_FLAG

If true, the protection services specified by the states of GSS_C_CONF_FLAG and GSS_C_INTEG_FLAG are available if the accompanying major status return value is either GSS_S_COMPLETE or GSS_S_CONTINUE_NEEDED. If false, the protection services are available only if the accompanying major status return value is GSS_S_COMPLETE.

GSS_C_TRANS_FLAG

If true, the resultant security context may be transferred to other processes by means of a call to [gss_export_sec_context\(3GSS\)](#). If false, the security context cannot be transferred.

time_rec

The number of seconds for which the context will remain valid. Specify NULL if the parameter is not required.

ERRORS

`gss_init_sec_context()` may return the following status codes:

GSS_S_COMPLETE

Successful completion.

GSS_S_CONTINUE_NEEDED

A token from the peer application is required to complete the context, and `gss_init_sec_context()` must be called again with that token.

GSS_S_DEFECTIVE_TOKEN

Consistency checks performed on the *input_token* failed.

GSS_S_DEFECTIVE_CREDENTIAL

Consistency checks performed on the credential failed.

GSS_S_NO_CRED

The supplied credentials are not valid for context acceptance, or the credential handle does not reference any credentials.

GSS_S_CREDENTIALS_EXPIRED

The referenced credentials have expired.

GSS_S_BAD_BINDINGS

The *input_token* contains different channel bindings than those specified by means of the *input_chan_bindings* parameter.

GSS_S_BAD_SIG

The *input_token* contains an invalid MIC or a MIC that cannot be verified.

`gss_init_sec_context(3GSS)`

<code>GSS_S_OLD_TOKEN</code>	The <i>input_token</i> is too old. This is a fatal error while establishing context.
<code>GSS_S_DUPLICATE_TOKEN</code>	The <i>input_token</i> is valid, but it is a duplicate of a token already processed. This is a fatal error while establishing context.
<code>GSS_S_NO_CONTEXT</code>	The supplied context handle does not refer to a valid context.
<code>GSS_S_BAD_NAME_TYPE</code>	The provided <i>target_name</i> parameter contains an invalid or unsupported <i>name</i> type.
<code>GSS_S_BAD_NAME</code>	The supplied <i>target_name</i> parameter is ill-formed.
<code>GSS_S_BAD_MECH</code>	The token received specifies a mechanism that is not supported by the implementation or the provided credential.
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

EXAMPLES

EXAMPLE 1 Invoking `gss_init_sec_context()` Within a Loop

A typical portable caller should always invoke `gss_init_sec_context()` within a loop:

```
int context_established = 0;
gss_ctx_id_t context_hdl = GSS_C_NO_CONTEXT;
...
input_token->length = 0;

while (!context_established) {
    maj_stat = gss_init_sec_context(&min_stat,
                                   cred_hdl,
                                   &context_hdl,
                                   target_name,
                                   desired_mech,
                                   desired_services,
                                   desired_time,
                                   input_bindings,
                                   input_token,
                                   &actual_mech,
                                   output_token,
                                   &actual_services,
                                   &actual_time);

    if (GSS_ERROR(maj_stat)) {
        report_error(maj_stat, min_stat);
    }
};
```

gss_init_sec_context(3GSS)

EXAMPLE 1 Invoking `gss_init_sec_context()` Within a Loop *(Continued)*

```
if (output_token->length != 0) {
    send_token_to_peer(output_token);
    gss_release_buffer(&min_stat, output_token)
};
if (GSS_ERROR(maj_stat)) {

    if (context_hdl != GSS_C_NO_CONTEXT)
        gss_delete_sec_context(&min_stat,
                               &context_hdl,
                               GSS_C_NO_BUFFER);

    break;
};
if (maj_stat & GSS_S_CONTINUE_NEEDED) {
    receive_token_from_peer(input_token);
} else {
    context_established = 1;
};
};
```

Solaris Security for Developers Guide

NAME	gss_inquire_context – obtain information about a security context														
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_inquire_context(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, gss_name_t *src_name, gss_name_t *targ_name, OM_uint32 *lifetime_rec, gss_OID *mech_type, OM_uint32 *ctx_flags, int *locally_initiated, int *open);</pre>														
DESCRIPTION	The <code>gss_inquire_context()</code> function obtains information about a security context. The caller must already have obtained a handle that refers to the context, although the context need not be fully established.														
PARAMETERS	<p>The parameter descriptions for <code>gss_inquire_context()</code> are as follows:</p> <table border="0"> <tr> <td style="vertical-align: top;"><i>minor_status</i></td> <td>A mechanism-specific status code.</td> </tr> <tr> <td style="vertical-align: top;"><i>context_handle</i></td> <td>A handle that refers to the security context.</td> </tr> <tr> <td style="vertical-align: top;"><i>src_name</i></td> <td>The name of the context initiator. If the context was established using anonymous authentication, and if the application invoking <code>gss_inquire_context()</code> is the context acceptor, an anonymous name is returned. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name()</code>. Specify NULL if the parameter is not required.</td> </tr> <tr> <td style="vertical-align: top;"><i>targ_name</i></td> <td>The name of the context acceptor. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name()</code>. If the context acceptor did not authenticate itself, and if the initiator did not specify a target name in its call to <code>gss_init_sec_context()</code>, the value <code>GSS_C_NO_NAME</code> is returned. Specify NULL if the parameter is not required.</td> </tr> <tr> <td style="vertical-align: top;"><i>lifetime_rec</i></td> <td>The number of seconds for which the context will remain valid. If the context has expired, this parameter will be set to zero. Specify NULL if the parameter is not required.</td> </tr> <tr> <td style="vertical-align: top;"><i>mech_type</i></td> <td>The security mechanism providing the context. The returned OID is a pointer to static storage that should be treated as read-only by the application; in particular, the application should not attempt to free it. Specify NULL if the parameter is not required.</td> </tr> <tr> <td style="vertical-align: top;"><i>ctx_flags</i></td> <td>Contains various independent flags, each of which indicates that the context supports (or is expected to support, if <code>ctx_open</code> is false) a specific service option. If not needed, specify NULL. Symbolic names are provided for each flag, and the symbolic names corresponding to the required flags should be logically ANDed with the <code>ret_flags</code> value to test whether a given option is supported by the context. The flags are:</td> </tr> </table>	<i>minor_status</i>	A mechanism-specific status code.	<i>context_handle</i>	A handle that refers to the security context.	<i>src_name</i>	The name of the context initiator. If the context was established using anonymous authentication, and if the application invoking <code>gss_inquire_context()</code> is the context acceptor, an anonymous name is returned. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name()</code> . Specify NULL if the parameter is not required.	<i>targ_name</i>	The name of the context acceptor. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name()</code> . If the context acceptor did not authenticate itself, and if the initiator did not specify a target name in its call to <code>gss_init_sec_context()</code> , the value <code>GSS_C_NO_NAME</code> is returned. Specify NULL if the parameter is not required.	<i>lifetime_rec</i>	The number of seconds for which the context will remain valid. If the context has expired, this parameter will be set to zero. Specify NULL if the parameter is not required.	<i>mech_type</i>	The security mechanism providing the context. The returned OID is a pointer to static storage that should be treated as read-only by the application; in particular, the application should not attempt to free it. Specify NULL if the parameter is not required.	<i>ctx_flags</i>	Contains various independent flags, each of which indicates that the context supports (or is expected to support, if <code>ctx_open</code> is false) a specific service option. If not needed, specify NULL. Symbolic names are provided for each flag, and the symbolic names corresponding to the required flags should be logically ANDed with the <code>ret_flags</code> value to test whether a given option is supported by the context. The flags are:
<i>minor_status</i>	A mechanism-specific status code.														
<i>context_handle</i>	A handle that refers to the security context.														
<i>src_name</i>	The name of the context initiator. If the context was established using anonymous authentication, and if the application invoking <code>gss_inquire_context()</code> is the context acceptor, an anonymous name is returned. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name()</code> . Specify NULL if the parameter is not required.														
<i>targ_name</i>	The name of the context acceptor. Storage associated with this name must be freed by the application after use with a call to <code>gss_release_name()</code> . If the context acceptor did not authenticate itself, and if the initiator did not specify a target name in its call to <code>gss_init_sec_context()</code> , the value <code>GSS_C_NO_NAME</code> is returned. Specify NULL if the parameter is not required.														
<i>lifetime_rec</i>	The number of seconds for which the context will remain valid. If the context has expired, this parameter will be set to zero. Specify NULL if the parameter is not required.														
<i>mech_type</i>	The security mechanism providing the context. The returned OID is a pointer to static storage that should be treated as read-only by the application; in particular, the application should not attempt to free it. Specify NULL if the parameter is not required.														
<i>ctx_flags</i>	Contains various independent flags, each of which indicates that the context supports (or is expected to support, if <code>ctx_open</code> is false) a specific service option. If not needed, specify NULL. Symbolic names are provided for each flag, and the symbolic names corresponding to the required flags should be logically ANDed with the <code>ret_flags</code> value to test whether a given option is supported by the context. The flags are:														

gss_inquire_context(3GSS)

GSS_C_DELEG_FLAG

If true, credentials were delegated from the initiator to the acceptor. If false, no credentials were delegated.

GSS_C_MUTUAL_FLAG

If true, the acceptor was authenticated to the initiator. If false, the acceptor did not authenticate itself.

GSS_C_REPLAY_FLAG

If true, the replay of protected messages will be detected. If false, replayed messages will not be detected.

GSS_C_SEQUENCE_FLAG

If true, out-of-sequence protected messages will be detected. If false, out-of-sequence messages will not be detected.

GSS_C_CONF_FLAG

If true, confidential service may be invoked by calling the [gss_wrap\(3GSS\)](#) routine. If false, no confidential service is available through `gss_wrap()`. `gss_wrap()` provides message encapsulation, data-origin authentication, and integrity services only.

GSS_C_INTEG_FLAG

If true, integrity service can be invoked by calling either the `gss_get_mic()` or the `gss_wrap()` routine. If false, per-message integrity service is unavailable.

GSS_C_ANON_FLAG

If true, the initiator's identity is not revealed to the acceptor. The `src_name` parameter, if requested, contains an anonymous internal name. If false, the initiator has been authenticated normally.

GSS_C_PROT_READY_FLAG

If true, the protection services, as specified by the states of the `GSS_C_CONF_FLAG` and `GSS_C_INTEG_FLAG`, are available for use. If false, they are available only if the context is fully established, that is, if the `open` parameter is non-zero.

GSS_C_TRANS_FLAG

If true, resultant security context can be transferred to other processes through a call to `gss_export_sec_context()`. If false, the security context is not transferable.

locally_initiated

Non-zero if the invoking application is the context initiator. Specify NULL if the parameter is not required.

open

Non-zero if the context is fully established; zero if a context-establishment token is expected from the peer application. Specify NULL if the parameter is not required.

ERRORS `gss_inquire_context()` returns one of the following status codes:

`gss_inquire_context(3GSS)`

<code>GSS_S_COMPLETE</code>	Successful completion.
<code>GSS_S_NO_CONTEXT</code>	The referenced context could not be accessed.
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

Solaris Security for Developers Guide

gss_inquire_cred_by_mech(3GSS)

NAME	gss_inquire_cred_by_mech – obtain per-mechanism information about a credential														
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_inquire_cred_by_mech(OM_uint32 *minor_status, const gss_cred_id_t cred_handle, const gss_OID mech_type, gss_name_t *name, OM_uint32 *initiator_lifetime, OM_uint32 *acceptor_lifetime, gss_cred_usage_t *cred_usage);</pre>														
DESCRIPTION	The <code>gss_inquire_cred_by_mech()</code> obtains per-mechanism information about a credential.														
PARAMETERS	The parameter descriptions for <code>gss_inquire_cred_by_mech()</code> follow: <table><tr><td><i>minor_status</i></td><td>A mechanism specific status code.</td></tr><tr><td><i>cred_handle</i></td><td>A handle that refers to the target credential. Specify <code>GSS_C_NO_CREDENTIAL</code> to inquire about the default initiator principal.</td></tr><tr><td><i>mech_type</i></td><td>The mechanism for which the information should be returned.</td></tr><tr><td><i>name</i></td><td>The name whose identity the credential asserts. Any storage associated with this <i>name</i> must be freed by the application after use by a call to <code>gss_release_name(3GSS)</code>.</td></tr><tr><td><i>initiator_lifetime</i></td><td>The number of seconds that the credential is capable of initiating security contexts under the specified mechanism. If the credential can no longer be used to initiate contexts, or if the credential usage for this mechanism is <code>GSS_C_ACCEPT</code>, this parameter will be set to 0. Specify <code>NULL</code> if this parameter is not required.</td></tr><tr><td><i>acceptor_lifetime</i></td><td>The number of seconds that the credential is capable of accepting security contexts under the specified mechanism. If the credential can no longer be used to accept contexts, or if the credential usage for this mechanism is <code>GSS_C_INITIATE</code>, this parameter will be set to 0. Specify <code>NULL</code> if this parameter is not required.</td></tr><tr><td><i>cred_usage</i></td><td>How the credential may be used with the specified mechanism. The <i>cred_usage</i> parameter may contain one of the following values: <code>GSS_C_INITIATE</code>, <code>GSS_C_ACCEPT</code>, or <code>GSS_C_BOTH</code>. Specify <code>NULL</code> if this parameter is not required.</td></tr></table>	<i>minor_status</i>	A mechanism specific status code.	<i>cred_handle</i>	A handle that refers to the target credential. Specify <code>GSS_C_NO_CREDENTIAL</code> to inquire about the default initiator principal.	<i>mech_type</i>	The mechanism for which the information should be returned.	<i>name</i>	The name whose identity the credential asserts. Any storage associated with this <i>name</i> must be freed by the application after use by a call to <code>gss_release_name(3GSS)</code> .	<i>initiator_lifetime</i>	The number of seconds that the credential is capable of initiating security contexts under the specified mechanism. If the credential can no longer be used to initiate contexts, or if the credential usage for this mechanism is <code>GSS_C_ACCEPT</code> , this parameter will be set to 0. Specify <code>NULL</code> if this parameter is not required.	<i>acceptor_lifetime</i>	The number of seconds that the credential is capable of accepting security contexts under the specified mechanism. If the credential can no longer be used to accept contexts, or if the credential usage for this mechanism is <code>GSS_C_INITIATE</code> , this parameter will be set to 0. Specify <code>NULL</code> if this parameter is not required.	<i>cred_usage</i>	How the credential may be used with the specified mechanism. The <i>cred_usage</i> parameter may contain one of the following values: <code>GSS_C_INITIATE</code> , <code>GSS_C_ACCEPT</code> , or <code>GSS_C_BOTH</code> . Specify <code>NULL</code> if this parameter is not required.
<i>minor_status</i>	A mechanism specific status code.														
<i>cred_handle</i>	A handle that refers to the target credential. Specify <code>GSS_C_NO_CREDENTIAL</code> to inquire about the default initiator principal.														
<i>mech_type</i>	The mechanism for which the information should be returned.														
<i>name</i>	The name whose identity the credential asserts. Any storage associated with this <i>name</i> must be freed by the application after use by a call to <code>gss_release_name(3GSS)</code> .														
<i>initiator_lifetime</i>	The number of seconds that the credential is capable of initiating security contexts under the specified mechanism. If the credential can no longer be used to initiate contexts, or if the credential usage for this mechanism is <code>GSS_C_ACCEPT</code> , this parameter will be set to 0. Specify <code>NULL</code> if this parameter is not required.														
<i>acceptor_lifetime</i>	The number of seconds that the credential is capable of accepting security contexts under the specified mechanism. If the credential can no longer be used to accept contexts, or if the credential usage for this mechanism is <code>GSS_C_INITIATE</code> , this parameter will be set to 0. Specify <code>NULL</code> if this parameter is not required.														
<i>cred_usage</i>	How the credential may be used with the specified mechanism. The <i>cred_usage</i> parameter may contain one of the following values: <code>GSS_C_INITIATE</code> , <code>GSS_C_ACCEPT</code> , or <code>GSS_C_BOTH</code> . Specify <code>NULL</code> if this parameter is not required.														
ERRORS	<code>gss_inquire_cred_by_mech()</code> may return the following status codes: <table><tr><td><code>GSS_S_COMPLETE</code></td><td>Successful completion.</td></tr></table>	<code>GSS_S_COMPLETE</code>	Successful completion.												
<code>GSS_S_COMPLETE</code>	Successful completion.														

`gss_inquire_cred_by_mech(3GSS)`

<code>GSS_S_NO_CRED</code>	The referenced credentials cannot be accessed.
<code>GSS_S_DEFECTIVE_CREDENTIAL</code>	The referenced credentials are invalid..
<code>GSS_S_CREDENTIALS_EXPIRED</code>	The credentials cannot be added because they have expired.
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

gss_inquire_mechs_for_name(3GSS)

NAME	<code>gss_inquire_mechs_for_name</code> – list mechanisms that support the specified name-type								
SYNOPSIS	<pre>cc [flag...] file... -lgss [library...] #include <gssapi/gssapi.h> OM_uint32 gss_inquire_mechs_for_name(OM_uint32 *minor_status, const gss_name_t input_name, gss_OID_set *mech_types);</pre>								
DESCRIPTION	<p>The <code>gss_inquire_mechs_for_name()</code> function returns the set of mechanisms supported by the GSS-API that may be able to process the specified name. Each mechanism returned will recognize at least one element within the internal name.</p> <p>Some implementations of the GSS-API may perform this test by checking nametype information contained within the passed name and registration information provided by individual mechanisms. This means that the <i>mech_types</i> set returned by the function may indicate that a particular mechanism will understand the name, when in fact the mechanism would refuse to accept the name as input to <code>gss_canonicalize_name(3GSS)</code>, <code>gss_init_sec_context(3GSS)</code>, <code>gss_acquire_cred(3GSS)</code>, or <code>gss_add_cred(3GSS)</code>, due to some property of the name itself rather than the name-type. Therefore, this function should be used only as a pre-filter for a call to a subsequent mechanism-specific function.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_inquire_mechs_for_name()</code> follow in alphabetical order:</p> <table><tr><td><i>minor_status</i></td><td>Mechanism-specific status code.</td></tr><tr><td><i>input_name</i></td><td>The name to which the inquiry relates.</td></tr><tr><td><i>mech_types</i></td><td>Set of mechanisms that may support the specified name. The returned OID set must be freed by the caller after use with a call to <code>gss_release_oid_set(3GSS)</code>.</td></tr></table>	<i>minor_status</i>	Mechanism-specific status code.	<i>input_name</i>	The name to which the inquiry relates.	<i>mech_types</i>	Set of mechanisms that may support the specified name. The returned OID set must be freed by the caller after use with a call to <code>gss_release_oid_set(3GSS)</code> .		
<i>minor_status</i>	Mechanism-specific status code.								
<i>input_name</i>	The name to which the inquiry relates.								
<i>mech_types</i>	Set of mechanisms that may support the specified name. The returned OID set must be freed by the caller after use with a call to <code>gss_release_oid_set(3GSS)</code> .								
ERRORS	<p>The <code>gss_inquire_mechs_for_name()</code> function may return the following status codes:</p> <table><tr><td>GSS_S_COMPLETE</td><td>Successful completion.</td></tr><tr><td>GSS_S_BAD_NAME</td><td>The <i>input_name</i> parameter was ill-formed.</td></tr><tr><td>GSS_S_BAD_NAME_TYPE</td><td>The <i>input_name</i> parameter contained an invalid or unsupported type of name.</td></tr><tr><td>GSS_S_FAILURE</td><td>The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</td></tr></table>	GSS_S_COMPLETE	Successful completion.	GSS_S_BAD_NAME	The <i>input_name</i> parameter was ill-formed.	GSS_S_BAD_NAME_TYPE	The <i>input_name</i> parameter contained an invalid or unsupported type of name.	GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.
GSS_S_COMPLETE	Successful completion.								
GSS_S_BAD_NAME	The <i>input_name</i> parameter was ill-formed.								
GSS_S_BAD_NAME_TYPE	The <i>input_name</i> parameter contained an invalid or unsupported type of name.								
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

NAME	gss_oid_to_str – convert an OID to a string								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> gss_oid_to_str(OM_uint32 *minor_status, const gss_OID *oid, gss_buffer_t oid_str);</pre>								
DESCRIPTION	<p>The <code>gss_oid_to_str()</code> function converts a GSS-API OID structure to a string. You can use the function to convert the name of a mechanism from an OID to a simple string. This function is a convenience function, as is its complementary function, <code>gss_str_to_oid(3GSS)</code>.</p> <p>If an OID must be created, use <code>gss_create_empty_oid_set(3GSS)</code> and <code>gss_add_oid_set_member(3GSS)</code> to create it. OIDs created in this way must be released with <code>gss_release_oid_set(3GSS)</code>. However, it is strongly suggested that applications use the default GSS-API mechanism instead of creating an OID for a specific mechanism.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_oid_to_str()</code> are as follows:</p> <p><i>minor_status</i> Status code returned by underlying mechanism.</p> <p><i>oid</i> GSS-API OID structure to convert.</p> <p><i>oid_str</i> String to receive converted OID.</p>								
ERRORS	<p><code>gss_oid_to_str()</code> returns one of the following status codes:</p> <p><code>GSS_S_CALL_INACCESSIBLE_READ</code> A required input parameter could not be read.</p> <p><code>GSS_S_CALL_INACCESSIBLE_WRITE</code> A required output parameter could not be written.</p> <p><code>GSS_S_COMPLETE</code> Successful completion.</p> <p><code>GSS_S_FAILURE</code> The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</p>								
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWgss (32-bit)</td> </tr> <tr> <td></td> <td>SUNWgssx (64-bit)</td> </tr> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWgss (32-bit)		SUNWgssx (64-bit)	MT-Level	Safe

Solaris Security for Developers Guide

WARNINGS | This function is included for compatibility only with programs using earlier versions of the GSS-API and should not be used for new programs. Other implementations of the GSS-API might not support this function, so portable programs should not rely on it. Sun might not continue to support this function.

NAME	gss_process_context_token – pass asynchronous token to security service
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_process_context_token(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, const gss_buffer_t token_buffer);</pre>
DESCRIPTION	<p>The <code>gss_process_context_token()</code> function provides a way to pass an asynchronous token to the security service. Most context-level tokens are emitted and processed synchronously by <code>gss_init_sec_context()</code> and <code>gss_accept_sec_context()</code>, and the application is informed as to whether further tokens are expected by the <code>GSS_C_CONTINUE_NEEDED</code> major status bit. Occasionally, a mechanism might need to emit a context-level token at a point when the peer entity is not expecting a token. For example, the initiator's final call to <code>gss_init_sec_context()</code> may emit a token and return a status of <code>GSS_S_COMPLETE</code>, but the acceptor's call to <code>gss_accept_sec_context()</code> might fail. The acceptor's mechanism might want to send a token containing an error indication to the initiator, but the initiator is not expecting a token at this point, believing that the context is fully established. <code>gss_process_context_token()</code> provides a way to pass such a token to the mechanism at any time.</p> <p>This function is provided for compatibility with the GSS-API version 1. Because <code>gss_delete_sec_context()</code> no longer returns a valid <i>output_token</i> to be sent to <code>gss_process_context_token()</code>, applications using a newer version of the GSS-API do not need to rely on this function.</p>
PARAMETERS	<p>The parameter descriptions for <code>gss_process_context_token()</code> are as follows:</p> <p><i>minor_status</i> A mechanism-specific status code.</p> <p><i>context_handle</i> Context handle of context on which token is to be processed.</p> <p><i>token_buffer</i> Token to process.</p>
ERRORS	<p><code>gss_process_context_token()</code> returns one of the following status codes:</p> <p><code>GSS_S_COMPLETE</code> Successful completion.</p> <p><code>GSS_S_DEFECTIVE_TOKEN</code> Indicates that consistency checks performed on the token failed.</p> <p><code>GSS_S_NO_CONTEXT</code> The <i>context_handle</i> did not refer to a valid context.</p> <p><code>GSS_S_FAILURE</code> The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</p>

Solaris Security for Developers Guide

NAME	gss_release_buffer – free buffer storage allocated by a GSS-API function								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_release_buffer(OM_uint32 *minor_status, gss_buffer_tbuffer);</pre>								
DESCRIPTION	The <code>gss_release_buffer()</code> function frees buffer storage allocated by a GSS-API function. The <code>gss_release_buffer()</code> function also zeros the length field in the descriptor to which the buffer parameter refers, while the GSS-API function sets the pointer field in the descriptor to NULL. Any buffer object returned by a GSS-API function may be passed to <code>gss_release_buffer()</code> , even if no storage is associated with the buffer.								
PARAMETERS	<p>The parameter descriptions for <code>gss_release_buffer()</code> follow:</p> <p><i>minor_status</i> Mechanism-specific status code.</p> <p><i>buffer</i> The storage associated with the buffer will be deleted. The <code>gss_buffer_desc()</code> object will not be freed; however, its length field will be zeroed.</p>								
ERRORS	<p>The <code>gss_release_buffer()</code> function may return the following status codes:</p> <p>GSS_S_COMPLETE Successful completion</p> <p>GSS_S_FAILURE The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</p>								
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

gss_release_cred(3GSS)

NAME	gss_release_cred – discard a credential handle								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_release_cred(OM_uint32 *minor_status, gss_cred_id_t *cred_handle) ;</pre>								
DESCRIPTION	The <code>gss_release_cred()</code> function informs the GSS-API that the specified credential handle is no longer required by the application and frees the associated resources. The <code>cred_handle</code> parameter is set to <code>GSS_C_NO_CREDENTIAL</code> when this call completes successfully.								
PARAMETERS	The parameter descriptions for <code>gss_release_cred()</code> follow: <i>minor_status</i> A mechanism specific status code. <i>cred_handle</i> An opaque handle that identifies the credential to be released. If <code>GSS_C_NO_CREDENTIAL</code> is specified, the <code>gss_release_cred()</code> function will complete successfully, but it will do nothing.								
ERRORS	<code>gss_release_cred()</code> may return the following status codes: <code>GSS_S_COMPLETE</code> Successful completion. <code>GSS_S_NO_CRED</code> The referenced credentials cannot be accessed. <code>GSS_S_FAILURE</code> The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.								
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWgss (32-bit)</td></tr><tr><td></td><td>SUNWgssx (64-bit)</td></tr><tr><td>MT-Level</td><td>Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWgss (32-bit)		SUNWgssx (64-bit)	MT-Level	Safe

- NAME** gss_release_name – discard an internal-form name
- SYNOPSIS**

```
cc [flag ...] file... -lgss [library ...]
#include <gssapi/gssapi.h

OM_uint32 gss_release_name(OM_uint32 *minor_status, gss_name_t
    *name);
```
- DESCRIPTION** The `gss_release_name()` function frees GSS-API-allocated storage associated with an internal-form name. The `name` is set to `GSS_C_NO_NAME` on successful completion of this call.
- PARAMETERS** The parameter descriptions for `gss_release_name()` follow:
- minor_status* A mechanism-specific status code.
- name* The name to be deleted.
- ERRORS** The `gss_release_name()` function may return the following status codes:
- `GSS_S_COMPLETE` Successful completion.
- `GSS_S_BAD_NAME` The `name` parameter did not contain a valid name.
- `GSS_S_FAILURE` The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the `minor_status` parameter details the error condition.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

gss_release_oid(3GSS)

NAME	<code>gss_release_oid</code> – release an object identifier								
SYNOPSIS	<pre>cc -flag ... file ...-lgss [library ...] #include <gssapi/gssapi.h> gss_release_oid(OM_uint32 *minor_status, const gss_OID *oid);</pre>								
DESCRIPTION	<p>The <code>gss_release_oid()</code> function deletes an OID. Such an OID might have been created with <code>gss_str_to_oid()</code>.</p> <p>Since creating and deleting individual OIDs is discouraged, it is preferable to use <code>gss_release_oid_set()</code> if it is necessary to deallocate a set of OIDs.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_release_oid()</code> are as follows:</p> <p><i>minor_status</i> A mechanism-specific status code.</p> <p><i>oid</i> The object identifier of the mechanism to be deleted.</p>								
ERRORS	<p><code>gss_release_oid()</code> returns one of the following status codes:</p> <p><code>GSS_S_COMPLETE</code> Successful completion.</p> <p><code>GSS_S_FAILURE</code> The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</p>								
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWgss (32-bit)</td></tr><tr><td></td><td>SUNWgssx (64-bit)</td></tr><tr><td>MT Level</td><td>Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWgss (32-bit)		SUNWgssx (64-bit)	MT Level	Safe

SEE ALSO	<p><code>gss_release_oid_set(3GSS)</code>, <code>gss_str_to_oid(3GSS)</code>, <code>attributes(5)</code></p> <p>Solaris Security for Developers Guide</p>								
WARNINGS	<p>This function is included for compatibility only with programs using earlier versions of the GSS-API and should not be used for new programs. Other implementations of the GSS-API might not support this function, so portable programs should not rely on it. Sun might not continue to support this function.</p>								

NAME	gss_release_oid_set – free storage associated with a GSS-API-generated gss_OID_set object								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_release_oid_set(OM_uint32 *minor_status, gss_OID_set *set);</pre>								
DESCRIPTION	<p>The gss_release_oid_set() function frees storage associated with a GSS-API-generated gss_OID_set object. The set parameter must refer to an OID-set that was returned from a GSS-API function. The gss_release_oid_set() function will free the storage associated with each individual member OID, the OID set's elements array, and gss_OID_set_desc.</p> <p>gss_OID_set is set to GSS_C_NO_OID_SET on successful completion of this function.</p>								
PARAMETERS	<p>The parameter descriptions for gss_release_oid_set() follow:</p> <p><i>minor_status</i> A mechanism-specific status code</p> <p><i>set</i> Storage associated with the gss_OID_set will be deleted</p>								
ERRORS	<p>The gss_release_oid_set() function may return the following status codes:</p> <p>GSS_S_COMPLETE Successful completion</p> <p>GSS_S_FAILURE The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.</p>								
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWgss (32-bit)</td> </tr> <tr> <td></td> <td>SUNWgssx (64-bit)</td> </tr> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWgss (32-bit)		SUNWgssx (64-bit)	MT-Level	Safe

gss_store_cred(3GSS)

NAME	gss_store_cred – store a credential in the current credential store
SYNOPSIS	<pre>cc [flag...] file... -lgss [library...] #include <gssapi/gssapi.h> OM_uint32 gss_store_cred(OM_uint32 *minor_status, const gss_cred_id_t input_cred, const gss_cred_usage_t cred_usage, const gss_OID desired_mech, OM_uint32 overwrite_cred, OM_uint32 default_cred, gss_OID_set *elements_stored, gss_cred_usage_t *cred_usage_stored);</pre>
PARAMETERS	The parameter descriptions for gss_store_cred() follow:
<i>input_cred</i>	The credential to be stored.
<i>cred_usage</i>	This parameter specifies whether to store an initiator, an acceptor, or both usage components of a credential.
<i>desired_mech</i>	The mechanism-specific component of a credential to be stored. If GSS_C_NULL_OID is specified, the gss_store_cred() function attempts to store all the elements of the given <i>input_cred_handle</i> . The gss_store_cred() function is not atomic when storing multiple elements of a credential. All delegated credentials, however, contain a single element.
<i>overwrite_cred</i>	A boolean that indicates whether to overwrite existing credentials in the current store for the same principal as that of the <i>input_cred_handle</i> . A non-zero value indicates that credentials are overwritten. A zero value indicates that credentials are not overwritten.
<i>default_cred</i>	A boolean that indicates whether to set the principal name of the <i>input_cred_handle</i> parameter as the default of the current credential store. A non-zero value indicates that the principal name is set as the default. A zero value indicates that the principal name is not set as the default. The default principal of a credential store matches GSS_C_NO_NAME as the <i>desired_name</i> input parameter for gss_store_cred(3GSS).
<i>elements_stored</i>	The set of mechanism OIDs for which <i>input_cred_handle</i> elements have been stored.
<i>cred_usage_stored</i>	The stored <i>input_cred_handle</i> usage elements: initiator, acceptor, or both.
<i>minor_status</i>	Minor status code that is specific to one of the following: the mechanism identified by the <i>desired_mech_element</i> parameter, or the element of a single mechanism in the <i>input_cred_handle</i> . In all other cases, <i>minor_status</i> has an undefined value on return.

DESCRIPTION The `gss_store_cred()` function stores a credential in the the current GSS-API credential store for the calling process. Input credentials can be re-acquired through `gss_add_cred(3GSS)` and `gss_acquire_cred(3GSS)`.

The `gss_store_cred()` function is specifically intended to make delegated credentials available to a user's login session.

The `gss_accept_sec_context()` function can return a delegated GSS-API credential to its caller. The function does not store delegated credentials to be acquired through `gss_add_cred(3GSS)`. Delegated credentials can be used only by a receiving process unless they are made available for acquisition by calling the `gss_store_cred()` function.

The Solaris Operating System supports a single GSS-API credential store per user. The current GSS-API credential store of a process is determined by its effective UID.

In general, acceptor applications should switch the current credential store by changing the effective UID before storing a delegated credential.

RETURN VALUES The `gss_store_cred()` can return the following status codes:

<code>GSS_S_COMPLETE</code>	Successful completion.
<code>GSS_S_CREDENTIALS_EXPIRED</code>	The credentials could not be stored because they have expired.
<code>GSS_S_NO_CRED</code>	No input credentials were given.
<code>GSS_S_UNAVAILABLE</code>	The credential store is unavailable.
<code>GSS_S_DUPLICATE_ELEMENT</code>	The credentials could not be stored because the <i>overwrite_cred</i> input parameter was set to false (0) and the <i>input_cred</i> parameter conflicts with a credential in the current credential store.
<code>GSS_S_FAILURE</code>	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

Solaris Security for Developers Guide

NAME	gss_str_to_oid – convert a string to an OID								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_str_to_oid(OM_uint32 *minor_status, const gss_buffer_t oid_str, gss_OID *oid);</pre>								
DESCRIPTION	<p>The <code>gss_str_to_oid()</code> function converts a string to a GSS-API OID structure. You can use the function to convert a simple string to an OID to . This function is a convenience function, as is its complementary function, <code>gss_oid_to_str(3GSS)</code>.</p> <p>OIDs created with <code>gss_str_to_oid()</code> must be deallocated through <code>gss_release_oid(3GSS)</code>, if available. If an OID must be created, use <code>gss_create_empty_oid_set(3GSS)</code> and <code>gss_add_oid_set_member(3GSS)</code> to create it. OIDs created in this way must be released with <code>gss_release_oid_set(3GSS)</code>. However, it is strongly suggested that applications use the default GSS-API mechanism instead of creating an OID for a specific mechanism.</p>								
PARAMETERS	<p>The parameter descriptions for <code>gss_str_to_oid()</code> are as follows:</p> <p><i>minor_status</i> Status code returned by underlying mechanism.</p> <p><i>oid</i> GSS-API OID structure to receive converted string.</p> <p><i>oid_str</i> String to convert.</p>								
ERRORS	<p><code>gss_str_to_oid()</code> returns one of the following status codes:</p> <table border="0"> <tr> <td style="vertical-align: top;">GSS_S_CALL_INACCESSIBLE_READ</td> <td>A required input parameter could not be read.</td> </tr> <tr> <td style="vertical-align: top;">GSS_S_CALL_INACCESSIBLE_WRITE</td> <td>A required output parameter could not be written.</td> </tr> <tr> <td style="vertical-align: top;">GSS_S_COMPLETE</td> <td>Successful completion.</td> </tr> <tr> <td style="vertical-align: top;">GSS_S_FAILURE</td> <td>The underlying mechanism detected an error for which no specific GSS status code is defined. Solaris Security for Developers Guide

WARNINGS This function is included for compatibility only with programs using earlier versions of the GSS-API and should not be used for new programs. Other implementations of the GSS-API might not support this function, so portable programs should not rely on it. Sun might not continue to support this function.

NAME	gss_test_oid_set_member – interrogate an object identifier set								
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_test_oid_set_member(OM_uint32 *minor_status, const gss_OID member, const gss_OID_set set, int *present);</pre>								
DESCRIPTION	The <code>gss_test_oid_set_member()</code> function interrogates an object identifier set to determine if a specified object identifier is a member. This function should be used with OID sets returned by <code>gss_indicate_mechs(3GSS)</code> , <code>gss_acquire_cred(3GSS)</code> , and <code>gss_inquire_cred(3GSS)</code> , but it will also work with user-generated sets.								
PARAMETERS	<p>The parameter descriptions for <code>gss_test_oid_set_member()</code> follow:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>minor_status</i></td> <td>A mechanism-specific status code</td> </tr> <tr> <td><i>member</i></td> <td>An object identifier whose presence is to be tested</td> </tr> <tr> <td><i>set</i></td> <td>An object identifier set.</td> </tr> <tr> <td><i>present</i></td> <td>The value of <i>present</i> is non-zero if the specified OID is a member of the set; if not, the value of <i>present</i> is zero.</td> </tr> </table>	<i>minor_status</i>	A mechanism-specific status code	<i>member</i>	An object identifier whose presence is to be tested	<i>set</i>	An object identifier set.	<i>present</i>	The value of <i>present</i> is non-zero if the specified OID is a member of the set; if not, the value of <i>present</i> is zero.
<i>minor_status</i>	A mechanism-specific status code								
<i>member</i>	An object identifier whose presence is to be tested								
<i>set</i>	An object identifier set.								
<i>present</i>	The value of <i>present</i> is non-zero if the specified OID is a member of the set; if not, the value of <i>present</i> is zero.								
ERRORS	<p>The <code>gss_test_oid_set_member()</code> function may return the following status codes:</p> <table border="0"> <tr> <td style="padding-right: 20px;">GSS_S_COMPLETE</td> <td>Successful completion</td> </tr> <tr> <td>GSS_S_FAILURE</td> <td>The underlying mechanism detected an error for which no specific GSS status code is defined. gss_unwrap(3GSS)

NAME	<code>gss_unwrap</code> – verify a message with attached cryptographic message												
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_unwrap(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, const gss_buffer_t input_message_buffer, gss_buffer_t output_message_buffer, int *conf_state, gss_qop_t *qop_state);</pre>												
DESCRIPTION	<p>The <code>gss_unwrap()</code> function converts a message previously protected by <code>gss_wrap(3GSS)</code> back to a usable form, verifying the embedded MIC. The <code>conf_state</code> parameter indicates whether the message was encrypted; the <code>qop_state</code> parameter indicates the strength of protection that was used to provide the confidentiality and integrity services.</p> <p>Since some application-level protocols may wish to use tokens emitted by <code>gss_wrap(3GSS)</code> to provide secure framing, the GSS-API supports the wrapping and unwrapping of zero-length messages.</p>												
PARAMETERS	<p>The parameter descriptions for <code>gss_unwrap()</code> follow:</p> <table><tr><td><i>minor_status</i></td><td>The status code returned by the underlying mechanism.</td></tr><tr><td><i>context_handle</i></td><td>Identifies the context on which the message arrived.</td></tr><tr><td><i>input_message_buffer</i></td><td>The message to be protected.</td></tr><tr><td><i>output_message_buffer</i></td><td>The buffer to receive the unwrapped message. Storage associated with this buffer must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code>.</td></tr><tr><td><i>conf_state</i></td><td>If the value of <i>conf_state</i> is non-zero, then confidentiality and integrity protection were used. If the value is zero, only integrity service was used. Specify NULL if this parameter is not required.</td></tr><tr><td><i>qop_state</i></td><td>Specifies the quality of protection provided. Specify NULL if this parameter is not required.</td></tr></table>	<i>minor_status</i>	The status code returned by the underlying mechanism.	<i>context_handle</i>	Identifies the context on which the message arrived.	<i>input_message_buffer</i>	The message to be protected.	<i>output_message_buffer</i>	The buffer to receive the unwrapped message. Storage associated with this buffer must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .	<i>conf_state</i>	If the value of <i>conf_state</i> is non-zero, then confidentiality and integrity protection were used. If the value is zero, only integrity service was used. Specify NULL if this parameter is not required.	<i>qop_state</i>	Specifies the quality of protection provided. Specify NULL if this parameter is not required.
<i>minor_status</i>	The status code returned by the underlying mechanism.												
<i>context_handle</i>	Identifies the context on which the message arrived.												
<i>input_message_buffer</i>	The message to be protected.												
<i>output_message_buffer</i>	The buffer to receive the unwrapped message. Storage associated with this buffer must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .												
<i>conf_state</i>	If the value of <i>conf_state</i> is non-zero, then confidentiality and integrity protection were used. If the value is zero, only integrity service was used. Specify NULL if this parameter is not required.												
<i>qop_state</i>	Specifies the quality of protection provided. Specify NULL if this parameter is not required.												
ERRORS	<p><code>gss_unwrap()</code> may return the following status codes:</p> <table><tr><td><code>GSS_S_COMPLETE</code></td><td>Successful completion.</td></tr><tr><td><code>GSS_S_DEFECTIVE_TOKEN</code></td><td>The token failed consistency checks.</td></tr><tr><td><code>GSS_S_BAD_SIG</code></td><td>The MIC was incorrect.</td></tr><tr><td><code>GSS_S_DUPLICATE_TOKEN</code></td><td>The token was valid, and contained a correct MIC for the message, but it had already been processed.</td></tr></table>	<code>GSS_S_COMPLETE</code>	Successful completion.	<code>GSS_S_DEFECTIVE_TOKEN</code>	The token failed consistency checks.	<code>GSS_S_BAD_SIG</code>	The MIC was incorrect.	<code>GSS_S_DUPLICATE_TOKEN</code>	The token was valid, and contained a correct MIC for the message, but it had already been processed.				
<code>GSS_S_COMPLETE</code>	Successful completion.												
<code>GSS_S_DEFECTIVE_TOKEN</code>	The token failed consistency checks.												
<code>GSS_S_BAD_SIG</code>	The MIC was incorrect.												
<code>GSS_S_DUPLICATE_TOKEN</code>	The token was valid, and contained a correct MIC for the message, but it had already been processed.												

gss_unwrap(3GSS)

GSS_S_OLD_TOKEN	The token was valid, and contained a correct MIC for the message, but it is too old to check for duplication.
GSS_S_UNSEQ_TOKEN	The token was valid, and contained a correct MIC for the message, but has been verified out of sequence; a later token has already been received.
GSS_S_GAP_TOKEN	The token was valid, and contained a correct MIC for the message, but has been verified out of sequence; an earlier expected token has not yet been received.
GSS_S_CONTEXT_EXPIRED	The context has already expired.
GSS_S_NO_CONTEXT	The <i>context_handle</i> parameter did not identify a valid context.
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

gss_verify_mic(3GSS)

NAME	<code>gss_verify_mic</code> – verify integrity of a received message												
SYNOPSIS	<pre>cc -flag ... file...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_verify_mic(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, const gss_buffer_t message_buffer, const gss_buffer_t token_buffer, gss_qop_t *qop_state);</pre>												
DESCRIPTION	<p>The <code>gss_verify_mic()</code> function verifies that a cryptographic MIC, contained in the token parameter, fits the supplied message. The <code>qop_state</code> parameter allows a message recipient to determine the strength of protection that was applied to the message.</p> <p>Since some application-level protocols may wish to use tokens emitted by gss_wrap(3GSS) to provide secure framing, the GSS-API supports the calculation and verification of MICs over zero-length messages.</p>												
PARAMETERS	<p>The parameter descriptions for <code>gss_verify_mic()</code> follow:</p> <table><tr><td><i>minor_status</i></td><td>The status code returned by the underlying mechanism.</td></tr><tr><td><i>context_handle</i></td><td>Identifies the context on which the message arrived.</td></tr><tr><td><i>message_buffer</i></td><td>The message to be verified.</td></tr><tr><td><i>token_buffer</i></td><td>The token associated with the message.</td></tr><tr><td><i>qop_state</i></td><td>Specifies the quality of protection gained from the MIC. Specify NULL if this parameter is not required.</td></tr></table>	<i>minor_status</i>	The status code returned by the underlying mechanism.	<i>context_handle</i>	Identifies the context on which the message arrived.	<i>message_buffer</i>	The message to be verified.	<i>token_buffer</i>	The token associated with the message.	<i>qop_state</i>	Specifies the quality of protection gained from the MIC. Specify NULL if this parameter is not required.		
<i>minor_status</i>	The status code returned by the underlying mechanism.												
<i>context_handle</i>	Identifies the context on which the message arrived.												
<i>message_buffer</i>	The message to be verified.												
<i>token_buffer</i>	The token associated with the message.												
<i>qop_state</i>	Specifies the quality of protection gained from the MIC. Specify NULL if this parameter is not required.												
ERRORS	<p><code>gss_verify_mic()</code> may return the following status codes:</p> <table><tr><td><code>GSS_S_COMPLETE</code></td><td>Successful completion.</td></tr><tr><td><code>GSS_S_DEFECTIVE_TOKEN</code></td><td>The token failed consistency checks.</td></tr><tr><td><code>GSS_S_BAD_SIG</code></td><td>The MIC was incorrect.</td></tr><tr><td><code>GSS_S_DUPLICATE_TOKEN</code></td><td>The token was valid and contained a correct MIC for the message, but it had already been processed.</td></tr><tr><td><code>GSS_S_OLD_TOKEN</code></td><td>The token was valid and contained a correct MIC for the message, but it is too old to check for duplication.</td></tr><tr><td><code>GSS_S_UNSEQ_TOKEN</code></td><td>The token was valid and contained a correct MIC for the message, but it has been verified out of sequence; a later token has already been received.</td></tr></table>	<code>GSS_S_COMPLETE</code>	Successful completion.	<code>GSS_S_DEFECTIVE_TOKEN</code>	The token failed consistency checks.	<code>GSS_S_BAD_SIG</code>	The MIC was incorrect.	<code>GSS_S_DUPLICATE_TOKEN</code>	The token was valid and contained a correct MIC for the message, but it had already been processed.	<code>GSS_S_OLD_TOKEN</code>	The token was valid and contained a correct MIC for the message, but it is too old to check for duplication.	<code>GSS_S_UNSEQ_TOKEN</code>	The token was valid and contained a correct MIC for the message, but it has been verified out of sequence; a later token has already been received.
<code>GSS_S_COMPLETE</code>	Successful completion.												
<code>GSS_S_DEFECTIVE_TOKEN</code>	The token failed consistency checks.												
<code>GSS_S_BAD_SIG</code>	The MIC was incorrect.												
<code>GSS_S_DUPLICATE_TOKEN</code>	The token was valid and contained a correct MIC for the message, but it had already been processed.												
<code>GSS_S_OLD_TOKEN</code>	The token was valid and contained a correct MIC for the message, but it is too old to check for duplication.												
<code>GSS_S_UNSEQ_TOKEN</code>	The token was valid and contained a correct MIC for the message, but it has been verified out of sequence; a later token has already been received.												

[gss_verify_mic\(3GSS\)](#)

GSS_S_GAP_TOKEN

The token was valid and contained a correct MIC for the message, but it has been verified out of sequence; an earlier expected token has not yet been received.

GSS_S_CONTEXT_EXPIRED

The context has already expired.

GSS_S_NO_CONTEXT

The *context_handle* parameter did not identify a valid context.

GSS_S_FAILURE

The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the *minor_status* parameter details the error condition.

gss_wrap(3GSS)

NAME	<code>gss_wrap</code> – attach a cryptographic message														
SYNOPSIS	<pre>cc -flag ... file ...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_wrap(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, int conf_req_flag, gss_qop_t qop_req, const gss_buffer_t input_message_buffer, int *conf_state, gss_buffer_t output_message_buffer);</pre>														
DESCRIPTION	<p>The <code>gss_wrap()</code> function attaches a cryptographic MIC and optionally encrypts the specified <code>input_message</code>. The <code>output_message</code> contains both the MIC and the message. The <code>qop_req</code> parameter allows a choice between several cryptographic algorithms, if supported by the chosen mechanism.</p> <p>Since some application-level protocols may wish to use tokens emitted by <code>gss_wrap()</code> to provide secure framing, the GSS-API supports the wrapping of zero-length messages.</p>														
PARAMETERS	<p>The parameter descriptions for <code>gss_wrap()</code> follow:</p> <table><tr><td><code>minor_status</code></td><td>The status code returned by the underlying mechanism.</td></tr><tr><td><code>context_handle</code></td><td>Identifies the context on which the message will be sent.</td></tr><tr><td><code>conf_req_flag</code></td><td>If the value of <code>conf_req_flag</code> is non-zero, both confidentiality and integrity services are requested. If the value is zero, then only integrity service is requested.</td></tr><tr><td><code>qop_req</code></td><td>Specifies the required quality of protection. A mechanism-specific default may be requested by setting <code>qop_req</code> to <code>GSS_C_QOP_DEFAULT</code>. If an unsupported protection strength is requested, <code>gss_wrap()</code> will return a <code>major_status</code> of <code>GSS_S_BAD_QOP</code>.</td></tr><tr><td><code>input_message_buffer</code></td><td>The message to be protected.</td></tr><tr><td><code>conf_state</code></td><td>If the value of <code>conf_state</code> is non-zero, confidentiality, data origin authentication, and integrity services have been applied. If the value is zero, then integrity services have been applied. Specify <code>NULL</code> if this parameter is not required.</td></tr><tr><td><code>output_message_buffer</code></td><td>The buffer to receive the protected message. Storage associated with this message must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code>.</td></tr></table>	<code>minor_status</code>	The status code returned by the underlying mechanism.	<code>context_handle</code>	Identifies the context on which the message will be sent.	<code>conf_req_flag</code>	If the value of <code>conf_req_flag</code> is non-zero, both confidentiality and integrity services are requested. If the value is zero, then only integrity service is requested.	<code>qop_req</code>	Specifies the required quality of protection. A mechanism-specific default may be requested by setting <code>qop_req</code> to <code>GSS_C_QOP_DEFAULT</code> . If an unsupported protection strength is requested, <code>gss_wrap()</code> will return a <code>major_status</code> of <code>GSS_S_BAD_QOP</code> .	<code>input_message_buffer</code>	The message to be protected.	<code>conf_state</code>	If the value of <code>conf_state</code> is non-zero, confidentiality, data origin authentication, and integrity services have been applied. If the value is zero, then integrity services have been applied. Specify <code>NULL</code> if this parameter is not required.	<code>output_message_buffer</code>	The buffer to receive the protected message. Storage associated with this message must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .
<code>minor_status</code>	The status code returned by the underlying mechanism.														
<code>context_handle</code>	Identifies the context on which the message will be sent.														
<code>conf_req_flag</code>	If the value of <code>conf_req_flag</code> is non-zero, both confidentiality and integrity services are requested. If the value is zero, then only integrity service is requested.														
<code>qop_req</code>	Specifies the required quality of protection. A mechanism-specific default may be requested by setting <code>qop_req</code> to <code>GSS_C_QOP_DEFAULT</code> . If an unsupported protection strength is requested, <code>gss_wrap()</code> will return a <code>major_status</code> of <code>GSS_S_BAD_QOP</code> .														
<code>input_message_buffer</code>	The message to be protected.														
<code>conf_state</code>	If the value of <code>conf_state</code> is non-zero, confidentiality, data origin authentication, and integrity services have been applied. If the value is zero, then integrity services have been applied. Specify <code>NULL</code> if this parameter is not required.														
<code>output_message_buffer</code>	The buffer to receive the protected message. Storage associated with this message must be freed by the application after use with a call to <code>gss_release_buffer(3GSS)</code> .														
ERRORS	<code>gss_wrap()</code> may return the following status codes:														

GSS_S_COMPLETE	Successful completion.
GSS_S_CONTEXT_EXPIRED	The context has already expired.
GSS_S_NO_CONTEXT	The <i>context_handle</i> parameter did not identify a valid context.
GSS_S_BAD_QOP	The specified QOP is not supported by the mechanism.
GSS_S_FAILURE	The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the <i>minor_status</i> parameter details the error condition.

gss_wrap_size_limit(3GSS)

NAME	<code>gss_wrap_size_limit</code> – allow application to determine maximum message size with resulting output token of a specified maximum size												
SYNOPSIS	<pre>cc -flag ... file ...-lgss [library ...] #include <gssapi/gssapi.h> OM_uint32 gss_process_context_token(OM_uint32 *minor_status, const gss_ctx_id_t context_handle, int conf_req_flag, gss_qop_t qop_req, OM_uint32 req_output_size, OM_uint32 *max_input_size);</pre>												
DESCRIPTION	<p>The <code>gss_wrap_size_limit()</code> function allows an application to determine the maximum message size that, if presented to <code>gss_wrap()</code> with the same <code>conf_req_flag</code> and <code>qop_req</code> parameters, results in an output token containing no more than <code>req_output_size</code> bytes. This call is intended for use by applications that communicate over protocols that impose a maximum message size. It enables the application to fragment messages prior to applying protection. The GSS-API detects invalid QOP values when <code>gss_wrap_size_limit()</code> is called. This routine guarantees only a maximum message size, not the availability of specific QOP values for message protection.</p> <p>Successful completion of <code>gss_wrap_size_limit()</code> does not guarantee that <code>gss_wrap()</code> will be able to protect a message of length <code>max_input_size</code> bytes, since this ability might depend on the availability of system resources at the time that <code>gss_wrap()</code> is called.</p>												
PARAMETERS	<p>The parameter descriptions for <code>gss_wrap_size_limit()</code> are as follows:</p> <table><tr><td><i>minor_status</i></td><td>A mechanism-specific status code.</td></tr><tr><td><i>context_handle</i></td><td>A handle that refers to the security over which the messages will be sent.</td></tr><tr><td><i>conf_req_flag</i></td><td>Indicates whether <code>gss_wrap()</code> will be asked to apply confidential protection in addition to integrity protection. See gss_wrap(3GSS) for more details.</td></tr><tr><td><i>qop_req</i></td><td>Indicates the level of protection that <code>gss_wrap()</code> will be asked to provide. See gss_wrap(3GSS) for more details.</td></tr><tr><td><i>req_output_size</i></td><td>The desired maximum size for tokens emitted by <code>gss_wrap()</code>.</td></tr><tr><td><i>max_input_size</i></td><td>The maximum input message size that can be presented to <code>gss_wrap()</code> to guarantee that the emitted token will be no larger than <code>req_output_size</code> bytes.</td></tr></table>	<i>minor_status</i>	A mechanism-specific status code.	<i>context_handle</i>	A handle that refers to the security over which the messages will be sent.	<i>conf_req_flag</i>	Indicates whether <code>gss_wrap()</code> will be asked to apply confidential protection in addition to integrity protection. See gss_wrap(3GSS) for more details.	<i>qop_req</i>	Indicates the level of protection that <code>gss_wrap()</code> will be asked to provide. See gss_wrap(3GSS) for more details.	<i>req_output_size</i>	The desired maximum size for tokens emitted by <code>gss_wrap()</code> .	<i>max_input_size</i>	The maximum input message size that can be presented to <code>gss_wrap()</code> to guarantee that the emitted token will be no larger than <code>req_output_size</code> bytes.
<i>minor_status</i>	A mechanism-specific status code.												
<i>context_handle</i>	A handle that refers to the security over which the messages will be sent.												
<i>conf_req_flag</i>	Indicates whether <code>gss_wrap()</code> will be asked to apply confidential protection in addition to integrity protection. See gss_wrap(3GSS) for more details.												
<i>qop_req</i>	Indicates the level of protection that <code>gss_wrap()</code> will be asked to provide. See gss_wrap(3GSS) for more details.												
<i>req_output_size</i>	The desired maximum size for tokens emitted by <code>gss_wrap()</code> .												
<i>max_input_size</i>	The maximum input message size that can be presented to <code>gss_wrap()</code> to guarantee that the emitted token will be no larger than <code>req_output_size</code> bytes.												
ERRORS	<p><code>gss_wrap_size_limit()</code> returns one of the following status codes:</p> <table><tr><td><code>GSS_S_COMPLETE</code></td><td>Successful completion.</td></tr><tr><td><code>GSS_S_NO_CONTEXT</code></td><td>The referenced context could not be accessed.</td></tr><tr><td><code>GSS_S_CONTEXT_EXPIRED</code></td><td>The context has expired.</td></tr></table>	<code>GSS_S_COMPLETE</code>	Successful completion.	<code>GSS_S_NO_CONTEXT</code>	The referenced context could not be accessed.	<code>GSS_S_CONTEXT_EXPIRED</code>	The context has expired.						
<code>GSS_S_COMPLETE</code>	Successful completion.												
<code>GSS_S_NO_CONTEXT</code>	The referenced context could not be accessed.												
<code>GSS_S_CONTEXT_EXPIRED</code>	The context has expired.												

`gss_wrap_size_limit(3GSS)`

`GSS_S_BAD_QOP`

The specified QOP is not supported by the mechanism.

`GSS_S_FAILURE`

The underlying mechanism detected an error for which no specific GSS status code is defined. The mechanism-specific status code reported by means of the *minor_status* parameter details the error condition.

htonl(3XNET)

NAME	htonl, htons, ntohl, ntohs – convert values between host and network byte order						
SYNOPSIS	<pre>cc [flag ...] file ... -lxnet [library ...] #include <arpa/inet.h> uint32_t htonl (uint32_t hostlong) ; uint16_t htons (uint16_t hostshort) ; uint32_t ntohl (uint32_t netlong) ; uint16_t ntohs (uint16_t netshort) ;</pre>						
DESCRIPTION	<p>These functions convert 16-bit and 32-bit quantities between network byte order and host byte order.</p> <p>The <code>uint32_t</code> and <code>uint16_t</code> types are made available by inclusion of <code><inttypes.h></code>.</p>						
USAGE	<p>These functions are most often used in conjunction with Internet addresses and ports as returned by <code>gethostent(3XNET)</code> and <code>getservent(3XNET)</code>.</p> <p>On some architectures these functions are defined as macros that expand to the value of their argument.</p>						
RETURN VALUES	<p>The <code>htonl()</code> and <code>htons()</code> functions return the argument value converted from host to network byte order.</p> <p>The <code>ntohl()</code> and <code>ntohs()</code> functions return the argument value converted from network to host byte order.</p>						
ERRORS	No errors are defined.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	icmp6_filter – Variable allocation datatype
SYNOPSIS	<pre>void ICMP6_FILTER_SETPASSALL (struct icmp6_filter *); void ICMP6_FILTER_SETBLOCKALL (struct icmp6_filter *); void ICMP6_FILTER_SETPASS (int, struct icmp6_filter *); void ICMP6_FILTER_SETBLOCK (int, struct icmp6_filter *); int ICMP6_FILTER_WILLPASS (int, const struct icmp6_filter *); int ICMP6_FILTER_WILLBLOCK (int, const struct icmp6_filter *);</pre>
DESCRIPTION	<p>The <code>icmp6_filter</code> structure is similar to the <code>fd_set</code> datatype used with the <code>select()</code> function in the sockets API. The <code>icmp6_filter</code> structure is an opaque datatype and the application should not care how it is implemented. The application allocates a variable of this type, then passes a pointer to it. Next it passes a pointer to a variable of this type to <code>getsockopt()</code> and <code>setsockopt()</code> and operates on a variable of this type using the six macros defined below.</p> <p>The <code>SETPASSALL</code> and <code>SETBLOCKALL</code> functions enable you to specify that all ICMPv6 messages are passed to the application or that all ICMPv6 messages are blocked from being passed.</p> <p>The <code>SETPASS</code> and <code>SETBLOCKALL</code> functions enable you to specify that messages of a given ICMPv6 type should be passed to the application or not passed to the application (blocked).</p> <p>The <code>WILLPASS</code> and <code>WILLBLOCK</code> return true or false depending whether the specified message type is passed to the application or blocked from being passed to the application by the filter pointed to by the second argument.</p> <p>The pointer argument to all six <code>icmp6_filter</code> macros is a pointer to a filter that is modified by the first four macros and is examined by <code>ICMP6_FILTER_SETBLOCK</code> and <code>ICMP6_FILTER_WILLBLOCK</code>. The first argument, (an integer), to the <code>ICMP6_FILTER_BLOCKALL</code>, <code>ICMP6_FILTER_SETPASS</code>, <code>ICMP6_FILTER_SETBLOCK</code>, and <code>ICMP6_FILTER_WILLBLOCK</code> macros is an ICMPv6 message type, between 0 and 255.</p> <p>The current filter is fetched and stored using <code>getsockopt()</code> and <code>setsockopt()</code> with a level of <code>IPPROTO_ICMPV6</code> and an option name of <code>ICMP6_FILTER</code>.</p>

if_nametoindex(3SOCKET)

NAME	if_nametoindex, if_indextoname, if_nameindex, if_freenameindex – routines to map Internet Protocol network interface names and interface indexes
SYNOPSIS	<pre>cc [flag...] file... -lsocket [library...] #include <net/if.h> unsigned int if_nametoindex(const char *ifname); char *if_indextoname(unsigned int ifindex, char *ifname); struct if_nameindex *if_nameindex(void); void if_freenameindex(struct if_nameindex *ptr);</pre>
PARAMETERS	<p><i>ifname</i> interface name</p> <p><i>ifindex</i> interface index</p> <p><i>ptr</i> pointer returned by if_nameindex()</p>
DESCRIPTION	<p>This API defines two functions that map between an Internet Protocol network interface name and index, a third function that returns all the interface names and indexes, and a fourth function to return the dynamic memory allocated by the previous function.</p> <p>Network interfaces are normally known by names such as <code>eri0</code>, <code>s11</code>, <code>ppp2</code>, and the like. The <i>ifname</i> argument must point to a buffer of at least <code>IF_NAMESIZE</code> bytes into which the interface name corresponding to the specified index is returned. <code>IF_NAMESIZE</code> is defined in <code><net/if.h></code> and its value includes a terminating null byte at the end of the interface name.</p> <p>if_nametoindex()</p> <p>The <code>if_nametoindex()</code> function returns the interface index corresponding to the interface name pointed to by the <i>ifname</i> pointer. If the specified interface name does not exist, the return value is 0, and <code>errno</code> is set to <code>ENXIO</code>. If there was a system error, such as running out of memory, the return value is 0 and <code>errno</code> is set to the proper value, for example, <code>ENOMEM</code>.</p> <p>if_indextoname()</p> <p>The <code>if_indextoname()</code> function maps an interface index into its corresponding name. This pointer is also the return value of the function. If there is no interface corresponding to the specified index, <code>NULL</code> is returned, and <code>errno</code> is set to <code>ENXIO</code>, if there was a system error, such as running out of memory, <code>if_indextoname()</code> returns <code>NULL</code> and <code>errno</code> would be set to the proper value, for example, <code>ENOMEM</code>.</p> <p>*if_nameindex()</p> <p>The <code>if_nameindex()</code> function returns an array of <code>if_nameindex</code> structures, one structure per interface. The <code>if_nameindex</code> structure holds the information about a single interface and is defined when the <code><net/if.h></code> header is included:</p> <pre>struct if_nameindex { unsigned int if_index; /* 1, 2, ... */ char *if_name; /* null terminated name: "eri0", ... */ };</pre>

`if_nameindex(3SOCKET)`

The end of the array of structures is indicated by a structure with an `if_index` of 0 and an `if_name` of NULL. The function returns a null pointer upon an error and sets `errno` to the appropriate value. The memory used for this array of structures along with the interface names pointed to by the `if_name` members is obtained dynamically. This memory is freed by the `if_freenameindex()` function.

`if_freenameindex()`

The `if_freenameindex()` function frees the dynamic memory that was allocated by `if_nameindex()`. The argument to this function must be a pointer that was returned by `if_nameindex()`.

if_nametoindex(3XNET)

NAME	if_nametoindex, if_indextoname, if_nameindex, if_freenameindex – functions to map Internet Protocol network interface names and interface indexes
SYNOPSIS	<pre>cc [flag...] file... -lxnet [library...] #include <net/if.h> unsigned int if_nametoindex(const char *ifname); char *if_indextoname(unsigned int ifindex, char *ifname); struct if_nameindex *if_nameindex(void); void if_freenameindex(struct if_nameindex *ptr);</pre>
PARAMETERS	These functions support the following parameters: <i>ifname</i> interface name <i>ifindex</i> interface index <i>ptr</i> pointer returned by if_nameindex()
DESCRIPTION	<p>This API defines two functions that map between an Internet Protocol network interface name and index, a third function that returns all the interface names and indexes, and a fourth function to return the dynamic memory allocated by the previous function.</p> <p>Network interfaces are normally known by names such as <code>eri0</code>, <code>s11</code>, <code>ppp2</code>, and the like. The <i>ifname</i> argument must point to a buffer of at least <code>IF_NAMESIZE</code> bytes into which the interface name corresponding to the specified index is returned. <code>IF_NAMESIZE</code> is defined in <code><net/if.h></code> and its value includes a terminating null byte at the end of the interface name.</p> <p>if_nametoindex() The <code>if_nametoindex()</code> function returns the interface index corresponding to the interface name pointed to by the <i>ifname</i> pointer. If the specified interface name does not exist, the return value is 0, and <code>errno</code> is set to <code>ENXIO</code>. If there was a system error, such as running out of memory, the return value is 0 and <code>errno</code> is set to the proper value, for example, <code>ENOMEM</code>.</p> <p>if_indextoname() The <code>if_indextoname()</code> function maps an interface index into its corresponding name. This pointer is also the return value of the function. If there is no interface corresponding to the specified index, <code>NULL</code> is returned, and <code>errno</code> is set to <code>ENXIO</code>, if there was a system error, such as running out of memory, <code>if_indextoname()</code> returns <code>NULL</code> and <code>errno</code> would be set to the proper value, for example, <code>ENOMEM</code>.</p> <p>*if_nameindex() The <code>if_nameindex()</code> function returns an array of <code>if_nameindex</code> structures, one structure per interface. The <code>if_nameindex</code> structure holds the information about a single interface and is defined when the <code><net/if.h></code> header is included:</p> <pre>struct if_nameindex { unsigned int if_index; /* 1, 2, ... */ char *if_name; /* null terminated name: "eri0", ... */</pre>

`if_nametoindex(3XNET)`

```
};
```

The end of the array of structures is indicated by a structure with an `if_index` of 0 and an `if_name` of `NULL`. The function returns a null pointer upon an error and sets `errno` to the appropriate value. The memory used for this array of structures along with the interface names pointed to by the `if_name` members is obtained dynamically. This memory is freed by the `if_freenameindex()` function.

`if_freenameindex()`

The `if_freenameindex()` function frees the dynamic memory that was allocated by `if_nameindex()`. The argument to this function must be a pointer that was returned by `if_nameindex()`.

inet(3SOCKET)

NAME	inet, inet6, inet_ntop, inet_pton, inet_addr, inet_network, inet_makeaddr, inet_lnaof, inet_netof, inet_ntoa – Internet address manipulation
SYNOPSIS	<pre>cc [flag ...] file... -lsocket -lnsl [library...] #include <sys/types.h> #include <sys/socket.h> #include <netinet/in.h> #include <arpa/inet.h> const char *inet_ntop(int af, const void *addr, char *cp, size_t size); int inet_pton(int af, const char *cp, void *addr); in_addr_t inet_addr(const char *cp); in_addr_t inet_network(const char *cp); struct in_addr inet_makeaddr(const int net, const int lna); int inet_lnaof(const struct in_addr in); int inet_netof(const struct in_addr in); char *inet_ntoa(const struct in_addr in);</pre>
DESCRIPTION	<p>The <code>inet_ntop()</code> and <code>inet_pton()</code> functions can manipulate both IPv4 and IPv6 addresses. The <code>inet_addr()</code>, <code>inet_network()</code>, <code>inet_makeaddr()</code>, <code>inet_lnaof()</code>, <code>inet_netof()</code>, and <code>inet_ntoa()</code> functions can only manipulate IPv4 addresses.</p> <p>The <code>inet_ntop()</code> function converts a numeric address into a string suitable for presentation. The <code>af</code> argument specifies the family of the address which can be <code>AF_INET</code> or <code>AF_INET6</code>. The <code>addr</code> argument points to a buffer that holds an IPv4 address if the <code>af</code> argument is <code>AF_INET</code>. The <code>addr</code> argument points to a buffer that holds an IPv6 address if the <code>af</code> argument is <code>AF_INET6</code>. The address must be in network byte order. The <code>cp</code> argument points to a buffer where the function stores the resulting string. The application must specify a non-NULL <code>cp</code> argument. The <code>size</code> argument specifies the size of this buffer. For IPv6 addresses, the buffer must be at least 46-octets. For IPv4 addresses, the buffer must be at least 16-octets. To allow applications to easily declare buffers of the proper size to store IPv4 and IPv6 addresses in string form, the following two constants are defined in <code><netinet/in.h></code>:</p> <pre>#define INET_ADDRSTRLEN 16 #define INET6_ADDRSTRLEN 46</pre> <p>The <code>inet_pton()</code> function converts the standard text presentation form of a function to the numeric binary form. The <code>af</code> argument specifies the family of the address. Currently, the <code>AF_INET</code> and <code>AF_INET6</code> address families are supported. The <code>cp</code> argument points to the string being passed in. The <code>addr</code> argument points to a buffer where the function stores the numeric address. The calling application must ensure that the buffer referred to by <code>addr</code> is large enough to hold the numeric address, at least 4 bytes for <code>AF_INET</code> or 16 bytes for <code>AF_INET6</code>.</p>

The `inet_addr()` and `inet_network()` functions interpret character strings that represent numbers expressed in the IPv4 standard '.' notation, returning numbers suitable for use as IPv4 addresses and IPv4 network numbers, respectively. The `inet_makeaddr()` function uses an IPv4 network number and a local network address to construct an IPv4 address. The `inet_netof()` and `inet_lnaof()` functions break apart IPv4 host addresses, then return the network number and local network address, respectively.

The `inet_ntoa()` function returns a pointer to a string in the base 256 notation d.d.d.d. See the following section on IPv4 addresses.

Internet addresses are returned in network order, bytes ordered from left to right. Network numbers and local address parts are returned as machine format integer values.

IPv6 Addresses

There are three conventional forms for representing IPv6 addresses as strings:

1. The preferred form is `x:x:x:x:x:x:x:x`, where the 'x's are the hexadecimal values of the eight 16-bit pieces of the address. For example:

```
1080:0:0:0:8:800:200C:417A
```

It is not necessary to write the leading zeros in an individual field. There must be at least one numeral in every field, except when the special syntax described in the following is used.

2. It is common for addresses to contain long strings of zero bits in some methods used to allocate certain IPv6 address styles. A special syntax is available to compress the zeros. The use of ":" indicates multiple groups of 16 bits of zeros. The "::" may only appear once in an address. The "::" can also be used to compress the leading and trailing zeros in an address. For example:

```
1080::8:800:200C:417A
```

3. The alternative form `x:x:x:x:x:x.d.d.d.d` is sometimes more convenient when dealing with a mixed environment of IPv4 and IPv6 nodes. The x's in this form represent the hexadecimal values of the six high-order 16-bit pieces of the address. The d's represent the decimal values of the four low-order 8-bit pieces of the standard IPv4 address. For example:

```
::FFFF:129.144.52.38
```

```
::129.144.52.38
```

The `::FFFF:d.d.d.d` and `::d.d.d.d` pieces are the general forms of an IPv4-mapped IPv6 address and an IPv4-compatible IPv6 address. The IPv4 portion must be in the `d.d.d.d` form. The following forms are invalid:

```
::FFFF:d.d.d
```

```
::FFFF:d.d
```

```
::d.d.d
```

```
::d.d
```

The `::FFFF:d` form is a valid but unconventional representation of the IPv4-compatible IPv6 address `::255.255.0.d`. The `::d` form corresponds to the general IPv6 address `0:0:0:0:0:0:0:d`.

IPv4 Addresses

Values specified using '.' notation take one of the following forms:

inet(3SOCKET)

```
d.d.d.d
d.d.d
d.d
d
```

When four parts are specified, each part is interpreted as a byte of data and assigned from left to right to the four bytes of an IPv4 address.

When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the right most two bytes of the network address. The three part address format is convenient for specifying Class B network addresses such as `128.net.host`.

When a two-part address is supplied, the last part is interpreted as a 24-bit quantity and placed in the right most three bytes of the network address. The two part address format is convenient for specifying Class A network addresses such as `net.host`.

When only one part is given, the value is stored directly in the network address without any byte rearrangement.

With the exception of `inet_pton()`, numbers supplied as *parts* in `'.'` notation may be decimal, octal, or hexadecimal, as specified in C language. For example, a leading `0x` or `0X` implies hexadecimal. A leading `0` implies octal. Otherwise, the number is interpreted as decimal.

For IPv4 addresses, `inet_pton()` accepts only a string in standard IPv4 dot notation:

```
d.d.d.d
```

Each number has one to three digits with a decimal value between 0 and 255.

RETURN VALUES

The `inet_ntop()` function returns a pointer to the buffer that contains a string if the conversion succeeds. Otherwise, `NULL` is returned. Upon failure, `errno` is set to `EAFNOSUPPORT` if the *af* argument is invalid or `ENOSPC` if the size of the result buffer is inadequate.

The `inet_pton()` function returns 1 if the conversion succeeds, 0 if the input is not a valid IPv4 dotted-decimal string or a valid IPv6 address string. The function returns -1 with `errno` set to `EAFNOSUPPORT` if the *af* argument is unknown.

The value `(in_addr_t) (-1)` is returned by `inet_addr()` and `inet_network()` for malformed requests.

The functions `inet_netof()` and `inet_lnaof()` break apart IPv4 host addresses, returning the network number and local network address part, respectively.

The function `inet_ntoa()` returns a pointer to a string in the base 256 notation `d.d.d.d`, described in the section on IPv4 addresses.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `gethostbyname(3NSL)`, `getipnodebyname(3SOCKET)`, `getnetbyname(3SOCKET)`, `inet.h(3HEAD)`, `hosts(4)`, `ipnodes(4)`, `networks(4)`, `attributes(5)`

NOTES The return value from `inet_ntoa()` points to a buffer which is overwritten on each call. This buffer is implemented as thread-specific data in multithreaded applications.

BUGS The problem of host byte ordering versus network byte ordering is confusing. A simple way to specify Class C network addresses in a manner similar to that for Class B and Class A is needed.

inet6_opt(3SOCKET)

NAME	inet6_opt – Option manipulation mechanism
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library...] #include <netinet/in.h> int inet_6_opt_init(void *extbuf, socklen_t extlen); int inet6_opt_append(void *extbuf, socklen_t extlen, int offset, uint8_t type, socklen_t len, uint_t align, void **databufp); int inet_6_opt_finish(void *extbuf, socklen_t extlen, int offset); int inet6_opt_set_val(void *databuf, int offset, void *val, socklen_t vallen); int inet6_opt_next(void *extbuf, socklen_t extlen, int offset, uint8_t *typep, socklen_t *lenp, void **databufp); int inet6_opt_find(void *extbuf, socklen_t extlen, int offset, uint8_t type, socklen_t *lenp, void **databufp); int inet6_opt_get_val(void *databuf, int offset, void *val, socklen_t *vallen);</pre>
DESCRIPTION	<p>The <code>inet6_opt</code> functions enable users to manipulate options without having to know the structure of the option header.</p> <p>The <code>inet6_opt_init()</code> function returns the number of bytes needed for the empty extension header, that is, without any options. If <code>extbuf</code> is not <code>NULL</code>, it also initializes the extension header to the correct length field. If the <code>extlen</code> value is not a positive (or non-zero) multiple of 8, the function fails and returns <code>-1</code>.</p> <p>The <code>inet6_opt_append()</code> function returns the updated total length while adding an option with length <code>len</code> and alignment <code>align</code>. If <code>extbuf</code> is not <code>NULL</code>, then, in addition to returning the length, the function inserts any needed Pad option, initializes the option (setting the type and length fields) and returns a pointer to the location for the option content in <code>databufp</code>. If the option does not fit in the extension header buffer, the function returns <code>-1</code>. <code>type</code> is the 8-bit option type. <code>len</code> is the length of the option data, excluding the option type and option length fields. Once <code>inet6_opt_append()</code> is called, the application can use the <code>databuf</code> directly, or use <code>inet6_opt_set_val()</code> to specify the content of the option. The option type must have a value from 2 to 255, inclusive. (0 and 1 are reserved for the Pad1 and PadN options, respectively.) The option data length must have a value between 0 and 255, inclusive, and is the length of the option data that follows. The align parameter must have a value of 1, 2, 4, or 8. The align value cannot exceed the value of <code>len</code>.</p> <p>The <code>inet6_opt_finish()</code> function returns the updated total length taking into account the final padding of the extension header to make it a multiple of 8 bytes. If <code>extbuf</code> is not <code>NULL</code>, the function also initializes the option by inserting a Pad1 or PadN option of the proper length. If the necessary pad does not fit in the extension header buffer, the function returns <code>-1</code>.</p>

The `inet6_opt_set_val()` function inserts data items of various sizes in the data portion of the option. *val* should point to the data data to be inserted. Offset specifies in which data portion of the option the value should be inserted. The first byte after the option type and length is accessed by specifying an offset of zero.

The `inet6_opt_next()` function parses received option extension headers returning the next option. *extbuf* and *extlen* specify the extension header. Offset should either be zero (for the first option) or the length returned by a previous call to `inet6_opt_next()` or `inet6_opt_find()`, and specifies where to continue scanning the extension buffer. The subsequent option is returned by updating *typep*, *lenp*, and *databufp*. *typep* stores the option type, *lenp* stores the length of the option data (that is, excluding the option type and option length fields), and *databufp* points to the data field of the option.

The `inet6_opt_find()` function is similar to the `inet6_opt_next()` function. However, unlike `inet6_opt_next()`, this function enables the caller to specify the option type to be searched for, instead of returning the next option in the extension header.

The `inet6_opt_get_val()` function extracts data items of various sizes in the portion of the option. *val* should point to the destination for the extracted data. Offset specifies at which point in the option's data portion the value should be extracted. The first byte following the option type and length is accessed by specifying an offset of zero.

RETURN VALUES

The `inet6_opt_init()` function returns the number of bytes needed for the empty extension header. If the *extlen* value is not a positive (or non-zero) multiple of 8, the function fails and returns -1.

The `inet6_opt_append()` function returns the updated total length.

The `inet6_opt_finish()` function returns the updated total length.

The `inet6_opt_set_val()` function returns the offset for the subsequent field.

The `inet6_opt_next()` function returns the updated "previous" length computed by advancing past the option that was returned. When there are no additional options or if the option extension header is malformed, the return value is -1.

The `inet6_opt_find()` function returns the updated "previous" total length. If an option of the specified type is not located, the return value is -1. If the option extension header is malformed, the return value is -1.

The `inet6_opt_get_val()` function returns the offset for the next field (that is, `offset + vallen`) which can be used when extracting option content with multiple fields.

inet6_opt(3SOCKET)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe
Interface Stability	Standard

SEE ALSO RFC 3542– *Advanced Sockets Application Programming Interface (API) for IPv6*, The Internet Society. May 2003

NAME	inet6_rth – Routing header manipulation
SYNOPSIS	<pre>cc [flag ...] file ... -lsocket -lnsl [library] #include <netinet/in.h> socklen_t inet6_rth_space(int type, int segments); void *inet6_rth_init(void *bp, socklen_t bp_len, int type, int segments); int inet6_rth_add(void *bp, const struct in6_addr *addr); int inet6_rth_reverse(const void *in, void *out); int inet6_rth_segments(const void *bp); struct in6_addr *inet6_rth_getaddr(const void *bp, int index);</pre>
DESCRIPTION	<p>The inet6_rth functions enable users to manipulate routing headers without having knowledge of their structure.</p> <p>The inet6_rth_init() function initializes the buffer pointed to by <i>bp</i> to contain a routing header of the specified type and sets <i>ip6r_len</i> based on the segments parameter. <i>bp_len</i> is only used to verify that the buffer is large enough. The <i>ip6r_segleft</i> field is set to zero and inet6_rth_add() increments it. The caller allocates the buffer and its size can be determined by calling inet6_rth_space().</p> <p>The inet6_rth_add() function adds the IPv6 address pointed to by <i>addr</i> to the end of the routing header that is being constructed.</p> <p>The inet6_rth_reverse() function takes a routing header extension header (pointed to by the first argument) and writes a new routing header that sends datagrams along the reverse of that route. The function reverses the order of the addresses and sets the <i>segleft</i> member in the new routing header to the number of segments. Both arguments can point to the same buffer (that is, the reversal can occur in place).</p> <p>The inet6_rth_segments() function returns the number of segments (addresses) contained in the routing header described by <i>bp</i>.</p> <p>The inet6_rth_getaddr() function returns a pointer to the IPv6 address specified by <i>index</i> (which must have a value between 0 and one less than the value returned by inet6_rth_segments() in the routing header described by <i>bp</i>). Applications should first call inet6_rth_segments() to obtain the number of segments in the routing header.</p> <p>The inet6_rth_space() function returns the size but does not allocate the space required for the ancillary data routing header.</p>
ROUTING HEADERS	<p>To receive a routing header, the application must enable the IPV6_RECVRTHDR socket option:</p> <pre>int on = 1; setsockopt (fd, IPPROTO_IPV6, IPV6_RECVRTHDR, &on, sizeof(on));</pre>

inet6_rth(3SOCKET)

Each received routing header is returned as one ancillary data object described by a `cmsghdr` structure with `cmsg_type` set to `IPV6_RTHDR`.

To send a routing header, the application specifies it either as ancillary data in a call to `sendmsg()` or by using `setsockopt()`. For the sending side, this API assumes the number of occurrences of the routing header as described in *RFC-2460*. That is, applications can specify no more than one outgoing routing header.

The application can remove any sticky routing header by calling `setsockopt()` for `IPV6_RTHDR` with a zero option length.

When using ancillary data, a routing header is passed between the application and the kernel as follows: The `cmsg_level` member has a value of `IPPROTO_IPV6` and the `cmsg_type` member has a value of `IPV6_RTHDR`. The contents of the `cmsg_data` member is implementation dependent and should not be accessed directly by the application, but should be accessed using the six `inet6_rth` functions.

The following constant is defined as a result of including the `<netinet/in.h>`:

```
#define IPV6_RTHDR_TYPE_0 0 /* IPv6 Routing header type 0 */
```

ROUTING HEADER OPTION

Source routing in IPv6 is accomplished by specifying a routing header as an extension header. There are a number of different routing headers, but IPv6 currently defines only the Type 0 header. See *RFC-2460*. The Type 0 header supports up to 127 intermediate nodes (limited by the length field in the extension header). With this maximum number of intermediate nodes, a source, and a destination, there are 128 hops.

RETURN VALUES

The `inet6_rth_init()` function returns a pointer to the buffer (bp) upon success.

For the `inet6_rth_add()` function, the `seglft` member of the routing header is updated to account for the new address in the routing header. The function returns 0 upon success and -1 upon failure.

The `inet6_rth_reverse()` function returns 0 upon success or -1 upon an error.

The `inet6_rth_segments()` function returns 0 or greater upon success and -1 upon an error.

The `inet6_rth_getaddr()` function returns NULL upon an error.

The `inet6_rth_space()` function returns the size of the buffer needed for the routing header.

inet_addr(3XNET)

NAME	inet_addr, inet_network, inet_makeaddr, inet_lnaof, inet_netof, inet_ntoa – Internet address manipulation				
SYNOPSIS	<pre>cc [flag ...] file ... -lxnet [library ...] #include <arpa/inet.h> in_addr_t inet_addr(const char *cp); in_addr_t inet_lnaof(struct in_addr in); struct in_addr inet_makeaddr(in_addr_t net, in_addr_t lna); in_addr_t inet_netof(struct in_addr in); in_addr_t inet_network(const char *cp); char *inet_ntoa(struct in_addr in);</pre>				
DESCRIPTION	<p>The <code>inet_addr()</code> function converts the string pointed to by <i>cp</i>, in the Internet standard dot notation, to an integer value suitable for use as an Internet address.</p> <p>The <code>inet_lnaof()</code> function takes an Internet host address specified by <i>in</i> and extracts the local network address part, in host byte order.</p> <p>The <code>inet_makeaddr()</code> function takes the Internet network number specified by <i>net</i> and the local network address specified by <i>lna</i>, both in host byte order, and constructs an Internet address from them.</p> <p>The <code>inet_netof()</code> function takes an Internet host address specified by <i>in</i> and extracts the network number part, in host byte order.</p> <p>The <code>inet_network()</code> function converts the string pointed to by <i>cp</i>, in the Internet standard dot notation, to an integer value suitable for use as an Internet network number.</p> <p>The <code>inet_ntoa()</code> function converts the Internet host address specified by <i>in</i> to a string in the Internet standard dot notation.</p> <p>All Internet addresses are returned in network order (bytes ordered from left to right).</p> <p>Values specified using dot notation take one of the following forms:</p> <table><tr><td>a . b . c . d</td><td>When four parts are specified, each is interpreted as a byte of data and assigned, from left to right, to the four bytes of an Internet address.</td></tr><tr><td>a . b . c</td><td>When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the rightmost two bytes of the network address. This makes the three-part address format convenient for specifying Class B network addresses as 128 . net . host.</td></tr></table>	a . b . c . d	When four parts are specified, each is interpreted as a byte of data and assigned, from left to right, to the four bytes of an Internet address.	a . b . c	When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the rightmost two bytes of the network address. This makes the three-part address format convenient for specifying Class B network addresses as 128 . net . host.
a . b . c . d	When four parts are specified, each is interpreted as a byte of data and assigned, from left to right, to the four bytes of an Internet address.				
a . b . c	When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the rightmost two bytes of the network address. This makes the three-part address format convenient for specifying Class B network addresses as 128 . net . host.				

- a . b When a two-part address is supplied, the last part is interpreted as a 24-bit quantity and placed in the rightmost three bytes of the network address. This makes the two-part address format convenient for specifying Class A network addresses as *net . host*.
- a When only one part is given, the value is stored directly in the network address without any byte rearrangement.

All numbers supplied as parts in dot notation may be decimal, octal, or hexadecimal, that is, a leading 0x or 0X implies hexadecimal, as specified in the *ISO C* standard; otherwise, a leading 0 implies octal; otherwise, the number is interpreted as decimal.

USAGE The return value of `inet_ntoa()` may point to static data that may be overwritten by subsequent calls to `inet_ntoa()`.

RETURN VALUES Upon successful completion, `inet_addr()` returns the Internet address. Otherwise, it returns `(in_addr_t)(-1)`.

Upon successful completion, `inet_network()` returns the converted Internet network number. Otherwise, it returns `(in_addr_t)(-1)`.

The `inet_makeaddr()` function returns the constructed Internet address.

The `inet_lnaof()` function returns the local network address part.

The `inet_netof()` function returns the network number.

The `inet_ntoa()` function returns a pointer to the network address in Internet-standard dot notation.

ERRORS No errors are defined.

inet_ntop(3XNET)

NAME	inet_ntop, inet_pton – convert IPv4 and IPv6 addresses between binary and text form
SYNOPSIS	<pre>cc [flag ...] file ... -lxnet [library ...] #include <arpa/inet.h> const char *inet_ntop(int af, const void *restrict src, char *restrict dst, socklen_t size); int inet_pton(int af, const char *restrict src, void *restrict dst);</pre>
DESCRIPTION	<p>The <code>inet_ntop()</code> function converts a numeric address into a text string suitable for presentation. The <code>af</code> argument specifies the family of the address. This can be <code>AF_INET</code> or <code>AF_INET6</code>. The <code>src</code> argument points to a buffer holding an IPv4 address if the <code>af</code> argument is <code>AF_INET</code>, or an IPv6 address if the <code>af</code> argument is <code>AF_INET6</code>. The <code>dst</code> argument points to a buffer where the function stores the resulting text string; it cannot be <code>NULL</code>. The <code>size</code> argument specifies the size of this buffer, which must be large enough to hold the text string (<code>INET_ADDRSTRLEN</code> characters for IPv4, <code>INET6_ADDRSTRLEN</code> characters for IPv6).</p> <p>The <code>inet_pton()</code> function converts an address in its standard text presentation form into its numeric binary form. The <code>af</code> argument specifies the family of the address. The <code>AF_INET</code> and <code>AF_INET6</code> address families are supported. The <code>src</code> argument points to the string being passed in. The <code>dst</code> argument points to a buffer into which the function stores the numeric address; this must be large enough to hold the numeric address (32 bits for <code>AF_INET</code>, 128 bits for <code>AF_INET6</code>).</p> <p>If the <code>af</code> argument of <code>inet_pton()</code> is <code>AF_INET</code>, the <code>src</code> string is in the standard IPv4 dotted-decimal form:</p> <pre>ddd.ddd.ddd.ddd</pre> <p>where "ddd" is a one to three digit decimal number between 0 and 255 (see inet_addr(3XNET)). The <code>inet_pton()</code> function does not accept other formats (such as the octal numbers, hexadecimal numbers, and fewer than four numbers that <code>inet_addr()</code> accepts).</p> <p>If the <code>af</code> argument of <code>inet_pton()</code> is <code>AF_INET6</code>, the <code>src</code> string is in one of the following standard IPv6 text forms:</p> <ol style="list-style-type: none">1. The preferred form is "x:x:x:x:x:x:x:x", where the 'x's are the hexadecimal values of the eight 16-bit pieces of the address. Leading zeros in individual fields can be omitted, but there must be at least one numeral in every field.2. A string of contiguous zero fields in the preferred form can be shown as "::". The "::" can only appear once in an address. Unspecified addresses ("0:0:0:0:0:0:0:0") can be represented simply as "::".3. A third form that is sometimes more convenient when dealing with a mixed environment of IPv4 and IPv6 nodes is "x:x:x:x:x:x.d.d.d.d", where the 'x's are the hexadecimal values of the six high-order 16-bit pieces of the address, and the 'd's are the decimal values of the four low-order 8-bit pieces of the address (standard IPv4 representation).

A more extensive description of the standard representations of IPv6 addresses can be found in RFC 2373.

RETURN VALUES The `inet_ntop()` function returns a pointer to the buffer containing the text string if the conversion succeeds. Otherwise it returns `NULL` and sets `errno` to indicate the error.

The `inet_pton()` function returns 1 if the conversion succeeds, with the address pointed to by `dst` in network byte order. It returns 0 if the input is not a valid IPv4 dotted-decimal string or a valid IPv6 address string. It returns -1 and sets `errno` to `EAFNOSUPPORT` if the `af` argument is unknown.

ERRORS The `inet_ntop()` and `inet_pton()` functions will fail if:

`EAFNOSUPPORT` The `af` argument is invalid.

`ENOSPC` The size of the `inet_ntop()` result buffer is inadequate.

ldap(3LDAP)

NAME	ldap – Lightweight Directory Access Protocol package
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h></pre>
DESCRIPTION	<p>The Lightweight Directory Access Protocol (“LDAP”) package (SUNWlldap) includes various command line LDAP clients and a LDAP client library to provide programmatic access to the LDAP protocol. This man page gives an overview of the LDAP client library functions.</p> <p>An application might use the LDAP client library functions as follows. The application would initialize a LDAP session with a LDAP server by calling <code>ldap_init(3LDAP)</code>. Next, it authenticates to the LDAP server by calling <code>ldap_sasl_bind(3LDAP)</code> and friends. It may perform some LDAP operations and obtain results by calling <code>ldap_search(3LDAP)</code> and friends. To parse the results returned from these functions, it calls <code>ldap_parse_result(3LDAP)</code>, <code>ldap_next_entry(3LDAP)</code>, and <code>ldap_first_entry(3LDAP)</code> and others. It closes the LDAP session by calling <code>ldap_unbind(3LDAP)</code>.</p> <p>LDAP operations can be either synchronous or asynchronous. By convention, the names of the synchronous functions end with “_s.” For example, a synchronous binding to the LDAP server can be performed by calling <code>ldap_sasl_bind_s(3LDAP)</code>. Complete an asynchronous binding with <code>ldap_sasl_bind(3LDAP)</code>. All synchronous functions return the actual outcome of the operation, either <code>LDAP_SUCCESS</code> or an error code. Asynchronous routines provide an invocation identifier which can be used to obtain the result of a specific operation by passing it to the <code>ldap_result(3LDAP)</code> function.</p>
Initializing a LDAP session	<p>Initializing a LDAP session involves calling the <code>ldap_init(3LDAP)</code> function. However, the call does not actually open a connection to the LDAP server. It merely initializes a LDAP structure that represents the session. The connection is opened when the first operation is attempted. Unlike <code>ldap_init()</code>, <code>ldap_open(3LDAP)</code> attempts to open a connection with the LDAP server. However, the use of <code>ldap_open()</code> is deprecated.</p>
Authenticating to a LDAP server	<p>The <code>ldap_sasl_bind(3LDAP)</code> and <code>ldap_sasl_bind_s(3LDAP)</code> functions provide general and extensible authentication for an LDAP client to a LDAP server. Both use the Simple Authentication Security Layer (SASL). Simplified routines <code>ldap_simple_bind(3LDAP)</code> and <code>ldap_simple_bind_s(3LDAP)</code> use cleartext passwords to bind to the LDAP server. Use of <code>ldap_bind(3LDAP)</code> and <code>ldap_bind_s(3LDAP)</code> is deprecated.</p>
Searching a LDAP directory	<p>Search for an entry in a LDAP directory by calling the <code>ldap_search_ext(3LDAP)</code> or the <code>ldap_search_ext_s(3LDAP)</code> functions. These functions support LDAPv3 server controls, client controls and variable size and time limits as arguments for each search operation. <code>ldap_search(3LDAP)</code> and <code>ldap_search_s(3LDAP)</code> are identical functions but do not support the controls and limits as arguments to the call.</p>

Adding or Deleting an entry	Use <code>ldap_add_ext(3LDAP)</code> and <code>ldap_delete_ext(3LDAP)</code> to add or delete entries in a LDAP directory server. The synchronous counterparts to these functions are <code>ldap_add_ext_s(3LDAP)</code> and <code>ldap_delete_ext_s(3LDAP)</code> . The <code>ldap_add(3LDAP)</code> , <code>ldap_add_s(3LDAP)</code> , <code>ldap_delete(3LDAP)</code> , and <code>ldap_delete_s(3LDAP)</code> provide identical functionality to add and to delete entries, but they do not support LDAP v3 server and client controls.
Modifying Entries	Use <code>ldap_modify_ext(3LDAP)</code> and <code>ldap_modify_ext_s(3LDAP)</code> to modify an existing entry in a LDAP server that supports for LDAPv3 server and client controls. Similarly, use <code>ldap_rename(3LDAP)</code> and <code>ldap_rename_s(3LDAP)</code> to change the name of an LDAP entry. The <code>ldap_modrdn(3LDAP)</code> , <code>ldap_modrdn_s(3LDAP)</code> , <code>ldap_modrdn2(3LDAP)</code> and <code>ldap_modrdn2_s(3LDAP)</code> interfaces are deprecated.
Obtaining Results	Use <code>ldap_result(3LDAP)</code> to obtain the results of a previous asynchronous operation. For all LDAP operations other than search, only one message is returned. For the search operation, a list of result messages can be returned.
Handling Errors and Parsing Results	Use the <code>ldap_parse_result(3LDAP)</code> , <code>ldap_parse_sasl_bind_result(3LDAP)</code> , and the <code>ldap_parse_extended_result(3LDAP)</code> functions to extract required information from results and to handle the returned errors. To convert a numeric error code into a null-terminated character string message describing the error, use <code>ldap_err2string(3LDAP)</code> . The <code>ldap_result2error(3LDAP)</code> and <code>ldap_perror(3LDAP)</code> functions are deprecated. To step through the list of messages in a result returned by <code>ldap_result()</code> , use <code>ldap_first_message(3LDAP)</code> and <code>ldap_next_message(3LDAP)</code> . <code>ldap_count_messages(3LDAP)</code> returns the number of messages contained in the list. You can use <code>ldap_first_entry(3LDAP)</code> and <code>ldap_next_entry(3LDAP)</code> to step through and obtain a list of entries from a list of messages returned by a search result. <code>ldap_count_entries(3LDAP)</code> returns the number of entries contained in a list of messages. Call either <code>ldap_first_attribute(3LDAP)</code> and <code>ldap_next_attribute(3LDAP)</code> to step through a list of attributes associated with an entry. Retrieve the values of a given attribute by calling <code>ldap_get_values(3LDAP)</code> and <code>ldap_get_values_len(3LDAP)</code> . Count the number of values returned by using <code>ldap_count_values(3LDAP)</code> and <code>ldap_count_values_len(3LDAP)</code> . Use the <code>ldap_get_lang_values(3LDAP)</code> and <code>ldap_get_lang_values_len(3LDAP)</code> to return an attribute's values that matches a specified language subtype. The <code>ldap_get_lang_values()</code> function returns an array of an attribute's string values that matches a specified language subtype. To retrieve the binary data from an attribute, call the <code>ldap_get_lang_values_len()</code> function instead.
Uniform Resource Locators (URLS)	You can use the <code>ldap_url(3LDAP)</code> functions to test a URL to verify that it is an LDAP URL, to parse LDAP URLs into their component pieces, to initiate searches directly using an LDAP URL, and to retrieve the URL associated with a DNS domain name or a distinguished name.

ldap(3LDAP)

User Friendly Naming

The `ldap_ufn(3LDAP)` functions implement a user friendly naming scheme by means of LDAP. This scheme allows you to look up entries using fuzzy, untyped names like “mark smith, umich, us”.

Caching

The `ldap_memcache(3LDAP)` functions provide an in-memory client side cache to store search requests. Caching improves performance and reduces network bandwidth when a client makes repeated requests.

Utility Functions

There are also various utility functions. You can use the `ldap_sort(3LDAP)` functions are used to sort the entries and values returned by means of the ldap search functions. The `ldap_friendly(3LDAP)` functions will map from short two letter country codes or other strings to longer “friendlier” names. Use the `ldap_charset(3LDAP)` functions to translate to and from the T.61 character set that is used for many character strings in the LDAP protocol.

Generating Filters

Make calls to `ldap_init_getfilter(3LDAP)` and `ldap_search(3LDAP)` to generate filters to be used in `ldap_search(3LDAP)` and `ldap_search_s(3LDAP)`. `ldap_init_getfilter()` reads `ldapfilter.conf(4)`, the LDAP configuration file, while `ldap_init_getfilter_buf()` reads the configuration information from *buf* of length *buflen*. `ldap_getfilter_free(3LDAP)` frees memory that has been allocated by means of `ldap_init_getfilter()`.

BER Library

The LDAP package includes a set of lightweight Basic Encoding Rules (“BER”) functions. The LDAP library functions use the BER functions to encode and decode LDAP protocol elements through the slightly simplified BER defined by LDAP. They are not normally used directly by an LDAP application program will not normally use the BER functions directly. Instead, these functions provide a `printf()` and `scanf()`-like interface, as well as lower-level access.

LIST OF INTERFACES

<code>ldap_open(3LDAP)</code>	Deprecated. Use <code>ldap_init(3LDAP)</code> .
<code>ldap_init(3LDAP)</code>	Initialize a session with a LDAP server without opening a connection to a server.
<code>ldap_result(3LDAP)</code>	Obtain the result from a previous asynchronous operation.
<code>ldap_abandon(3LDAP)</code>	Abandon or abort an asynchronous operation.
<code>ldap_add(3LDAP)</code>	Asynchronously add an entry
<code>ldap_add_s(3LDAP)</code>	Synchronously add an entry.
<code>ldap_add_ext(3LDAP)</code>	Asynchronously add an entry with support for LDAPv3 controls.
<code>ldap_add_ext_s(3LDAP)</code>	Synchronously add an entry with support for LDAPv3 controls.

ldap(3LDAP)

<code>ldap_bind(3LDAP)</code>	Deprecated. Use <code>ldap_sasl_bind(3LDAP)</code> or <code>ldap_simple_bind(3LDAP)</code> .
<code>ldap_sasl_bind(3LDAP)</code>	Asynchronously bind to the directory using SASL authentication
<code>ldap_sasl_bind_s(3LDAP)</code>	Synchronously bind to the directory using SASL authentication
<code>ldap_bind_s(3LDAP)</code>	Deprecated. Use <code>ldap_sasl_bind_s(3LDAP)</code> or <code>ldap_simple_bind_s(3LDAP)</code> .
<code>ldap_simple_bind(3LDAP)</code>	Asynchronously bind to the directory using simple authentication.
<code>ldap_simple_bind_s(3LDAP)</code>	Synchronously bind to the directory using simple authentication.
<code>ldap_unbind(3LDAP)</code>	Synchronously unbind from the LDAP server, close the connection, and dispose the session handle.
<code>ldap_unbind_ext(3LDAP)</code>	Synchronously unbind from the LDAP server and close the connection. <code>ldap_unbind_ext()</code> allows you to explicitly include both server and client controls in the unbind request.
<code>ldap_set_rebind_proc(3LDAP)</code>	Set callback function for obtaining credentials from a referral.
<code>ldap_memcache_init(3LDAP)</code>	Create the in-memory client side cache.
<code>ldap_memcache_set(3LDAP)</code>	Associate an in-memory cache that has been already created by calling the <code>ldap_memcache_init(3LDAP)</code> function with an LDAP connection handle.
<code>ldap_memcache_get(3LDAP)</code>	Get the cache associated with the specified LDAP structure.
<code>ldap_memcache_flush(3LDAP)</code>	Flushes search requests from the cache.

ldap(3LDAP)

<code>ldap_memcache_destroy(3LDAP)</code>	Frees the specified LDAPMemCache structure pointed to by cache from memory.
<code>ldap_memcache_update(3LDAP)</code>	Checks the cache for items that have expired and removes them.
<code>ldap_compare(3LDAP)</code>	Asynchronous compare with a directory entry.
<code>ldap_compare_s(3LDAP)</code>	Synchronous compare with a directory entry.
<code>ldap_compare_ext(3LDAP)</code>	Asynchronous compare with a directory entry, with support for LDAPv3 controls.
<code>ldap_compare_ext_s(3LDAP)</code>	Synchronous compare with a directory entry, with support for LDAPv3 controls.
<code>ldap_control_free(3LDAP)</code>	Dispose of an LDAP control.
<code>ldap_controls_free(3LDAP)</code>	Dispose of an array of LDAP controls.
<code>ldap_delete(3LDAP)</code>	Asynchronously delete an entry.
<code>ldap_delete_s(3LDAP)</code>	Synchronously delete an entry.
<code>ldap_delete_ext(3LDAP)</code>	Asynchronously delete an entry, with support for LDAPv3 controls.
<code>ldap_delete_ext_s(3LDAP)</code>	Synchronously delete an entry, with support for LDAPv3 controls.
<code>ldap_init_templates(3LDAP)</code>	Read a sequence of templates from a LDAP template configuration file.
<code>ldap_init_templates_buf(3LDAP)</code>	Read a sequence of templates from a buffer.
<code>ldap_free_templates(3LDAP)</code>	Dispose of the templates allocated.
<code>ldap_first_reference(3LDAP)</code>	Step through a list of continuation references from a search result.
<code>ldap_next_reference(3LDAP)</code>	Step through a list of continuation references from a search result.
<code>ldap_count_references(3LDAP)</code>	Count the number of messages in a search result.
<code>ldap_first_message(3LDAP)</code>	Step through a list of messages in a search result.

ldap(3LDAP)

<code>ldap_count_messages(3LDAP)</code>	Count the messages in a list of messages in a search result.
<code>ldap_next_message(3LDAP)</code>	Step through a list of messages in a search result.
<code>ldap_msgtype(3LDAP)</code>	Return the type of LDAP message.
<code>ldap_first_disptmpl(3LDAP)</code>	Get first display template in a list.
<code>ldap_next_disptmpl(3LDAP)</code>	Get next display template in a list.
<code>ldap_oc2template(3LDAP)</code>	Return template appropriate for the objectclass.
<code>ldap_name2template(3LDAP)</code>	Return named template
<code>ldap_tmplattrs(3LDAP)</code>	Return attributes needed by the template.
<code>ldap_first_tmplrow(3LDAP)</code>	Return first row of displayable items in a template.
<code>ldap_next_tmplrow(3LDAP)</code>	Return next row of displayable items in a template.
<code>ldap_first_tmplcol(3LDAP)</code>	Return first column of displayable items in a template.
<code>ldap_next_tmplcol(3LDAP)</code>	Return next column of displayable items in a template.
<code>ldap_entry2text(3LDAP)</code>	Display an entry as text by using a display template.
<code>ldap_entry2text_search(3LDAP)</code>	Search for and display an entry as text by using a display template.
<code>ldap_vals2text(3LDAP)</code>	Display values as text.
<code>ldap_entry2html(3LDAP)</code>	Display an entry as HTML (HyperText Markup Language) by using a display template.
<code>ldap_entry2html_search(3LDAP)</code>	Search for and display an entry as HTML by using a display template.
<code>ldap_vals2html(3LDAP)</code>	Display values as HTML.
<code>ldap_perror(3LDAP)</code>	Deprecated. Use <code>ldap_parse_result(3LDAP)</code> .
<code>ldap_result2error(3LDAP)</code>	Deprecated. Use <code>ldap_parse_result(3LDAP)</code> .

ldap(3LDAP)

<code>ldap_err2string(3LDAP)</code>	Convert LDAP error indication to a string.
<code>ldap_first_attribute(3LDAP)</code>	Return first attribute name in an entry.
<code>ldap_next_attribute(3LDAP)</code>	Return next attribute name in an entry.
<code>ldap_first_entry(3LDAP)</code>	Return first entry in a chain of search results.
<code>ldap_next_entry(3LDAP)</code>	Return next entry in a chain of search results.
<code>ldap_count_entries(3LDAP)</code>	Return number of entries in a search result.
<code>ldap_friendly_name(3LDAP)</code>	Map from unfriendly to friendly names.
<code>ldap_free_friendlymap(3LDAP)</code>	Free resources used by <code>ldap_friendly(3LDAP)</code> .
<code>ldap_get_dn(3LDAP)</code>	Extract the DN from an entry.
<code>ldap_explode_dn(3LDAP)</code>	Convert a DN into its component parts.
<code>ldap_explode_dns(3LDAP)</code>	Convert a DNS-style DN into its component parts (experimental).
<code>ldap_is_dns_dn(3LDAP)</code>	Check to see if a DN is a DNS-style DN (experimental).
<code>ldap_dns_to_dn(3LDAP)</code>	Convert a DNS domain name into an X.500 distinguished name.
<code>ldap_dn2ufn(3LDAP)</code>	Convert a DN into user friendly form.
<code>ldap_get_values(3LDAP)</code>	Return an attribute's values.
<code>ldap_get_values_len(3LDAP)</code>	Return an attribute's values with lengths.
<code>ldap_value_free(3LDAP)</code>	Free memory allocated by <code>ldap_get_values(3LDAP)</code> .
<code>ldap_value_free_len(3LDAP)</code>	Free memory allocated by <code>ldap_get_values_len(3LDAP)</code> .
<code>ldap_count_values(3LDAP)</code>	Return number of values.
<code>ldap_count_values_len(3LDAP)</code>	Return number of values.

ldap(3LDAP)

<code>ldap_init_getfilter(3LDAP)</code>	Initialize getfilter functions from a file.
<code>ldap_init_getfilter_buf(3LDAP)</code>	Initialize getfilter functions from a buffer.
<code>ldap_getfilter_free(3LDAP)</code>	Free resources allocated by <code>ldap_init_getfilter(3LDAP)</code> .
<code>ldap_getfirstfilter(3LDAP)</code>	Return first search filter.
<code>ldap_getnextfilter(3LDAP)</code>	Return next search filter.
<code>ldap_build_filter(3LDAP)</code>	Construct an LDAP search filter from a pattern.
<code>ldap_setfilteraffixes(3LDAP)</code>	Set prefix and suffix for search filters.
<code>ldap_modify(3LDAP)</code>	Asynchronously modify an entry.
<code>ldap_modify_s(3LDAP)</code>	Synchronously modify an entry.
<code>ldap_modify_ext(3LDAP)</code>	Asynchronously modify an entry, return value, and place message.
<code>ldap_modify_ext_s(3LDAP)</code>	Synchronously modify an entry, return value, and place message.
<code>ldap_mods_free(3LDAP)</code>	Free array of pointers to mod structures used by <code>ldap_modify(3LDAP)</code> .
<code>ldap_modrdn2(3LDAP)</code>	Deprecated. Use <code>ldap_rename(3LDAP)</code> instead.
<code>ldap_modrdn2_s(3LDAP)</code>	Deprecated. Use <code>ldap_rename_s(3LDAP)</code> instead.
<code>ldap_modrdn(3LDAP)</code>	Deprecated. Use <code>ldap_rename(3LDAP)</code> instead.
<code>ldap_modrdn_s(3LDAP)</code>	Deprecated. Use <code>ldap_rename_s(3LDAP)</code> instead.
<code>ldap_rename(3LDAP)</code>	Asynchronously modify the name of an LDAP entry.
<code>ldap_rename_s(3LDAP)</code>	Synchronously modify the name of an LDAP entry.
<code>ldap_msgfree(3LDAP)</code>	Free result messages.
<code>ldap_parse_result(3LDAP)</code>	Search for a message to parse.
<code>ldap_parse_extended_result(3LDAP)</code>	Search for a message to parse.

ldap(3LDAP)

<code>ldap_parse_sasl_bind_result(3LDAP)</code>	Search for a message to parse.
<code>ldap_search(3LDAP)</code>	Asynchronously search the directory.
<code>ldap_search_s(3LDAP)</code>	Synchronously search the directory.
<code>ldap_search_ext(3LDAP)</code>	Asynchronously search the directory with support for LDAPv3 controls.
<code>ldap_search_ext_s(3LDAP)</code>	Synchronously search the directory with support for LDAPv3 controls.
<code>ldap_search_st(3LDAP)</code>	Synchronously search the directory with support for a local timeout value.
<code>ldap_ufn_search_s(3LDAP)</code>	User friendly search the directory.
<code>ldap_ufn_search_c(3LDAP)</code>	User friendly search the directory with cancel.
<code>ldap_ufn_search_ct(3LDAP)</code>	User friendly search the directory with cancel and timeout.
<code>ldap_ufn_setfilter(3LDAP)</code>	Set filter file used by <code>ldap_ufn(3LDAP)</code> functions.
<code>ldap_ufn_setprefix(3LDAP)</code>	Set prefix used by <code>ldap_ufn(3LDAP)</code> functions.
<code>ldap_ufn_timeout(3LDAP)</code>	Set timeout used by <code>ldap_ufn(3LDAP)</code> functions.
<code>ldap_is_ldap_url(3LDAP)</code>	Check a URL string to see if it is an LDAP URL.
<code>ldap_url_parse(3LDAP)</code>	Break up an LDAP URL string into its components.
<code>ldap_free_urldesc(3LDAP)</code>	Free an LDAP URL structure.
<code>ldap_url_search(3LDAP)</code>	Asynchronously search by using an LDAP URL.
<code>ldap_url_search_s(3LDAP)</code>	Synchronously search by using an LDAP URL.
<code>ldap_url_search_st(3LDAP)</code>	Asynchronously search by using an LDAP URL, with support for a local timeout value.
<code>ldap_dns_to_url(3LDAP)</code>	Locate the LDAP URL associated with a DNS domain name.

ldap(3LDAP)

<code>ldap_dn_to_url(3LDAP)</code>	Locate the LDAP URL associated with a distinguished name.
<code>ldap_init_searchprefs(3LDAP)</code>	Initialize searchprefs functions from a file.
<code>ldap_init_searchprefs_buf(3LDAP)</code>	Initialize searchprefs functions from a buffer.
<code>ldap_free_searchprefs(3LDAP)</code>	Free memory allocated by searchprefs functions.
<code>ldap_first_searchobj(3LDAP)</code>	Return first searchpref object.
<code>ldap_next_searchobj(3LDAP)</code>	Return next searchpref object.
<code>ldap_sort_entries(3LDAP)</code>	Sort a list of search results.
<code>ldap_sort_values(3LDAP)</code>	Sort a list of attribute values.
<code>ldap_sort_strcasecmp(3LDAP)</code>	Case insensitive string comparison.
<code>ldap_set_string_translators(3LDAP)</code>	Set character set translation functions used by LDAP library.
<code>ldap_translate_from_t61(3LDAP)</code>	Translate from the T.61 character set to another character set.
<code>ldap_translate_to_t61(3LDAP)</code>	Translate to the T.61 character set from another character set.
<code>ldap_enable_translation(3LDAP)</code>	Enable or disable character translation for an LDAP entry result.
<code>ldap_version(3LDAP)</code>	Get version information about the LDAP SDK for C.
<code>ldap_get_lang_values(3LDAP)</code>	Return an attribute's value that matches a specified language subtype.
<code>ldap_get_lang_values_len(3LDAP)</code>	Return an attribute's value that matches a specified language subtype along with lengths.
<code>ldap_get_entry_controls(3LDAP)</code>	Get the LDAP controls included with a directory entry in a set of search results.
<code>ldap_get_option(3LDAP)</code>	Get session preferences in an LDAP structure.
<code>ldap_set_option(3LDAP)</code>	Set session preferences in an LDAP structure.

ldap(3LDAP)

[ldap_memfree\(3LDAP\)](#)

Free memory allocated by LDAP API functions.

ATTRIBUTES

See [attributes\(5\)](#) for a description of the following attributes:

NAME	ldap_abandon – abandon an LDAP operation in progress						
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_abandon(LDAP *ld, int msgid);</pre>						
DESCRIPTION	<p>The <code>ldap_abandon()</code> function is used to abandon or cancel an LDAP operation in progress. The <code>msgid</code> passed should be the message id of an outstanding LDAP operation, as returned by <code>ldap_search(3LDAP)</code>, <code>ldap_modify(3LDAP)</code>, etc.</p> <p><code>ldap_abandon()</code> checks to see if the result of the operation has already come in. If it has, it deletes it from the queue of pending messages. If not, it sends an LDAP abandon operation to the the LDAP server.</p> <p>The caller can expect that the result of an abandoned operation will not be returned from a future call to <code>ldap_result(3LDAP)</code>.</p>						
ERRORS	<code>ldap_abandon()</code> returns 0 if successful or -1 otherwise and setting <code>ld_errno</code> appropriately. See <code>ldap_error(3LDAP)</code> for details.						
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsl (32-bit) SUNWcslx (64-bit)</td> </tr> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)	Interface Stability	Evolving

ldap_add(3LDAP)

NAME	ldap_add, ldap_add_s, ldap_add_ext, ldap_add_ext_s – perform an LDAP add operation
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_add(LDAP *ld, char *dn, LDAPMod *attrs[]); int ldap_add_s(LDAP *ld, char *dn, LDAPMod *attrs[]); int ldap_add_ext(LDAP *ld, char *dn, LDAPMod **attrs, LDAPControl **serverctrls, int *msgidp); int ldap_add_ext_s(LDAP *ld, char *dn, LDAPMod **attrs, LDAPControl **serverctrls, LDAPControl **clientctrls);</pre>
DESCRIPTION	<p>The <code>ldap_add_s()</code> function is used to perform an LDAP add operation. It takes <i>dn</i>, the DN of the entry to add, and <i>attrs</i>, a null-terminated array of the entry's attributes. The LDAPMod structure is used to represent attributes, with the <i>mod_type</i> and <i>mod_values</i> fields being used as described under <code>ldap_modify(3LDAP)</code>, and the <i>ldap_op</i> field being used only if you need to specify the LDAP_MOD_BVALUES option. Otherwise, it should be set to zero.</p> <p>Note that all entries except that specified by the last component in the given DN must already exist. <code>ldap_add_s()</code> returns an LDAP error code indicating success or failure of the operation. See <code>ldap_error(3LDAP)</code> for more details.</p> <p>The <code>ldap_add()</code> function works just like <code>ldap_add_s()</code>, but it is asynchronous. It returns the message id of the request it initiated. The result of this operation can be obtained by calling <code>ldap_result(3LDAP)</code>.</p> <p>The <code>ldap_add_ext()</code> function initiates an asynchronous add operation and returns LDAP_SUCCESS if the request was successfully sent to the server, or else it returns a LDAP error code if not (see <code>ldap_error(3LDAP)</code>). If successful, <code>ldap_add_ext()</code> places the message id of <i>msgidp</i>. A subsequent call to <code>ldap_result()</code>, can be used to obtain the result of the add request.</p> <p>The <code>ldap_add_ext_s()</code> function initiates a synchronous add operation and returns the result of the operation itself.</p>
ERRORS	<code>ldap_add()</code> returns -1 in case of error initiating the request, and will set the <i>ld_errno</i> field in the <i>ld</i> parameter to indicate the error. <code>ldap_add_s()</code> will return an LDAP error code directly.
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:

ldap_ber_free(3LDAP)

NAME ldap_ber_free – free a BerElement structure from memory

SYNOPSIS cc -flag ... file ...-lldap [-library ...]
#include <ldap.h>

```
void ldap_ber_free(BerElement *ber, int freebuf);
```

DESCRIPTION You can make a call to the ldap_ber_free() function to free BerElement structures allocated by ldap_first_attribute() and by ldap_next_attribute() function calls. When freeing structures allocated by these functions, specify 0 for the freebuf argument. The ldap_first_attribute() and by ldap_next_attribute() functions do not allocate the extra buffer in the BerElement structure.

For example, to retrieve attributes from a search result entry, you need to call the ldap_first_attribute() function. A call to this function allocates a BerElement structure, which is used to help track the current attribute. When you are done working with the attributes, this structure should be freed from memory, if it still exists.

This function is deprecated . Use the ber_free() function instead.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit)
	SUNWcslx (64-bit)
Interface Stability	Obsolete

SEE ALSO ber_free(3LDAP), ldap_first_attribute(3LDAP), ldap_next_attribute(3LDAP), attributes(5)

ldap_bind(3LDAP)

NAME	ldap_bind, ldap_bind_s, ldap_sasl_bind, ldap_sasl_bind_s, ldap_simple_bind, ldap_simple_bind_s, ldap_unbind, ldap_unbind_s, ldap_unbind_ext, ldap_set_rebind_proc, ldap_sasl_interactive_bind_s – LDAP bind functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_bind(LDAP *ld, char *who, char *cred, int method); int ldap_bind_s(LDAP *ld, char *who, char *cred, int method); int ldap_simple_bind(LDAP *ld, char *who, char *passwd); int ldap_simple_bind_s(LDAP *ld, char *who, char *passwd); int ldap_unbind(LDAP *ld); int ldap_unbind_s(LDAP *ld); int ldap_unbind_ext(LDAP *ld, LDAPControl **serverctrls, LDAPControl **clientctrls); void ldap_set_rebind_proc(LDAP *ld, int (*rebindproc)); int ldap_sasl_bind(LDAP *ld, char *dn, char *mechanism, struct berval **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_sasl_bind_s(LDAP *ld, char *dn, char *mechanism, struct berval *cred, LDAPControl **serverctrls, LDAPControl **clientctrls); int ldap_sasl_interactive_bind_s(LDAP *ld, char *dn, char *saslMechanism, LDAPControl **sctrl, LDAPControl **cctrl, LDAPControl **unsigned_flags, LDAP_SASL_INTERACT_PROC *callback, void *defaults);</pre>
DESCRIPTION	<p>These functions provide various interfaces to the LDAP bind operation. After a connection is made to an LDAP server, the <code>ldap_bind()</code> function returns the message ID of the request initiated. The <code>ldap_bind_s()</code> function returns an LDAP error code.</p>
Simple Authentication	<p>The simplest form of the bind call is <code>ldap_simple_bind_s()</code>. The function takes the DN (Distinguished Name) of the <code>dn</code> parameter and the userPassword associated with the entry in <code>passwd</code> to return an LDAP error code. See <code>ldap_error(3LDAP)</code>.</p> <p>The <code>ldap_simple_bind()</code> call is asynchronous. The function takes the same parameters as <code>ldap_simple_bind_s()</code> but initiates the bind operation and returns the message ID of the request sent. The result of the operation can be obtained by a subsequent call to <code>ldap_result(3LDAP)</code>.</p>
General Authentication	<p>The <code>ldap_bind()</code> and <code>ldap_bind_s()</code> functions are used to select the authentication method at runtime. Both functions take an extra <code>method</code> parameter to set the authentication method. For simple authentication, the <code>method</code> parameter is set to <code>LDAP_AUTH_SIMPLE</code>. The <code>ldap_bind()</code> function returns the message id of the request initiated. The <code>ldap_bind_s()</code> function returns an LDAP error code.</p>

ldap_bind(3LDAP)

SASL Authentication

The `ldap_sasl_bind()` and `ldap_sasl_bind_s()` functions are used for general and extensible authentication over LDAP through the use of the Simple Authentication Security Layer. The routines both take the DN to bind as the authentication method. A dotted-string representation of an OID identifies the method, and the `berval` structure holds the credentials. The special constant value `LDAP_SASL_SIMPLE` ("") can be passed to request simple authentication. Otherwise, the `ldap_simple_bind()` function or the `ldap_simple_bind_s()` function can be used.

The `ldap_sasl_interactive_bind_s()` helper function takes its data and performs the necessary `ldap_sasl_bind()` and associated SASL library authentication sequencing with the LDAP server that uses the provided connection (*ld*).

Upon a successful bind, the `ldap_sasl_bind()` function will, if negotiated by the SASL interface, install the necessary internal `libldap` plumbing to enable SASL integrity and privacy (over the wire encryption) with the LDAP server.

The `LDAP_SASL_INTERACTIVE` option flag is passed to the `libldap` API through the `flags` argument of the API. The flag tells the API to use the SASL interactive mode and to have the API request SASL authentication data through the `LDAP_SASL_INTERACTIVE_PROC` callback as needed. The callback provided is in the form:

```
typedef int (LDAP_SASL_INTERACT_PROC)
    (LDAP *ld, unsigned flags, void* defaults, void *interact);
```

The user-provided SASL callback is passed to the current LDAP connection pointer, the current flags field, an optional pointer to user-defined data, and the list of `sasl_interact_t` authentication values requested by `libsasl(3LIB)` to complete authentication.

The user-defined callback collects and returns the authentication information in the `sasl_interact_t` array according to `libsasl` rules. The authentication information can include user IDs, passwords, realms, or other information defined by SASL. The SASL library uses this data during sequencing to complete authentication.

Unbinding

The `ldap_unbind()` call is used to unbind from a directory, to terminate the current association, and to free the resources contained in the *ld* structure. Once the function is called, the connection to the LDAP server is closed and the *ld* structure is invalid. The `ldap_unbind_s()` and `ldap_unbind()` calls are identical and synchronous in nature.

The `ldap_unbind_ext()` function is used to unbind from a directory, to terminate the current association, and to free the resources contained in the LDAP structure. Unlike `ldap_unbind()` and `ldap_unbind_s()`, both server and client controls can be explicitly included with `ldap_unbind_ext()` requests. No server response is made to an unbind request and responses should not be expected from server controls included with unbind requests.

Rebinding While Following Referral

The `ldap_set_rebind_proc()` call is used to set a function called back to obtain bind credentials. The credentials are used when a new server is contacted after an LDAP referral. If `ldap_set_rebind_proc()` is never called, or if it is called with a NULL *rebindproc* parameter, an unauthenticated simple LDAP bind is always done when chasing referrals.

The `rebindproc()` function is declared as shown below:

```
int rebindproc(LDAP *ld, char **whop, char **credp,
              int *methodp, int freeit);
```

The LDAP library first calls the `rebindproc()` to obtain the referral bind credentials. The *freeit* parameter is zero. The *whop*, *credp*, and *methodp* parameters should be set as appropriate. If `rebindproc()` returns `LDAP_SUCCESS`, referral processing continues. The `rebindproc()` is called a second time with a non-zero *freeit* value to give the application a chance to free any memory allocated in the previous call.

If anything but `LDAP_SUCCESS` is returned by the first call to `rebindproc()`, referral processing is stopped and the error code is returned for the original LDAP operation.

RETURN VALUES

Make a call to `ldap_result(3LDAP)` to obtain the result of a bind operation.

ERRORS

Asynchronous functions will return `-1` in case of error. See `ldap_error(3LDAP)` for more information on error codes returned. If no credentials are returned, the result parameter is set to `NULL`.

ldap_charset(3LDAP)

NAME	ldap_charset, ldap_set_string_translators, ldap_t61_to_8859, ldap_8859_to_t61, ldap_translate_from_t61, ldap_translate_to_t61, ldap_enable_translation – LDAP character set translation functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> void ldap_set_string_translators(LDAP *ld, BERTranslateProc encode_proc, BERTranslateProc decode_proc); typedef int (*BERTranslateProc)(char **bufp, unsigned long *buflenp, int free_input); int ldap_t61_to_8859(char **bufp, unsigned long *buflenp, int free_input); int ldap_8859_to_t61(char **bufp, unsigned long *buflenp, int free_input); int ldap_translate_from_t61(LDAP *ld, char **bufp, unsigned long *lenp, int free_input); int ldap_translate_to_t61(LDAP *ld, char **bufp, unsigned long *lenp, int free_input); void ldap_enable_translation(LDAP *ld, LDAPMessage *entry, int enable);</pre>
DESCRIPTION	<p>These functions are used to enable translation of character strings used in the LDAP library to and from the T.61 character set used in the LDAP protocol. These functions are only available if the LDAP and LBER libraries are compiled with STR_TRANSLATION defined. It is also possible to turn on character translation by default so that all LDAP library callers will experience translation; see the LDAP Make-common source file for details.</p> <p>ldap_set_string_translators() sets the translation functions that will be used by the LDAP library. They are not actually used until the <i>ld_ldapoptions</i> field of the LDAP structure is set to include the LBER_TRANSLATE_STRINGS option.</p> <p>ldap_t61_to_8859() and ldap_8859_to_t61() are translation functions for converting between T.61 characters and ISO-8859 characters. The specific 8859 character set used is determined at compile time.</p> <p>ldap_translate_from_t61() is used to translate a string of characters from the T.61 character set to a different character set. The actual translation is done using the <i>decode_proc</i> that was passed to a previous call to <i>ldap_set_string_translators</i> (). On entry, <i>*bufp</i> should point to the start of the T.61 characters to be translated and <i>*lenp</i> should contain the number of bytes to translate. If <i>free_input</i> is non-zero, the input buffer will be freed if translation is a success. If the translation is a success, LDAP_SUCCESS will be returned, <i>*bufp</i> will point to a newly malloc'd buffer that contains the translated characters, and <i>*lenp</i> will contain the length of the result. If translation fails, an LDAP error code will be returned.</p>

ldap_charset(3LDAP)

`ldap_translate_to_t61()` is used to translate a string of characters to the T.61 character set from a different character set. The actual translation is done using the *encode_proc* that was passed to a previous call to `ldap_set_string_translators()`. This function is called just like `ldap_translate_from_t61()`.

`ldap_enable_translation()` is used to turn on or off string translation for the LDAP entry *entry* (typically obtained by calling `ldap_first_entry()` or `ldap_next_entry()` after a successful LDAP search operation). If *enable* is zero, translation is disabled; if non-zero, translation is enabled. This function is useful if you need to ensure that a particular attribute is not translated when it is extracted using `ldap_get_values()` or `ldap_get_values_len()`. For example, you would not want to translate a binary attributes such as `jpegPhoto`.

ATTRIBUTES See `attributes(5)` for a description of the following attributes:

ldap_compare(3LDAP)

NAME	ldap_compare, ldap_compare_s, ldap_compare_ext, ldap_compare_ext_s – LDAP compare operation				
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_compare(LDAP *ld, char *dn, char *attr, char *value); int ldap_compare_s(LDAP *ld, char *dn, char *attr, char *value); int ldap_compare_ext(LDAP *ld, char *dn, char *attr, struct berval *bvalue, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_compare_ext_s(LDAP *ld, char *dn, char *attr, struct berval *bvalue, LDAPControl **serverctrls, LDAPControl **clientctrls);</pre>				
DESCRIPTION	<p>The <code>ldap_compare_s()</code> function is used to perform an LDAP compare operation synchronously. It takes <code>dn</code>, the DN of the entry upon which to perform the compare, and <code>attr</code> and <code>value</code>, the attribute type and value to compare to those found in the entry. It returns an LDAP error code, which will be <code>LDAP_COMPARE_TRUE</code> if the entry contains the attribute value and <code>LDAP_COMPARE_FALSE</code> if it does not. Otherwise, some error code is returned.</p> <p>The <code>ldap_compare()</code> function is used to perform an LDAP compare operation asynchronously. It takes the same parameters as <code>ldap_compare_s()</code>, but returns the message id of the request it initiated. The result of the compare can be obtained by a subsequent call to <code>ldap_result(3LDAP)</code>.</p> <p>The <code>ldap_compare_ext()</code> function initiates an asynchronous compare operation and returns <code>LDAP_SUCCESS</code> if the request was successfully sent to the server, or else it returns a LDAP error code if not (see <code>ldap_error(3LDAP)</code>). If successful, <code>ldap_compare_ext()</code> places the message id of the request in <code>*msgidp</code>. A subsequent call to <code>ldap_result()</code>, can be used to obtain the result of the add request.</p> <p>The <code>ldap_compare_ext_s()</code> function initiates a synchronous compare operation and as such returns the result of the operation itself.</p>				
ERRORS	<code>ldap_compare_s()</code> returns an LDAP error code which can be interpreted by calling one of <code>ldap_perror(3LDAP)</code> and friends. <code>ldap_compare()</code> returns -1 if something went wrong initiating the request. It returns the non-negative message id of the request if it was successful.				
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:

BUGS There is no way to compare binary values using `ldap_compare()`.

ldap_control_free(3LDAP)

NAME ldap_control_free, ldap_controls_free – LDAP control disposal

SYNOPSIS

```
cc [ flag... ] file... -lldap [ library... ]

#include <lber.h>
#include <ldap.h>

void ldap_control_free(LDAPControl *ctrl);
void ldap_controls_free(LDAPControl *ctrls);
```

DESCRIPTION ldap_controls_free() and ldap_control_free() are routines which can be used to dispose of a single control or an array of controls allocated by other LDAP APIs.

RETURN VALUES None.

ERRORS No errors are defined for these functions.

ATTRIBUTES See attributes(5) for a description of the following attributes:

ldap_disptmpl(3LDAP)

NAME	ldap_disptmpl, ldap_init_templates, ldap_init_templates_buf, ldap_free_templates, ldap_first_disptmpl, ldap_next_disptmpl, ldap_oc2template, ldap_name2template, ldap_tmplattrs, ldap_first_tmplrow, ldap_next_tmplrow, ldap_first_tmplcol, ldap_next_tmplcol – LDAP display template functions
SYNOPSIS	<pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> int ldap_init_templates(char *file, struct ldap_disptmpl **tmplist); int ldap_init_templates_buf(char *buf, unsigned long len, struct ldap_disptmpl **tmplist); void ldap_free_templates(struct ldap_disptmpl *tmplist); struct ldap_disptmpl *ldap_first_disptmpl(struct ldap_disptmpl *tmplist); struct ldap_disptmpl *ldap_next_disptmpl(struct ldap_disptmpl *tmplist, struct ldap_disptmpl *tmpl); struct ldap_disptmpl *ldap_oc2template(char **oclist, struct ldap_disptmpl *tmplist); struct ldap_disptmpl *ldap_name2template(char *name, struct ldap_disptmpl *tmplist); char **ldap_tmplattrs(struct ldap_disptmpl *tmpl, char **includeatrs, int exclude;, unsigned long syntaxmask); struct ldap_tmplitem *ldap_first_tmplrow(struct ldap_disptmpl *tmpl); struct ldap_tmplitem *ldap_next_tmplrow(struct ldap_disptmpl *tmpl, struct ldap_tmplitem *row); struct ldap_tmplitem *ldap_first_tmplcol(struct ldap_disptmpl *tmpl, struct ldap_tmplitem *row, struct ldap_tmplitem *col); struct ldap_tmplitem *ldap_next_tmplcol(struct ldap_disptmpl *tmpl, struct ldap_tmplitem *row, struct ldap_tmplitem *col);</pre>
DESCRIPTION	<p>These functions provide a standard way to access LDAP entry display templates. Entry display templates provide a standard way for LDAP applications to display directory entries. The general idea is that it is possible to map the list of object class values present in an entry to an appropriate display template. Display templates are defined in a configuration file. See <code>ldaptemplates.conf(4)</code>. Each display template contains a pre-determined list of items, where each item generally corresponds to an attribute to be displayed. The items contain information and flags that the caller can use to display the attribute and values in a reasonable fashion. Each item has a syntaxid, which are described in the SYNTAX IDS section below. The ldap_entry2text(3LDAP) functions use the display template functions and produce text output.</p>

`ldap_init_templates()` reads a sequence of templates from a valid LDAP template configuration file (see `ldaptemplates.conf(4)`). Upon success, 0 is returned, and `tmplist` is set to point to a list of templates. Each member of the list is an `ldap_disptmpl` structure (defined below in the DISPTMPL Structure Elements section).

`ldap_init_templates_buf()` reads a sequence of templates from `buf` (whose size is `buflen`). `buf` should point to the data in the format defined for an LDAP template configuration file (see `ldaptemplates.conf(4)`). Upon success, 0 is returned, and `tmplist` is set to point to a list of templates.

The `LDAP_SET_DISPTMPL_APPDATA()` macro is used to set the value of the `dt_appdata` field in an `ldap_disptmpl` structure. This field is reserved for the calling application to use; it is not used internally.

The `LDAP_GET_DISPTMPL_APPDATA()` macro is used to retrieve the value in the `dt_appdata` field.

The `LDAP_IS_DISPTMPL_OPTION_SET()` macro is used to test a `ldap_disptmpl` structure for the existence of a template option. The options currently defined are: `LDAP_DTmpl_OPT_ADDABLE` (it is appropriate to allow entries of this type to be added), `LDAP_DTmpl_OPT_ALLOWMODRDN` (it is appropriate to offer the "modify rdn" operation), `LDAP_DTmpl_OPT_ALTVIEW` (this template is merely an alternate view of another template, typically used for templates pointed to be an `LDAP_SYN_LINKACTION` item).

`ldap_free_templates()` disposes of the templates allocated by `ldap_init_templates()`.

`ldap_first_disptmpl()` returns the first template in the list `tmplist`. The `tmplist` is typically obtained by calling `ldap_init_templates()`.

`ldap_next_disptmpl()` returns the template after `tmpl` in the template list `tmplist`. A NULL pointer is returned if `tmpl` is the last template in the list.

`ldap_oc2template()` searches `tmplist` for the best template to use to display an entry that has a specific set of objectClass values. `oclist` should be a null-terminated array of strings that contains the values of the objectClass attribute of the entry. A pointer to the first template where all of the object classes listed in one of the template's `dt_oclist` elements are contained in `oclist` is returned. A NULL pointer is returned if no appropriate template is found.

`ldap_tmplatattrs()` returns a null-terminated array that contains the names of attributes that need to be retrieved if the template `tmpl` is to be used to display an entry. The attribute list should be freed using `ldap_value_free()`. The `includeattrs` parameter contains a null-terminated array of attributes that should always be included (it may be NULL if no extra attributes are required). If `syntaxmask` is non-zero, it is used to restrict the attribute set returned. If `exclude` is zero, only attributes where the logical AND of the template item syntax id and the `syntaxmask` is non-zero are included. If `exclude` is non-zero, attributes where the logical AND of the template item syntax id and the `syntaxmask` is non-zero are excluded.

ldap_disptmpl(3LDAP)

`ldap_first_tmplrow()` returns a pointer to the first row of items in template *tmpl*.

`ldap_next_tmplrow()` returns a pointer to the row that follows *row* in template *tmpl*.

`ldap_first_tmplcol()` returns a pointer to the first item (in the first column) of row *row* within template *tmpl*. A pointer to an `ldap_tmplitem` structure (defined below in the TEMPLITEM Structure Elements section) is returned.

The `LDAP_SET_TEMPLITEM_APPDATA()` macro is used to set the value of the `ti_appdata` field in a `ldap_tmplitem` structure. This field is reserved for the calling application to use; it is not used internally.

The `LDAP_GET_TEMPLITEM_APPDATA()` macro is used to retrieve the value of the `ti_appdata` field.

The `LDAP_IS_TEMPLITEM_OPTION_SET()` macro is used to test a `ldap_tmplitem` structure for the existence of an item option. The options currently defined are: `LDAP_DITEM_OPT_READONLY` (this attribute should not be modified), `LDAP_DITEM_OPT_SORTVALUES` (it makes sense to sort the values), `LDAP_DITEM_OPT_SINGLEVALUED` (this attribute can only hold a single value), `LDAP_DITEM_OPT_VALUEREQUIRED` (this attribute must contain at least one value), `LDAP_DITEM_OPT_HIDEIFEMPTY` (do not show this item if there are no values), and `LDAP_DITEM_OPT_HIDEIFFALSE` (for boolean attributes only: hide this item if the value is FALSE).

`ldap_next_tmplcol()` returns a pointer to the item (column) that follows column *col* within row *row* of template *tmpl*.

DISPTMPL Structure Elements

The `ldap_disptmpl` structure is defined as:

```
struct ldap_disptmpl {
    char                *dt_name;
    char                *dt_pluralname;
    char                *dt_iconname;
    unsigned long       dt_options;
    char                *dt_authattrname;
    char                *dt_defrdnattrname;
    char                *dt_defaddlocation;
    struct ldap_oclist  *dt_oclist;
    struct ldap_addeflist *dt_addeflist;
    struct ldap_tmplitem *dt_items;
    void                *dt_appdata;
    struct ldap_disptmpl *dt_next;
};
```

The `dt_name` member is the singular name of the template. The `dt_pluralname` is the plural name. The `dt_iconname` member will contain the name of an icon or other graphical element that can be used to depict entries that correspond to this display template. The `dt_options` contains options which may be tested using the `LDAP_IS_TEMPLITEM_OPTION_SET()` macro.

The `dt_authattrname` contains the name of the DN-syntax attribute whose value(s) should be used to authenticate to make changes to an entry. If `dt_authattrname` is NULL, then authenticating as the entry itself is appropriate. The `dt_defrdnattrname` is the name of the attribute that is normally used to name entries of this type, for example, "cn" for person entries. The `dt_defaddlocation` is the distinguished name of an entry below which new entries of this type are typically created (its value is site-dependent).

`dt_oclist` is a pointer to a linked list of object class arrays, defined as:

```
struct ldap_oclist {
    char          **oc_objclasses;
    struct ldap_oclist *oc_next;
};
```

These are used by the `ldap_oc2template()` function.

`dt_adddeflist` is a pointer to a linked list of rules for defaulting the values of attributes when new entries are created. The `ldap_adddeflist` structure is defined as:

```
struct ldap_adddeflist {
    int          ad_source;
    char         *ad_attrname;
    char         *ad_value;
    struct ldap_adddeflist *ad_next;
};
```

The `ad_attrname` member contains the name of the attribute whose value this rule sets. If `ad_source` is `LDAP_ADSRC_CONSTANTVALUE` then the `ad_value` member contains the (constant) value to use. If `ad_source` is `LDAP_ADSRC_ADDERSDN` then `ad_value` is ignored and the distinguished name of the person who is adding the new entry is used as the default value for `ad_attrname`.

TMPLITEM Structure Elements

The `ldap_tmplitem` structure is defined as:

```
struct ldap_tmplitem {
    unsigned long    ti_syntaxid;
    unsigned long    ti_options;
    char             *ti_attrname;
    char             *ti_label;
    char             **ti_args;
    struct ldap_tmplitem *ti_next_in_row;
    struct ldap_tmplitem *ti_next_in_col;
    void             *ti_appdata;
};
```

Syntax IDs

Syntax ids are found in the `ldap_tmplitem` structure element `ti_syntaxid`, and they can be used to determine how to display the values for the attribute associated with an item. The `LDAP_GET_SYN_TYPE()` macro can be used to return a general type from a syntax id. The five general types currently defined are:

`LDAP_SYN_TYPE_TEXT` (for attributes that are most appropriately shown as text),

`LDAP_SYN_TYPE_IMAGE` (for JPEG or FAX format images),

`LDAP_SYN_TYPE_BOOLEAN` (for boolean attributes), `LDAP_SYN_TYPE_BUTTON` (for

ldap_disptmpl(3LDAP)

attributes whose values are to be retrieved and display only upon request, for example, in response to the press of a button, a JPEG image is retrieved, decoded, and displayed), and `LDAP_SYN_TYPE_ACTION` (for special purpose actions such as "search for the entries where this entry is listed in the `seeAlso` attribute").

The `LDAP_GET_SYN_OPTIONS` macro can be used to retrieve an unsigned long bitmap that defines options. The only currently defined option is `LDAP_SYN_OPT_DEFER`, which (if set) implies that the values for the attribute should not be retrieved until requested.

There are sixteen distinct syntax ids currently defined. These generally correspond to one or more X.500 syntaxes.

`LDAP_SYN_CASEIGNORESTR` is used for text attributes which are simple strings whose case is ignored for comparison purposes.

`LDAP_SYN_MULTILINESTR` is used for text attributes which consist of multiple lines, for example, `postalAddress`, `homePostalAddress`, `multilineDescription`, or any attributes of syntax `caseIgnoreList`.

`LDAP_SYN_RFC822ADDR` is used for case ignore string attributes that are RFC-822 conformant mail addresses, for example, mail.

`LDAP_SYN_DN` is used for attributes with a Distinguished Name syntax, for example, `seeAlso`.

`LDAP_SYN_BOOLEAN` is used for attributes with a boolean syntax.

`LDAP_SYN_JPEGIMAGE` is used for attributes with a jpeg syntax, for example, `jpegPhoto`.

`LDAP_SYN_JPEGBUTTON` is used to provide a button (or equivalent interface element) that can be used to retrieve, decode, and display an attribute of jpeg syntax.

`LDAP_SYN_FAXIMAGE` is used for attributes with a photo syntax, for example, `Photo`. These are actually Group 3 Fax (T.4) format images.

`LDAP_SYN_FAXBUTTON` is used to provide a button (or equivalent interface element) that can be used to retrieve, decode, and display an attribute of photo syntax.

`LDAP_SYN_AUDIOBUTTON` is used to provide a button (or equivalent interface element) that can be used to retrieve and play an attribute of audio syntax. Audio values are in the "mu law" format, also known as "au" format.

`LDAP_SYN_TIME` is used for attributes with the `UTCTime` syntax, for example, `lastModifiedTime`. The value(s) should be displayed in complete date and time fashion.

`LDAP_SYN_DATE` is used for attributes with the `UTCTime` syntax, for example, `lastModifiedTime`. Only the date portion of the value(s) should be displayed.

`LDAP_SYN_LABELEDURL` is used for `labeledURL` attributes.

LDAP_SYN_SEARCHACTION is used to define a search that is used to retrieve related information. If `ti_attrname` is not NULL, it is assumed to be a boolean attribute which will cause no search to be performed if its value is FALSE. The `ti_args` structure member will have four strings in it: `ti_args[0]` should be the name of an attribute whose values are used to help construct a search filter or "-dn" is the distinguished name of the entry being displayed should be used, `ti_args[1]` should be a filter pattern where any occurrences of "%v" are replaced with the value derived from `ti_args[0]`, `ti_args[2]` should be the name of an additional attribute to retrieve when performing the search, and `ti_args[3]` should be a human-consumable name for that attribute. The `ti_args[2]` attribute is typically displayed along with a list of distinguished names when multiple entries are returned by the search.

LDAP_SYN_LINKACTION is used to define a link to another template by name. `ti_args[0]` will contain the name of the display template to use. The `ldap_name2template()` function can be used to obtain a pointer to the correct `ldap_disptmpl` structure.

LDAP_SYN_ADDDNACTION and LDAP_SYN_VERIFYDNACTION are reserved as actions but currently undefined.

ERRORS

The init template functions return LDAP_TMPL_ERR_VERSION if *buf* points to data that is newer than can be handled, LDAP_TMPL_ERR_MEM if there is a memory allocation problem, LDAP_TMPL_ERR_SYNTAX if there is a problem with the format of the templates buffer or file. LDAP_TMPL_ERR_FILE is returned by `ldap_init_templates` if the file cannot be read. Other functions generally return NULL upon error.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

ldap_entry2text(3LDAP)

NAME	ldap_entry2text, ldap_entry2text_search, ldap_entry2html, ldap_entry2html_search, ldap_vals2html, ldap_vals2text – LDAP entry display functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_entry2text(LDAP *ld, char *buf, LDAPMessage *entry, struct ldap_disptmpl *tmpl, char **defattrs, char ***defvals, int (*writeproc)(), void *writeparm, char *eol, int rdncount, unsigned long opts); int ldap_entry2text_search(LDAP *ld, char *dn, char *base, LDAPMessage *entry, struct ldap_disptmpl *tmplist, char **defattrs, char ***defvals, int (*writeproc)(), void *writeparm, char *eol, int rdncount, unsigned long opts); int ldap_vals2text(LDAP *ld, char *buf, char **vals, char *label, int labelwidth, unsigned long syntaxid, int (*writeproc)(), void *writeparm, char *eol, int rdncount); int ldap_entry2html(LDAP *ld, char *buf, LDAPMessage *entry, struct ldap_disptmpl *tmpl, char **defattrs, char ***defvals, int (*writeproc)(), void *writeparm, char *eol, int rdncount, unsigned long opts, char *urlprefix, char *base); int ldap_entry2html_search(LDAP *ld, char *dn, LDAPMessage *entry, struct ldap_disptmpl *tmplist, char **defattrs, char ***defvals, int (*writeproc)(), void *writeparm, char *eol, int rdncount, unsigned long opts, char *urlprefix); int ldap_vals2html(LDAP *ld, char *buf, char **vals, char *label, int labelwidth, unsigned long syntaxid, int (*writeproc)(), void *writeparm, char *eol, int rdncount, char *urlprefix); #define LDAP_DISP_OPT_AUTOLABELWIDTH 0x00000001 #define LDAP_DISP_OPT_HTMLBODYONLY 0x00000002 #define LDAP_DTmpl_BUFSIZ 2048</pre>
DESCRIPTION	<p>These functions use the LDAP display template functions (see ldap_disptmpl(3LDAP) and <code>ldap_templates.conf(4)</code>) to produce a plain text or an HyperText Markup Language (HTML) display of an entry or a set of values. Typical plain text output produced for an entry might look like:</p> <pre>"Barbara J Jensen, Information Technology Division" Also Known As: Babs Jensen Barbara Jensen Barbara J Jensen E-Mail Address: bjensen@terminator.rs.itd.umich.edu Work Address:</pre>

```

535 W. William
Ann Arbor, MI 48103
Title:
Mythical Manager, Research Systems
...

```

The exact output produced will depend on the display template configuration. HTML output is similar to the plain text output, but more richly formatted.

`ldap_entry2text()` produces a text representation of *entry* and writes the text by calling the *writeproc* function. All of the attributes values to be displayed must be present in *entry*; no interaction with the LDAP server will be performed within `ldap_entry2text`. `ld` is the LDAP pointer obtained by a previous call to `ldap_open`. *writeproc* should be declared as:

```

int writeproc( writeparm, p, len )
void *writeparm;
char *p;
int len;

```

where *p* is a pointer to text to be written and *len* is the length of the text. *p* is guaranteed to be zero-terminated. Lines of text are terminated with the string *eol*. *buf* is a pointer to a buffer of size `LDAP_DTmpl_BUFSIZ` or larger. If *buf* is NULL then a buffer is allocated and freed internally. *tmpl* is a pointer to the display template to be used (usually obtained by calling `ldap_oc2template`). If *tmpl* is NULL, no template is used and a generic display is produced. *defattrs* is a NULL-terminated array of LDAP attribute names which you wish to provide default values for (only used if *entry* contains no values for the attribute). An array of NULL-terminated arrays of default values corresponding to the attributes should be passed in *defvals*. The *rdncount* parameter is used to limit the number of Distinguished Name (DN) components that are actually displayed for DN attributes. If *rdncount* is zero, all components are shown. *opts* is used to specify output options. The only values currently allowed are zero (default output), `LDAP_DISP_OPT_AUTOLABELWIDTH` which causes the width for labels to be determined based on the longest label in *tmpl*, and `LDAP_DISP_OPT_HTMLBODYONLY`. The `LDAP_DISP_OPT_HTMLBODYONLY` option instructs the library not to include `<HTML>`, `<HEAD>`, `<TITLE>`, and `<BODY>` tags. In other words, an HTML fragment is generated, and the caller is responsible for prepending and appending the appropriate HTML tags to construct a correct HTML document.

`ldap_entry2text_search()` is similar to `ldap_entry2text`, and all of the like-named parameters have the same meaning except as noted below. If *base* is not NULL, it is the search base to use when executing search actions. If it is NULL, search action template items are ignored. If *entry* is not NULL, it should contain the *objectClass* attribute values for the entry to be displayed. If *entry* is NULL, *dn* must not be NULL, and `ldap_entry2text_search` will retrieve the *objectClass* values itself by calling `ldap_search_s`. `ldap_entry2text_search` will determine the appropriate display template to use by calling `ldap_oc2template`, and will call `ldap_search_s` to retrieve any attribute values to be displayed. The *tmplist* parameter is a pointer to the entire list of templates available (usually obtained by calling `ldap_init_templates` or `ldap_init_templates_buf`). If *tmplist* is NULL, `ldap_entry2text_search` will attempt to read a load templates from the default template configuration file `ETCDIR/ldaptemplates.conf`.

ldap_entry2text(3LDAP)

`ldap_vals2text` produces a text representation of a single set of LDAP attribute values. The *ld*, *buf*, *writeproc*, *writeparm*, *eol*, and *rdncount* parameters are the same as the like-named parameters for `ldap_entry2text`. *vals* is a NULL-terminated list of values, usually obtained by a call to `ldap_get_values`. *label* is a string shown next to the values (usually a friendly form of an LDAP attribute name). *labelwidth* specifies the label margin, which is the number of blank spaces displayed to the left of the values. If zero is passed, a default label width is used. *syntaxid* is a display template attribute syntax identifier (see `ldap_disptmpl(3LDAP)` for a list of the pre-defined LDAP_SYN_... values).

`ldap_entry2html` produces an HTML representation of *entry*. It behaves exactly like `ldap_entry2text(3LDAP)`, except for the formatted output and the addition of two parameters. *urlprefix* is the starting text to use when constructing an LDAP URL. The default is the string `ldap:///`. The second additional parameter, *base*, the search base to use when executing search actions. If it is NULL, search action template items are ignored.

`ldap_entry2html_search` behaves exactly like `ldap_entry2text_search(3LDAP)`, except HTML output is produced and one additional parameter is required. *urlprefix* is the starting text to use when constructing an LDAP URL. The default is the string `ldap:///`

`ldap_vals2html` behaves exactly like `ldap_vals2text`, except HTML output is produced and one additional parameter is required. *urlprefix* is the starting text to use when constructing an LDAP URL. The default is the string `ldap:///`

ERRORS These functions all return an LDAP error code. LDAP_SUCCESS is returned if no error occurs. See `ldap_error(3LDAP)` for details. The *ld_errno* field of the *ld* parameter is also set to indicate the error.

NAME	ldap_error, ldap_err2string, ldap_perror, ldap_result2error – LDAP protocol error handling functions																		
SYNOPSIS	<pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> char *ldap_err2string(int <i>err</i>); void ldap_perror(LDAP *<i>ld</i>, const char *<i>s</i>); int ldap_result2error(LDAP *<i>ld</i>, LDAPMessage *<i>res</i>, int <i>freeit</i>);</pre>																		
DESCRIPTION	<p>These functions interpret the error codes that are returned by the LDAP API routines. The <code>ldap_perror()</code> and <code>ldap_result2error()</code> functions are deprecated for all new development. Use <code>ldap_err2string()</code> instead.</p> <p>You can also use <code>ldap_parse_sasl_bind_result(3LDAP)</code>, <code>ldap_parse_extended_result(3LDAP)</code>, and <code>ldap_parse_result(3LDAP)</code> to provide error handling and interpret error codes returned by LDAP API functions.</p> <p>The <code>ldap_err2string()</code> function takes <i>err</i>, a numeric LDAP error code, returned either by <code>ldap_parse_result(3LDAP)</code> or another LDAP API call. It returns an informative, null-terminated, character string that describes the error.</p> <p>The <code>ldap_result2error()</code> function takes <i>res</i>, a result produced by <code>ldap_result(3LDAP)</code> or other synchronous LDAP calls, and returns the corresponding error code. If the <i>freeit</i> parameter is non-zero, it indicates that the <i>res</i> parameter should be freed by a call to <code>ldap_msgfree(3LDAP)</code> after the error code has been extracted.</p> <p>Similar to the way <code>perror(3C)</code> works, the <code>ldap_perror()</code> function can be called to print an indication of the error to standard error.</p>																		
ERRORS	<p>The possible values for an LDAP error code are:</p> <table border="0"> <tr> <td style="padding-right: 20px;">LDAP_SUCCESS</td> <td>The request was successful.</td> </tr> <tr> <td>LDAP_OPERATIONS_ERROR</td> <td>An operations error occurred.</td> </tr> <tr> <td>LDAP_PROTOCOL_ERROR</td> <td>A protocol violation was detected.</td> </tr> <tr> <td>LDAP_TIMELIMIT_EXCEEDED</td> <td>An LDAP time limit was exceeded.</td> </tr> <tr> <td>LDAP_SIZELIMIT_EXCEEDED</td> <td>An LDAP size limit was exceeded.</td> </tr> <tr> <td>LDAP_COMPARE_FALSE</td> <td>A compare operation returned false.</td> </tr> <tr> <td>LDAP_COMPARE_TRUE</td> <td>A compare operation returned true.</td> </tr> <tr> <td>LDAP_STRONG_AUTH_NOT_SUPPORTED</td> <td>The LDAP server does not support strong authentication.</td> </tr> <tr> <td>LDAP_STRONG_AUTH_REQUIRED</td> <td>Strong authentication is required for the operation.</td> </tr> </table>	LDAP_SUCCESS	The request was successful.	LDAP_OPERATIONS_ERROR	An operations error occurred.	LDAP_PROTOCOL_ERROR	A protocol violation was detected.	LDAP_TIMELIMIT_EXCEEDED	An LDAP time limit was exceeded.	LDAP_SIZELIMIT_EXCEEDED	An LDAP size limit was exceeded.	LDAP_COMPARE_FALSE	A compare operation returned false.	LDAP_COMPARE_TRUE	A compare operation returned true.	LDAP_STRONG_AUTH_NOT_SUPPORTED	The LDAP server does not support strong authentication.	LDAP_STRONG_AUTH_REQUIRED	Strong authentication is required for the operation.
LDAP_SUCCESS	The request was successful.																		
LDAP_OPERATIONS_ERROR	An operations error occurred.																		
LDAP_PROTOCOL_ERROR	A protocol violation was detected.																		
LDAP_TIMELIMIT_EXCEEDED	An LDAP time limit was exceeded.																		
LDAP_SIZELIMIT_EXCEEDED	An LDAP size limit was exceeded.																		
LDAP_COMPARE_FALSE	A compare operation returned false.																		
LDAP_COMPARE_TRUE	A compare operation returned true.																		
LDAP_STRONG_AUTH_NOT_SUPPORTED	The LDAP server does not support strong authentication.																		
LDAP_STRONG_AUTH_REQUIRED	Strong authentication is required for the operation.																		

ldap_error(3LDAP)

LDAP_PARTIAL_RESULTS	Only partial results are returned.
LDAP_NO_SUCH_ATTRIBUTE	The attribute type specified does not exist in the entry.
LDAP_UNDEFINED_TYPE	The attribute type specified is invalid.
LDAP_INAPPROPRIATE_MATCHING	The filter type is not supported for the specified attribute.
LDAP_CONSTRAINT_VIOLATION	An attribute value specified violates some constraint. For example, a <code>postalAddress</code> has too many lines, or a line that is too long.
LDAP_TYPE_OR_VALUE_EXISTS	An attribute type or attribute value specified already exists in the entry.
LDAP_INVALID_SYNTAX	An invalid attribute value was specified.
LDAP_NO_SUCH_OBJECT	The specified object does not exist in the directory.
LDAP_ALIAS_PROBLEM	An alias in the directory points to a nonexistent entry.
LDAP_INVALID_DN_SYNTAX	A syntactically invalid DN was specified.
LDAP_IS_LEAF	The object specified is a leaf.
LDAP_ALIAS_DEREF_PROBLEM	A problem was encountered when dereferencing an alias.
LDAP_INAPPROPRIATE_AUTH	Inappropriate authentication was specified. For example, <code>LDAP_AUTH_SIMPLE</code> was specified and the entry does not have a <code>userPassword</code> attribute.
LDAP_INVALID_CREDENTIALS	Invalid credentials were presented, for example, the wrong password.
LDAP_INSUFFICIENT_ACCESS	The user has insufficient access to perform the operation.
LDAP_BUSY	The DSA is busy.
LDAP_UNAVAILABLE	The DSA is unavailable.
LDAP_UNWILLING_TO_PERFORM	The DSA is unwilling to perform the operation.
LDAP_LOOP_DETECT	A loop was detected.
LDAP_NAMING_VIOLATION	A naming violation occurred.

ldap_error(3LDAP)

LDAP_OBJECT_CLASS_VIOLATION	An object class violation occurred. For example, a must attribute was missing from the entry.
LDAP_NOT_ALLOWED_ON_NONLEAF	The operation is not allowed on a nonleaf object.
LDAP_NOT_ALLOWED_ON_RDN	The operation is not allowed on an RDN.
LDAP_ALREADY_EXISTS	The entry already exists.
LDAP_NO_OBJECT_CLASS_MODS	Object class modifications are not allowed.
LDAP_OTHER	An unknown error occurred.
LDAP_SERVER_DOWN	The LDAP library cannot contact the LDAP server.
LDAP_LOCAL_ERROR	Some local error occurred. This is usually a failed <code>malloc()</code> .
LDAP_ENCODING_ERROR	An error was encountered encoding parameters to send to the LDAP server.
LDAP_DECODING_ERROR	An error was encountered decoding a result from the LDAP server.
LDAP_TIMEOUT	A time limit was exceeded while waiting for a result.
LDAP_AUTH_UNKNOWN	The authentication method specified to <code>ldap_bind(3LDAP)</code> is not known.
LDAP_FILTER_ERROR	An invalid filter was supplied to <code>ldap_search(3LDAP)</code> , for example, unbalanced parentheses.
LDAP_PARAM_ERROR	An LDAP function was called with a bad parameter, for example, a NULL <i>ld</i> pointer, and the like.
LDAP_NO_MEMORY	A memory allocation call failed in an LDAP library function, for example, <code>malloc(3C)</code> .
LDAP_CONNECT_ERROR	The LDAP client has either lost its connection to an LDAP server or it cannot establish a connection.
LDAP_NOT_SUPPORTED	The requested functionality is not supported., for example, when an LDAPv2 client requests some LDAPv3 functionality.
LDAP_CONTROL_NOT_FOUND	An LDAP client requested a control not found in the list of supported controls sent by the server.

ldap_error(3LDAP)

LDAP_NO_RESULTS_RETURNED	The LDAP server sent no results.
LDAP_MORE_RESULTS_TO_RETURN	More results are chained in the message chain.
LDAP_CLIENT_LOOP	A loop has been detected, for example, when following referrals.
LDAP_REFERRAL_LIMIT_EXCEEDED	The referral exceeds the hop limit. The hop limit determines the number of servers that the client can hop through to retrieve data.

ATTRIBUTES See `attributes(5)` for a description of the following attributes:

NAME	ldap_first_attribute, ldap_next_attribute – step through LDAP entry attributes						
SYNOPSIS	<pre>cc [flag...] file... -lldap[library...] #include <lber.h> #include <ldap.h> char *ldap_first_attribute(LDAP *ld, LDAPMessage *entry, BerElement **berptr) ; char *ldap_next_attribute(LDAP *ld, LDAPMessage *entry, BerElement *ber) ;</pre>						
DESCRIPTION	<p>The <code>ldap_first_attribute()</code> function gets the value of the first attribute in an entry.</p> <p>The <code>ldap_first_attribute()</code> function returns the name of the first attribute in the entry. To get the value of the first attribute, pass the attribute name to the <code>ldap_get_values()</code> function or to the <code>ldap_get_values_len()</code> function.</p> <p>The <code>ldap_next_attribute()</code> function gets the value of the next attribute in an entry.</p> <p>After stepping through the attributes, the application should call <code>ber_free()</code> to free the <code>BerElement</code> structure allocated by the <code>ldap_first_attribute()</code> function if the structure is other than <code>NULL</code>.</p>						
ERRORS	If an error occurs, <code>NULL</code> is returned and the <code>ld_errno</code> field in the <code>ld</code> parameter is set to indicate the error. See ldap_error(3LDAP) for a description of possible error codes.						
ATTRIBUTES	See attributes(5) for a description of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>SUNWcsl (32-bit) SUNWcslx (64-bit)</td> </tr> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	SUNWcsl (32-bit) SUNWcslx (64-bit)	Interface Stability	Evolving
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
MT-Level	SUNWcsl (32-bit) SUNWcslx (64-bit)						
Interface Stability	Evolving						
SEE ALSO	ldap(3LDAP) , ldap_first_entry(3LDAP) , ldap_get_values(3LDAP) , ldap_error(3LDAP) , attributes(5)						
NOTES	The <code>ldap_first_attribute()</code> function allocates memory that might need to be freed by the caller by means of ber_free(3LDAP) .						

ldap_first_entry(3LDAP)

NAME	ldap_first_entry, ldap_next_entry, ldap_count_entries, ldap_count_references, ldap_first_reference, ldap_next_reference – LDAP entry parsing and counting functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> LDAPMessage *ldap_first_entry(LDAP*ld, LDAPMessage *result); LDAPMessage *ldap_next_entry(LDAP *ld, LDAPMessage *entry); ldap_count_entries(LDAP *ld, LDAPMessage *result); LDAPMessage *ldap_first_reference(LDAP *ld, LDAPMessage *res); LDAPMessage *ldap_next_reference(LDAP *ld, LDAPMessage *res); int ldap_count_references(LDAP *ld, LDAPMessage *res);</pre>
DESCRIPTION	<p>These functions are used to parse results received from <code>ldap_result(3LDAP)</code> or the synchronous LDAP search operation functions <code>ldap_search_s(3LDAP)</code> and <code>ldap_search_st(3LDAP)</code>.</p> <p>The <code>ldap_first_entry()</code> function is used to retrieve the first entry in a chain of search results. It takes the <i>result</i> as returned by a call to <code>ldap_result(3LDAP)</code> or <code>ldap_search_s(3LDAP)</code> or <code>ldap_search_st(3LDAP)</code> and returns a pointer to the first entry in the result.</p> <p>This pointer should be supplied on a subsequent call to <code>ldap_next_entry()</code> to get the next entry, the result of which should be supplied to the next call to <code>ldap_next_entry()</code>, etc. <code>ldap_next_entry()</code> will return NULL when there are no more entries. The entries returned from these calls are used in calls to the functions described in <code>ldap_get_dn(3LDAP)</code>, <code>ldap_first_attribute(3LDAP)</code>, <code>ldap_get_values(3LDAP)</code>, etc.</p> <p>A count of the number of entries in the search result can be obtained by calling <code>ldap_count_entries()</code>.</p> <p><code>ldap_first_reference()</code> and <code>ldap_next_reference()</code> are used to step through and retrieve the list of continuation references from a search result chain.</p> <p>The <code>ldap_count_references()</code> function is used to count the number of references that are contained in and remain in a search result chain.</p>
ERRORS	<p>If an error occurs in <code>ldap_first_entry()</code> or <code>ldap_next_entry()</code>, NULL is returned and the <code>ld_errno</code> field in the <i>ld</i> parameter is set to indicate the error. If an error occurs in <code>ldap_count_entries()</code>, -1 is returned, and <code>ld_errno</code> is set appropriately. See <code>ldap_error(3LDAP)</code> for a description of possible error codes.</p>

ldap_first_entry(3LDAP)

ldap_first_message(3LDAP)

NAME	ldap_first_message, ldap_count_messages, ldap_next_message, ldap_msgtype – LDAP message processing functions						
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_count_messages(LDAP *ld, LDAPMessage *res); LDAPMessage *ldap_first_message(LDAP *ld, LDAPMessage *res); LDAPMessage *ldap_next_message(LDAP *ld, LDAPMessage *msg); int ldap_msgtype(LDAPMessage *res);</pre>						
DESCRIPTION	<p>ldap_count_messages() is used to count the number of messages that remain in a chain of results if called with a message, entry, or reference returned by ldap_first_message(), ldap_next_message(), ldap_first_entry(), ldap_next_entry(), ldap_first_reference(), and ldap_next_reference()</p> <p>ldap_first_message() and ldap_next_message() functions are used to step through the list of messages in a result chain returned by ldap_result().</p> <p>ldap_msgtype() function returns the type of an LDAP message.</p>						
RETURN VALUES	<p>ldap_first_message() and ldap_next_message() return LDAPMessage which can include referral messages, entry messages and result messages.</p> <p>ldap_count_messages() returns the number of messages contained in a chain of results.</p>						
ERRORS	ldap_first_message() and ldap_next_message() return NULL when no more messages exist. NULL is also returned if an error occurs while stepping through the entries, in which case the error parameters in the session handle ld will be set to indicate the error.						
ATTRIBUTES	See attributes(5) for a description of the following attributes:

NAME	ldap_friendly, ldap_friendly_name, ldap_free_friendlymap – LDAP attribute remapping functions						
SYNOPSIS	<pre>cc[flag...] file... -lldap[library...] #include <lber.h> #include <ldap.h> char *ldap_friendly_name(char *filename, char *name, FriendlyMap **map) ; void ldap_free_friendlymap(FriendlyMap **map) ;</pre>						
DESCRIPTION	<p>This function is used to map one set of strings to another. Typically, this is done for country names, to map from the two-letter country codes to longer more readable names. The mechanism is general enough to be used with other things, though.</p> <p><i>filename</i> is the name of a file containing the unfriendly to friendly mapping, <i>name</i> is the unfriendly name to map to a friendly name, and <i>map</i> is a result-parameter that should be set to NULL on the first call. It is then used to hold the mapping in core so that the file need not be read on subsequent calls.</p> <p>For example:</p> <pre> FriendlyMap *map = NULL; printf("unfriendly %s => friendly %s\n", name, ldap_friendly_name("ETCDIR/ldapfriendly", name, &map));</pre> <p>The mapping file should contain lines like this: unfriendlyname\tfriendlyname. Lines that begin with a '#' character are comments and are ignored.</p> <p>The ldap_free_friendlymap() call is used to free structures allocated by ldap_friendly_name() when no more calls to ldap_friendly_name() are to be made.</p>						
ERRORS	NULL is returned by ldap_friendly_name() if there is an error opening <i>filename</i> , or if the file has a bad format, or if the <i>map</i> parameter is NULL.						
FILES	ETCDIR/ldapfriendly.conf						
ATTRIBUTES	See attributes(5) for a description of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsl (32-bit) SUNWcslx (64-bit)</td> </tr> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)	Interface Stability	Evolving

ldap_get_dn(3LDAP)

NAME	ldap_get_dn, ldap_explode_dn, ldap_dn2ufn, ldap_is_dns_dn, ldap_explode_dns, ldap_dns_to_dn – LDAP DN handling functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> char *ldap_get_dn(LDAP *ld, LDAPMessage *entry); char **ldap_explode_dn(char *dn, int notypes); char *ldap_dn2ufn(char *dn); int ldap_is_dns_dn(char *dn); char **ldap_explode_dns(char *dn); char *ldap_dns_to_dn(char *dns_name, int *nameparts);</pre>
DESCRIPTION	<p>These functions allow LDAP entry names (Distinguished Names, or DN's) to be obtained, parsed, converted to a user-friendly form, and tested. A DN has the form described in RFC 1779 <i>A String Representation of Distinguished Names</i>, unless it is an experimental DNS-style DN which takes the form of an RFC 822 mail address.</p> <p>The <code>ldap_get_dn()</code> function takes an <i>entry</i> as returned by <code>ldap_first_entry(3LDAP)</code> or <code>ldap_next_entry(3LDAP)</code> and returns a copy of the entry's DN. Space for the DN will have been obtained by means of <code>malloc(3C)</code>, and should be freed by the caller by a call to <code>free(3C)</code>.</p> <p>The <code>ldap_explode_dn()</code> function takes a DN as returned by <code>ldap_get_dn()</code> and breaks it up into its component parts. Each part is known as a Relative Distinguished Name, or RDN. <code>ldap_explode_dn()</code> returns a null-terminated array, each component of which contains an RDN from the DN. The <i>notypes</i> parameter is used to request that only the RDN values be returned, not their types. For example, the DN "cn=Bob,c=US" would return as either { "cn=Bob", "c=US", NULL } or { "Bob", "US", NULL }, depending on whether <i>notypes</i> was 0 or 1, respectively. The result can be freed by calling <code>ldap_value_free(3LDAP)</code>.</p> <p><code>ldap_dn2ufn()</code> is used to turn a DN as returned by <code>ldap_get_dn()</code> into a more user-friendly form, stripping off type names. See RFC 1781 "Using the Directory to Achieve User Friendly Naming" for more details on the UFN format. The space for the UFN returned is obtained by a call to <code>malloc(3C)</code>, and the user is responsible for freeing it by means of a call to <code>free(3C)</code>.</p> <p><code>ldap_is_dns_dn()</code> returns non-zero if the dn string is an experimental DNS-style DN (generally in the form of an RFC 822 e-mail address). It returns zero if the dn appears to be an RFC 1779 format DN.</p> <p><code>ldap_explode_dns()</code> takes a DNS-style DN and breaks it up into its component parts. <code>ldap_explode_dns()</code> returns a null-terminated array. For example, the DN "mcs.umich.edu" will return { "mcs", "umich", "edu", NULL }. The result can be freed by calling <code>ldap_value_free(3LDAP)</code>.</p>

ldap_get_dn(3LDAP)

`ldap_dns_to_dn()` converts a DNS domain name into an X.500 distinguished name. A string distinguished name and the number of nameparts is returned.

ERRORS If an error occurs in `ldap_get_dn()`, `NULL` is returned and the `ld_errno` field in the `ld` parameter is set to indicate the error. See [ldap_error\(3LDAP\)](#) for a description of possible error codes. `ldap_explode_dn()`, `ldap_explode_dns()` and `ldap_dn2ufn()` will return `NULL` with `errno(3C)` set appropriately in case of trouble.

If an error in `ldap_dns_to_dn()` is encountered zero is returned. The caller should free the returned string if it is non-zero.

ATTRIBUTES See [attributes\(5\)](#) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO [ldap\(3LDAP\)](#), [ldap_first_entry\(3LDAP\)](#), [ldap_error\(3LDAP\)](#), [ldap_value_free\(3LDAP\)](#)

NOTES These functions allocate memory that the caller must free.

ldap_get_entry_controls(3LDAP)

NAME	ldap_get_entry_controls – get the LDAP controls included with a directory entry in a set of search results								
SYNOPSIS	<pre>cc -flag ... file ...-lldap [-library ...] #include <ldap.h> int ldap_get_entry_controls(LDAP *ld, LDAPMessage *entry, LDAPControl ***serverctrlsp);</pre>								
DESCRIPTION	<p>The <code>ldap_get_entry_controls()</code> function retrieves the LDAP v3 controls included in a directory entry in a chain of search results. The LDAP controls are specified in an array of <code>LDAPControl</code> structures. Each <code>LDAPControl</code> structure represents an LDAP control. The function takes <i>entry</i> as a parameter, which points to an <code>LDAPMessage</code> structure that represents an entry in a chain of search results.</p> <p>The entry notification controls that are used with persistent search controls are the only controls that are returned with individual entries. Other controls are returned with results sent from the server. You can call <code>ldap_parse_result()</code> to retrieve those controls.</p>								
ERRORS	<p><code>ldap_get_entry_controls()</code> returns the following error codes.</p> <table><tr><td><code>LDAP_SUCCESS</code></td><td>LDAP controls were successfully retrieved.</td></tr><tr><td><code>LDAP_DECODING_ERROR</code></td><td>An error occurred when decoding the BER-encoded message.</td></tr><tr><td><code>LDAP_PARAM_ERROR</code></td><td>An invalid parameter was passed to the function.</td></tr><tr><td><code>LDAP_NO_MEMORY</code></td><td>Memory cannot be allocated.</td></tr></table>	<code>LDAP_SUCCESS</code>	LDAP controls were successfully retrieved.	<code>LDAP_DECODING_ERROR</code>	An error occurred when decoding the BER-encoded message.	<code>LDAP_PARAM_ERROR</code>	An invalid parameter was passed to the function.	<code>LDAP_NO_MEMORY</code>	Memory cannot be allocated.
<code>LDAP_SUCCESS</code>	LDAP controls were successfully retrieved.								
<code>LDAP_DECODING_ERROR</code>	An error occurred when decoding the BER-encoded message.								
<code>LDAP_PARAM_ERROR</code>	An invalid parameter was passed to the function.								
<code>LDAP_NO_MEMORY</code>	Memory cannot be allocated.								
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsl (32-bit)</td></tr><tr><td></td><td>SUNWcslx (64-bit)</td></tr><tr><td>Interface Stability</td><td>Evolving</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsl (32-bit)		SUNWcslx (64-bit)	Interface Stability	Evolving
ATTRIBUTE TYPE	ATTRIBUTE VALUE								
Availability	SUNWcsl (32-bit)								
	SUNWcslx (64-bit)								
Interface Stability	Evolving								
SEE ALSO	<code>ldap_error(3LDAP)</code> , <code>ldap_parse_result(3LDAP)</code> , <code>attributes(5)</code>								

NAME	ldap_getfilter, ldap_init_getfilter, ldap_init_getfilter_buf, ldap_getfilter_free, ldap_getfirstfilter, ldap_getnextfilter, ldap_setfilteraffixes, ldap_build_filter – LDAP filter generating functions
SYNOPSIS	<pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> #define LDAP_FILT_MAXSIZ 1024 LDAPFiltDesc *ldap_init_getfilter(char *file); LDAPFiltDesc *ldap_init_getfilter_buf(char *buf, long buflen); ldap_getfilter_free(LDAPFiltDesc *lfdp); LDAPFiltInfo *ldap_getfirstfilter(LDAPFiltDesc *lfdp, char *tagpat, char *value); LDAPFiltInfo *ldap_getnextfilter(LDAPFiltDesc *lfdp); void ldap_setfilteraffixes(LDAPFiltDesc *lfdp, char *prefix, char *suffix); void ldap_build_filter(char *buf, unsigned long buflen, char *pattern, char *prefix, char *suffix, char *attr, char *value, char **valwords);</pre>
DESCRIPTION	<p>These functions are used to generate filters to be used in ldap_search(3LDAP) or ldap_search_s(3LDAP). Either <code>ldap_init_getfilter</code> or <code>ldap_init_getfilter_buf</code> must be called prior to calling any of the other functions except <code>ldap_build_filter</code>.</p> <p><code>ldap_init_getfilter()</code> takes a file name as its only argument. The contents of the file must be a valid LDAP filter configuration file (see <code>ldapfilter.conf(4)</code>). If the file is successfully read, a pointer to an <code>LDAPFiltDesc</code> is returned. This is an opaque object that is passed in subsequent get filter calls.</p> <p><code>ldap_init_getfilter_buf()</code> reads from <code>buf</code>, whose length is <code>buflen</code>, the LDAP filter configuration information. <code>buf</code> must point to the contents of a valid LDAP filter configuration file. See <code>ldapfilter.conf(4)</code>. If the filter configuration information is successfully read, a pointer to an <code>LDAPFiltDesc</code> is returned. This is an opaque object that is passed in subsequent get filter calls.</p> <p><code>ldap_getfilter_free()</code> deallocates the memory consumed by <code>ldap_init_getfilter</code>. Once it is called, the <code>LDAPFiltDesc</code> is no longer valid and cannot be used again.</p> <p><code>ldap_getfirstfilter()</code> retrieves the first filter that is appropriate for <code>value</code>. Only filter sets that have tags that match the regular expression <code>tagpat</code> are considered. <code>ldap_getfirstfilter</code> returns a pointer to an <code>LDAPFiltInfo</code> structure, which contains a filter with <code>value</code> inserted as appropriate in <code>lfi_filter</code>, a text match</p>

ldap_getfilter(3LDAP)

description in `lfi_desc`, `lfi_scope` set to indicate the search scope, and `lfi_isexact` set to indicate the type of filter. NULL is returned if no matching filters are found. `lfi_scope` will be one of LDAP_SCOPE_BASE, LDAP_SCOPE_ONELEVEL, or LDAP_SCOPE_SUBTREE. `lfi_isexact` will be zero if the filter has any '~' or '*' characters in it and non-zero otherwise.

`ldap_getnextfilter()` retrieves the next appropriate filter in the filter set that was determined when `ldap_getfirstfilter` was called. It returns NULL when the list has been exhausted.

`ldap_setfilteraffixes()` sets a *prefix* to be prepended and a *suffix* to be appended to all filters returned in the future.

`ldap_build_filter()` constructs an LDAP search filter in *buf*. *buflen* is the size, in bytes, of the largest filter *buf* can hold. A pattern for the desired filter is passed in *pattern*. Where the string %a appears in the pattern it is replaced with *attr*. *prefix* is pre-pended to the resulting filter, and *suffix* is appended. Either can be NULL, in which case they are not used. *value* and *valwords* are used when the string %v appears in *pattern*. See `ldapfilter.conf(4)` for a description of how %v is handled.

ERRORS NULL is returned by `ldap_init_getfilter` if there is an error reading *file*. NULL is returned by `ldap_getfirstfilter` and `ldap_getnextfilter` when there are no more appropriate filters to return.

FILES `ETCDIR/ldapfilter.conf` LDAP filtering routine configuration file.

ATTRIBUTES See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO `ldap(3LDAP)`, `ldapfilter.conf(4)`, `attributes(5)`

NOTES The return values for all of these functions are declared in the `<ldap.h>` header file. Some functions may allocate memory which must be freed by the calling application.

NAME	ldap_get_lang_values, ldap_get_lang_values_len – return an attribute’s values that matches a specified language subtype
SYNOPSIS	<pre>cc -flag ... file...-lldap [-library ...] #include <ldap.h> char **ldap_get_lang_values(LDAP *ld, LDAPMessage *entry, const char *target, char **type); struct berval **ldap_get_lang_values_len(LDAP *ld, LDAPMessage *entry, const char *target, char **type);</pre>
DESCRIPTION	<p>The <code>ldap_get_lang_values()</code> function returns an array of an attribute’s string values that matches a specified language subtype. To retrieve the binary data from an attribute, call the <code>ldap_get_lang_values_len()</code> function instead.</p> <p><code>ldap_get_lang_values()</code> should be called to retrieve a null-terminated array of an attribute’s string values that match a specified language subtype. The <i>entry</i> parameter is the entry retrieved from the directory. The <i>target</i> parameter should contain the attribute type the values that are required, including the optional language subtype. The <i>type</i> parameter points to a buffer that returns the attribute type retrieved by this function. Unlike the <code>ldap_get_values()</code> function, if a language subtype is specified, this function first attempts to find and return values that match that subtype, for example, <code>cn;lang-en</code>.</p> <p><code>ldap_get_lang_values_len()</code> returns a null-terminated array of pointers to <code>berval</code> structures, each containing the length and pointer to a binary value of an attribute for a given entry. The <i>entry</i> parameter is the result returned by <code>ldap_result()</code> or <code>ldap_search_s()</code> functions. The <i>target</i> parameter is the attribute returned by the call to <code>ldap_first_attribute()</code> or <code>ldap_next_attribute()</code>, or the attribute as a literal string, such as <code>jpegPhoto</code> or <code>audio</code>.</p> <p>These functions are deprecated. Use <code>ldap_get_values()</code> or <code>ldap_get_values_len()</code> instead.</p>
RETURN VALUES	<p>If successful, <code>ldap_get_lang_values()</code> returns a null-terminated array of the attribute’s values. If the call is unsuccessful, or if no such attribute exists in the <i>entry</i>, it returns a NULL and sets the appropriate error code in the LDAP structure.</p> <p>The <code>ldap_get_lang_values_len()</code> function returns a null-terminated array of pointers to <code>berval</code> structures, which in turn, if successful, contain pointers to the attribute’s binary values. If the call is unsuccessful, or if no such attribute exists in the <i>entry</i>, it returns a NULL and sets the appropriate error code in the LDAP structure.</p>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ldap_get_lang_values(3LDAP)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit)
	SUNWcslx (64-bit)
Interface Stability	Obsolete

SEE ALSO `ldap_first_attribute(3LDAP)`, `ldap_next_attribute(3LDAP)`,

NAME	ldap_get_option, ldap_set_option – get or set session preferences in the ldap structure.								
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> LDAP ldap_set_option(LDAP *ld, int option, void *optdata []); LDAP ldap_get_option(LDAP *ld, int option, void optdata []);</pre>								
DESCRIPTION	<p>These functions provide an LDAP structure with access to session preferences. The ldap_get_option() function gets session preferences from the LDAP structure. The ldap_set_option() function sets session preferences in the LDAP structure.</p> <p>The <i>ld</i> parameter specifies the connection handle, a pointer to an LDAP structure that contains information about the LDAP server connection. The <i>option</i> parameter specifies the name of the option to be read or modified. The <i>optdata</i> parameter serves as a pointer to the value of the option that you set or get.</p>								
PARAMETERS	<p>The following values can be specified for the <i>option</i> parameter:</p> <p>LDAP_OPT_API_INFO Retrieves basic information about the LDAP API implementation at execution time. The data type for the <i>optdata</i> parameter is (LDAPAPIInfo *). This option is READ-ONLY and cannot be set.</p> <p>LDAP_OPT_DEREF Determines how aliases are handled during a search. The data type for the <i>optdata</i> parameter is (int *). The following values can be specified for the <i>optdata</i> parameter:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">LDAP_DEREF_NEVER</td> <td>Specifies that aliases are never dereferenced.</td> </tr> <tr> <td>LDAP_DEREF_SEARCHING</td> <td>Specifies that aliases are dereferenced when searching under the base object, but not when finding the base object.</td> </tr> <tr> <td>LDAP_DEREF_FINDING</td> <td>Specifies that aliases are dereferenced when finding the base object, but not when searching under the base object.</td> </tr> <tr> <td>LDAP_DEREF_ALWAYS</td> <td>Specifies that aliases are always dereferenced when finding the base object and searching under the base object.</td> </tr> </table> <p>LDAP_OPT_SIZELIMIT Specifies the maximum number of entries returned by the server in search results. The data type for the <i>optdata</i> parameter is (int *). Setting the <i>optdata</i> parameter to LDAP_NO_LIMIT removes any size limit enforced by the client.</p>	LDAP_DEREF_NEVER	Specifies that aliases are never dereferenced.	LDAP_DEREF_SEARCHING	Specifies that aliases are dereferenced when searching under the base object, but not when finding the base object.	LDAP_DEREF_FINDING	Specifies that aliases are dereferenced when finding the base object, but not when searching under the base object.	LDAP_DEREF_ALWAYS	Specifies that aliases are always dereferenced when finding the base object and searching under the base object.
LDAP_DEREF_NEVER	Specifies that aliases are never dereferenced.								
LDAP_DEREF_SEARCHING	Specifies that aliases are dereferenced when searching under the base object, but not when finding the base object.								
LDAP_DEREF_FINDING	Specifies that aliases are dereferenced when finding the base object, but not when searching under the base object.								
LDAP_DEREF_ALWAYS	Specifies that aliases are always dereferenced when finding the base object and searching under the base object.								

ldap_get_option(3LDAP)

LDAP_OPT_TIMELIMIT

Specifies the maximum number of seconds spent by the server when answering a search request. The data type for the *optdata* parameter is (int *). Setting the *optdata* parameter to LDAP_NO_LIMIT removes any time limit enforced by the client.

LDAP_OPT_REFERRALS

Determines whether the client should follow referrals. The data type for the *optdata* parameter is (int *). The following values can be specified for the *optdata* parameter:

LDAP_OPT_ON Specifies that the client should follow referrals.

LDAP_OPT_OFF Specifies that the client should not follow referrals.

By default, the client follows referrals.

LDAP_OPT_RESTART

Determines whether LDAP I/O operations are automatically restarted if aborted prematurely. It can be set to one of the constants LDAP_OPT_ON or LDAP_OPT_OFF.

LDAP_OPT_PROTOCOL_VERSION

Specifies the version of the protocol supported by the client. The data type for the *optdata* parameter is (int *). The version LDAP_VERSION2 or LDAP_VERSION3 can be specified. If no version is set, the default version LDAP_VERSION2 is set. To use LDAP v3 features, set the protocol version to LDAP_VERSION3.

LDAP_OPT_SERVER_CONTROLS

Specifies a pointer to an array of LDAPControl structures that represent the LDAP v3 server controls sent by default with every request. The data type for the *optdata* parameter for ldap_set_option() is (LDAPControl **). For ldap_get_option(), the data type is (LDAPControl ***).

LDAP_OPT_CLIENT_CONTROLS

Specifies a pointer to an array of LDAPControl structures that represent the LDAP v3 client controls sent by default with every request. The data type for the *optdata* parameter for ldap_set_option() is (LDAPControl **). For ldap_get_option(), the data type is (LDAPControl ***).

LDAP_OPT_API_FEATURE_INFO

Retrieves version information at execution time about extended features of the LDAP API. The data type for the *optdata* parameter is (LDAPAPIFeatureInfo *). This option is READ-ONLY and cannot be set.

LDAP_OPT_HOST_NAME

Sets the host name or a list of hosts for the primary LDAP server. The data type for the *optdata* parameter for ldap_set_option() is (char *). For ldap_get_option(), the data type is (char **).

LDAP_OPT_ERROR_NUMBER

Specifies the code of the most recent LDAP error that occurred for this session. The data type for the *optdata* parameter is (int *).

ldap_get_option(3LDAP)

LDAP_OPT_ERROR_STRING

Specifies the message returned with the most recent LDAP error that occurred for this session. The data type for the *optdata* parameter for `ldap_set_option()` is (char *) and for `ldap_get_option()` is (char **).

LDAP_OPT_MATCHED_DN

Specifies the matched DN value returned with the most recent LDAP error that occurred for this session. The data type for the *optdata* parameter for `ldap_set_option()` is (char *) and for `ldap_get_option()` is (char **).

LDAP_OPT_REBIND_ARG

Sets the last argument passed to the routine specified by `LDAP_OPT_REBIND_FN`. This option can also be set by calling the `ldap_set_rebind_proc()` function. The data type for the *optdata* parameter is (void *).

LDAP_OPT_REBIND_FN

Sets the routine to be called to authenticate a connection with another LDAP server. For example, the option is used to set the routine called during the course of a referral. This option can also be by calling the `ldap_set_rebind_proc()` function. The data type for the *optdata* parameter is (LDAP_REBINDPROC_CALLBACK *).

LDAP_OPT_X_SASL_MECH

Sets the default SASL mechanism to call `ldap_interactive_bind_s()`. The data type for the *optdata* parameter is (char *).

LDAP_OPT_X_SASL_REALM

Sets the default SASL_REALM. The default SASL_REALM should be used during a SASL challenge in response to a SASL_CB_GETREALM request when using the `ldap_interactive_bind_s()` function. The data type for the *optdata* parameter is (char *).

LDAP_OPT_X_SASL_AUTHCID

Sets the default SASL_AUTHNAME used during a SASL challenge in response to a SASL_CB_AUTHNAME request when using the `ldap_interactive_bind_s()` function. The data type for the *optdata* parameter is (char *).

LDAP_OPT_X_SASL_AUTHZID

Sets the default SASL_USER that should be used during a SASL challenge in response to a SASL_CB_USER request when using the `ldap_interactive_bind_s` function. The data type for the *optdata* parameter is (char *).

LDAP_OPT_X_SASL_SSF

A read-only option used exclusively with the `ldap_get_option()` function. The `ldap_get_option()` function performs a `sasl_getprop()` operation that gets the SASL_SSF value for the current connection. The data type for the *optdata* parameter is (sasl_ssf_t *).

ldap_get_option(3LDAP)

LDAP_OPT_X_SASL_SSF_EXTERNAL

A write-only option used exclusively with the `ldap_set_option()` function. The `ldap_set_option()` function performs a `sasl_setprop()` operation to set the `SASL_SSF_EXTERNAL` value for the current connection. The data type for the *optdata* parameter is `(sasl_ssf_t *)`.

LDAP_OPT_X_SASL_SECPROPS

A write-only option used exclusively with the `ldap_set_option()`. This function performs a `sasl_setprop(3SASL)` operation for the `SASL_SEC_PROPS` value for the current connection during an `ldap_interactive_bind_s()` operation. The data type for the *optdata* parameter is `(char *)`, a comma delimited string containing text values for any of the `SASL_SEC_PROPS` that should be set. The text values are:

<code>noanonymous</code>	Sets the <code>SASL_SEC_NOANONYMOUS</code> flag
<code>nodict</code>	Sets the <code>SASL_SEC_NODICTIONARY</code> flag
<code>noplain</code>	Sets the <code>SASL_SEC_NOPLAINTEXT</code> flag
<code>forwardsec</code>	Sets the <code>SASL_SEC_FORWARD_SECRECY</code> flag
<code>passcred</code>	Sets the <code>SASL_SEC_PASS_CREDENTIALS</code> flag
<code>minssf=N</code>	Sets <code>minssf</code> to the integer value <code>N</code>
<code>maxssf=N</code>	Sets <code>maxssf</code> to the integer value <code>N</code>
<code>maxbufsize=N</code>	Sets <code>maxbufsize</code> to the integer value <code>N</code>

LDAP_OPT_X_SASL_SSF_MIN

Sets the default `SSF_MIN` value used during a `ldap_interactive_bind_s()` operation. The data type for the *optdata* parameter is `(char *)` numeric string.

LDAP_OPT_X_SASL_SSF_MAX

Sets the default `SSF_MAX` value used during a `ldap_interactive_bind_s()` operation. The data type for the *optdata* parameter is `(char *)` numeric string.

LDAP_OPT_X_SASL_MAXBUFSIZE

Sets the default `SSF_MAXBUFSIZE` value used during a `ldap_interactive_bind_s()` operation. The data type for the *optdata* parameter is `(char *)` numeric string.

RETURN VALUES The `ldap_set_option()` and `ldap_get_option()` functions return:

<code>LDAP_SUCCESS</code>	If successful
<code>-1</code>	If unsuccessful

NOTES There are other elements in the LDAP structure that should not be changed. No assumptions should be made about the order of elements in the LDAP structure.

ldap_get_values(3LDAP)

NAME	ldap_get_values, ldap_get_values_len, ldap_count_values, ldap_count_values_len, ldap_value_free, ldap_value_free_len – LDAP attribute value handling functions				
SYNOPSIS	<pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> char **ldap_get_values(LDAP *ld, LDAPMessage *entry, char *attr); struct berval **ldap_get_values_len(LDAP *ld, LDAPMessage *entry, char *attr); ldap_count_values(char **vals); ldap_count_values_len(struct berval **vals); ldap_value_free(char **vals); ldap_value_free_len(struct berval **vals);</pre>				
DESCRIPTION	<p>These functions are used to retrieve and manipulate attribute values from an LDAP entry as returned by <code>ldap_first_entry(3LDAP)</code> or <code>ldap_next_entry(3LDAP)</code>. <code>ldap_get_values()</code> takes the <i>entry</i> and the attribute <i>attr</i> whose values are desired and returns a null-terminated array of the attribute's values. <i>attr</i> may be an attribute type as returned from <code>ldap_first_attribute(3LDAP)</code> or <code>ldap_next_attribute(3LDAP)</code>, or if the attribute type is known it can simply be given.</p> <p>The number of values in the array can be counted by calling <code>ldap_count_values()</code>. The array of values returned can be freed by calling <code>ldap_value_free()</code>.</p> <p>If the attribute values are binary in nature, and thus not suitable to be returned as an array of char *'s, the <code>ldap_get_values_len()</code> function can be used instead. It takes the same parameters as <code>ldap_get_values()</code>, but returns a null-terminated array of pointers to berval structures, each containing the length of and a pointer to a value.</p> <p>The number of values in the array can be counted by calling <code>ldap_count_values_len()</code>. The array of values returned can be freed by calling <code>ldap_value_free_len()</code>.</p>				
ERRORS	If an error occurs in <code>ldap_get_values()</code> or <code>ldap_get_values_len()</code> , NULL returned and the <code>ld_errno</code> field in the <code>ld</code> parameter is set to indicate the error. See <code>ldap_error(3LDAP)</code> for a description of possible error codes.				
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">Availability</td> <td>SUNWcsl (32-bit) SUNWcslx (64-bit)</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)

NOTES These functions allocates memory that the caller must free.

ldap_memcache(3LDAP)

NAME	<code>ldap_memcache</code> , <code>ldap_memcache_init</code> , <code>ldap_memcache_set</code> , <code>ldap_memcache_get</code> , <code>ldap_memcache_flush</code> , <code>ldap_memcache_destroy</code> , <code>ldap_memcache_update</code> – LDAP client caching functions
SYNOPSIS	<pre>cc -flag ... file ...-lldap [-library ...] #include <ldap.h> int ldap_memcache_init(unsigned long ttl, unsigned long size, char **baseDNs, struct ldap_thread_fns *thread_fns, LDAPMemCache **cachep); int ldap_memcache_set(LDAP *ld, LDAPMemCache **cache); int ldap_memcache_get(LDAP *ld, LDAPMemCache **cachep); void ldap_memcache_flush(LDAPMemCache *cache, char *dn, int scope); void ldap_memcache_destroy(LDAPMemCache *cache); void ldap_memcache_update(LDAPMemCache *cache);</pre>
DESCRIPTION	<p>Use the <code>ldap_memcache</code> functions to maintain an in-memory client side cache to store search requests. Caching improves performance and reduces network bandwidth when a client makes repeated requests. The <i>cache</i> uses search criteria as the key to the cached items. When you send a search request, the <i>cache</i> checks the search criteria to determine if that request has been previously stored. If the request was stored, the search results are read from the <i>cache</i>.</p> <p>Make a call to <code>ldap_memcache_init()</code> to create the in-memory client side <i>cache</i>. The function passes back a pointer to an <code>LDAPMemCache</code> structure, which represents the <i>cache</i>. Make a call to the <code>ldap_memcache_set()</code> function to associate this <i>cache</i> with an LDAP connection handle, an LDAP structure. <i>ttl</i> is the the maximum amount of time (in seconds) that an item can be cached. If a <i>ttl</i> value of 0 is passed, there is no limit to the amount of time that an item can be cached. <i>size</i> is the maximum amount of memory (in bytes) that the cache will consume. A zero value of <i>size</i> means the cache has no size limit. <i>baseDNS</i> is an array of the base DN strings representing the base DN's of the search requests you want cached. If <i>baseDNS</i> is not <code>NULL</code>, only the search requests with the specified base DN's will be cached. If <i>baseDNS</i> is <code>NULL</code>, all search requests are cached. The <i>thread_fns</i> parameter takes an <code>ldap_thread_fns</code> structure specifying the functions that you want used to ensure that the cache is thread-safe. You should specify this if you have multiple threads that are using the same connection handle and cache. If you are not using multiple threads, pass <code>NULL</code> for this parameter.</p> <p><code>ldap_memcache_set()</code> associates an in-memory <i>cache</i> that you have already created by calling the <code>ldap_memcache_init()</code> function with an LDAP connection handle. The <i>ld</i> parameter should be the result of a successful call to <code>ldap_open(3LDAP)</code>. The <i>cache</i> parameter should be the result of a <i>cache</i> created by the <code>ldap_memcache_init()</code> call. After you call this function, search requests made over the specified LDAP connection will use this cache. To disassociate the cache from the LDAP connection handle, make a call to the <code>ldap_unbind(3LDAP)</code> or <code>ldap_unbind_ext(3LDAP)</code> function. Make a call to <code>ldap_memcache_set()</code> if you want to associate a cache</p>

ldap_memcache(3LDAP)

with multiple LDAP connection handles. For example, call the `ldap_memcache_get()` function to get the *cache* associated with one connection, then you can call this function and associate the *cache* with another connection.

The `ldap_memcache_get()` function gets the *cache* associated with the specified connection handle (LDAP structure). This *cache* is used by all search requests made through that connection. When you call this function, the function sets the *cachep* parameter as a pointer to the `LDAPMemCache` structure that is associated with the connection handle.

`ldap_memcache_flush()` flushes search requests from the *cache*. If the base DN of a search request is within the scope specified by the *dn* and *scope* arguments, the search request is flushed from the *cache*. If no DN is specified, the entire cache is flushed. The *scope* parameter, along with the *dn* parameter, identifies the search requests that you want flushed from the *cache*. This argument can have one of the following values:

`LDAP_SCOPE_BASE`
`LDAP_SCOPE_ONELEVEL`
`LDAP_SCOPE_SUBTREE`

`ldap_memcache_destroy()` frees the specified `LDAPMemCache` structure pointed to by *cache* from memory. Call this function after you are done working with a *cache*.

`ldap_memcache_update()` checks the cache for items that have expired and removes them. This check is typically done as part of the way the *cache* normally works. You do not need to call this function unless you want to update the *cache* at this point in time. This function is only useful in a multithreaded application, since it will not return until the *cache* is destroyed.

PARAMETERS

<i>ttl</i>	The maximum amount of time (in seconds) that an item can be cached
<i>size</i>	The maximum amount of memory (in bytes) that the cache will consume.
<i>baseDNs</i>	An array of the base DN strings representing the base DN's of the search requests you want cached
<i>thread_fns</i>	A pointer to the <code>ldap_thread_fns</code> structure.
<i>cachep</i>	A pointer to the <code>LDAPMemCache</code> structure
<i>cache</i>	The result of a <i>cache</i> created by the <code>ldap_memcache_init()</code> call
<i>ld</i>	The result of a successful call to <code>ldap_open(3LDAP)</code>
<i>dn</i>	The search requests that you want flushed from the <i>cache</i>
<i>scope</i>	The search requests that you want flushed from the <i>cache</i>

ERRORS

The functions that have `int` return values return `LDAP_SUCCESS` if the operation was successful. Otherwise, they return another LDAP error code. See `ldap_error(3LDAP)` for a list of the LDAP error codes.

ldap_memcache(3LDAP)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit)

NAME	ldap_memfree – free memory allocated by LDAP API functions
SYNOPSIS	<pre>cc -flag ... file...-lldap [-library ...] #include < lber.h> #include < ldap.h> void ldap_memfree(void *p);</pre>
DESCRIPTION	<p>The ldap_memfree() function frees the memory allocated by certain LDAP API functions that do not have corresponding functions to free memory. These functions include ldap_get_dn(3LDAP), ldap_first_attribute(3LDAP), and ldap_next_attribute(3LDAP).</p> <p>The ldap_memfree() function takes one parameter, <i>p</i>, which is a pointer to the memory to be freed.</p>
PARAMETERS	<i>p</i> A pointer to the memory to be freed.
RETURN VALUES	There are no return values for the ldap_memfree() function.
ERRORS	No errors are defined for the ldap_memfree() function.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit)
	SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO ldap(3LDAP), ldap_first_attribute(3LDAP), ldap_get_dn(3LDAP), ldap_next_attribute(3LDAP), attributes(5)

ldap_modify(3LDAP)

NAME	ldap_modify, ldap_modify_s, ldap_mods_free, ldap_modify_ext, ldap_modify_ext_s – LDAP entry modification functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_modify(LDAP *ld, char *dn, LDAPMod *mods[]); int ldap_modify_s(LDAP *ld, char *dn, LDAPMod *mods[]); void ldap_mods_free(LDAPMod **mods, int freemods); int ldap_modify_ext(LDAP *ld, char *dn, LDAPMod **mods, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_modify_ext_s(LDAP *ld, char *dn, LDAPMod **mods, LDAPControl **serverctrls, LDAPControl **clientctrls);</pre>
DESCRIPTION	<p>The function <code>ldap_modify_s()</code> is used to perform an LDAP modify operation. <i>dn</i> is the DN of the entry to modify, and <i>mods</i> is a null-terminated array of modifications to make to the entry. Each element of the <i>mods</i> array is a pointer to an LDAPMod structure, which is defined below.</p> <pre>typedef struct ldapmod { int mod_op; char *mod_type; union { char **modv_strvals; struct berval **modv_bvals; } mod_vals; } LDAPMod; #define mod_values mod_vals.modv_strvals #define mod_bvalues mod_vals.modv_bvals</pre> <p>The <i>mod_op</i> field is used to specify the type of modification to perform and should be one of LDAP_MOD_ADD, LDAP_MOD_DELETE, or LDAP_MOD_REPLACE. The <i>mod_type</i> and <i>mod_values</i> fields specify the attribute type to modify and a null-terminated array of values to add, delete, or replace respectively.</p> <p>If you need to specify a non-string value (for example, to add a photo or audio attribute value), you should set <i>mod_op</i> to the logical OR of the operation as above (for example, LDAP_MOD_REPLACE) and the constant LDAP_MOD_BVALUES. In this case, <i>mod_bvalues</i> should be used instead of <i>mod_values</i>, and it should point to a null-terminated array of struct berval, as defined in <code><lber.h></code>.</p> <p>For LDAP_MOD_ADD modifications, the given values are added to the entry, creating the attribute if necessary. For LDAP_MOD_DELETE modifications, the given values are deleted from the entry, removing the attribute if no values remain. If the entire attribute is to be deleted, the <i>mod_values</i> field should be set to NULL. For LDAP_MOD_REPLACE modifications, the attribute will have the listed values after the modification, having been created if necessary. All modifications are performed in the order in which they are listed.</p>

ldap_modify(3LDAP)

ldap_modify_s() returns the LDAP error code resulting from the modify operation.

The ldap_modify() operation works the same way as ldap_modify_s(), except that it is asynchronous, returning the message id of the request it initiates, or -1 on error. The result of the operation can be obtained by calling ldap_result(3LDAP).

ldap_mods_free() can be used to free each element of a null-terminated array of mod structures. If freemods is non-zero, the mods pointer itself is freed as well.

The ldap_modify_ext() function initiates an asynchronous modify operation and returns LDAP_SUCCESS if the request was successfully sent to the server, or else it returns a LDAP error code if not. See ldap_error(3LDAP). If successful, ldap_modify_ext() places the message id of the request in *msgidp. A subsequent call to ldap_result(3LDAP), can be used to obtain the result of the add request.

The ldap_modify_ext_s() function initiates a synchronous modify operation and returns the result of the operation itself.

ERRORS ldap_modify_s() returns an LDAP error code, either LDAP_SUCCESS or an error. See ldap_error(3LDAP).

ldap_modify() returns -1 in case of trouble, setting the error field of ld.

ATTRIBUTES See attributes(5) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO ldap(3LDAP), ldap_add(3LDAP), ldap_error(3LDAP), ldap_get_option(3LDAP), attributes(5)

ldap_modrdn(3LDAP)

NAME	ldap_modrdn, ldap_modrdn_s, ldap_modrdn2, ldap_modrdn2_s, ldap_rename, ldap_rename_s – modify LDAP entry RDN
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_modrdn(LDAP *ld, const char *dn, const char *newrdn); int ldap_modrdn_s(LDAP *ld, const char *dn, const char *newrdn, int deleteoldrdn); int ldap_modrdn2(LDAP *ld, const char *dn, const char *newrdn, int deleteoldrdn); int ldap_modrdn2_s(LDAP *ld, const char *dn, const char *newrdn, int deleteoldrdn); int ldap_rename(LDAP *ld, const char *dn, const char *newrdn, const char *newparent, int deleteoldrdn, LDAPControl **serverctrls, LDAPControl **clientctrls, int *msgidp); int ldap_rename_s(LDAP *ld, const char *dn, const char *newrdn, const char *newparent, const int deleteoldrdn, LDAPControl **serverctrls, LDAPControl **clientctrls);</pre>
DESCRIPTION	<p>The <code>ldap_modrdn()</code> and <code>ldap_modrdn_s()</code> functions perform an LDAP modify RDN (Relative Distinguished Name) operation. They both take <code>dn</code>, the DN (Distinguished Name) of the entry whose RDN is to be changed, and <code>newrdn</code>, the new RDN, to give the entry. The old RDN of the entry is never kept as an attribute of the entry. <code>ldap_modrdn()</code> is asynchronous. It returns the message id of the operation it initiates. <code>ldap_modrdn_s()</code> is synchronous. It returns the LDAP error code that indicates the success or failure of the operation.</p> <p>The <code>ldap_modrdn2()</code> and <code>ldap_modrdn2_s()</code> functions also perform an LDAP modify RDN operation. They take the same parameters as above. In addition, they both take the <code>deleteoldrdn</code> parameter, which is used as a boolean value to indicate whether or not the old RDN values should be deleted from the entry.</p> <p>The <code>ldap_rename()</code>, <code>ldap_rename_s()</code> routines are used to change the name, that is, the RDN of an entry. These routines deprecate the <code>ldap_modrdn()</code> and <code>ldap_modrdn_s()</code> routines, as well as <code>ldap_modrdn2()</code> and <code>ldap_modrdn2_s()</code>.</p> <p>The <code>ldap_rename()</code> and <code>ldap_rename_s()</code> functions both support LDAPv3 server controls and client controls.</p>
ERRORS	<p>The synchronous (<code>_s</code>) versions of these functions return an LDAP error code, either <code>LDAP_SUCCESS</code> or an error. See ldap_error(3LDAP).</p> <p>The asynchronous versions return <code>-1</code> in the event of an error, setting the <code>ld_errno</code> field of <code>ld</code>. See ldap_error(3LDAP) for more details. Use ldap_result(3LDAP) to determine a particular unsuccessful result.</p>

ldap_modrdn(3LDAP)

ATTRIBUTES See `attributes(5)` for a description of the following attributes of the `ldap_modrdn()`, `ldap_modrdn_s()`, `ldap_modrdn2()` and `ldap_modrdn2_s()` functions:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)
Interface Stability	Obsolete

The `ldap_rename()` and `ldap_rename_s()` functions have the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO `ldap(3LDAP)`, `ldap_error(3LDAP)`, `attributes(5)`

ldap_open(3LDAP)

NAME	ldap_open, ldap_init – initialize an LDAP session				
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> LDAP *ldap_open(const char *host, int port); LDAP *ldap_init(const char *host, int port);</pre>				
DESCRIPTION	<p>The <code>ldap_open()</code> function initializes an LDAP session and also opens a connection to an LDAP server before it returns to the caller. Unlike <code>ldap_open()</code>, <code>ldap_init()</code> does not open a connection to the LDAP server until an operation, such as a search request, is performed.</p> <p>The <code>ldap_open()</code> function is deprecated and should no longer be used. Call <code>ldap_init()</code> instead.</p> <p>A list of LDAP hostnames or an IPv4 or IPv6 address can be specified with the <code>ldap_open()</code> and <code>ldap_init()</code> functions. The hostname can include a port number, separated from the hostname by a colon (:). A port number included as part of the hostname takes precedence over the <i>port</i> parameter. The <code>ldap_open()</code> and <code>ldap_init()</code> functions attempt connections with LDAP hosts in the order listed and return the first successful connection.</p>				
PARAMETERS	<p>These functions support the following parameters.</p> <table><tr><td><i>host</i></td><td>The hostname, IPv4 or IPv6 address of the host that runs the LDAP server. A space-separated list of hostnames can also be used for this parameter.</td></tr><tr><td><i>port</i></td><td>TCP port number of a connection. Supply the constant <code>LDAP_PORT</code> to obtain the default LDAP port of 389. If a host includes a port number, the default parameter is ignored.</td></tr></table>	<i>host</i>	The hostname, IPv4 or IPv6 address of the host that runs the LDAP server. A space-separated list of hostnames can also be used for this parameter.	<i>port</i>	TCP port number of a connection. Supply the constant <code>LDAP_PORT</code> to obtain the default LDAP port of 389. If a host includes a port number, the default parameter is ignored.
<i>host</i>	The hostname, IPv4 or IPv6 address of the host that runs the LDAP server. A space-separated list of hostnames can also be used for this parameter.				
<i>port</i>	TCP port number of a connection. Supply the constant <code>LDAP_PORT</code> to obtain the default LDAP port of 389. If a host includes a port number, the default parameter is ignored.				
RETURN VALUES	<p>The <code>ldap_open()</code> and <code>ldap_init()</code> functions return a handle to an LDAP session that contains a pointer to an opaque structure. The structure must be passed to subsequent calls for the session. If a session cannot be initialized, the functions return <code>NULL</code> and <code>errno</code> should be set appropriately.</p> <p>Various aspects of this opaque structure can be read or written to control the session-wide parameters. Use the <code>ldap_get_option(3LDAP)</code> to access the current option values and the <code>ldap_set_option(3LDAP)</code> to set values for these options.</p>				
EXAMPLES	<p>EXAMPLE 1 Specifying IPv4 and IPv6 Addresses</p> <p>LDAP sessions can be initialized with hostnames, IPv4 or IPv6 addresses, such as those shown in the following examples.</p> <pre>ldap_init("hosta:636 hostb", 389) ldap_init("192.168.82.110:389", 389) ldap_init("[fec0::114:a00:20ff:ab3d:83ed]", 389)</pre>				

ldap_open(3LDAP)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving

ldap_parse_result(3LDAP)

NAME	ldap_parse_result, ldap_parse_extended_result, ldap_parse_sasl_bind_result – LDAP message result parser						
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_parse_result(LDAP *ld, LDAPMessage *res, int *errcodep, char **matcheddn, char **errmsgp, char ***referralsp, LDAPControl ***serverctrlsp, int freeit); int ldap_parse_sasl_bind_result(LDAP *ld, LDAPMessage *res, struct berval**servercredp, int freeit); int ldap_parse_extended_result(LDAP *ld, LDAPMessage *res, char **resultoidp, struct berval **resultdata, int freeit);</pre>						
DESCRIPTION	The ldap_parse_extended_result(), ldap_parse_result() and ldap_parse_sasl_bind_result() routines search for a message to parse. These functions skip messages of type LDAP_RES_SEARCH_ENTRY and LDAP_RES_SEARCH_REFERENCE.						
RETURN VALUES	They return LDAP_SUCCESS if the result was successfully parsed or an LDAP error code if not (see ldap_error(3LDAP)).						
ATTRIBUTES	See attributes(5) for a description of the following attributes:

NAME	ldap_result, ldap_msgfree – wait for and return LDAP operation result
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_result(LDAP *ld, int msgid, int all, struct timeval *timeout, LDAPMessage **result); int ldap_msgfree(LDAPMessage *msg);</pre>
DESCRIPTION	<p>The <code>ldap_result()</code> function is used to wait for and return the result of an operation previously initiated by one of the LDAP asynchronous operation functions, for example, <code>ldap_search(3LDAP)</code>, and <code>ldap_modify(3LDAP)</code>. Those functions all return <code>-1</code> in case of error, and an invocation identifier upon successful initiation of the operation. The invocation identifier is picked by the library and is guaranteed to be unique across the LDAP session. It can be used to request the result of a specific operation from <code>ldap_result()</code> through the <code>msgid</code> parameter.</p> <p>The <code>ldap_result()</code> function will block or not, depending upon the setting of the <code>timeout</code> parameter. If <code>timeout</code> is not a null pointer, it specifies a maximum interval to wait for the selection to complete. If <code>timeout</code> is a null pointer, the select blocks indefinitely. To effect a poll, the <code>timeout</code> argument should be a non-null pointer, pointing to a zero-valued <code>timeval</code> structure. See <code>select(1)</code> for further details.</p> <p>If the result of a specific operation is required, <code>msgid</code> should be set to the invocation identifier returned when the operation was initiated, otherwise <code>LDAP_RES_ANY</code> should be supplied. The <code>all</code> parameter only has meaning for search responses and is used to select whether a single entry of the search response should be returned, or all results of the search should be returned.</p> <p>A search response is made up of zero or more search entries followed by a search result. If <code>all</code> is set to <code>-</code>, search entries will be returned one at a time as they come in, by means of separate calls to <code>ldap_result()</code>. If it is set to <code>-1</code>, the search response will only be returned in its entirety, that is, after all entries and the final search result have been received.</p> <p>Upon success, the type of the result received is returned and the <code>result</code> parameter will contain the result of the operation. This result should be passed to the LDAP parsing functions, (see <code>ldap_first_entry(3LDAP)</code>) for interpretation.</p> <p>The possible result types returned are:</p> <pre>#define LDAP_RES_BIND 0x61L #define LDAP_RES_SEARCH_ENTRY 0x64L #define LDAP_RES_SEARCH_RESULT 0x65L #define LDAP_RES_MODIFY 0x67L #define LDAP_RES_ADD 0x69L #define LDAP_RES_DELETE 0x6bL #define LDAP_RES_MODRDN 0x6dL #define LDAP_RES_COMPARE 0x6fL</pre>

ldap_result(3LDAP)

The `ldap_msgfree()` function is used to free the memory allocated for a result by `ldap_result()` or `ldap_search_s(3LDAP)` functions. It takes a pointer to the result to be freed and returns the type of the message it freed.

ERRORS `ldap_result()` returns `-1` if something bad happens, and zero if the timeout specified was exceeded.

ATTRIBUTES See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit) SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO `select(1)`, `ldap(3LDAP)`, `ldap_search(3LDAP)`, `attributes(5)`

NOTES This function allocates memory for results that it receives. The memory can be freed by calling `ldap_msgfree`.

NAME	ldap_search, ldap_search_s, ldap_search_ext, ldap_search_ext_s, ldap_search_st – LDAP search operations
SYNOPSIS	<pre>cc [flag...] file... -lldap[library...] #include <sys/time.h> /* for struct timeval definition */ #include <lber.h> #include <ldap.h> int ldap_search(LDAP *ld, char *base, int scope, char *filter, char *attrs[], int attrsonly); int ldap_search_s(LDAP *ld, char *base, int scope, char *filter, char *attrs[], int attrsonly, LDAPMessage **res); int ldap_search_st(LDAP *ld, char *base, int scope, char *filter, char *attrs[], int attrsonly, struct timeval *timeout, LDAPMessage **res); int ldap_search_ext(LDAP *ld, char *base, int scope, char *filter, char **attrs, int attrsonly, LDAPControl **serverctrls, LDAPControl **clientctrls, struct timeval *timeoutp, int sizelimit, int *msgidp); int ldap_search_ext_s(LDAP *ld, char *base, int scope, char *filter, char **attrs, int attrsonly, LDAPControl **serverctrls, LDAPControl **clientctrls, struct timeval *timeoutp, int sizelimit, LDAPMessage **res);</pre>
DESCRIPTION	<p>These functions are used to perform LDAP search operations. The <code>ldap_search_s()</code> function does the search synchronously (that is, not returning until the operation completes). The <code>ldap_search_st()</code> function does the same, but allows a <i>timeout</i> to be specified. The <code>ldap_search()</code> function is the asynchronous version, initiating the search and returning the message ID of the operation it initiated.</p> <p>The <i>base</i> is the DN of the entry at which to start the search. The <i>scope</i> is the scope of the search and should be one of <code>LDAP_SCOPE_BASE</code>, to search the object itself, <code>LDAP_SCOPE_ONELEVEL</code>, to search the object's immediate children, or <code>LDAP_SCOPE_SUBTREE</code>, to search the object and all its descendents.</p> <p>The <i>filter</i> is a string representation of the filter to apply in the search. Simple filters can be specified as <i>attributetype=attributevalue</i>. More complex filters are specified using a prefix notation according to the following BNF:</p> <pre><filter> ::= '(' <filtercomp> ')' <filtercomp> ::= <and> <or> <not> <simple> <and> ::= '&' <filterlist> <or> ::= ' ' <filterlist> <not> ::= '!' <filter> <filterlist> ::= <filter> <filter> <filterlist> <simple> ::= <attributetype> <filtertype> <attributevalue> <filtertype> ::= '=' '~=' '<' '>'</pre> <p>The <code>'~='</code> construct is used to specify approximate matching. The representation for <code><attributetype></code> and <code><attributevalue></code> are as described in RFC 1778. In addition, <code><attributevalue></code> can be a single <code>*</code> to achieve an attribute existence test, or can contain text and <code>*</code>'s interspersed to achieve substring matching.</p>

ldap_search(3LDAP)

For example, the filter `mail=*` finds entries that have a mail attribute. The filter `mail=*@terminator.rs.itd.umich.edu` finds entries that have a mail attribute ending in the specified string. Use a backslash (`\`) to escape parentheses characters in a filter. See RFC 1588 for a more complete description of the filters that are allowed. See [ldap_getfilter\(3LDAP\)](#) for functions to help construct search filters automatically.

The *attrs* is a null-terminated array of attribute types to return from entries that match *filter*. If `NULL` is specified, all attributes are returned. The *attrsonly* is set to 1 when attribute types only are wanted. The *attrsonly* is set to 0 when both attributes types and attribute values are wanted.

The *sizelimit* argument returns the number of matched entries specified for a search operation. When *sizelimit* is set to 50, for example, no more than 50 entries are returned. When *sizelimit* is set to 0, all matched entries are returned. The LDAP server can be configured to send a maximum number of entries, different from the size limit specified. If 5000 entries are matched in the database of a server configured to send a maximum number of 500 entries, no more than 500 entries are returned even when *sizelimit* is set to 0.

The `ldap_search_ext()` function initiates an asynchronous search operation and returns `LDAP_SUCCESS` when the request is successfully sent to the server. Otherwise, `ldap_search_ext()` returns an LDAP error code. See [ldap_error\(3LDAP\)](#). If successful, `ldap_search_ext()` places the message ID of the request in **msgidp*. A subsequent call to [ldap_result\(3LDAP\)](#) can be used to obtain the result of the add request.

The `ldap_search_ext_s()` function initiates a synchronous search operation and returns the result of the operation itself.

ERRORS The `ldap_search_s()` and `ldap_search_st()` functions return the LDAP error code that results from a search operation. See [ldap_error\(3LDAP\)](#) for details.

The `ldap_search()` function returns `-1` when the operation terminates unsuccessfully.

ATTRIBUTES See [attributes\(5\)](#) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving

SEE ALSO [ldap\(3LDAP\)](#), [ldap_result\(3LDAP\)](#), [ldap_getfilter\(3LDAP\)](#), [ldap_error\(3LDAP\)](#), [attributes\(5\)](#)

Howes, T., Kille, S., Yeong, W., Robbins, C., Wenn, J. *RFC 1778, The String Representation of Standard Attribute Syntaxes*. Network Working Group. March 1995.

Postel, J., Anderson, C. *RFC 1588, White Pages Meeting Report*. Network Working Group. February 1994.

NOTES | The read and list functionality are subsumed by `ldap_search()` functions, when a filter such as `objectclass=*` is used with the scope `LDAP_SCOPE_BASE` to emulate read or the scope `LDAP_SCOPE_ONELEVEL` to emulate list.

The `ldap_search()` functions may allocate memory which must be freed by the calling application. Return values are contained in `<ldap.h>`.

ldap_searchprefs(3LDAP)

NAME	<code>ldap_searchprefs</code> , <code>ldap_init_searchprefs</code> , <code>ldap_init_searchprefs_buf</code> , <code>ldap_free_searchprefs</code> , <code>ldap_first_searchobj</code> , <code>ldap_next_searchobj</code> – LDAP search preference configuration routines
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] # include <lber.h> # include <ldap.h> int ldap_init_searchprefs(char **file, struct ldap_searchobj **solist); int ldap_init_searchprefs_buf(char **buf, unsigned longlen, struct ldap_searchobj **solist); struct ldap_searchobj **ldap_free_searchprefs(struct ldap_searchobj **solist); struct ldap_searchobj **ldap_first_searchobj(struct ldap_seachobj **solist); struct ldap_searchobj **ldap_next_searchobj(struct ldap_seachobj **solist, struct ldap_seachobj **so);</pre>
DESCRIPTION	<p>These functions provide a standard way to access LDAP search preference configuration data. LDAP search preference configurations are typically used by LDAP client programs to specify which attributes a user may search by, labels for the attributes, and LDAP filters and scopes associated with those searches. Client software presents these choices to a user, who can then specify the type of search to be performed.</p> <p><code>ldap_init_searchprefs()</code> reads a sequence of search preference configurations from a valid LDAP searchpref configuration file. See <code>ldapsearchprefs.conf(4)</code>. Upon success, 0 is returned and <i>solist</i> is set to point to a list of search preference data structures.</p> <p><code>ldap_init_searchprefs_buf()</code> reads a sequence of search preference configurations from <i>buf</i>, whose size is <i>buflen</i>. <i>buf</i> should point to the data in the format defined for an LDAP search preference configuration file. See <code>ldapsearchprefs.conf(4)</code>. Upon success, 0 is returned and <i>solist</i> is set to point to a list of search preference data structures.</p> <p><code>ldap_free_searchprefs()</code> disposes of the data structures allocated by <code>ldap_init_searchprefs()</code>.</p> <p><code>ldap_first_searchpref()</code> returns the first search preference data structure in the list <i>solist</i>. The <i>solist</i> is typically obtained by calling <code>ldap_init_searchprefs()</code>.</p> <p><code>ldap_next_searchpref()</code> returns the search preference after <i>so</i> in the template list <i>solist</i>. A NULL pointer is returned if <i>so</i> is the last entry in the list.</p>
ERRORS	<code>ldap_init_search_prefs()</code> and <code>ldap_init_search_prefs_bufs()</code> return:

ldap_searchprefs(3LDAP)

LDAP_SEARCHPREF_ERR_VERSION ***buf* points to data that is newer than can be handled.

LDAP_SEARCHPREF_ERR_MEM Memory allocation problem.

ldap_sort(3LDAP)

NAME	ldap_sort, ldap_sort_entries, ldap_sort_values, ldap_sort_strcasecmp – LDAP entry sorting functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> ldap_sort_entries(LDAP *ld, LDAPMessage **chain, char *attr, int (*cmp) ()); ldap_sort_values(LDAP *ld, char **vals, int (*cmp) ()); ldap_sort_strcasecmp(char *a, char *b);</pre>
DESCRIPTION	<p>These functions are used to sort lists of entries and values retrieved from an LDAP server. <code>ldap_sort_entries()</code> is used to sort a chain of entries retrieved from an LDAP search call either by DN or by some arbitrary attribute in the entries. It takes <code>ld</code>, the LDAP structure, which is only used for error reporting, <code>chain</code>, the list of entries as returned by <code>ldap_search_s(3LDAP)</code> or <code>ldap_result(3LDAP)</code>. <code>attr</code> is the attribute to use as a key in the sort or NULL to sort by DN, and <code>cmp</code> is the comparison function to use when comparing values (or individual DN components if sorting by DN). In this case, <code>cmp</code> should be a function taking two single values of the <code>attr</code> to sort by, and returning a value less than zero, equal to zero, or greater than zero, depending on whether the first argument is less than, equal to, or greater than the second argument. The convention is the same as used by <code>qsort(3C)</code>, which is called to do the actual sorting.</p> <p><code>ldap_sort_values()</code> is used to sort an array of values from an entry, as returned by <code>ldap_get_values(3LDAP)</code>. It takes the LDAP connection structure <code>ld</code>, the array of values to sort <code>vals</code>, and <code>cmp</code>, the comparison function to use during the sort. Note that <code>cmp</code> will be passed a pointer to each element in the <code>vals</code> array, so if you pass the normal <code>char **</code> for this parameter, <code>cmp</code> should take two <code>char **</code>'s as arguments (that is, you cannot pass <code>strcasecmp</code> or its friends for <code>cmp</code>). You can, however, pass the function <code>ldap_sort_strcasecmp()</code> for this purpose.</p> <p>For example:</p> <pre>LDAP *ld; LDAPMessage *res; /* ... call to ldap_search_s(), fill in res, retrieve sn attr ... */ /* now sort the entries on surname attribute */ if (ldap_sort_entries(ld, &res, "sn", ldap_sort_strcasecmp) != 0) ldap_perror(ld, "ldap_sort_entries");</pre>
ATTRIBUTES	See <code>attributes(5)</code> for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsl (32-bit)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
	SUNWcslx (64-bit)
Interface Stability	Evolving

SEE ALSO [ldap\(3LDAP\)](#), [ldap_search\(3LDAP\)](#), [ldap_result\(3LDAP\)](#), [qsort\(3C\)](#), [attributes\(5\)](#)

NOTES The `ldap_sort_entries()` function applies the comparison function to each value of the attribute in the array as returned by a call to [ldap_get_values\(3LDAP\)](#), until a mismatch is found. This works fine for single-valued attributes, but may produce unexpected results for multi-valued attributes. When sorting by DN, the comparison function is applied to an exploded version of the DN, without types. The return values for all of these functions are declared in the `<ldap.h>` header file. Some functions may allocate memory which must be freed by the calling application.

ldap_ufn(3LDAP)

NAME	ldap_ufn, ldap_ufn_search_s, ldap_ufn_search_c, ldap_ufn_search_ct, ldap_ufn_setfilter, ldap_ufn_setprefix, ldap_ufn_timeout – LDAP user friendly search functions
SYNOPSIS	<pre>cc [flag...] file... -lldap [library...] #include <lber.h> #include <ldap.h> int ldap_ufn_search_c(LDAP *ld, char *ufn, char **attrs, int attrsonly, LDAPMessage **res, int (*cancelproc)(), void *cancelparm); int ldap_ufn_search_ct(LDAP *ld, char *ufn, char **attrs, int attrsonly, LDAPMessage **res, int (*cancelproc)(), void *cancelparm, char *tag1, char *tag2, char *tag3); int ldap_ufn_search_s(LDAP *ld, char *ufn, char **attrs, int attrsonly, LDAPMessage **res); LDAPFiltDesc *ldap_ufn_setfilter(LDAP *ld, char *fname); void ldap_ufn_setprefix(LDAP *ld, char *prefix); int ldap_ufn_timeout(void *toparam);</pre>
DESCRIPTION	<p>These functions are used to perform LDAP user friendly search operations. <code>ldap_ufn_search_s()</code> is the simplest form. It does the search synchronously. It takes <code>ld</code> to identify the the LDAP connection. The <code>ufn</code> parameter is the user friendly name for which to search. The <code>attrs</code>, <code>attrsonly</code> and <code>res</code> parameters are the same as for <code>ldap_search(3LDAP)</code>.</p> <p>The <code>ldap_ufn_search_c()</code> function functions the same as <code>ldap_ufn_search_s()</code>, except that it takes <code>cancelproc</code>, a function to call periodically during the search. It should be a function taking a single void * argument, given by <code>cancelparm</code>. If <code>cancelproc</code> returns a non-zero result, the search will be abandoned and no results returned. The purpose of this function is to provide a way for the search to be cancelled, for example, by a user or because some other condition occurs.</p> <p>The <code>ldap_ufn_search_ct()</code> function is like <code>ldap_ufn_search_c()</code>, except that it takes three extra parameters. <code>tag1</code> is passed to the <code>ldap_init_getfilter(3LDAP)</code> function when resolving the first component of the UFN. <code>tag2</code> is used when resolving intermediate components. <code>tag3</code> is used when resolving the last component. By default, the tags used by the other UFN search functions during these three phases of the search are "ufn first", "ufn intermediate", and "ufn last".</p> <p>The <code>ldap_ufn_setfilter()</code> function is used to set the <code>ldapfilter.conf(4)</code> file for use with the <code>ldap_init_getfilter(3LDAP)</code> function to <code>fname</code>.</p> <p>The <code>ldap_ufn_setprefix()</code> function is used to set the default prefix (actually, it's a suffix) appended to UFNs before searching. UFNs with fewer than three components have the prefix appended first, before searching. If that fails, the UFN is tried with progressively shorter versions of the prefix, stripping off components. If the UFN has three or more components, it is tried by itself first. If that fails, a similar process is applied with the prefix appended.</p>

The `ldap_ufn_timeout()` function is used to set the timeout associated with `ldap_ufn_search_s()` searches. The *timeout* parameter should actually be a pointer to a struct `timeval`. This is so `ldap_ufn_timeout()` can be used as a `cancelproc` in the above functions.

ATTRIBUTES See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO `gettimeofday(3C)`, `ldap(3LDAP)`, `ldap_search(3LDAP)`, `ldap_getfilter(3LDAP)`, `ldapfilter.conf(4)`, `ldap_error(3LDAP)`, `attributes(5)`

NOTES These functions may allocate memory. Return values are contained in `<ldap.h>`.

ldap_url(3LDAP)

NAME	ldap_url, ldap_is_ldap_url, ldap_url_parse, ldap_url_parse_nodn, ldap_free_urldesc, ldap_url_search, ldap_url_search_s, ldap_url_search_st, ldap_dns_to_url, ldap_dn_to_url – LDAP Uniform Resource Locator functions										
SYNOPSIS	<pre>cc[<i>flag...</i>] <i>file...</i> -lldap[<i>library...</i>] #include <lber.h> #include <ldap.h> int ldap_is_ldap_url(char *url); int ldap_url_parse(char *url, LDAPURLDesc **ludpp); int ldap_url_parse_nodn(char *url, LDAPURLDesc **ludpp); ldap_free_urldesc(LDAPURLDesc *ludp); int ldap_url_search(LDAP *ld, char *url, int attrsonly); int ldap_url_search_s(LDAP *ld, char *url, int attrsonly, LDAPMessage **res); int ldap_url_search_st(LDAP *ld, char *url, int attrsonly, struct timeval *timeout, LDAPMessage **res); char *ldap_dns_to_url(LDAP *ld, char *dns_name, char *attrs, char *scope, char *filter); char *ldap_dn_to_url(LDAP *ld, char *dn, int nameparts);</pre>										
DESCRIPTION	<p>These functions support the use of LDAP URLs (Uniform Resource Locators). The following shows the formatting used for LDAP URLs.</p> <pre>ldap://hostport/dn[?attributes[?scope[?filter]]]</pre> <p>where:</p> <table><tr><td><i>hostport</i></td><td>Host name with an optional :portnumber.</td></tr><tr><td><i>dn</i></td><td>Base DN to be used for an LDAP search operation.</td></tr><tr><td><i>attributes</i></td><td>Comma separated list of attributes to be retrieved.</td></tr><tr><td><i>scope</i></td><td>One of these three strings: base one sub (default=base).</td></tr><tr><td><i>filter</i></td><td>LDAP search filter as used in a call to <code>ldap_search(3LDAP)</code>.</td></tr></table> <p>The following is an example of an LDAP URL:</p> <pre>ldap://ldap.itd.umich.edu/c=US?o,description?one?o=umich</pre> <p>URLs preceded URL: or wrapped in angle-brackets are tolerated. URLs can also be preceded by URL: and wrapped in angle-brackets.</p> <p>ldap_is_ldap_url() returns a non-zero value if <i>url</i> looks like an LDAP URL (as opposed to some other kind of URL). It can be used as a quick check for an LDAP URL; the ldap_url_parse() function should be used if a more thorough check is needed.</p>	<i>hostport</i>	Host name with an optional :portnumber.	<i>dn</i>	Base DN to be used for an LDAP search operation.	<i>attributes</i>	Comma separated list of attributes to be retrieved.	<i>scope</i>	One of these three strings: base one sub (default=base).	<i>filter</i>	LDAP search filter as used in a call to <code>ldap_search(3LDAP)</code> .
<i>hostport</i>	Host name with an optional :portnumber.										
<i>dn</i>	Base DN to be used for an LDAP search operation.										
<i>attributes</i>	Comma separated list of attributes to be retrieved.										
<i>scope</i>	One of these three strings: base one sub (default=base).										
<i>filter</i>	LDAP search filter as used in a call to <code>ldap_search(3LDAP)</code> .										

ldap_url(3LDAP)

`ldap_url_parse()` breaks down an LDAP URL passed in *url* into its component pieces. If successful, zero is returned, an LDAP URL description is allocated, filled in, and *ludpp* is set to point to it. See RETURN VALUES for values returned upon error.

`ldap_url_parse_nodn()` acts just like `ldap_url_parse()` but does not require *dn* in the LDAP URL.

`ldap_free_urldesc()` should be called to free an LDAP URL description that was obtained from a call to `ldap_url_parse()`.

`ldap_url_search()` initiates an asynchronous LDAP search based on the contents of the *url* string. This function acts just like `ldap_search(3LDAP)` except that many search parameters are pulled out of the URL.

`ldap_url_search_s()` performs a synchronous LDAP search based on the contents of the *url* string. This function acts just like `ldap_search_s(3LDAP)` except that many search parameters are pulled out of the URL.

`ldap_url_search_st()` performs a synchronous LDAP URL search with a specified *timeout*. This function acts just like `ldap_search_st(3LDAP)` except that many search parameters are pulled out of the URL.

`ldap_dns_to_url()` locates the LDAP URL associated with a DNS domain name. The supplied DNS domain name is converted into a distinguished name. The directory entry specified by that distinguished name is searched for a labeled URI attribute. If successful then the corresponding LDAP URL is returned. If unsuccessful then that entry's parent is searched and so on until the target distinguished name is reduced to only two nameparts. If *dns_name* is NULL then the environment variable LOCALDOMAIN is used. If *attrs* is not NULL then it is appended to the URL's attribute list. If *scope* is not NULL then it overrides the URL's scope. If *filter* is not NULL then it is merged with the URL's filter. If an error is encountered then zero is returned, otherwise a string URL is returned. The caller should free the returned string if it is non-zero.

`ldap_dn_to_url()` locates the LDAP URL associated with a distinguished name. The number of nameparts in the supplied distinguished name must be provided. The specified directory entry is searched for a labeledURI attribute. If successful then the LDAP URL is returned. If unsuccessful then that entry's parent is searched and so on until the target distinguished name is reduced to only two nameparts. If an error is encountered then zero is returned, otherwise a string URL is returned. The caller should free the returned string if it is non-zero.

RETURN VALUES

Upon error, one of these values is returned for `ldap_url_parse()`:

LDAP_URL_ERR_BADSCOPE	URL scope string is invalid.
LDAP_URL_ERR_HOSTPORT	URL hostport is invalid.
LDAP_URL_ERR_MEM	Can't allocate memory space.
LDAP_URL_ERR_NODN	URL has no DN (required).

ldap_url(3LDAP)

LDAP_URL_ERR_NOTLDAP URL doesn't begin with ldap://.

An LDAP URL Format, Tim Howes and Mark Smith, December 1995. Internet Draft (work in progress). Currently available at this URL.

`ftp://ds.internic.net/internet-drafts/draft-ietf-asid-ldap-format-03.txt`

- NAME** ldap_version – get version information about the LDAP SDK for C
- SYNOPSIS**
- ```
cc -flag ... file ...-lldap [-library ...]
#include <ldap.h>

int ldap_version(LDAPVERSION *ver);
```
- DESCRIPTION** A call to this function returns the version information for the LDAP SDK for C. This is a deprecated function. Use `ldap_get_option(3LDAP)` instead. The version information is returned in the `LDAPVersion` structure pointed to by *ver*. If `NULL` is passed for *ver*, then only the SDK version will be returned.
- RETURN VALUES** The `ldap_version()` function returns the version number of the LDAP SDK for C, multiplied by 100. For example, for version 1.0 of the LDAP SDK for C, the function returns 100.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|---------------------|-------------------|
| Availability        | SUNWcsl (32-bit)  |
|                     | SUNWcslx (64-bit) |
| Interface Stability | Obsolete          |

| <b>SYNOPSIS</b>         | <pre>cc [ flag ... ] file ... -lsocket -lnsl [ library ... ] #include &lt;sys/types.h&gt; #include &lt;sys/socket.h&gt;  int listen(int s, int backlog);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                    |                                                       |                       |                                        |                         |                                                                                 |
| <b>DESCRIPTION</b>      | <p>To accept connections, a socket is first created with <code>socket(3SOCKET)</code>, a backlog for incoming connections is specified with <code>listen()</code> and then the connections are accepted with <code>accept(3SOCKET)</code>. The <code>listen()</code> call applies only to sockets of type <code>SOCK_STREAM</code> or <code>SOCK_SEQPACKET</code>.</p> <p>The <i>backlog</i> parameter defines the maximum length the queue of pending connections may grow to.</p> <p>If a connection request arrives with the queue full, the client will receive an error with an indication of <code>ECONNREFUSED</code> for <code>AF_UNIX</code> sockets. If the underlying protocol supports retransmission, the connection request may be ignored so that retries may succeed. For <code>AF_INET</code> and <code>AF_INET6</code> sockets, the TCP will retry the connection. If the <i>backlog</i> is not cleared by the time the tcp times out, the connect will fail with <code>ETIMEDOUT</code>.</p> |                    |                                                       |                       |                                        |                         |                                                                                 |
| <b>RETURN VALUES</b>    | A 0 return value indicates success; -1 indicates an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                       |                       |                                        |                         |                                                                                 |

| <b>NAME</b>          | listen – listen for socket connections and limit the queue of incoming connections                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |                                                            |              |                                                                                                               |        |                                         |          |                                                        |            |                                                              |        |                                                               |        |                                       |         |                                                                          |
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lxnet [ library ... ] #include &lt;sys/socket.h&gt;  int listen(int socket, int backlog);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |                                                            |              |                                                                                                               |        |                                         |          |                                                        |            |                                                              |        |                                                               |        |                                       |         |                                                                          |
| <b>DESCRIPTION</b>   | <p>The <code>listen()</code> function marks a connection-mode socket, specified by the <i>socket</i> argument, as accepting connections, and limits the number of outstanding connections in the socket's listen queue to the value specified by the <i>backlog</i> argument.</p> <p>If <code>listen()</code> is called with a <i>backlog</i> argument value that is less than 0, the function sets the length of the socket's listen queue to 0.</p> <p>The implementation may include incomplete connections in the queue subject to the queue limit. The implementation may also increase the specified queue limit internally if it includes such incomplete connections in the queue subject to this limit.</p> <p>Implementations may limit the length of the socket's listen queue. If <i>backlog</i> exceeds the implementation-dependent maximum queue length, the length of the socket's listen queue will be set to the maximum supported value.</p> <p>The socket in use may require the process to have appropriate privileges to use the <code>listen()</code> function.</p> |       |                                                            |              |                                                                                                               |        |                                         |          |                                                        |            |                                                              |        |                                                               |        |                                       |         |                                                                          |
| <b>RETURN VALUES</b> | Upon successful completions, <code>listen()</code> returns 0. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |       |                                                            |              |                                                                                                               |        |                                         |          |                                                        |            |                                                              |        |                                                               |        |                                       |         |                                                                          |

| <b>DESCRIPTION</b> | <p>The netdir functions provide a generic interface for name-to-address mapping that will work with all transport protocols. This interface provides a generic way for programs to convert transport specific addresses into common structures and back again. The netconfig structure, described on the netconfig(4) manual page, identifies the transport.</p> <p>The netdir_getbyname() function maps the machine name and service name in the nd_hostserv structure to a collection of addresses of the type understood by the transport identified in the netconfig structure. This function returns all addresses that are valid for that transport in the nd_addrlist structure. The nd_hostserv structure contains the following members:</p> <pre>char      /* host name */ *h_serv; /* service name */</pre> <p>The nd_addrlist structure contains the following members:</p> <pre>int  n_cnt;      /* number of addresses */ struct netbuf *n_addrs;</pre> <p>The netdir_getbyname() function accepts some special-case host names. The host names are defined in &lt;netdir.h&gt;. The currently defined host names are:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">HOST_SELF</td> <td>Represents the address to which local programs will bind their endpoints. HOST_SELF differs from the host name provided by gethostname(3C), which represents the address to which <i>remote</i> programs will bind their endpoints.</td> </tr> </table> | HOST_SELF | Represents the address to which local programs will bind their endpoints. HOST_SELF differs from the host name provided by gethostname(3C), which represents the address to which <i>remote</i> programs will bind their endpoints. |
| HOST_SELF          | Represents the address to which local programs will bind their endpoints. HOST_SELF differs from the host name provided by gethostname(3C), which represents the address to which <i>remote</i> programs will bind their endpoints.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |           |                                                                                                                                                                                                                                     |

## netdir(3NSL)

|                   |                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HOST_ANY          | Represents any host accessible by this transport provider. HOST_ANY allows applications to specify a required service without specifying a particular host name. |
| HOST_SELF_CONNECT | Represents the host address that can be used to connect to the local host.                                                                                       |
| HOST_BROADCAST    | Represents the address for all hosts accessible by this transport provider. Network requests to this address are received by all machines.                       |

All fields of the `nd_hostserv` structure must be initialized.

To find the address of a given host and service on all available transports, call the `netdir_getbyname()` function with each `struct netconfig` structure returned by `getnetconfig(3NSL)`.

The `netdir_getbyaddr()` function maps addresses to service names. The function returns *service*, a list of host and service pairs that yield these addresses. If more than one tuple of host and service name is returned, the first tuple contains the preferred host and service names:

```
struct nd_hostservlist {
 int *h_cnt; /* number of hostservs found */
 struct hostserv *h_hostservs;
}
```

The `netdir_free()` structure is used to free the structures allocated by the name to address translation functions. The *ptr* parameter points to the structure that has to be freed. The parameter `struct_type` identifies the structure:

```
struct netbuf ND_ADDR
struct nd_addrlist ND_ADDRLIST
struct hostserv ND_HOSTSERV
struct nd_hostservlist ND_HOSTSERVLIST
```

The `free()` function is used to free the universal address returned by the `taddr2uaddr()` function.

The `netdir_options()` function is used to do all transport-specific setups and option management. *fildev* is the associated file descriptor. *option*, *fildev*, and *pointer\_to\_args* are passed to the `netdir_options()` function for the transport specified in *config*. Currently four values are defined for *option*:

```
ND_SET_BROADCAST
ND_SET_RESERVEDPORT
ND_CHECK_RESERVEDPORT
ND_MERGEADDR
```

The `taddr2uaddr()` and `uaddr2taddr()` functions support translation between universal addresses and TLI type `netbufs`. The `taddr2uaddr()` function takes a `struct netbuf` data structure and returns a pointer to a string that contains the universal address. It returns `NULL` if the conversion is not possible. This is not a fatal condition as some transports do not support a universal address form.

The `uaddr2taddr()` function is the reverse of the `taddr2uaddr()` function. It returns the `struct netbuf` data structure for the given universal address.

If a transport provider does not support an option, `netdir_options` returns `-1` and the error message can be printed through `netdir_perror()` or `netdir_sperror()`.

The specific actions of each option follow.

#### ND\_SET\_BROADCAST

Sets the transport provider up to allow broadcast if the transport supports broadcast. *fildev* is a file descriptor into the transport, that is, the result of a `t_open` of `/dev/udp`. *pointer\_to\_args* is not used. If this completes, broadcast operations can be performed on file descriptor *fildev*.

#### ND\_SET\_RESERVEDPORT

Allows the application to bind to a reserved port if that concept exists for the transport provider. *fildev* is an unbound file descriptor into the transport. If *pointer\_to\_args* is `NULL`, *fildev* is bound to a reserved port. If *pointer\_to\_args* is a pointer to a `netbuf` structure, an attempt is made to bind to any reserved port on the specified address.

#### ND\_CHECK\_RESERVEDPORT

Used to verify that the address corresponds to a reserved port if that concept exists for the transport provider. *fildev* is not used. *pointer\_to\_args* is a pointer to a `netbuf` structure that contains the address. This option returns `0` only if the address specified in *pointer\_to\_args* is reserved.

#### ND\_MERGEADDR

Used to take a “local address” such as a `0.0.0.0` TCP address and return a “real address” to which client machines can connect. *fildev* is not used. *pointer\_to\_args* is a pointer to a `struct nd_mergearg` which has the following members:

```
char s_uaddr; /* server's universal address */
char c_uaddr; /* client's universal address */
char m_uaddr; /* the result */
```

If *s\_uaddr* is an address such as `0.0.0.0.1.12`, and the call is successful *m\_uaddr* is set to an address such as `192.11.109.89.1.12`. For most transports, *m\_uaddr* is identical to *s\_uaddr*.

## RETURN VALUES

The `netdir_perror()` function prints an error message in standard output that states the cause of a name-to-address mapping failure. The error message is preceded by the string given as an argument.

## netdir(3NSL)

The `netdir_serror()` function returns a string with an error message that states the cause of a name-to-address mapping failure.

The `netdir_serror()` function returns a pointer to a buffer which contains the error message string. The buffer is overwritten on each call. In multithreaded applications, this buffer is implemented as thread-specific data.

The `netdir_getbyaddr()` function returns 0 on success and a non-zero value on failure.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| <b>DESCRIPTION</b> | <p>These functions convert NIS+ status values into text strings.</p> <p><code>nis_sperrno()</code> simply returns a pointer to a string constant which is the error string.</p> <p><code>nis_perror()</code> prints the error message corresponding to <i>status</i> as “<i>label</i>: error message” on standard error.</p> <p><code>nis_terror()</code> sends the error text to <code>syslog(3C)</code> at level <code>LOG_ERR</code>.</p> <p>The function <code>nis_sperror_r()</code>, returns a pointer to a string that can be used or copied using the <code>strdup()</code> function (See <code>string(3C)</code>). The caller must supply a string buffer, <i>buf</i>, large enough to hold the error string (a buffer size of 128 bytes is guaranteed to be sufficiently large). <i>status</i> and <i>label</i> are the same as for <code>nis_perror()</code>. The pointer returned by <code>nis_sperror_r()</code> is the same as <i>buf</i>, that is, the pointer returned by the function is a pointer to <i>buf</i>. <i>length</i> specifies the number of characters to copy from the error string to <i>buf</i>.</p> <p>The last function, <code>nis_sperror()</code>, is similar to <code>nis_sperror_r()</code> except that the string is returned as a pointer to a buffer that is reused on each call. <code>nis_sperror_r()</code> is the preferred interface, since it is suitable for single-threaded and multi-threaded programs.</p> <p>When compiling multithreaded applications, see <code>Intro(3), Notes On Multithread Applications</code>, for information about the use of the <code>_REENTRANT</code> flag.</p> |                |                 |          |      |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |      |

| <b>DESCRIPTION</b> | <p>These functions manipulate NIS+ groups. They are used by NIS+ clients and servers, and are the interfaces to the group authorization object.</p> <p>The names of NIS+ groups are syntactically similar to names of NIS+ objects but they occupy a separate namespace. A group named "a.b.c.d." is represented by a NIS+ group object named "a.groups_dir.b.c.d."; the functions described here all expect the name of the group, not the name of the corresponding group object.</p> <p>There are three types of group members:</p> <ul style="list-style-type: none"> <li>■ An <i>explicit</i> member is just a NIS+ principal-name, for example "wickedwitch.west.oz."</li> <li>■ An <i>implicit</i> ("domain") member, written "*.west.oz.", means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed: "wickedwitch.*.oz." is invalid, as is "wickedwitch.west.*.". Note that principals in subdomains of the given domain are <i>not</i> included.</li> <li>■ A <i>recursive</i> ("group") member, written "@cowards.oz.", refers to another group. All principals that belong to that group are considered to belong here.</li> </ul> <p>Any member may be made <i>negative</i> by prefixing it with a minus sign ('-'). A group may thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative recursive members.</p> <p>A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.</p> <p>The <code>nis_ismember()</code> function returns TRUE if it can establish that <i>principal</i> belongs to <i>group</i>; otherwise it returns FALSE.</p> <p>The <code>nis_addmember()</code> and <code>nis_removemember()</code> functions add or remove a member. They do not check whether the member is valid. The user must have read and modify rights for the group in question.</p> |

## nis\_groups(3NSL)

The `nis_creategroup()` and `nis_destroygroup()` functions create and destroy group objects. The user must have create or destroy rights, respectively, for the `groups_dir` directory in the appropriate domain. The parameter `flags` to `nis_creategroup()` is currently unused and should be set to zero.

The `nis_print_group_entry()` function lists a group's members on the standard output.

The `nis_verifygroup()` function returns `NIS_SUCCESS` if the given group exists, otherwise it returns an error code.

These functions only accept fully-qualified NIS+ names.

A group is represented by a NIS+ object with a variant part that is defined in the `group_obj` structure. See `nis_objects(3NSL)`. It contains the following fields:

```
uint_t gr_flags; /* Interpretation Flags
 (currently unused) */
struct {
 uint_t gr_members_len;
 nis_name *gr_members_val;
} gr_members; /* Array of members */
```

NIS+ servers and clients maintain a local cache of expanded groups to enhance their performance when checking for group membership. Should the membership of a group change, servers and clients with that group cached will not see the change until either the group cache has expired or it is explicitly flushed. A server's cache may be flushed programmatically by calling the `nis_servstate()` function with tag `TAG_GCACHE` and a value of 1.

There are currently no known methods for `nis_ismember()`, `nis_print_group_entry()`, and `nis_verifygroup()` to get their answers from only the master server.

### EXAMPLES

#### EXAMPLE 1 Simple Memberships

Given a group `sadsouls.oz.` with members `tinman.oz.`, `lion.oz.`, and `scarecrow.oz.`, the function call

```
bool_var = nis_ismember("lion.oz.", "sadsouls.oz.");
```

will return 1 (TRUE) and the function call

```
bool_var = nis_ismember("toto.oz.", "sadsouls.oz.");
```

will return 0 (FALSE).

#### EXAMPLE 2 Implicit Memberships

Given a group `baddies.oz.` with members `wickedwitch.west.oz.` and `*.monkeys.west.oz.`, the function call `bool_var = nis_ismember("hogan.monkeys.west.oz.", "baddies.oz.");` will return 1 (TRUE) because any principal from the `monkeys.west.oz.` domain belongs to the implicit group `*.monkeys.west.oz.`, but the function call

**EXAMPLE 2** Implicit Memberships *(Continued)*

```
bool_var = nis_ismember("hogan.big.monkeys.west.oz.", "baddies.oz.");
will return 0 (FALSE).
```

**EXAMPLE 3** Recursive Memberships

Given a group `goodandbad.oz.`, with members `toto.kansas`, `@sadsouls.oz.`, and `@baddies.oz.`, and the groups `sadsouls.oz.` and `baddies.oz.` defined above, the function call

```
bool_var = nis_ismember("wickedwitch.west.oz.", "goodandbad.oz.");
```

will return 1 (TRUE), because `wickedwitch.west.oz.` is a member of the `baddies.oz.` group which is recursively included in the `goodandbad.oz.` group.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

**SEE ALSO** `nisgrpadm(1)`, `nis_objects(3NSL)`, `attributes(5)`

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

## nis\_local\_names(3NSL)

| <b>NAME</b>                  | nis_local_names, nis_local_directory, nis_local_host, nis_local_group, nis_local_principal – NIS+ local names                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |          |         |

| <b>DESCRIPTION</b>           | <p>These functions return several default NIS+ names associated with the current process.</p> <p>nis_local_directory() returns the name of the NIS+ domain for this machine. This is currently the same as the Secure RPC domain returned by the sysinfo(2) system call.</p> <p>nis_local_host() returns the NIS+ name of the current machine. This is the fully qualified name for the host and is either the value returned by the gethostname(3C) function or, if the host name is only partially qualified, the concatenation of that value and the name of the NIS+ directory. Note that if a machine's name and address cannot be found in the local NIS+ directory, its hostname must be fully qualified.</p> <p>nis_local_group() returns the name of the current NIS+ group name. This is currently set by setting the environment variable NIS_GROUP to the groupname.</p> <p>nis_local_principal() returns the NIS+ principal name for the user associated with the effective UID of the calling process. This function maps the effective uid into a principal name by looking for a LOCAL type credential in the table named cred.org_dir in the default domain. See nisaddcred(1M).</p> <p>The result returned by these routines is a pointer to a data structure with the NIS+ library, and should be considered a "read-only" result and should not be modified.</p> |                |                 |          |         |
| <b>ENVIRONMENT VARIABLES</b> | <p>NIS_GROUP      This variable contains the name of the local NIS+ group. If the name is not fully qualified, the value returned by nis_local_directory() will be concatenated to it.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |          |         |

| <b>DESCRIPTION</b> | <p>The NIS+ namespace functions are used to locate and manipulate all NIS+ objects except the NIS+ entry objects. See <a href="#">nis_objects(3NSL)</a>. To look up the NIS+ entry objects within a NIS+ table, refer to <a href="#">nis_subr(3NSL)</a>.</p> <p><code>nis_lookup()</code> resolves a NIS+ name and returns a copy of that object from a NIS+ server. <code>nis_add()</code> and <code>nis_remove()</code> add and remove objects to the NIS+ namespace, respectively. <code>nis_modify()</code> can change specific attributes of an object that already exists in the namespace.</p> <p>These functions should be used only with names that refer to an NIS+ Directory, NIS+ Table, NIS+ Group, or NIS+ Private object. If a name refers to an NIS+ entry object, the functions listed in <a href="#">nis_subr(3NSL)</a> should be used.</p> <p><code>nis_freeresult()</code> frees all memory associated with a <code>nis_result</code> structure. This function must be called to free the memory associated with a NIS+ result. <code>nis_lookup()</code>, <code>nis_add()</code>, <code>nis_remove()</code>, and <code>nis_modify()</code> all return a pointer to a <code>nis_result()</code> structure which must be freed by calling <code>nis_freeresult()</code> when you have finished using it. If one or more of the objects returned in the structure need to be retained, they can be copied with <a href="#">nis_clone_object(3NSL)</a>. See <a href="#">nis_subr(3NSL)</a>.</p> <p><code>nis_lookup()</code> takes two parameters, the name of the object to be resolved in <i>name</i>, and a flags parameter, <i>flags</i>, which is defined below. The object name is expected to correspond to the syntax of a non-indexed NIS+ name. See <a href="#">nis_tables(3NSL)</a>. The <code>nis_lookup()</code> function is the only function from this group that can use a non-fully qualified name. If the parameter <i>name</i> is not a fully qualified name, then the flag <code>EXPAND_NAME</code> must be specified in the call. If this flag is not specified, the function will fail with the error <code>NIS_BADNAME</code>.</p> <p>The <i>flags</i> parameter is constructed by logically ORing zero or more flags from the following list.</p> |

|              |                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FOLLOW_LINKS | When specified, the client library will “follow” links by issuing another NIS+ lookup call for the object named by the link. If the linked object is itself a link, then this process will iterate until either an object is found that is not a LINK type object, or the library has followed 16 links.                                        |
| HARD_LOOKUP  | When specified, the client library will retry the lookup until it is answered by a server. Using this flag will cause the library to block until at least one NIS+ server is available. If the network connectivity is impaired, this can be a relatively long time.                                                                            |
| NO_CACHE     | When specified, the client library will bypass any object caches and will get the object from either the master NIS+ server or one of its replicas.                                                                                                                                                                                             |
| MASTER_ONLY  | When specified, the client library will bypass any object caches and any domain replicas and fetch the object from the NIS+ master server for the object’s domain. This insures that the object returned is up to date at the cost of a possible performance degradation and failure if the master server is unavailable or physically distant. |
| EXPAND_NAME  | When specified, the client library will attempt to expand a partially qualified name by calling the function <code>nis_getnames()</code> , which uses the environment variable <code>NIS_PATH</code> . See <a href="#">nis_subr(3NSL)</a> .                                                                                                     |

The status value may be translated to ASCII text using the function `nis_sperrno()`. See [nis\\_error\(3NSL\)](#).

On return, the *objects* array in the result will contain one and possibly several objects that were resolved by the request. If the FOLLOW\_LINKS flag was present, on success the function could return several entry objects if the link in question pointed within a table. If an error occurred when following a link, the objects array will contain a copy of the link object itself.

The function `nis_add()` will take the object *obj* and add it to the NIS+ namespace with the name *name*. This operation will fail if the client making the request does not have the *create* access right for the domain in which this object will be added. The parameter *name* must contain a fully qualified NIS+ name. The object members *zo\_name* and *zo\_domain* will be constructed from this name. This operation will fail if the object already exists. This feature prevents the accidental addition of objects over another object that has been added by another process.

## nis\_names(3NSL)

The function `nis_remove()` will remove the object with name *name* from the NIS+ namespace. The client making this request must have the *destroy* access right for the domain in which this object resides. If the named object is a link, the link is removed and *not* the object that it points to. If the parameter *obj* is not NULL, it is assumed to point to a copy of the object being removed. In this case, if the object on the server does not have the same object identifier as the object being passed, the operation will fail with the NIS\_NOTSAMEOBJ error. This feature allows the client to insure that it is removing the desired object. The parameter *name* must contain a fully qualified NIS+ name.

The function `nis_modify()` will modify the object named by *name* to the field values in the object pointed to by *obj*. This object should contain a copy of the object from the name space that is being modified. This operation will fail with the error NIS\_NOTSAMEOBJ if the object identifier of the passed object does not match that of the object being modified in the namespace.

Normally the contents of the member *zo\_name* in the *nis\_object* structure would be constructed from the name passed in the *name* parameter. However, if it is non-null the client library will use the name in the *zo\_name* member to perform a rename operation on the object. This name *must not* contain any unquoted '.'(dot) characters. If these conditions are not met the operation will fail and return the NIS\_BADNAME error code.

You cannot modify the name of an object if that modification would cause the object to reside in a different domain.

You cannot modify the schema of a table object.

**Results** These functions return a pointer to a structure of type `nis_result`:

```
struct nis_result {
 nis_error status;
 struct {
 uint_t objects_len;
 nis_object *objects_val;
 } objects;
 netobj cookie;
 uint32_t zticks;
 uint32_t dticks;
 uint32_t aticks;
 uint32_t cticks;
};
```

The *status* member contains the error status of the the operation. A text message that describes the error can be obtained by calling the function `nis_sperrno()`. See [nis\\_error\(3NSL\)](#).

The *objects* structure contains two members. *objects\_val* is an array of *nis\_object* structures; *objects\_len* is the number of cells in the array. These objects will be freed by the call to `nis_freeresult()`. If you need to keep a copy of one or more objects, they can be copied with the function `nis_clone_object()` and freed with the function `nis_destroy_object()`. See [nis\\_server\(3NSL\)](#). Refer to [nis\\_objects\(3NSL\)](#) for a description of the *nis\_object* structure.

The various ticks contain details of where the time was taken during a request. They can be used to tune one's data organization for faster access and to compare different database implementations.

|               |                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>zticks</i> | The time spent in the NIS+ service itself. This count starts when the server receives the request and stops when it sends the reply.                                                                                                                            |
| <i>dticks</i> | The time spent in the database backend. This time is measured from the time a database call starts, until the result is returned. If the request results in multiple calls to the database, this is the sum of all the time spent in those calls.               |
| <i>aticks</i> | The time spent in any "accelerators" or caches. This includes the time required to locate the server needed to resolve the request.                                                                                                                             |
| <i>cticks</i> | The total time spent in the request. This clock starts when you enter the client library and stops when a result is returned. By subtracting the sum of the other ticks values from this value, you can obtain the local overhead of generating a NIS+ request. |

Subtracting the value in *dticks* from the value in *zticks* will yield the time spent in the service code itself. Subtracting the sum of the values in *zticks* and *aticks* from the value in *cticks* will yield the time spent in the client library itself. Note: all of the tick times are measured in microseconds.

## RETURN VALUES

The client library can return a variety of error returns and diagnostics. The more salient ones are documented below.

|                  |                                                                                                                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS_SUCCESS      | The request was successful.                                                                                                                                                                                                                                 |
| NIS_S_SUCCESS    | The request was successful, however the object returned came from an object cache and not directly from the server. If you do not wish to see objects from object caches you must specify the flag <code>NO_CACHE</code> when you call the lookup function. |
| NIS_NOTFOUND     | The named object does not exist in the namespace.                                                                                                                                                                                                           |
| NIS_CACHEEXPIRED | The object returned came from an object cache that has <i>expired</i> . The time to live value has gone to zero and the object may have changed. If the flag <code>NO_CACHE</code> was passed                                                               |

## nis\_names(3NSL)

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | to the lookup function then the lookup function will retry the operation to get an unexpired copy of the object.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| NIS_NAMEUNREACHABLE | A server for the directory of the named object could not be reached. This can occur when there is a network partition or all servers have crashed. See the <code>HARD_LOOKUP</code> flag.                                                                                                                                                                                                                                                                                                                                            |
| NIS_UNKNOWNOBJ      | The object returned is of an unknown type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| NIS_TRYAGAIN        | The server connected to was too busy to handle your request. For the <i>add</i> , <i>remove</i> , and <i>modify</i> operations this is returned when either the master server for a directory is unavailable, or it is in the process of checkpointing its database. It can also be returned when the server is updating its internal state. In the case of <code>nis_list()</code> , <code>NIS_TRYAGAIN</code> is returned if the client specifies a callback and the server does not have enough resources to handle the callback. |
| NIS_SYSTEMERROR     | A generic system error occurred while attempting the request. Most commonly the server has crashed or the database has become corrupted. Check the syslog record for error messages from the server.                                                                                                                                                                                                                                                                                                                                 |
| NIS_NOT_ME          | A request was made to a server that does not serve the name in question. Normally this will not occur, however if you are not using the built in location mechanism for servers you may see this if your mechanism is broken.                                                                                                                                                                                                                                                                                                        |
| NIS_NOMEMORY        | Generally a fatal result. It means that the service ran out of heap space.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| NIS_NAMEEXISTS      | An attempt was made to add a name that already exists. To add the name, first remove the existing name and then add the new object or modify the existing named object.                                                                                                                                                                                                                                                                                                                                                              |
| NIS_NOTMASTER       | An attempt was made to update the database on a replica server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                   |                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS_INVALIDOBJ    | The object pointed to by <i>obj</i> is not a valid NIS+ object.                                                                                                                                                                                                                                                |
| NIS_BADNAME       | The name passed to the function is not a legal NIS+ name.                                                                                                                                                                                                                                                      |
| NIS_LINKNAMEERROR | The name passed resolved to a LINK type object and the contents of the link pointed to an invalid name.                                                                                                                                                                                                        |
| NIS_NOTSAMEOBJ    | An attempt to remove an object from the namespace was aborted because the object that would have been removed was not the same object that was passed in the request.                                                                                                                                          |
| NIS_NOSUCHNAME    | This hard error indicates that the named directory of the table object does not exist. This occurs when the server that should be the parent of the server that serves the table, does not know about the directory in which the table resides.                                                                |
| NIS_NOSUCHTABLE   | The named table does not exist.                                                                                                                                                                                                                                                                                |
| NIS_MODFAIL       | The attempted modification failed.                                                                                                                                                                                                                                                                             |
| NIS_FOREIGNNS     | The name could not be completely resolved. When the name passed to the function would resolve in a namespace that is outside the NIS+ name tree, this error is returned with a NIS+ object of type DIRECTORY, which contains the type of namespace and contact information for a server within that namespace. |
| NIS_RPCERROR      | This fatal error indicates the RPC subsystem failed in some way. Generally there will be a syslog(3C) message indicating why the RPC request failed.                                                                                                                                                           |

**ENVIRONMENT VARIABLES**

NIS\_PATH      If the flag EXPAND\_NAME is set, this variable is the search path used by nis\_lookup().

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

| <b>NAME</b>              | nisl_objects – NIS+ object formats                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>          | cc [ <i>flag</i> ... ] <i>file</i> ... -lnsl [ <i>library</i> ... ]<br>/usr/include/rpcsvc/nisl_objects.x                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Common Attributes</b> | <p>The NIS+ service uses a variant record structure to hold the contents of the objects that are used by the NIS+ service. These objects all share a common structure that defines a set of attributes that all objects possess. The <code>nisl_object</code> structure contains the following members:</p> <pre>typedef  char    *nisl_name; struct   nisl_object {     nisl_oid    zo_oid;     nisl_name   zo_name;     nisl_name   zo_owner;     nisl_name   zo_group;     nisl_name   zo_domain;     uint_t     zo_access;     uint32_t    zo_ttl;     objdata    zo_data; };</pre> <p>In this structure, the first member <code>zo_oid</code>, is a 64 bit number that uniquely identifies this instance of the object on this server. This member is filled in by the server when the object is created and changed by the server when the object is modified. When used in conjunction with the object's name and domain it uniquely identifies the object in the entire NIS+ namespace.</p> <p>The second member, <code>zo_name</code>, contains the leaf name of the object. This name is never terminated with a '.' (dot). When an object is created or added to the namespace, the client library will automatically fill in this field and the domain name from the name that was passed to the function.</p> <p><code>zo_domain</code> contains the name of the NIS+ domain to which this object belongs. This information is useful when tracking the parentage of an object from a cache. When used in conjunction with the members <code>zo_name</code> and <code>zo_oid</code>, it uniquely identifies an object. This makes it possible to always reconstruct the name of an object by using the code fragment</p> <pre>sprintf(buf, "%s.%s", obj-&gt;zo_name, obj-&gt;zo_domain);</pre> <p>The <code>zo_owner</code> and <code>zo_group</code> members contain the NIS+ names of the object's principal owner and group owner, respectively. Both names must be NIS+ fully qualified names. However, neither name can be used directly to identify the object they represent. This stems from the condition that NIS+ uses itself to store information that it exports.</p> <p>The <code>zo_owner</code> member contains a fully qualified NIS+ name of the form <i>principal.domain</i>. This name is called a NIS+ principal name and is used to identify authentication information in a credential table. When the server constructs a search query of the form</p> |

## nis\_objects(3NSL)

```
[cname=principal] , cred.org_dir.domain .
```

The query will return to the server credential information about *principal* for all flavors of RPC authentication that are in use by that principal. When an RPC request is made to the server, the authentication flavor is extracted from the request and is used to find out the NIS+ principal name of the client. For example, if the client is using the AUTH\_DES authentication flavor, it will include in the authentication credentials the network name or *netname* of the user making the request. This netname will be of the form

```
unix.UID@domain
```

The NIS+ server will then construct a query on the credential database of the form

```
[auth_name=netname , auth_type=AUTH_DES] , cred.org_dir.domain .
```

This query will return an entry which contains a principal name in the first column. This NIS+ principal name is used to control access to NIS+ objects.

The group owner for the object is treated differently. The group owner member is optional (it should be the null string if not present) but must be fully qualified if present. A group name takes the form

```
group.domain.
```

which the server then maps into a name of the form

```
group.groups_dir.domain.
```

The purpose of this mapping is to prevent NIS+ group names from conflicting with user specified domain or table names. For example, if a domain was called *engineering.foo.com.*, then without the mapping a NIS+ group of the same name to represent members of engineering would not be possible. The contents of groups are lists of NIS+ principal names which are used exactly like the *zo\_owner* name in the object. See [nis\\_groups\(3NSL\)](#) for more details.

The *zo\_access* member contains the bitmask of access rights assigned to this object. There are four access rights defined, and four are reserved for future use and must be zero. This group of 8 access rights can be granted to four categories of client. These categories are the object's owner, the object's group owner, all authenticated clients (world), and all unauthenticated clients (nobody). Note that access granted to "nobody" is really access granted to everyone, authenticated and unauthenticated clients.

The *zo\_ttl* member contains the number of seconds that the object can "live" in a cache before it is expired. This value is called the time to live for this object. This number is particularly important on group and directory (domain) objects. When an object is cached, the current time is added to the value in *zo\_ttl*. Then each time the cached object is used, the time in *zo\_ttl* is compared with the current time. If the current time is later than the time in *zo\_ttl* the object is said to have expired and the cached copy should not be used.

Setting the TTL is somewhat of an art. You can think of it as the “half life” of the object, or half the amount of time you believe will pass before the object changes. The benefit of setting the ttl to a large number is that the object will stay in a cache for long periods of time. The problem with setting it to a large value is that when the object changes it will take a long time for the caches to flush out old copies of that object. The problems and benefits are reversed for setting the time to a small value. Generally setting the value to 43200 (12 hrs) is reasonable for things that change day to day, and 3024000 is good for things that change week to week. Setting the value to 0 will prevent the object from ever being cached since it would expire immediately.

The `zo_data` member is a discriminated union with the following members:

```
zotypes zo_type;
union {
 struct directory_obj di_data;
 struct group_obj gr_data;
 struct table_obj ta_data;
 struct entry_obj en_data;
 struct link_obj li_data;
 struct {
 uint_t po_data_len;
 char *po_data_val;
 } po_data;
} objdata_u;
```

The union is discriminated based on the type value contained in `zo_type`. There six types of objects currently defined in the NIS+ service. These types are the directory, link, group, table, entry, and private types.

```
enum zotypes {
 BOGUS_OBJ = 0,
 NO_OBJ = 1,
 DIRECTORY_OBJ = 2,
 GROUP_OBJ = 3,
 TABLE_OBJ = 4,
 ENTRY_OBJ = 5,
 LINK_OBJ = 6,
 PRIVATE_OBJ = 7
};
typedef enum zotypes zotypes;
```

All object types define a structure that contains data specific to that type of object. The simplest are private objects which are defined to contain a variable length array of octets. Only the owner of the object is expected to understand the contents of a private object. The following section describe the other five object types in more significant detail.

## Directory Objects

The first type of object is the *directory* object. This object’s variant part is defined as follows:

```
enum nstype {
 UNKNOWN = 0,
 NIS = 1,
 SUNYP = 2,
```

## nis\_objects(3NSL)

```
 DNS = 4,
 X500 = 5,
 DNANS = 6,
 XCHS = 7,
}
typedef enum nstype nstype;
struct oar_mask {
 uint_t oa_rights;
 zotypes oa_otype;
}
typedef struct oar_mask oar_mask;
struct endpoint {
 char *uaddr;
 char *family;
 char *proto;
}
typedef struct endpoint endpoint;
struct nis_server {
 nis_name name;
 struct {
 uint_t ep_len;
 endpoint *ep_val;
 } ep;
 uint_t key_type;
 netobj pkey;
}
typedef struct nis_server nis_server;
struct directory_obj {
 nis_name do_name;
 nstype do_type;
 struct {
 uint_t do_servers_len;
 nis_server *do_servers_val;
 } do_servers;
 uint32_t do_ttl;
 struct {
 uint_t do_armask_len;
 oar_mask *do_armask_val;
 } do_armask;
}
typedef struct directory_obj directory_obj;
```

The main structure contains five primary members: `do_name`, `do_type`, `do_servers`, `do_ttl`, and `do_armask`. The information in the `do_servers` structure is sufficient for the client library to create a network connection with the named server for the directory.

The `do_name` member contains the name of the directory or domain represented in a format that is understandable by the type of nameservice serving that domain. In the case of NIS+ domains, this is the same as the name that can be composed using the `zo_name` and `zo_domain` members. For other name services, this name will be a name that they understand. For example, if this were a directory object describing an X.500 namespace that is "under" the NIS+ directory *eng.sun.com.*, this name might contain `"/C=US, /O=Sun Microsystems, /OU=Engineering/"`. The type of nameservice that is being described is determined by the value of the member `do_type`.

The `do_servers` structure contains two members. `do_servers_val` is an array of `nis_server` structures; `do_servers_len` is the number of cells in the array. The `nis_server` structure is designed to contain enough information such that machines on the network providing name services can be contacted without having to use a name service. In the case of NIS+ servers, this information is the name of the machine in `name`, its public key for authentication in `pkey`, and a variable length array of endpoints, each of which describes the network endpoint for the `rpcbind` daemon on the named machine. The client library uses the addresses to contact the server using a transport that both the client and server can communicate on and then queries the `rpcbind` daemon to get the actual transport address that the server is using.

Note that the first server in the `do_servers` list is always the master server for the directory.

The `key_type` field describes the type of key stored in the `pkey` netobj (see `/usr/include/rpc/xdr.h` for a definition of the network object structure). Currently supported types are `NIS_PK_NONE` for no public key, `NIS_PK_DH` for a Diffie-Hellman type public key, and `NIS_PK_DHEXT` for an extended Diffie-Hellman public key.

The `do_ttl` member contains a copy of the `zo_ttl` member from the common attributes. This is duplicated because the cache manager only caches the variant part of the directory object.

The `do_armask` structure contains two members. `do_armask_val` is an array of `oar_mask` structures; `do_armask_len` is the number of cells in the array. The `oar_mask` structure contains two members: `oa_rights` specifies the access rights allowed for objects of type `oa_otype`. These access rights are used for objects of the given type in the directory when they are present in this array.

The granting of access rights for objects contained within a directory is actually two-tiered. If the directory object itself grants a given access right (using the `zo_access` member in the `nis_object` structure representing the directory), then all objects within the directory are allowed that access. Otherwise, the `do_armask` structure is examined to see if the access is allowed specifically for that type of structure. This allows the administrator of a namespace to set separate policies for different object types, for example, one policy for the creation of tables and another policy for the creation of other directories. See `nis+(1)` for more details.

## Link Objects

Link objects provide a means of providing *aliases* or symbolic links within the namespace. Their variant part is defined as follows.

```
struct link_obj {
 zotypes li_rtype;
 struct {
 uint_t li_attrs_len;
 nis_attr *li_attrs_val;
 } li_attrs;
 nis_name li_name;
}
```

## nis\_objects(3NSL)

The `li_rtype` member contains the object type of the object pointed to by the link. This is only a hint, since the object which the link points to may have changed or been removed. The fully qualified name of the object (table or otherwise) is specified in the member `li_name`.

NIS+ links can point to either other objects within the NIS+ namespace, or to entries within a NIS+ table. If the object pointed to by the link is a table and the member `li_attrs` has a nonzero number of attributes (index name/value pairs) specified, the table is searched when this link is followed. All entries which match the specified search pattern are returned. Note, that unless the flag `FOLLOW_LINKS` is specified, the [nis\\_lookup\(3NSL\)](#) function will always return non-entry objects.

### Group Objects

Group objects contain a membership list of NIS+ principals. The group objects' variant part is defined as follows.

```
struct group_obj {
 uint_t gr_flags;
 struct {
 uint_t gr_members_len;
 nis_name *gr_members_val;
 } gr_members;
}
```

The `gr_flags` member contains flags that are currently unused. The `gr_members` structure contains the list of principals. For a complete description of how group objects are manipulated see [nis\\_groups\(3NSL\)](#).

### Table Objects

The NIS+ table object is analogous to a YP map. The differences stem from the access controls, and the variable schemas that NIS+ allows. The table objects data structure is defined as follows:

```
#define TA_BINARY 1
#define TA_CRYPT 2
#define TA_XDR 4
#define TA_SEARCHABLE 8
#define TA_CASE 16
#define TA_MODIFIED 32
struct table_col {
 char *tc_name;
 uint_t tc_flags;
 uint_t tc_rights;
}
typedef struct table_col table_col;
struct table_obj {
 char *ta_type;
 uint_t ta_maxcol;
 uchar_t ta_sep;
 struct {
 uint_t ta_cols_len;
 table_col *ta_cols_val;
 } ta_cols;
 char *ta_path;
}
```

The `ta_type` member contains a string that identifies the type of entries in this table. NIS+ does not enforce any policies as to the contents of this string. However, when entries are added to the table, the NIS+ service will check to see that they have the same “type” as the table as specified by this member.

The structure `ta_cols` contains two members. `ta_cols_val` is an array of `table_col` structures. The length of the array depends on the number of columns in the table; it is defined when the table is created and is stored in `ta_cols_len`. `ta_maxcol` also contains the number of columns in the table and always has the same value as `ta_cols_len`. Once the table is created, this length field cannot be changed.

The `ta_sep` character is used by client applications that wish to print out an entry from the table. Typically this is either space (“ ”) or colon (“:”).

The `ta_path` string defines a concatenation path for tables. This string contains an ordered list of fully qualified table names, separated by colons, that are to be searched if a search on this table fails to match any entries. This path is only used with the flag `FOLLOW_PATH` with a `nis_list()` call. See [nis\\_tables\(3NSL\)](#) for information on these flags.

In addition to checking the type, the service will check that the number of columns in an entry is the same as those in the table before allowing that entry to be added.

Each column has associated with it a name in `tc_name`, a set of flags in `tc_flags`, and a set of access rights in `tc_rights`. The name should be indicative of the contents of that column.

The `TA_BINARY` flag indicates that data in the column is binary (rather than text). Columns that are searchable cannot contain binary data. The `TA_CRYPT` flag specifies that the information in this column should be encrypted prior to sending it over the network. This flag has no effect in the export version of NIS+. The `TA_XDR` flag is used to tell the client application that the data in this column is encoded using the XDR protocol. The `TA_BINARY` flag must be specified with the XDR flag. Further, by convention, the name of a column that has the `TA_XDR` flag set is the name of the XDR function that will decode the data in that column.

The `TA_SEARCHABLE` flag specifies that values in this column can be searched. Searchable columns must contain textual data and must have a name associated with them. The flag `TA_CASE` specifies that searches involving this column ignore the case of the value in the column. At least one of the columns in the table should be searchable. Also, the combination of all searchable column values should uniquely select an entry within the table. The `TA_MODIFIED` flag is set only when the table column is modified. When `TA_MODIFIED` is set, and the object is modified again, the modified access rights for the table column must be copied, not the default access rights.

## Entry Objects

Entry objects are stored in tables. The structure used to define the entry data is as follows.

```
#define EN_BINARY 1
#define EN_CRYPT 2
```

## nis\_objects(3NSL)

```
#define EN_XDR 4
#define EN_MODIFIED 8
struct entry_col {
 uint_t ec_flags;
 struct {
 uint_t ec_value_len;
 char *ec_value_val;
 } ec_value;
}
typedef struct entry_col entry_col;
struct entry_obj {
 char *en_type;
 struct {
 uint_t en_cols_len;
 entry_col *en_cols_val;
 } en_cols;
}
```

The `en_type` member contains a string that specifies the type of data this entry represents. The NIS+ server will compare this string to the type string specified in the table object and disallow any updates or modifications if they differ.

The `en_cols` structure contains two members: `en_cols_len` and `en_cols_val`. `en_cols_val` is an array of `entry_col` structures. `en_cols_len` contains a count of the number of cells in the `en_cols_val` array and reflects the number of columns in the table -- it always contains the same value as the `table_obj.ta_cols.ta_cols_len` member from the table which contains the entry.

The `entry_col` structure contains information about the entry's per-column values. `ec_value` contains information about a particular value. It has two members: `ec_value_val`, which is the value itself, and `ec_value_len`, which is the length (in bytes) of the value. `entry_col` also contains the member `ec_flags`, which contains a set of flags for the entry.

The flags in `ec_flags` are primarily used when adding or modifying entries in a table. All columns that have the flag `EN_CRYPT` set will be encrypted prior to sending them over the network. Columns with `EN_BINARY` set are presumed to contain binary data. The server will ensure that the column in the table object specifies binary data prior to allowing the entry to be added. When modifying entries in a table, only those columns that have changed need be sent to the server. Those columns should each have the `EN_MODIFIED` flag set to indicate this to the server.

| <b>DESCRIPTION</b> | <p><code>nis_ping()</code> is called by the master server for a directory when a change has occurred within that directory. The parameter <code>dirname</code> identifies the directory with the change. If the parameter <code>diobj</code> is <code>NULL</code>, this function looks up the directory object for <code>dirname</code> and uses the list of replicas it contains. The parameter <code>utime</code> contains the timestamp of the last change made to the directory. This timestamp is used by the replicas when retrieving updates made to the directory.</p> <p>The effect of calling <code>nis_ping()</code> is to schedule an update on the replica. A short time after a ping is received, typically about two minutes, the replica compares the last update time for its databases to the timestamp sent by the ping. If the ping timestamp is later, the replica establishes a connection with the master server and request all changes from the log that occurred after the last update that it had recorded in its local log.</p> <p><code>nis_checkpoint()</code> is used to force the service to checkpoint information that has been entered in the log but has not been checkpointed to disk. When called, this function checkpoints the database for each table in the directory, the database containing the directory and the transaction log. Care should be used in calling this function since directories that have seen a lot of changes may take several minutes to checkpoint. During the checkpointing process, the service will be unavailable for updates for all directories that are served by this machine as master.</p> <p><code>nis_checkpoint()</code> returns a pointer to a <code>nis_result</code> structure. See <a href="#">nis_tables(3NSL)</a>. This structure should be freed with <code>nis_freeresult()</code>. See <a href="#">nis_names(3NSL)</a>. The only items of interest in the returned result are the status value and the statistics.</p> |                |                 |          |         |
| <b>ATTRIBUTES</b>  | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |          |         |

| <b>DESCRIPTION</b> | <p>These functions provide a variety of services for NIS+ applications.</p> <p>The <code>nis_mkdir()</code> function is used to create the necessary databases to support NIS+ service for a directory, <i>dirname</i>, on a server, <i>machine</i>. If this operation is successful, it means that the directory object describing <i>dirname</i> has been updated to reflect that server <i>machine</i> is serving the named directory. For a description of the <code>nis_server</code> structure, refer to <a href="#">nis_objects(3NSL)</a>.</p> <p>Per-server and per-directory access restrictions can apply to the <code>nis_mkdir()</code> function. See <a href="#">nisopaccess(1)</a>.</p> <p>The <code>nis_rmdir()</code> function is used to delete the directory, <i>dirname</i>, from the specified server machine. The <i>machine</i> parameter cannot be NULL. The <code>nis_rmdir()</code> function does not remove the directory <i>dirname</i> from the namespace or remove a server from the server list in the directory object. To remove a directory from the namespace you must call <code>nis_remove()</code> to remove the directory <i>dirname</i> from the namespace and call <code>nis_rmdir()</code> for each server in the server list to remove the directory from the server. To remove a replica from the server list, you need to first call <code>nis_modify()</code> to remove the server from the directory object and then call <code>nis_rmdir()</code> to remove the replica.</p> <p>Per-server and per-directory access restrictions can apply to <code>nis_rmdir()</code>. See <a href="#">nisopaccess(1)</a>.</p> <p>For a description of the <code>nis_server</code> structure, refer to <a href="#">nis_objects(3NSL)</a>.</p> <p>The <code>nis_servstate()</code> function is used to set and read the various state variables of the NIS+ servers. In particular the internal debugging state of the servers can be set and queried.</p> |

The `nis_stats()` function is used to retrieve statistics about how the server is operating. Tracking these statistics can help administrators determine when they need to add additional replicas or to break up a domain into two or more subdomains. For more information on reading statistics, see `nisstat(1M)`.

The `nis_servstate()` and `nis_stats()` functions use the tag list. The tag list is a variable length array of `nis_tag` structures whose length is passed to the function in the `numtags` parameter. The set of legal tags are defined in the file `<rpcsvc/nis_tags.h>` which is included in `<rpcsvc/nis.h>`. Because these tags can and do vary between implementations of the NIS+ service, it is best to consult this file for the supported list. Passing unrecognized tags to a server will result in their `tag_value` member being set to the string `unknown`. Both of these functions return their results in malloced tag structure, `*result`. If there is an error, `*result` is set to `NULL`. The `tag_value` pointers points to allocated string memory which contains the results. Use `nis_frehtags()` to free the tag structure.

Per-server and per-directory access restrictions can apply to the `NIS_SERVSTATE` or `NIS_STATUS(nis_stats())` operations and their sub-operations (`tags`). See `nisopaccess(1)`.

The `nis_getservlist()` function returns a null terminated list of `nis_server` structures that represent the list of servers that serve the domain named `dirname`. Servers from this list can be used when calling functions that require the name of a NIS+ server. For a description of the `nis_server` refer to `nis_objects(3NSL)`. `nis_freeservlist()` frees the list of servers list of servers returned by `nis_getservlist()`. Note that this is the only legal way to free that list.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

**SEE ALSO** `nisopaccess(1)`, `nisstat(1M)`, `nis_names(3NSL)`, `nis_objects(3NSL)`, `nis_subr(3NSL)`, `attributes(5)`

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>DESCRIPTION</b> | <p>These subroutines are provided to assist in the development of NIS+ applications. They provide several useful operations on both NIS+ names and objects.</p> <p>The first group, <code>nis_leaf_of()</code>, <code>nis_domain_of()</code>, and <code>nis_name_of()</code> provide the functions for parsing NIS+ names. <code>nis_leaf_of()</code> will return the first label in an NIS+ name. It takes into account the double quote character <code>""</code> which can be used to protect embedded <code>'.'</code> (dot) characters in object names. Note that the name returned will never have a trailing dot character. If passed the global root directory name <code>."</code>, it will return the null string.</p> <p><code>nis_domain_of()</code> returns the name of the NIS+ domain in which an object resides. This name will always be a fully qualified NIS+ name and ends with a dot. By iteratively calling <code>nis_leaf_of()</code> and <code>nis_domain_of()</code> it is possible to break a NIS+ name into its individual components.</p> <p><code>nis_name_of()</code> is used to extract the unique part of a NIS+ name. This function removes from the tail portion of the name all labels that are in common with the local domain. Thus if a machine were in domain <code>foo.bar.baz.</code> and <code>nis_name_of()</code> were passed a name <code>bob.friends.foo.bar.baz.</code>, then <code>nis_name_of()</code> would return the unique part, <code>bob.friends</code>. If the name passed to this function is not in either the local domain or one of its children, this function will return null.</p> <p><code>nis_getnames()</code> will return a list of candidate names for the name passed in as <i>name</i>. If this name is not fully qualified, <code>nis_getnames()</code> will generate a list of names using the default NIS+ directory search path, or the environment variable <code>NIS_PATH</code> if it is set. The returned array of pointers is terminated by a null pointer, and the memory associated with this array should be freed by calling <code>nis_freenames()</code></p> |

Though `nis_dir_cmp()` can be used to compare any two NIS+ names, it is used primarily to compare domain names. This comparison is done in a case independent fashion, and the results are an enum of type `name_pos`. When the names passed to this function are identical, the function returns a value of `SAME_NAME`. If the name *n1* is a direct ancestor of name *n2*, then this function returns the result `HIGHER_NAME`. Similarly, if the name *n1* is a direct descendant of name *n2*, then this function returns the result `LOWER_NAME`. When the name *n1* is neither a direct ancestor nor a direct descendant of *n2*, as it would be if the two names were siblings in separate portions of the namespace, then this function returns the result `NOT_SEQUENTIAL`. Finally, if either name cannot be parsed as a legitimate name then this function returns the value `BAD_NAME`.

The second set of functions, consisting of `nis_clone_object()` and `nis_destroy_object()`, are used for manipulating objects. `nis_clone_object()` creates an exact duplicate of the NIS+ object *src*. If the value of *dest* is non-null, it creates the clone of the object into this object structure and allocate the necessary memory for the variable length arrays. If this parameter is null, a pointer to the cloned object is returned. Refer to `nis_objects(3NSL)` for a description of the `nis_object` structure.

`nis_destroy_object()` can be used to destroy an object created by `nis_clone_object()`. This will free up all memory associated with the object and free the pointer passed. If the object was cloned into an array using the *dest* parameter to `nis_clone_object()`, then the object *cannot* be freed with this function. Instead, the function `xdr_free(xdr_nis_object, dest)` must be used.

`nis_print_object()` prints out the contents of a NIS+ object structure on the standard output. Its primary use is for debugging NIS+ programs.

`nis_leaf_of()`, `nis_name_of()` and `nis_clone_object()` return their results as thread-specific data in multithreaded applications.

## ENVIRONMENT VARIABLES

**NIS\_PATH** This variable overrides the default NIS+ directory search path used by `nis_getnames()`. It contains an ordered list of directories separated by ':' (colon) characters. The '\$' (dollar sign) character is treated specially. Directory names that end in '\$' have the default domain appended to them, and a '\$' by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is '\$'.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Safe            |

**SEE ALSO** `nis_names(3NSL)`, `nis_objects(3NSL)`, `nis_tables(3NSL)`, `attributes(5)`

nis\_subr(3NSL)

**NOTES** | NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>DESCRIPTION</b> | <p>Use the NIS+ table functions to search and modify NIS+ tables. <code>nis_list()</code> is used to search a table in the NIS+ namespace. <code>nis_first_entry()</code> and <code>nis_next_entry()</code> are used to enumerate a table one entry at a time. <code>nis_add_entry()</code>, <code>nis_remove_entry()</code>, and <code>nis_modify_entry()</code> are used to change the information stored in a table. <code>nis_freeresult()</code> is used to free the memory associated with the <code>nis_result</code> structure.</p> <p>Entries within a table are named by NIS+ indexed names. An indexed name is a compound name that is composed of a search criteria and a simple NIS+ name that identifies a table object. A search criteria is a series of column names and their associated values enclosed in bracket '[' ]' characters. Indexed names have the following form:</p> <pre>[ colname=value, . . . ], tablename</pre> <p>The list function, <code>nis_list()</code>, takes an indexed name as the value for the <code>name</code> parameter. Here, the <code>tablename</code> should be a fully qualified NIS+ name unless the <code>EXPAND_NAME</code> flag (described below) is set. The second parameter, <code>flags</code>, defines how the function will respond to various conditions. The value for this parameter is created by logically ORing together one or more flags from the following list.</p> <p><b>FOLLOW_LINKS</b> If the table specified in <code>name</code> resolves to be a LINK type object (see <a href="#">nis_objects(3NSL)</a>), this flag specifies that the client library follow that link and do the search at that object. If this flag is not set and the name resolves to a link, the error <code>NIS_NOTSEARCHABLE</code> will be returned.</p> <p><b>FOLLOW_PATH</b> This flag specifies that if the entry is not found within this table, the list operation should follow the path specified in the table</p> |

## nis\_tables(3NSL)

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | <p>object. When used in conjunction with the <code>ALL_RESULTS</code> flag below, it specifies that the path should be followed regardless of the result of the search. When used in conjunction with the <code>FOLLOW_LINKS</code> flag above, named tables in the path that resolve to links will be followed until the table they point to is located. If a table in the path is not reachable because no server that serves it is available, the result of the operation will be either a “soft” success or a “soft” failure to indicate that not all tables in the path could be searched. If a name in the path names is either an invalid or non-existent object then it is silently ignored.</p> |
| <code>HARD_LOOKUP</code>   | <p>This flag specifies that the operation should continue trying to contact a server of the named table until a definitive result is returned (such as <code>NIS_NOTFOUND</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>ALL_RESULTS</code>   | <p>This flag can only be used in conjunction with <code>FOLLOW_PATH</code> and a callback function. When specified, it forces all of the tables in the path to be searched. If <i>name</i> does not specify a search criteria (imply that all entries are to be returned), then this flag will cause all of the entries in all of the tables in the path to be returned.</p>                                                                                                                                                                                                                                                                                                                             |
| <code>NO_CACHE</code>      | <p>This flag specifies that the client library should bypass any client object caches and get its information directly from either the master server or a replica server for the named table.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>MASTER_ONLY</code>   | <p>This flag is even stronger than <code>NO_CACHE</code> in that it specifies that the client library should <i>only</i> get its information from the master server for a particular table. This guarantees that the information will be up to date. However, there may be severe performance penalties associated with contacting the master server directly on large networks. When used in conjunction with the <code>HARD_LOOKUP</code> flag, this will block the list operation until the master server is up and available.</p>                                                                                                                                                                    |
| <code>EXPAND_NAME</code>   | <p>When specified, the client library will attempt to expand a partially qualified name by calling <code>nis_getnames()</code>, which uses the environment variable <code>NIS_PATH</code>. See <a href="#">nis_local_names(3NSL)</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>RETURN_RESULT</code> | <p>This flag is used to specify that a copy of the returning object be returned in the <code>nis_result</code> structure if the operation was successful.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

The third parameter to `nis_list()`, *callback*, is an optional pointer to a function that will process the `ENTRY` type objects that are returned from the search. If this pointer is `NULL`, then all entries that match the search criteria are returned in the `nis_result` structure, otherwise this function will be called once for each entry returned. When

called, this function should return 0 when additional objects are desired and 1 when it no longer wishes to see any more objects. The fourth parameter, *userdata*, is simply passed to callback function along with the returned entry object. The client can use this pointer to pass state information or other relevant data that the callback function might need to process the entries.

The `nis_list()` function is not MT-Safe with callbacks.

`nis_add_entry()` will add the NIS+ object to the NIS+ *table\_name*. The *flags* parameter is used to specify the failure semantics for the add operation. The default (*flags* equal 0) is to fail if the entry being added already exists in the table. The `ADD_OVERWRITE` flag may be used to specify that existing object is to be overwritten if it exists, (a modify operation) or added if it does not exist. With the `ADD_OVERWRITE` flag, this function will fail with the error `NIS_PERMISSION` if the existing object does not allow modify privileges to the client.

If the flag `RETURN_RESULT` has been specified, the server will return a copy of the resulting object if the operation was successful.

`nis_remove_entry()` removes the identified entry from the table or a set of entries identified by *table\_name*. If the parameter *object* is non-null, it is presumed to point to a cached copy of the entry. When the removal is attempted, and the object that would be removed is not the same as the cached object pointed to by *object* then the operation will fail with an `NIS_NOTSAMEOBJ` error. If an object is passed with this function, the search criteria in name is optional as it can be constructed from the values within the entry. However, if no object is present, the search criteria must be included in the *name* parameter. If the flags variable is null, and the search criteria does not uniquely identify an entry, the `NIS_NOTUNIQUE` error is returned and the operation is aborted. If the flag parameter `REM_MULTIPLE` is passed, and if remove permission is allowed for each of these objects, then all objects that match the search criteria will be removed. Note that a null search criteria and the `REM_MULTIPLE` flag will remove all entries in a table.

`nis_modify_entry()` modifies an object identified by *name*. The parameter *object* should point to an entry with the `EN_MODIFIED` flag set in each column that contains new information.

The owner, group, and access rights of an entry are modified by placing the modified information into the respective fields of the parameter, *object*: `zo_owner`, `zo_group`, and `zo_access`.

These columns will replace their counterparts in the entry that is stored in the table. The entry passed must have the same number of columns, same type, and valid data in the modified columns for this operation to succeed.

## nis\_tables(3NSL)

If the flags parameter contains the flag `MOD_SAMEOBJ` then the object pointed to by *object* is assumed to be a cached copy of the original object. If the OID of the object passed is different than the OID of the object the server fetches, then the operation fails with the `NIS_NOTSAMEOBJ` error. This can be used to implement a simple read-modify-write protocol which will fail if the object is modified before the client can write the object back.

If the flag `RETURN_RESULT` has been specified, the server will return a copy of the resulting object if the operation was successful.

`nis_first_entry()` fetches entries from a table one at a time. This mode of operation is extremely inefficient and callbacks should be used instead wherever possible. The table containing the entries of interest is identified by *name*. If a search criteria is present in *name* it is ignored. The value of *cookie* within the `nis_result` structure must be copied by the caller into local storage and passed as an argument to `nis_next_entry()`.

`nis_next_entry()` retrieves the “next” entry from a table specified by *table\_name*. The order in which entries are returned is not guaranteed. Further, should an update occur in the table between client calls to `nis_next_entry()` there is no guarantee that an entry that is added or modified will be seen by the client. Should an entry be removed from the table that would have been the “next” entry returned, the error `NIS_CHAINBROKEN` is returned instead.

The path used when the flag `FOLLOW_PATH` is specified, is the one present in the *first* table searched. The path values in tables that are subsequently searched are ignored.

It is legal to call functions that would access the nameservice from within a list callback. However, calling a function that would itself use a callback, or calling `nis_list()` with a callback from within a list callback function is not currently supported.

There are currently no known methods for `nis_first_entry()` and `nis_next_entry()` to get their answers from only the master server.

The `nis_list()` function is not MT-Safe with callbacks. `nis_list()` callbacks are serialized. A call to `nis_list()` with a callback from within `nis_list()` will deadlock. `nis_list()` with a callback cannot be called from an rpc server. See [rpc\\_svc\\_calls\(3NSL\)](#). Otherwise, this function is MT-Safe.

## RETURN VALUES

These functions return a pointer to a structure of type `nis_result`:

```
struct nis_result {
 nis_error status;
 struct {
 uint_t objects_len;
 nis_object *objects_val;
 } objects;
 netobj cookie;
 uint32_t zticks;
 uint32_t dticks;
```

```

uint32_t aticks;
uint32_t cticks;
};

```

The *status* member contains the error status of the the operation. A text message that describes the error can be obtained by calling the function `nis_sperrno()`. See [nis\\_error\(3NSL\)](#).

The *objects* structure contains two members. *objects\_val* is an array of *nis\_object* structures; *objects\_len* is the number of cells in the array. These objects will be freed by a call to `nis_freeresult()`. See [nis\\_names\(3NSL\)](#). If you need to keep a copy of one or more objects, they can be copied with the function `nis_clone_object()` and freed with the function `nis_destroy_object()`. See [nis\\_server\(3NSL\)](#).

The various ticks contain details of where the time, in microseconds, was taken during a request. They can be used to tune one's data organization for faster access and to compare different database implementations.

*zticks*      The time spent in the NIS+ service itself, this count starts when the server receives the request and stops when it sends the reply.

*dticks*      The time spent in the database backend, this time is measured from the time a database call starts, until a result is returned. If the request results in multiple calls to the database, this is the sum of all the time spent in those calls.

*aticks*      The time spent in any "accelerators" or caches. This includes the time required to locate the server needed to resolve the request.

*cticks*      The total time spent in the request, this clock starts when you enter the client library and stops when a result is returned. By subtracting the sum of the other ticks values from this value you can obtain the local overhead of generating a NIS+ request.

Subtracting the value in *dticks* from the value in *zticks* will yield the time spent in the service code itself. Subtracting the sum of the values in *zticks* and *aticks* from the value in *cticks* will yield the time spent in the client library itself. Note: all of the tick times are measured in microseconds.

**ERRORS**      The client library can return a variety of error returns and diagnostics. The more salient ones are documented below.

`NIS_BADATTRIBUTE`      The name of an attribute did not match up with a named column in the table, or the attribute did not have an associated value.

`NIS_BADNAME`      The name passed to the function is not a legal NIS+ name.

`NIS_BADREQUEST`      A problem was detected in the request structure passed to the client library.

## nis\_tables(3NSL)

|                     |                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS_CACHEEXPIRED    | The entry returned came from an object cache that has <i>expired</i> . This means that the time to live value has gone to zero and the entry may have changed. If the flag NO_CACHE was passed to the lookup function then the lookup function will retry the operation to get an unexpired copy of the object.              |
| NIS_CBERROR         | An RPC error occurred on the server while it was calling back to the client. The transaction was aborted at that time and any unsend data was discarded.                                                                                                                                                                     |
| NIS_CBRESULTS       | Even though the request was successful, all of the entries have been sent to your callback function and are thus not included in this result.                                                                                                                                                                                |
| NIS_FOREIGNNS       | The name could not be completely resolved. When the name passed to the function would resolve in a namespace that is outside the NIS+ name tree, this error is returned with a NIS+ object of type DIRECTORY. The returned object contains the type of namespace and contact information for a server within that namespace. |
| NIS_INVALIDOBJ      | The object pointed to by <i>object</i> is not a valid NIS+ entry object for the given table. This could occur if it had a mismatched number of columns, or a different data type than the associated column in the table, for example, binary or text.                                                                       |
| NIS_LINKNAMEERROR   | The name passed resolved to a LINK type object and the contents of the object pointed to an invalid name.                                                                                                                                                                                                                    |
| NIS_MODFAIL         | The attempted modification failed for some reason.                                                                                                                                                                                                                                                                           |
| NIS_NAMEEXISTS      | An attempt was made to add a name that already exists. To add the name, first remove the existing name and then add the new name or modify the existing named object.                                                                                                                                                        |
| NIS_NAMEUNREACHABLE | This soft error indicates that a server for the desired directory of the named table object could not be reached. This can occur when there is a network partition or the server has crashed. Attempting the operation again may succeed. See the HARD_LOOKUP flag.                                                          |
| NIS_NOCALLBACK      | The server was unable to contact the callback service on your machine. This results in no data being returned.                                                                                                                                                                                                               |
| NIS_NOMEMORY        | Generally a fatal result. It means that the service ran out of heap space.                                                                                                                                                                                                                                                   |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS_NOSUCHNAME    | This hard error indicates that the named directory of the table object does not exist. This occurs when the server that should be the parent of the server that serves the table, does not know about the directory in which the table resides.                                                                                                                                                          |
| NIS_NOSUCHTABLE   | The named table does not exist.                                                                                                                                                                                                                                                                                                                                                                          |
| NIS_NOT_ME        | A request was made to a server that does not serve the given name. Normally this will not occur, however if you are not using the built in location mechanism for servers, you may see this if your mechanism is broken.                                                                                                                                                                                 |
| NIS_NOTFOUND      | No entries in the table matched the search criteria. If the search criteria was null (return all entries) then this result means that the table is empty and may safely be removed by calling the <code>nis_remove()</code> .<br><br>If the FOLLOW_PATH flag was set, this error indicates that none of the tables in the path contain entries that match the search criteria.                           |
| NIS_NOTMASTER     | A change request was made to a server that serves the name, but it is not the master server. This can occur when a directory object changes and it specifies a new master server. Clients that have cached copies of the directory object in the <code>/var/nis/NIS_SHARED_DIRCACHE</code> file will need to have their cache managers restarted to flush this cache. Use <code>nis_cachemgr -i</code> . |
| NIS_NOTSAMEOBJ    | An attempt to remove an object from the namespace was aborted because the object that would have been removed was not the same object that was passed in the request.                                                                                                                                                                                                                                    |
| NIS_NOTSEARCHABLE | The table name resolved to a NIS+ object that was not searchable.                                                                                                                                                                                                                                                                                                                                        |
| NIS_PARTIAL       | This result is similar to NIS_NOTFOUND except that it means the request succeeded but resolved to zero entries. When this occurs, the server returns a copy of the table object instead of an entry so that the client may then process the path or implement some other local policy.                                                                                                                   |
| NIS_RPCERROR      | This fatal error indicates the RPC subsystem failed in some way. Generally there will be a <code>syslog(3C)</code> message indicating why the RPC request failed.                                                                                                                                                                                                                                        |

nis\_tables(3NSL)

|                  |                                                                                                                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS_S_NOTFOUND   | The named entry does not exist in the table, however not all tables in the path could be searched, so the entry may exist in one of those tables.                                                                                                                                                                                       |
| NIS_S_SUCCESS    | Even though the request was successful, a table in the search path was not able to be searched, so the result may not be the same as the one you would have received if that table had been accessible.                                                                                                                                 |
| NIS_SUCCESS      | The request was successful.                                                                                                                                                                                                                                                                                                             |
| NIS_SYSTEMERROR  | Some form of generic system error occurred while attempting the request. Check the syslog(3C) record for error messages from the server.                                                                                                                                                                                                |
| NIS_TOOMANYATTRS | The search criteria passed to the server had more attributes than the table had searchable columns.                                                                                                                                                                                                                                     |
| NIS_TRYAGAIN     | The server connected to was too busy to handle your request. add_entry(), remove_entry(), and modify_entry() return this error when the master server is currently updating its internal state. It can be returned to nis_list() when the function specifies a callback and the server does not have the resources to handle callbacks. |
| NIS_TYPEMISMATCH | An attempt was made to add or modify an entry in a table, and the entry passed was of a different type than the table.                                                                                                                                                                                                                  |

**ENVIRONMENT VARIABLES**

NIS\_PATH      When set, this variable is the search path used by nis\_list() if the flag EXPAND\_NAME is set.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE         |
|----------------|-------------------------|
| MT-Level       | MT-Safe with exceptions |

**SEE ALSO**

niscat(1), niserror(1), nismatch(1), nis\_cachemgr(1M), nis\_clone\_object(3NSL), n, nis\_destroy\_object(3NSL), nis\_error(3NSL), nis\_getnames(3NSL), nis\_local\_names(3NSL), nis\_names(3NSL), nis\_objects(3NSL), nis\_server(3NSL), rpc\_svc\_calls(3NSL), syslog(3C), attributes(5)

**WARNINGS**

Use the flag HARD\_LOOKUP carefully since it can cause the application to block indefinitely during a network partition.

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

## nlsgetcall(3NSL)

| <b>NAME</b>          | nlsgetcall – get client’s data passed via the listener                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |        |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|--------|
| <b>SYNOPSIS</b>      | <pre>#include &lt;sys/tiuser.h&gt; struct t_call *nlsgetcall(int fildes);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>nlsgetcall() allows server processes started by the listener process to access the client’s t_call structure, that is, the <i>sndcall</i> argument of t_connect(3NSL).</p> <p>The t_call structure returned by nlsgetcall() can be released using t_free(3NSL).</p> <p>nlsgetcall() returns the address of an allocated t_call structure or NULL if a t_call structure cannot be allocated. If the t_alloc() succeeds, undefined environment variables are indicated by a negative <i>len</i> field in the appropriate netbuf structure. A <i>len</i> field of zero in the netbuf structure is valid and means that the original buffer in the listener’s t_call structure was NULL.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | A NULL pointer is returned if a t_call structure cannot be allocated by t_alloc(). t_errno can be inspected for further error information. Undefined environment variables are indicated by a negative length field ( <i>len</i> ) in the appropriate netbuf structure.                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |        |
| <b>FILES</b>         | /usr/lib/libnls.so.1 shared object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |          |        |

| <b>WARNINGS</b>      | <p>The <i>len</i> field in the netbuf structure is defined as being unsigned. In order to check for error returns, it should first be cast to an int.</p> <p>The listener process limits the amount of user data (<i>udata</i>) and options data (<i>opt</i>) to 128 bytes each. Address data <i>addr</i> is limited to 64 bytes. If the original data was longer, no indication of overflow is given.</p>                                                                                                                                                                                                                                                                                  |                |                 |          |        |
| <b>NOTES</b>         | <p>Server processes must call t_sync(3NSL) before calling this routine.</p> <p>This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |        |

**NAME** nlsprovider – get name of transport provider

**SYNOPSIS** `char *nlsprovider(void);`

**DESCRIPTION** `nlsprovider()` returns a pointer to a null-terminated character string which contains the name of the transport provider as placed in the environment by the listener process. If the variable is not defined in the environment, a NULL pointer is returned.

The environment variable is only available to server processes started by the listener process.

**RETURN VALUES** If the variable is not defined in the environment, a NULL pointer is returned.

**FILES** `/usr/lib/libnls.so.1` shared object

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** `nlsadmin(1M)`, `attributes(5)`

**NOTES** This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

## nlsrequest(3NSL)

| <b>NAME</b>          | nlsrequest – format and send listener service request message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |        |

| <b>DESCRIPTION</b>   | Given a virtual circuit to a listener process ( <i>fildes</i> ) and a service code of a server process, <code>nlsrequest()</code> formats and sends a <i>service request message</i> to the remote listener process requesting that it start the given service. <code>nlsrequest()</code> waits for the remote listener process to return a <i>service request response message</i> , which is made available to the caller in the static, null-terminated data buffer pointed to by <code>_nlsrmsg</code> . The <i>service request response message</i> includes a success or failure code and a text message. The entire message is printable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |        |
| <b>RETURN VALUES</b> | <p>The success or failure code is the integer return code from <code>nlsrequest()</code>. Zero indicates success, other negative values indicate <code>nlsrequest()</code> failures as follows:</p> <ul style="list-style-type: none"><li>-1 Error encountered by <code>nlsrequest()</code>, see <code>t_errno</code>.</li></ul> <p>Positive values are error return codes from the <i>listener</i> process. Mnemonics for these codes are defined in <code>&lt;listen.h&gt;</code>.</p> <ul style="list-style-type: none"><li>2 Request message not interpretable.</li><li>3 Request service code unknown.</li><li>4 Service code known, but currently disabled.</li></ul> <p>If non-null, <code>_nlsrmsg</code> contains a pointer to a static, null-terminated character buffer containing the <i>service request response message</i>. Note that both <code>_nlsrmsg</code> and the data buffer are overwritten by each call to <code>nlsrequest()</code>.</p> <p>If <code>_nlslog</code> is non-zero, <code>nlsrequest()</code> prints error messages on <code>stderr</code>. Initially, <code>_nlslog</code> is zero.</p> |                |                 |          |        |

| <b>DESCRIPTION</b> | <p>The <code>rcmd()</code> function is used by the superuser to execute a command on a remote machine with an authentication scheme based on reserved port numbers. An <code>AF_INET</code> socket is returned with <code>rcmd()</code>. The <code>rcmd_af()</code> function supports <code>AF_INET</code>, <code>AF_INET6</code> or <code>AF_UNSPEC</code> for the address family. An application can choose which type of socket is returned by passing <code>AF_INET</code> or <code>AF_INET6</code> as the address family. The use of <code>AF_UNSPEC</code> means that the caller will accept any address family. Choosing <code>AF_UNSPEC</code> provides a socket that best suits the connectivity to the remote host.</p> <p>The <code>rresvport()</code> function returns a descriptor to a socket with an address in the privileged port space. The <code>rresvport_af()</code> function is the equivalent to <code>rresvport()</code>, except that you can choose <code>AF_INET</code> or <code>AF_INET6</code> as the socket address family to be returned by <code>rresvport_af()</code>. <code>AF_UNSPEC</code> does not apply to the <code>rresvport()</code> function.</p> <p>The <code>ruserok()</code> function is a routine used by servers to authenticate clients that request as service with <code>rcmd</code>.</p> <p>All of these functions are present in the same file and are used by the <code>in.rshd(1M)</code> server among others.</p> <p>The <code>rcmd()</code> and <code>rcmd_af()</code> functions look up the host <code>*ahost</code> using <a href="#">getaddrinfo(3SOCKET)</a> and return <code>-1</code> if the host does not exist. Otherwise, <code>*ahost</code> is set to the standard name of the host and a connection is established to a server residing at the Internet port <code>inport</code>.</p> <p>If the connection succeeds, a socket in the Internet domain of type <code>SOCK_STREAM</code> is returned to the caller. The socket is given to the remote command as standard input (file descriptor 0) and standard output (file descriptor 1). If <code>fd2p</code> is non-zero, an auxiliary channel to a control process is set up and a descriptor for it is placed in <code>*fd2p</code>. The control process returns diagnostic output file (descriptor 2) from the command on the auxiliary channel. The control process also accepts bytes on this channel as signal</p> |

numbers to be forwarded to the process group of the command. If *fd2p* is 0, the standard error (file descriptor 2) of the remote command is made the same as its standard output. No provision is made for sending arbitrary signals to the remote process, other than possibly sending out-of-band data.

The protocol is described in detail in *in.rshd(1M)*.

The `rresvport()` and `rresvport_af()` functions are used to obtain a socket bound to a privileged port number. The socket is suitable for use by `rcmd()` and `rresvport_af()` and several other routines. Privileged Internet ports are those in the range 1 to 1023. Only the superuser is allowed to bind a socket to a privileged port number. The application must pass in *port*, which must be in the range 512 to 1023. The system first tries to bind to that port number. If it fails, the system then tries to bind to another unused privileged port, if one is available.

The `ruserok()` function takes a remote host name returned by the `gethostbyaddr()` function with two user names and a flag to indicate whether the local user's name is that of the superuser. See `gethostbyname(3NSL)`. The `ruserok()` function then checks the files `/etc/hosts.equiv` and possibly `.rhosts` in the local user's home directory to see if the request for service is allowed. A 0 value is returned if the machine name is listed in the `/etc/hosts.equiv` file, or if the host and remote user name are found in the `.rhosts` file. Otherwise, the `ruserok()` function returns -1. If the superuser flag is 1, the `/etc/hosts.equiv` is not checked.

The error code `EAGAIN` is overloaded to mean "All network ports in use."

**RETURN VALUES**

The `rcmd()` and `rcmd_af()` functions return a valid socket descriptor upon success. The functions return -1 upon error and print a diagnostic message to standard error.

The `rresvport()` and `rresvport_af()` functions return a valid, bound socket descriptor upon success. The functions return -1 upon error with the global value `errno` set according to the reason for failure.

**FILES**

`/etc/hosts.equiv`            system trusted hosts and users  
`~/ .rhosts`                user's trusted hosts and users

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

This interface is Unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| <b>DESCRIPTION</b>        | <p>The <code>recv()</code>, <code>recvfrom()</code>, and <code>recvmsg()</code> functions are used to receive messages from another socket. The <code>s</code> socket is created with <code>socket(3SOCKET)</code>.</p> <p>If <code>from</code> is a non-NULL pointer, the source address of the message is filled in. The value-result parameter <code>fromlen</code> is initialized to the size of the buffer associated with <code>from</code> and modified on return to indicate the actual size of the address stored in the buffer. The length of the message is returned. If a message is too long to fit in the supplied buffer, excess bytes may be discarded depending on the type of socket from which the message is received. See <code>socket(3SOCKET)</code>.</p> <p>If no messages are available at the socket, the receive call waits for a message to arrive. If the socket is non-blocking, -1 is returned with the external variable <code>errno</code> set to <code>EWOULDBLOCK</code>. See <code>fcntl(2)</code>.</p> <p>For processes on the same host, <code>recvmsg()</code> can be used to receive a file descriptor from another process.</p> <p>If a zero-length buffer is specified for a message, an EOF condition results that is indistinguishable from the successful transfer of a file descriptor. For that reason, one or more bytes of data should be provided when <code>recvmsg()</code> passes a file descriptor.</p> <p>The <code>select(3C)</code> call can be used to determine when more data arrives.</p> <p>The <code>flags</code> parameter is formed by an OR operation on one or more of the following:</p> <table><tr><td><code>MSG_OOB</code></td><td>Read any <i>out-of-band</i> data present on the socket rather than the regular <i>in-band</i> data.</td></tr><tr><td><code>MSG_PEEK</code></td><td>Peek at the data present on the socket. The data is returned, but not consumed to allow a subsequent receive operation to see the same data.</td></tr><tr><td><code>MSG_WAITALL</code></td><td>Messages are blocked until the full amount of data requested is returned. The <code>recv()</code> function can return a smaller amount of data if a signal is caught, the connection is terminated, <code>MSG_PEEK</code> is specified, or if an error is pending for the socket.</td></tr><tr><td><code>MSG_DONTWAIT</code></td><td>Pending messages received on the connection are returned. If data is unavailable, the function does not block. This behavior is the equivalent to specifying <code>O_NONBLOCK</code> on the file descriptor of a</td></tr></table> | <code>MSG_OOB</code> | Read any <i>out-of-band</i> data present on the socket rather than the regular <i>in-band</i> data. | <code>MSG_PEEK</code> | Peek at the data present on the socket. The data is returned, but not consumed to allow a subsequent receive operation to see the same data. | <code>MSG_WAITALL</code> | Messages are blocked until the full amount of data requested is returned. The <code>recv()</code> function can return a smaller amount of data if a signal is caught, the connection is terminated, <code>MSG_PEEK</code> is specified, or if an error is pending for the socket. | <code>MSG_DONTWAIT</code> | Pending messages received on the connection are returned. If data is unavailable, the function does not block. This behavior is the equivalent to specifying <code>O_NONBLOCK</code> on the file descriptor of a |
| <code>MSG_OOB</code>      | Read any <i>out-of-band</i> data present on the socket rather than the regular <i>in-band</i> data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                                     |                       |                                                                                                                                              |                          |                                                                                                                                                                                                                                                                                   |                           |                                                                                                                                                                                                                  |
| <code>MSG_PEEK</code>     | Peek at the data present on the socket. The data is returned, but not consumed to allow a subsequent receive operation to see the same data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                      |                                                                                                     |                       |                                                                                                                                              |                          |                                                                                                                                                                                                                                                                                   |                           |                                                                                                                                                                                                                  |
| <code>MSG_WAITALL</code>  | Messages are blocked until the full amount of data requested is returned. The <code>recv()</code> function can return a smaller amount of data if a signal is caught, the connection is terminated, <code>MSG_PEEK</code> is specified, or if an error is pending for the socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                      |                                                                                                     |                       |                                                                                                                                              |                          |                                                                                                                                                                                                                                                                                   |                           |                                                                                                                                                                                                                  |
| <code>MSG_DONTWAIT</code> | Pending messages received on the connection are returned. If data is unavailable, the function does not block. This behavior is the equivalent to specifying <code>O_NONBLOCK</code> on the file descriptor of a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                      |                                                                                                     |                       |                                                                                                                                              |                          |                                                                                                                                                                                                                                                                                   |                           |                                                                                                                                                                                                                  |

socket, except that write requests are unaffected.

The `recvmsg()` function call uses a `msg_hdr` structure to minimize the number of directly supplied parameters. This structure is defined in `<sys/socket.h>` and includes the following members:

```

caddr_t msg_name; /* optional address */
int msg_namelen; /* size of address */
struct iovec *msg_iov; /* scatter/gather array */
int msg_iovlen; /* # elements in msg_iov */
caddr_t msg_accrightrights; /* access rights sent/received */
int msg_accrightrightslen;

```

The `msg_name` and `msg_namelen` parameters specify the destination address when the socket is unconnected. The `msg_name` can be specified as a NULL pointer if no names are desired or required. The `msg_iov` and `msg_iovlen` parameters describe the scatter-gather locations, as described in `read(2)`. The `msg_accrightrights` parameter specifies the buffer in which access rights sent along with the message are received. The `msg_accrightrightslen` specifies the length of the buffer.

## RETURN VALUES

Upon successful completion, these functions return the number of bytes received. Otherwise, they return -1 and set `errno` to indicate the error.

## ERRORS

The `recv()`, `recvfrom()`, and `recvmsg()` functions return errors under the following conditions:

|              |                                                                                                                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EBADF        | The <code>s</code> file descriptor is invalid.                                                                                                                                                      |
| EINVAL       | The <code>MSG_OOB</code> flag is set and no out-of-band data is available.                                                                                                                          |

| ENOSR        | Insufficient STREAMS resources are available for the operation to complete.                                                                                                                         |
| ENOTSOCK     | <code>s</code> is not a socket.                                                                                                                                                                     |
| ESTALE       | A stale NFS file handle exists.                                                                                                                                                                     |
| EWOULDBLOCK  | The socket is marked non-blocking and the requested operation would block.                                                                                                                          |
| ECONNREFUSED | The requested connection was refused by the peer. For connected IPv4 and IPv6 datagram sockets, this indicates that the system received an ICMP Destination Port Unreachable message from the peer. |

The `recv()` and `recvfrom()` functions fail under the following conditions:

recv(3SOCKET)

EINVAL The *len* argument overflows a *ssize\_t*.

The `recvmsg()` function returns errors under the following conditions:

EINVAL The *msg\_iovlen* member of the *msg\_hdr* structure pointed to by *msg* is less than or equal to 0, or greater than `[IOV_MAX]`. See `Intro(2)` for a definition of `[IOV_MAX]`.

EINVAL One of the *iov\_len* values in the *msg\_iov* array member of the *msg\_hdr* structure pointed to by *msg* is negative, or the sum of the *iov\_len* values in the *msg\_iov* array overflows a *ssize\_t*.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Stable          |
| MT-Level            | Safe            |

| <b>NAME</b>        | recv – receive a message from a connected socket                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lxnet [ <i>library</i> ... ] #include &lt;sys/socket.h&gt;  ssize_t <b>recv</b>(int <i>socket</i>, void *<i>buffer</i>, size_t <i>length</i>, int <i>flags</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The <code>recv()</code> function receives a message from a connection-mode or connectionless-mode socket. It is normally used with connected sockets because it does not permit the application to retrieve the source address of received data. The function takes the following arguments:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><i>socket</i></td> <td>Specifies the socket file descriptor.</td> </tr> <tr> <td><i>buffer</i></td> <td>Points to a buffer where the message should be stored.</td> </tr> <tr> <td><i>length</i></td> <td>Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.</td> </tr> <tr> <td><i>flags</i></td> <td>Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:</td> </tr> <tr> <td style="padding-left: 40px;">MSG_PEEK</td> <td>Peeks at an incoming message. The data is treated as unread and the next <code>recv()</code> or similar function will still return this data.</td> </tr> <tr> <td style="padding-left: 40px;">MSG_OOB</td> <td>Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</td> </tr> <tr> <td style="padding-left: 40px;">MSG_WAITALL</td> <td>Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if <code>MSG_PEEK</code> was specified, or if an error is pending for the socket.</td> </tr> </table> <p>The <code>recv()</code> function returns the length of the message written to the buffer pointed to by the <i>buffer</i> argument. For message-based sockets such as <code>SOCK_DGRAM</code> and <code>SOCK_SEQPACKET</code>, the entire message must be read in a single operation. If a message is too long to fit in the supplied buffer, and <code>MSG_PEEK</code> is not set in the <i>flags</i> argument, the excess bytes are discarded. For stream-based sockets such as <code>SOCK_STREAM</code>, message boundaries are ignored. In this case, data is returned to the user as soon as it becomes available, and no data is discarded.</p> <p>If the <code>MSG_WAITALL</code> flag is not set, data will be returned only up to the end of the first message.</p> | <i>socket</i> | Specifies the socket file descriptor. | <i>buffer</i> | Points to a buffer where the message should be stored. | <i>length</i> | Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument. | <i>flags</i> | Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values: | MSG_PEEK | Peeks at an incoming message. The data is treated as unread and the next <code>recv()</code> or similar function will still return this data. | MSG_OOB | Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific. | MSG_WAITALL | Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if <code>MSG_PEEK</code> was specified, or if an error is pending for the socket. |
| <i>socket</i>      | Specifies the socket file descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |
| <i>buffer</i>      | Points to a buffer where the message should be stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |
| <i>length</i>      | Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |
| <i>flags</i>       | Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |
| MSG_PEEK           | Peeks at an incoming message. The data is treated as unread and the next <code>recv()</code> or similar function will still return this data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |

The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if <code>MSG_PEEK</code> was specified, or if an error is pending for the socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |               |                                       |               |                                                        |               |                                                                                       |              |                                                                                                                                       |          |                                                                                                                                               |         |                                                                                                      |             |                                                                                                                                                                                                                                                                                      |

## recv(3XNET)

If no messages are available at the socket and `O_NONBLOCK` is not set on the socket's file descriptor, `recv()` blocks until a message arrives. If no messages are available at the socket and `O_NONBLOCK` is set on the socket's file descriptor, `recv()` fails and sets `errno` to `EAGAIN` or `EWOULDBLOCK`.

**USAGE** The `recv()` function is identical to `recvfrom(3XNET)` with a zero `address_len` argument, and to `read()` if no flags are used.

The `select(3C)` and `poll(2)` functions can be used to determine when data is available to be received.

**RETURN VALUES** Upon successful completion, `recv()` returns the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, `recv()` returns 0. Otherwise, `-1` is returned and `errno` is set to indicate the error.

**ERRORS** The `recv()` function will fail if:

|                          |                                                                                                                                                                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>EAGAIN</code>      |                                                                                                                                                                                                                                                                                                                        |
| <code>EWOULDBLOCK</code> | The socket's file descriptor is marked <code>O_NONBLOCK</code> and no data is waiting to be received; or <code>MSG_OOB</code> is set and no out-of-band data is available and either the socket's file descriptor is marked <code>O_NONBLOCK</code> or the socket does not support blocking to await out-of-band data. |
| <code>EBADF</code>       | The <i>socket</i> argument is not a valid file descriptor.                                                                                                                                                                                                                                                             |
| <code>ECONNRESET</code>  | A connection was forcibly closed by a peer.                                                                                                                                                                                                                                                                            |

| <code>ENOTSOCK</code>    | The <i>socket</i> argument does not refer to a socket.                                                                                                                                                                                                                                                                 |
| <code>EOPNOTSUPP</code>  | The specified flags are not supported for this socket type or protocol.                                                                                                                                                                                                                                                |
| <code>ETIMEDOUT</code>   | The connection timed out during connection establishment, or due to a transmission timeout on active connection.                                                                                                                                                                                                       |

The `recv()` function may fail if:

recv(3XNET)

EIO An I/O error occurred while reading from or writing to the file system.

ENOBUFS Insufficient resources were available in the system to perform the operation.

ENOMEM Insufficient memory was available to fulfill the request.

ENOSR There were insufficient STREAMS resources available for the operation to complete.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|

| <b>DESCRIPTION</b> | <p>The <code>recvfrom()</code> function receives a message from a connection-mode or connectionless-mode socket. It is normally used with connectionless-mode sockets because it permits the application to retrieve the source address of received data.</p> <p>The function takes the following arguments:</p> <table><tr><td><i>socket</i></td><td>Specifies the socket file descriptor.</td></tr><tr><td><i>buffer</i></td><td>Points to the buffer where the message should be stored.</td></tr><tr><td><i>length</i></td><td>Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.</td></tr><tr><td><i>flags</i></td><td>Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:</td></tr><tr><td></td><td><table><tr><td>MSG_PEEK</td><td>Peeks at an incoming message. The data is treated as unread and the next <code>recvfrom()</code> or similar function will still return this data.</td></tr><tr><td>MSG_OOB</td><td>Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</td></tr><tr><td>MSG_WAITALL</td><td>Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.</td></tr></table></td></tr><tr><td><i>address</i></td><td>A null pointer, or points to a <code>sockaddr</code> structure in which the sending address is to be stored. The length and format of the address depend on the address family of the socket.</td></tr><tr><td><i>address_len</i></td><td>Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.</td></tr></table> | <i>socket</i> | Specifies the socket file descriptor.                                                                                                             | <i>buffer</i> | Points to the buffer where the message should be stored.                                             | <i>length</i> | Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.                                                                                                                                                                                   | <i>flags</i> | Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values: |  | <table><tr><td>MSG_PEEK</td><td>Peeks at an incoming message. The data is treated as unread and the next <code>recvfrom()</code> or similar function will still return this data.</td></tr><tr><td>MSG_OOB</td><td>Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</td></tr><tr><td>MSG_WAITALL</td><td>Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.</td></tr></table> | MSG_PEEK | Peeks at an incoming message. The data is treated as unread and the next <code>recvfrom()</code> or similar function will still return this data. | MSG_OOB | Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific. | MSG_WAITALL | Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket. | <i>address</i> | A null pointer, or points to a <code>sockaddr</code> structure in which the sending address is to be stored. The length and format of the address depend on the address family of the socket. | <i>address_len</i> | Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument. |
| <i>socket</i>      | Specifies the socket file descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |
| <i>buffer</i>      | Points to the buffer where the message should be stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |
| <i>length</i>      | Specifies the length in bytes of the buffer pointed to by the <i>buffer</i> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |
| <i>flags</i>       | Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |

The significance and semantics of out-of-band data are protocol-specific.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |
| MSG_WAITALL        | Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |
| <i>address</i>     | A null pointer, or points to a <code>sockaddr</code> structure in which the sending address is to be stored. The length and format of the address depend on the address family of the socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |
| <i>address_len</i> | Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>address</i> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |               |                                                                                                                                                   |               |                                                                                                      |               |                                                                                                                                                                                                                                                                         |              |                                                                                                                                       |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                   |         |                                                                                                      |             |                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                               |                    |                                                                                                        |

The `recvfrom()` function returns the length of the message written to the buffer pointed to by the *buffer* argument. For message-based sockets such as `SOCK_DGRAM` and `SOCK_SEQPACKET`, the entire message must be read in a single operation. If a message is too long to fit in the supplied buffer, and `MSG_PEEK` is not set in the *flags* argument, the excess bytes are discarded. For stream-based sockets such as `SOCK_STREAM`, message boundaries are ignored. In this case, data is returned to the user as soon as it becomes available, and no data is discarded.

If the `MSG_WAITALL` flag is not set, data will be returned only up to the end of the first message.

Not all protocols provide the source address for messages. If the *address* argument is not a null pointer and the protocol provides the source address of messages, the source address of the received message is stored in the `sockaddr` structure pointed to by the *address* argument, and the length of this address is stored in the object pointed to by the *address\_len* argument.

If the actual length of the address is greater than the length of the supplied `sockaddr` structure, the stored address will be truncated.

If the *address* argument is not a null pointer and the protocol does not provide the source address of messages, the value stored in the object pointed to by *address* is unspecified.

If no messages are available at the socket and `O_NONBLOCK` is not set on the socket's file descriptor, `recvfrom()` blocks until a message arrives. If no messages are available at the socket and `O_NONBLOCK` is set on the socket's file descriptor, `recvfrom()` fails and sets `errno` to `EAGAIN` or `EWOULDBLOCK`.

**USAGE** The `select(3C)` and `poll(2)` functions can be used to determine when data is available to be received.

**RETURN VALUES** Upon successful completion, `recvfrom()` returns the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, `recvfrom()` returns 0. Otherwise the function returns `-1` and sets `errno` to indicate the error.

**ERRORS** The `recvfrom()` function will fail if:

`EAGAIN`

`EWOULDBLOCK`

The socket's file descriptor is marked `O_NONBLOCK` and no data is waiting to be received, or `MSG_OOB` is set and no out-of-band data is available and either the socket's file descriptor is marked `O_NONBLOCK` or the socket does not support blocking to await out-of-band data.

`EBADF`

The *socket* argument is not a valid file descriptor.

`ECONNRESET`

A connection was forcibly closed by a peer.

## recvfrom(3XNET)

|            |                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------|
| EFAULT     | The <i>buffer</i> , <i>address</i> or <i>address_len</i> parameter can not be accessed or written.               |
| EINTR      | A signal interrupted <code>recvfrom()</code> before any data was available.                                      |
| EINVAL     | The <code>MSG_OOB</code> flag is set and no out-of-band data is available.                                       |
| ENOTCONN   | A receive is attempted on a connection-mode socket that is not connected.                                        |
| ENOTSOCK   | The <i>socket</i> argument does not refer to a socket.                                                           |
| EOPNOTSUPP | The specified flags are not supported for this socket type.                                                      |
| ETIMEDOUT  | The connection timed out during connection establishment, or due to a transmission timeout on active connection. |

The `recvfrom()` function may fail if:

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| EIO     | An I/O error occurred while reading from or writing to the file system.            |
| ENOBUFS | Insufficient resources were available in the system to perform the operation.      |
| ENOMEM  | Insufficient memory was available to fulfill the request.                          |
| ENOSR   | There were insufficient STREAMS resources available for the operation to complete. |

| <b>NAME</b>             | recvmsg – receive a message from a socket                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                      |                                                            |                      |                                |                        |                            |                         |                             |
| <b>SYNOPSIS</b>         | <pre>cc [ flag ... ] file ... -lxnet [ library ... ] #include &lt;sys/socket.h&gt;  ssize_t <b>recvmsg</b>(int socket, struct msghdr *message, int flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                      |                                                            |                      |                                |                        |                            |                         |                             |
| <b>DESCRIPTION</b>      | <p>The <code>recvmsg()</code> function receives a message from a connection-mode or connectionless-mode socket. It is normally used with connectionless-mode sockets because it permits the application to retrieve the source address of received data.</p> <p>The <code>recvmsg()</code> function receives messages from unconnected or connected sockets and returns the length of the message.</p> <p>The <code>recvmsg()</code> function returns the total length of the message. For message-based sockets such as <code>SOCK_DGRAM</code> and <code>SOCK_SEQPACKET</code>, the entire message must be read in a single operation. If a message is too long to fit in the supplied buffers, and <code>MSG_PEEK</code> is not set in the <code>flags</code> argument, the excess bytes are discarded, and <code>MSG_TRUNC</code> is set in the <code>msg_flags</code> member of the <code>msghdr</code> structure. For stream-based sockets such as <code>SOCK_STREAM</code>, message boundaries are ignored. In this case, data is returned to the user as soon as it becomes available, and no data is discarded.</p> <p>If the <code>MSG_WAITALL</code> flag is not set, data will be returned only up to the end of the first message.</p> <p>If no messages are available at the socket, and <code>O_NONBLOCK</code> is not set on the socket's file descriptor, <code>recvmsg()</code> blocks until a message arrives. If no messages are available at the socket and <code>O_NONBLOCK</code> is set on the socket's file descriptor, the <code>recvmsg()</code> function fails and sets <code>errno</code> to <code>EAGAIN</code> or <code>EWOULDBLOCK</code>.</p> <p>In the <code>msghdr</code> structure, the <code>msg_name</code> and <code>msg_namelen</code> members specify the source address if the socket is unconnected. If the socket is connected, the <code>msg_name</code> and <code>msg_namelen</code> members are ignored. The <code>msg_name</code> member may be a null pointer if no names are desired or required. The <code>msg_iov</code> and <code>msg_iovlen</code> fields are used to specify where the received data will be stored. <code>msg_iov</code> points to an array of <code>iovec</code> structures; <code>msg_iovlen</code> must be set to the dimension of this array. In each <code>iovec</code> structure, the <code>iov_base</code> field specifies a storage area and the <code>iov_len</code> field gives its size in bytes. Each storage area indicated by <code>msg_iov</code> is filled with received data in turn until all of the received data is stored or all of the areas have been filled.</p> <p>On successful completion, the <code>msg_flags</code> member of the message header is the bitwise-inclusive OR of all of the following flags that indicate conditions detected for the received message:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>MSG_EOR</code></td> <td>End of record was received (if supported by the protocol).</td> </tr> <tr> <td><code>MSG_OOB</code></td> <td>Out-of-band data was received.</td> </tr> <tr> <td><code>MSG_TRUNC</code></td> <td>Normal data was truncated.</td> </tr> <tr> <td><code>MSG_CTRUNC</code></td> <td>Control data was truncated.</td> </tr> </table> | <code>MSG_EOR</code> | End of record was received (if supported by the protocol). | <code>MSG_OOB</code> | Out-of-band data was received. | <code>MSG_TRUNC</code> | Normal data was truncated. | <code>MSG_CTRUNC</code> | Control data was truncated. |
| <code>MSG_EOR</code>    | End of record was received (if supported by the protocol).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                      |                                                            |                      |                                |                        |                            |                         |                             |

## recvmsg(3XNET)

### PARAMETERS

The function takes the following arguments:

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>socket</i>  | Specifies the socket file descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>message</i> | Points to a <code>msg_hdr</code> structure, containing both the buffer to store the source address and the buffers for the incoming message. The length and format of the address depend on the address family of the socket. The <code>msg_flags</code> member is ignored on input, but may contain meaningful values on output.                                                                                                                                                                                                                                                                                                                              |
| <i>flags</i>   | Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:<br><br>MSG_OOB                      Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.<br><br>MSG_PEEK                      Peeks at the incoming message.<br><br>MSG_WAITALL                  Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket. |

### USAGE

The `select(3C)` and `poll(2)` functions can be used to determine when data is available to be received.

### RETURN VALUES

Upon successful completion, `recvmsg()` returns the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, `recvmsg()` returns 0. Otherwise, `-1` is returned and `errno` is set to indicate the error.

### ERRORS

The `recvmsg()` function will fail if:

|                       |                                                                                                                                                                                                                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EAGAIN<br>EWOULDBLOCK | The socket's file descriptor is marked <code>O_NONBLOCK</code> and no data is waiting to be received; or <code>MSG_OOB</code> is set and no out-of-band data is available and either the socket's file descriptor is marked <code>O_NONBLOCK</code> or the socket does not support blocking to await out-of-band data. |
| EBADF                 | The <i>socket</i> argument is not a valid open file descriptor.                                                                                                                                                                                                                                                        |
| ECONNRESET            | A connection was forcibly closed by a peer.                                                                                                                                                                                                                                                                            |

- EFAULT            The *message* parameter, or storage pointed to by the *msg\_name*, *msg\_control* or *msg\_iov* fields of the *message* parameter, or storage pointed to by the *iovec* structures pointed to by the *msg\_iov* field can not be accessed or written.
- EINTR            This function was interrupted by a signal before any data was available.
- EINVAL           The sum of the *iov\_len* values overflows an *ssize\_t*. or the MSG\_OOB flag is set and no out-of-band data is available.
- EMSGSIZE        The *msg\_iovlen* member of the *msghdr* structure pointed to by *message* is less than or equal to 0, or is greater than IOV\_MAX.
- ENOTCONN        A receive is attempted on a connection-mode socket that is not connected.
- ENOTSOCK        The *socket* argument does not refer to a socket.
- EOPNOTSUPP     The specified flags are not supported for this socket type.
- ETIMEDOUT      The connection timed out during connection establishment, or due to a transmission timeout on active connection.

The `recvmsg()` function may fail if:

- EIO              An IO error occurred while reading from or writing to the file system.
- ENOBUFS        Insufficient resources were available in the system to perform the operation.
- ENOMEM         Insufficient memory was available to fulfill the request.
- ENOSR           There were insufficient STREAMS resources available for the operation to complete.

## resolver(3RESOLV)

**NAME** resolver, res\_ninit, fp\_resstat, res\_hostalias, res\_nquery, res\_nsearch, res\_nquerydomain, res\_nmkquery, res\_nsend, res\_nclose, res\_nsendsigned, dn\_comp, dn\_expand, hstrerror, res\_init, res\_query, res\_search, res\_mkquery, res\_send, horror, res\_getservers, res\_setservers – resolver routines

**SYNOPSIS** BIND 8.2.2 Interfaces

```
cc [flag ...] file ... -lresolv -lsocket -lnsl [library ...]
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>
#include <netdb.h>

int res_ninit(res_state statp);

void fp_resstat(const res_state statp, FILE *fp);

const char *res_hostalias(const res_state statp, const char *name,
 char * name, char *buf, size_t buflen);

int res_nquery(res_state statp, const char *dname, int class, int type,
 u_char *answer, int datalen, int anslen);

int res_nsearch(res_state statp, const char *dname, int class, int
 type, u_char *answer, int anslen);

int res_nquerydomain(res_state statp, const char *name, const char
 *domain, int class, int type, u_char *answer, int anslen);

int res_nmkquery(res_state statp, int op, const char *dname, int
 class, int type, u_char *answer, int datalen, int anslen);

int res_nsend(res_state statp, const u_char *msg, int msglen, u_char
 *answer, int anslen);

void res_nclose(res_state statp);

int res_nsendsigned(res_state statp, const u_char *msg, int msglen,
 ns_tsig_key *key, u_char *answer, int anslen);

int dn_comp(const char *exp_dn, u_char *comp_dn, int length, u_char
 **dnptrs, **lastdnptr);

int dn_expand(const u_char *msg, *eomorig, *comp_dn, char *exp_dn,
 int length);

const char *hstrerror(int err);

void res_setservers(res_state statp, const union
 res_sockaddr_union *set, int cnt);

int res_getservers(res_state statp, union res_sockaddr_union *set,
 int cnt);

Deprecated Interfaces

cc [flag ...] file ... -lresolv -lsocket -lnsl [library ...]
#include <sys/types.h>
```

```

#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>
#include <netdb.h>

int res_init(void);

int res_query(const char *dname, int class, int type, u_char *answer,
 int anslen);

int res_search(const char *dname, int class, int type, u_char *answer,
 int anslen);

int res_mkquery(int op, const char *dname, int class, int type, const
 char *data, int datalen, struct rrec *newrr, u_char *buf, int
 buflen);

int res_send(const u_char *msg, int msglen, u_char *answer, int
 anslen);

void herror(const char *s);

```

**DESCRIPTION**

These routines are used for making, sending, and interpreting query and reply messages with Internet domain name servers.

State information is kept in *statp* and is used to control the behavior of these functions. Set *statp* to all zeros prior to making the first call to any of these functions.

The functions `res_init()`, `res_query()`, `res_search()`, `res_mkquery()`, `res_send()`, and `herror()` are deprecated. They are supplied for backwards compatibility. They use global configuration and state information that is kept in the structure `_res` rather than state information referenced through *statp*.

Most of the values in *statp* and `_res` are initialized to reasonable defaults on the first call to `res_ninit()` or `res_init()` and can be ignored. Options stored in `statp->options` or `_res.options` are defined in `<resolv.h>`. They are stored as a simple bit mask containing the bitwise OR of the options enabled.

|            |                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RES_INIT   | True if the initial name server address and default domain name are initialized, that is, <code>res_init()</code> or <code>res_ninit()</code> has been called.                                 |
| RES_DEBUG  | Print debugging messages.                                                                                                                                                                      |
| RES_AAONLY | Accept authoritative answers only. With this option, <code>res_send()</code> will continue until it finds an authoritative answer or finds an error. Currently this option is not implemented. |
| RES_USEVC  | Use TCP connections for queries instead of UDP datagrams.                                                                                                                                      |

## resolver(3RESOLV)

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RES_STAYOPEN               | Use with RES_USEVC to keep the TCP connection open between queries. This is a useful option for programs that regularly do many queries. The normal mode used should be UDP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| RES_IGNTC                  | Ignore truncation errors; that is, do not retry with TCP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| RES_RECURSE                | Set the recursion-desired bit in queries. This is the default. <code>res_send()</code> and <code>res_nsend()</code> do not do iterative queries and expect the name server to handle recursion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RES_DEFNAMES               | If set, <code>res_search()</code> and <code>res_nsearch()</code> append the default domain name to single-component names, that is, names that do not contain a dot. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| RES_DNSRCH                 | If this option is set, <code>res_search()</code> and <code>res_nsearch()</code> search for host names in the current domain and in parent domains. See <code>hostname(1)</code> . This option is used by the standard host lookup routine <code>gethostbyname(3NSL)</code> . This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RES_NOALIASES              | This option turns off the user level aliasing feature controlled by the <code>HOSTALIASES</code> environment variable. Network daemons should set this option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| RES_BLAST                  | If the <code>RES_BLAST</code> option is defined, <code>resolver()</code> queries will be sent to all servers. If the <code>RES_BLAST</code> option is not defined, but <code>RES_ROTATE</code> is, the list of nameservers are rotated according to a round-robin scheme. <code>RES_BLAST</code> overrides <code>RES_ROTATE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| RES_ROTATE                 | This option causes <code>res_nsend()</code> and <code>res_send()</code> to rotate the list of nameservers in <code>statp-&gt;nsaddr_list</code> or <code>_res.nsaddr_list</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| RES_KEEPTSIG               | This option causes <code>res_nsendsigned()</code> to leave the message unchanged after TSIG verification. Otherwise the TSIG record would be removed and the header would be updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>res_ninit, res_init</b> | The <code>res_ninit()</code> and <code>res_init()</code> routines read the configuration file, if any is present, to get the default domain name, search list and the Internet address of the local name server(s). See <code>resolv.conf(4)</code> . If no server is configured, <code>res_init()</code> or <code>res_ninit()</code> will try to obtain name resolution services from the host on which it is running. The current domain name is defined by <code>domainname(1M)</code> , or by the <code>hostname</code> if it is not specified in the configuration file. Use the environment variable <code>LOCALDOMAIN</code> to override the domain name. This environment variable may contain several blank-separated tokens if you wish to override the search list on a per-process |

basis. This is similar to the search command in the configuration file. You can set the `RES_OPTIONS` environment variable to override certain internal resolver options. You can otherwise set them by changing fields in the `statp / _res` structure. Alternatively, they are inherited from the configuration file's `options` command. See `resolv.conf(4)` for information regarding the syntax of the `RES_OPTIONS` environment variable. Initialization normally occurs on the first call to one of the other resolver routines.

**res\_nquery,  
res\_query**

The `res_nquery()` and `res_query()` functions provides interfaces to the server query mechanism. They construct a query, send it to the local server, await a response, and make preliminary checks on the reply. The query requests information of the specified *type* and *class* for the specified fully-qualified domain name *dname*. The reply message is left in the *answer* buffer with length *anslen* supplied by the caller. `res_nquery()` and `res_query()` return the length of the *answer*, or -1 upon error.

The `res_nquery()` and `res_query()` routines return a length that may be bigger than *anslen*. In that case, retry the query with a larger *buf*. The *answer* to the second query may be larger still], so it is recommended that you supply a *buf* larger than the *answer* returned by the previous query. *answer* must be large enough to receive a maximum UDP response from the server or parts of the *answer* will be silently discarded. The default maximum UDP response size is 512 bytes.

**res\_nsearch,  
res\_search**

The `res_nsearch()` and `res_search()` routines make a query and await a response, just like like `res_nquery()` and `res_query()`. In addition, they implement the default and search rules controlled by the `RES_DEFNAMES` and `RES_DNSRCH` options. They return the length of the first successful reply which is stored in *answer*. On error, they return -1.

The `res_nsearch()` and `res_search()` routines return a length that may be bigger than *anslen*. In that case, retry the query with a larger *buf*. The *answer* to the second query may be larger still], so it is recommended that you supply a *buf* larger than the *answer* returned by the previous query. *answer* must be large enough to receive a maximum UDP response from the server or parts of the *answer* will be silently discarded. The default maximum UDP response size is 512 bytes.

**res\_nmkquery,  
res\_mkquery**

These routines are used by `res_nquery()` and `res_query()`. The `res_nmkquery()` and `res_mkquery()` functions construct a standard query message and place it in *buf*. The routine returns the *size* of the query, or -1 if the query is larger than *buflen*. The query type *op* is usually `QUERY`, but can be any of the query types defined in `<arpa/nameser.h>`. The domain name for the query is given by *dname*. *newrr* is currently unused but is intended for making update messages.

## resolver(3RESOLV)

**res\_nsend,  
res\_send,  
res\_nsendsigned**

The `res_nsend()`, `res_send()`, and `res_nsendsigned()` routines send a preformatted query that returns an *answer*. The routine calls `res_ninit()` or `res_init()`. If `RES_INIT` is not set, the routine sends the query to the local name server and handles timeouts and retries. Additionally, the `res_nsendsigned()` uses TSIG signatures to add authentication to the query and verify the response. In this case, only one name server will be contacted. The routines return the length of the reply message, or -1 if there are errors.

The `res_nsend()` and `res_send()` routines return a length that may be bigger than *anslen*. In that case, retry the query with a larger *buf*. The *answer* to the second query may be larger still, so it is recommended that you supply a *buf* larger than the *answer* returned by the previous query. *answer* must be large enough to receive a maximum UDP response from the server or parts of the *answer* will be silently discarded. The default maximum UDP response size is 512 bytes.

**fp\_resstat**

The function `fp_resstat()` prints out the active flag bits in `statp->options` preceded by the text `;; res options:` on *file*.

**res\_hostalias**

The function `res_hostalias()` looks up *name* in the file referred to by the `HOSTALIASES` environment variable and returns the fully qualified host name. If *name* is not found or an error occurs, `NULL` is returned. `res_hostalias()` stores the result in *buf*.

**res\_nclose**

The `res_nclose()` function closes any open files referenced through *statp*.

**dn\_comp**

`dn_comp()` compresses the domain name *exp\_dn* and stores it in *comp\_dn*. `dn_comp()` returns the size of the compressed name, or -1 if there were errors. *length* is the size of the array pointed to by *comp\_dn*.

*dnptrs* is a pointer to the head of the list of pointers to previously compressed names in the current message. The first pointer must point to the beginning of the message. The list ends with `NULL`. The limit to the array is specified by *lastdnptr*.

A side effect of calling `dn_comp()` is to update the list of pointers for labels inserted into the message by `dn_comp()` as the name is compressed. If *dnptrs* is `NULL`, names are not compressed. If *lastdnptr* is `NULL`, `dn_comp()` does not update the list of labels.

**dn\_expand**

`dn_expand()` expands the compressed domain name *comp\_dn* to a full domain name. The compressed name is contained in a query or reply message. *msg* is a pointer to the beginning of that message. The uncompressed name is placed in the buffer indicated by *exp\_dn*, which is of size *length*. `dn_expand()` returns the size of the compressed name, or -1 if there was an error.

**hsterror, herror**

The variables `statp->res_h_errno` and `_res.res_h_errno` and external variable *h\_errno* are set whenever an error occurs during a resolver operation. The following definitions are given in `<netdb.h>`:

```
#define NETDB_INTERNAL -1 /* see errno */
#define NETDB_SUCCESS 0 /* no problem */
#define HOST_NOT_FOUND 1 /* Authoritative Answer Host not found */
```

## resolver(3RESOLV)

```
#define TRY_AGAIN 2 /* Non-Authoritative not found, or SERVFAIL */
#define NO_RECOVERY 3 /* Non-Recoverable: FORMERR, REFUSED, NOTIMP*/
#define NO_DATA 4 /* Valid name, no data for requested type */
```

The `herror()` function writes a message to the diagnostic output consisting of the string parameters, the constant string ":", and a message corresponding to the value of `h_errno`.

The `hstrerror()` function returns a string, which is the message text that corresponds to the value of the `err` parameter.

**res\_setservers, res\_getservers** The functions `res_getservers()` and `res_setservers()` are used to get and set the list of servers to be queried.

**FILES** `/etc/resolv.conf` resolver configuration file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                                           |
|---------------------|-----------------------------------------------------------|
| Availability        | SUNWcsl (32-bit)<br>SUNWcslx (64-bit)                     |
| Interface Stability | Evolving                                                  |
| MT-Level            | Unsafe for Deprecated Interfaces; MT-Safe for all others. |

resolver(3RESOLV)

**NOTES** | When the caller supplies a work buffer, for example the *answer* buffer argument to `res_nsend()` or `res_send()`, the buffer should be aligned on an eight byte boundary. Otherwise, an error such as a `SIGBUS` may result.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>          | rexec, rexec_af – return stream to a remote command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file... -lsocket -lnsl [ library... ] #include &lt;netdb.h&gt; #include &lt;unistd.h&gt;  int rexec(char **ahost, unsigned short inport, const char *user, const char *passwd, const char *cmd, int *fd2p);  int rexec_af(char **ahost, unsigned short inport, const char *user, const char *passwd, const char *cmd, int *fd2p, int af);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>   | <p>The rexec() and rexec_af() functions look up the host <i>ahost</i> using <a href="#">getaddrinfo(3SOCKET)</a> and return -1 if the host does not exist. Otherwise <i>ahost</i> is set to the standard name of the host. The username and password are used in remote host authentication. When a username and password are not specified, the <code>.netrc</code> file in the user's home directory is searched for the appropriate information. If the search fails, the user is prompted for the information.</p> <p>The rexec() function always returns a socket of the AF_INET address family. The rexec_af() function supports AF_INET, AF_INET6, or AF_UNSPEC for the address family. An application can choose which type of socket is returned by passing AF_INET or AF_INET6 as the address family. The use of AF_UNSPEC means that the caller will accept any address family. Choosing AF_UNSPEC provides a socket that best suits the connectivity to the remote host.</p> <p>The port <i>inport</i> specifies which DARPA Internet port to use for the connection. The port number used must be in network byte order, as supplied by a call to <code>htons(3XNET)</code>. The protocol for connection is described in detail in <code>in.rexecd(1M)</code>.</p> <p>If the call succeeds, a socket of type SOCK_STREAM is returned to the caller, and given to the remote command as its standard input and standard output. If <i>fd2p</i> is non-zero, an auxiliary channel to a control process is set up and a file descriptor for it is placed in <i>fd2p</i>. The control process returns diagnostic output (file descriptor 2), from the command on the auxiliary channel. The control process also accepts bytes on this channel as signal numbers to be forwarded to the process group of the command. If <i>fd2p</i> is 0, the standard error (file descriptor 2) of the remote command is made the same as its standard output. No provision is made for sending arbitrary signals to the remote process, other than possibly sending out-of-band data.</p> <p>There is no way to specify options to the socket() call made by the rexec() or rexec_af() functions.</p> |
| <b>RETURN VALUES</b> | <p>If rexec() succeeds, a file descriptor number is returned of the socket type SOCK_STREAM and the address family AF_INET. The parameter <i>ahost</i> is set to the standard name of the host. If the value of <i>fd2p</i> is other than NULL, a file descriptor number is placed in <i>fd2p</i> which represents the standard error stream of the command.</p> <p>If rexec_af() succeeds, the routine returns a file descriptor number of the socket type SOCK_STREAM in the address family AF_INET or AF_INET6, as determined by the value of the <i>af</i> parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

rexec(3SOCKET)

If either `rexec()` or `rexec_af()` fails, `-1` is returned.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

This interface is `Unsafe` in multithreaded applications. `Unsafe` interfaces should be called only from the main thread.

| <b>DESCRIPTION</b>                | <p>These routines allow C language programs to make procedure calls on other machines across a network. First, the client sends a request to the server. On receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends back a reply.</p> <p>All RPC routines require the header <code>&lt;rpc/rpc.h&gt;</code>. Routines that take a <code>netconfig</code> structure also require that <code>&lt;netconfig.h&gt;</code> be included. Applications using RPC and XDR routines should be linked with the <code>libnsl</code> library.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                      |                                                                                                                                                                                                                                                                                |                      |                                                                                                                   |                        |                                                                                                                                                                                                                               |
| <b>Multithread Considerations</b> | <p>In the case of multithreaded applications, the <code>-mt</code> option must be specified on the command line at compilation time to enable a thread-specific version of <code>rpc_createerr()</code>. See <a href="#">rpc_clnt_create(3NSL)</a> and <a href="#">threads(5)</a>.</p> <p>When used in multithreaded applications, client-side routines are MT-Safe. CLIENT handles can be shared between threads; however, in this implementation, requests by different threads are serialized (that is, the first request will receive its results before the second request is sent). See <a href="#">rpc_clnt_create(3NSL)</a>.</p> <p>When used in multithreaded applications, server-side routines are usually Unsafe. In this implementation the service transport handle, <code>SVCXPRT</code> contains a single data area for decoding arguments and encoding results. See <a href="#">rpc_svc_create(3NSL)</a>. Therefore, this structure cannot be freely shared between threads that call functions that do this. Routines that are affected by this restriction are marked as unsafe for MT applications. See <a href="#">rpc_svc_calls(3NSL)</a>.</p>                                                     |                      |                                                                                                                                                                                                                                                                                |                      |                                                                                                                   |                        |                                                                                                                                                                                                                               |
| <b>Nettyp</b>                     | <p>Some of the high-level RPC interface routines take a <i>nettype</i> string as one of the parameters (for example, <code>clnt_create()</code>, <code>svc_create()</code>, <code>rpc_reg()</code>, <code>rpc_call()</code>). This string defines a class of transports which can be used for a particular application.</p> <p><i>nettype</i> can be one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>netpath</code></td> <td>Choose from the transports which have been indicated by their token names in the <code>NETPATH</code> environment variable. If <code>NETPATH</code> is unset or <code>NULL</code>, it defaults to <code>visible</code>. <code>netpath</code> is the default <i>nettype</i>.</td> </tr> <tr> <td><code>visible</code></td> <td>Choose the transports which have the visible flag (<code>v</code>) set in the <code>/etc/netconfig</code> file.</td> </tr> <tr> <td><code>circuit_v</code></td> <td>This is same as <code>visible</code> except that it chooses only the connection oriented transports (semantics <code>tpi_cots</code> or <code>tpi_cots_ord</code>) from the entries in the <code>/etc/netconfig</code> file.</td> </tr> </table> | <code>netpath</code> | Choose from the transports which have been indicated by their token names in the <code>NETPATH</code> environment variable. If <code>NETPATH</code> is unset or <code>NULL</code> , it defaults to <code>visible</code> . <code>netpath</code> is the default <i>nettype</i> . | <code>visible</code> | Choose the transports which have the visible flag ( <code>v</code> ) set in the <code>/etc/netconfig</code> file. | <code>circuit_v</code> | This is same as <code>visible</code> except that it chooses only the connection oriented transports (semantics <code>tpi_cots</code> or <code>tpi_cots_ord</code> ) from the entries in the <code>/etc/netconfig</code> file. |
| <code>netpath</code>              | Choose from the transports which have been indicated by their token names in the <code>NETPATH</code> environment variable. If <code>NETPATH</code> is unset or <code>NULL</code> , it defaults to <code>visible</code> . <code>netpath</code> is the default <i>nettype</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                                                                                                                                                                                                                                                                |                      |                                                                                                                   |                        |                                                                                                                                                                                                                               |
| <code>visible</code>              | Choose the transports which have the visible flag ( <code>v</code> ) set in the <code>/etc/netconfig</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                      |                                                                                                                                                                                                                                                                                |                      |                                                                                                                   |                        |                                                                                                                                                                                                                               |
| <code>circuit_v</code>            | This is same as <code>visible</code> except that it chooses only the connection oriented transports (semantics <code>tpi_cots</code> or <code>tpi_cots_ord</code> ) from the entries in the <code>/etc/netconfig</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                      |                                                                                                                                                                                                                                                                                |                      |                                                                                                                   |                        |                                                                                                                                                                                                                               |

|                         |                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>datagram_v</code> | This is same as <code>visible</code> except that it chooses only the connectionless datagram transports (semantics <code>tpi_clts</code> ) from the entries in the <code>/etc/netconfig</code> file. |
| <code>circuit_n</code>  | This is same as <code>netpath</code> except that it chooses only the connection oriented datagram transports (semantics <code>tpi_cots</code> or <code>tpi_cots_ord</code> ).                        |
| <code>datagram_n</code> | This is same as <code>netpath</code> except that it chooses only the connectionless datagram transports (semantics <code>tpi_clts</code> ).                                                          |
| <code>udp</code>        | This refers to Internet UDP.                                                                                                                                                                         |
| <code>tcp</code>        | This refers to Internet TCP.                                                                                                                                                                         |

If `nettype` is NULL, it defaults to `netpath`. The transports are tried in left to right order in the `NETPATH` variable or in top to down order in the `/etc/netconfig` file.

### Derived Types

In a 64-bit environment, the derived types are defined as follows:

```
typedef uint32_t rpcprog_t;
typedef uint32_t rpcvers_t;
typedef uint32_t rpcproc_t;
typedef uint32_t rpcprot_t;
typedef uint32_t rpcport_t;
typedef int32_t rpc_inline_t;
```

In a 32-bit environment, the derived types are defined as follows:

```
typedef unsigned long rpcprog_t;
typedef unsigned long rpcvers_t;
typedef unsigned long rpcproc_t;
typedef unsigned long rpcprot_t;
typedef unsigned long rpcport_t;
typedef long rpc_inline_t;
```

### Data Structures

Some of the data structures used by the RPC package are shown below.

#### The AUTH Structure

```
union des_block {
 struct {
 u_int32 high;
 u_int32 low;
 } key;
 char c[8];
};
```

**The CLIENT  
Structure**

```

};
typedef union des_block des_block;
extern bool_t xdr_des_block();
/*
 * Authentication info. Opaque to client.
 */
struct opaque_auth {
 enum_t oa_flavor; /* flavor of auth */
 caddr_t oa_base; /* address of more auth stuff */
 uint_t oa_length; /* not to exceed MAX_AUTH_BYTES */
};
/*
 * Auth handle, interface to client side authenticators.
 */
typedef struct {
 struct opaque_auth ah_cred;
 struct opaque_auth ah_verf;
 union des_block ah_key;
 struct auth_ops {
 void(*ah_nextverf)();
 int(*ah_marshall)(); /* nextverf & serialize */
 int(*ah_validate)(); /* validate verifier */
 int(*ah_refresh)(); /* refresh credentials */
 void(*ah_destroy)(); /* destroy this structure */
 } *ah_ops;
 caddr_t ah_private;
} AUTH;

/*
 * Client rpc handle.
 * Created by individual implementations.
 * Client is responsible for initializing auth.
 */
typedef struct {
 AUTH *cl_auth; /* authenticator */
 struct clnt_ops {
 enum clnt_stat (*cl_call)(); /* call remote procedure */
 void (*cl_abort)(); /* abort a call */
 void (*cl_geterr)(); /* get specific error code */
 bool_t (*cl_freeres)(); /* frees results */
 void (*cl_destroy)(); /* destroy this structure */
 bool_t (*cl_control)(); /* the ioctl() of rpc */
 int (*cl_settimers)(); /* set rpc level timers */
 } *cl_ops;
 caddr_t cl_private; /* private stuff */
 char *cl_netid; /* network identifier */
 char *cl_tp; /* device name */
} CLIENT;

```

**The SVCXPRT  
Structure**

```

enum xpirt_stat {
 XPRT_DIED,
 XPRT_MOREREQS,
 XPRT_IDLE
};
/*
 * Server side transport handle
 */
typedef struct {

```

## rpc(3NSL)

### The svc\_req Structure

### The XDR Structure

```
int xp_fd; /* file descriptor for the
ushort_t xp_port; /* obsolete */
struct xp_ops {
 bool_t (*xp_rcv)(); /* receive incoming requests */
 enum xprt_stat (*xp_stat)(); /* get transport status */
 bool_t (*xp_getargs)(); /* get arguments */
 bool_t (*xp_reply)(); /* send reply */
 bool_t (*xp_freeargs)(); /* free mem allocated
 for args */
 void (*xp_destroy)(); /* destroy this struct */
} *xp_ops;
int xp_addrlen; /* length of remote addr.
 Obsolete */
char *xp_tp; /* transport provider device
 name */
char *xp_netid; /* network identifier */
struct netbuf xp_ltaddr; /* local transport address */
struct netbuf xp_rtaddr; /* remote transport address */
char xp_raddr[16]; /* remote address. Obsolete */
struct opaque_auth xp_verf; /* raw response verifier */
caddr_t xp_p1; /* private: for use
 by svc ops */
caddr_t xp_p2; /* private: for use
 by svc ops */
caddr_t xp_p3; /* private: for use
 by svc lib */
int xp_type /* transport type */
} SVCXPRT;

struct svc_req {
 rpcprog_t rq_prog; /* service program number */
 rpcvers_t rq_vers; /* service protocol version */
 rpcproc_t rq_proc; /* the desired procedure */
 struct opaque_auth rq_cred; /* raw creds from the wire */
 caddr_t rq_clntcred; /* read only cooked cred */
 SVCXPRT *rq_xprt; /* associated transport */
};

/*
 * XDR operations.
 * XDR_ENCODE causes the type to be encoded into the stream.
 * XDR_DECODE causes the type to be extracted from the stream.
 * XDR_FREE can be used to release the space allocated by an XDR_DECODE
 * request.
 */
enum xdr_op {
 XDR_ENCODE=0,
 XDR_DECODE=1,
 XDR_FREE=2
};

/*
 * This is the number of bytes per unit of external data.
 */
#define BYTES_PER_XDR_UNIT (4)
#define RNDUP(x) (((x) + BYTES_PER_XDR_UNIT - 1) /
 BYTES_PER_XDR_UNIT) \ * BYTES_PER_XDR_UNIT)
/*
```

```

* A xdrproc_t exists for each data type which is to be encoded or
* decoded. The second argument to the xdrproc_t is a pointer to
* an opaque pointer. The opaque pointer generally points to a
* structure of the data type to be decoded. If this points to 0,
* then the type routines should allocate dynamic storage of the
* appropriate size and return it.
* bool_t (*xdrproc_t)(XDR *, caddr_t *);
*/
typedef bool_t (*xdrproc_t)();
/*
* The XDR handle.
* Contains operation which is being applied to the stream,
* an operations vector for the particular implementation
*/
typedef struct {
enum xdr_op x_op; /* operation; fast additional param */
struct xdr_ops {
bool_t (*x_getlong)(); /* get long from underlying stream */
bool_t (*x_putlong)(); /* put long to underlying stream */
bool_t (*x_getbytes)(); /* get bytes from underlying stream */
bool_t (*x_putbytes)(); /* put bytes to underlying stream */
uint_t (*x_getpostn)(); /* returns bytes off from beginning */
bool_t (*x_setpostn)(); /* reposition the stream */
rpc_inline_t (*x_inline)(); /* buf quick ptr to buffered data */
void (*x_destroy)(); /* free privates of this xdr_stream */
bool_t (*x_control)(); /* changed/retrieve client object info*/
bool_t (*x_getint32)(); /* get int from underlying stream */
bool_t (*x_putint32)(); /* put int to underlying stream */
} *x_ops;

caddr_t x_public; /* users' data */
caddr_t x_priv; /* pointer to private data */
caddr_t x_base; /* private used for position info */
int x_handy; /* extra private word */
XDR;

```

**Index to Routines**

The following table lists RPC routines and the manual reference pages on which they are described:

| RPC Routine            | Manual Reference Page               |
|------------------------|-------------------------------------|
| auth_destroy           | <a href="#">rpc_clnt_auth(3NSL)</a> |
| authdes_create         | <a href="#">rpc_soc(3NSL)</a>       |
| authdes_getucred       | <a href="#">secure_rpc(3NSL)</a>    |
| authdes_seccreate      | <a href="#">secure_rpc(3NSL)</a>    |
| authnone_create        | <a href="#">rpc_clnt_auth(3NSL)</a> |
| authsys_create         | <a href="#">rpc_clnt_auth(3NSL)</a> |
| authsys_create_default | <a href="#">rpc_clnt_auth(3NSL)</a> |
| authunix_create        | <a href="#">rpc_soc(3NSL)</a>       |

| <b>DESCRIPTION</b> | These routines allow client C programs to make procedure calls to the RPC binder service. rpcbind maintains a list of mappings between programs and their universal addresses. See rpcbind(1M).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Routines</b>    | <p><b>rpcb_getmaps()</b><br/>An interface to the rpcbind service, which returns a list of the current RPC program-to-address mappings on <i>host</i>. It uses the transport specified through <i>netconf</i> to contact the remote rpcbind service on <i>host</i>. This routine will return NULL, if the remote rpcbind could not be contacted.</p> <p><b>rpcb_getaddr()</b><br/>An interface to the rpcbind service, which finds the address of the service on <i>host</i> that is registered with program number <i>prognum</i>, version <i>versnum</i>, and speaks the transport protocol associated with <i>netconf</i>. The address found is returned in <i>svcaddr</i>. <i>svcaddr</i> should be preallocated. This routine returns TRUE if it succeeds. A return value of FALSE means that the mapping does not exist or that the RPC system failed to contact the remote rpcbind service. In the latter case, the global variable <i>rpc_createerr</i> contains the RPC status. See <a href="#">rpc_clnt_create(3NSL)</a>.</p> <p><b>rpcb_gettime()</b><br/>This routine returns the time on <i>host</i> in <i>timep</i>. If <i>host</i> is NULL, <i>rpcb_gettime()</i> returns the time on its own machine. This routine returns TRUE if it succeeds, FALSE if it fails. <i>rpcb_gettime()</i> can be used to synchronize the time between the client and the remote server. This routine is particularly useful for secure RPC.</p> <p><b>rpcb_rmtcall()</b><br/>An interface to the rpcbind service, which instructs rpcbind on <i>host</i> to make an RPC call on your behalf to a procedure on that host. The netconfig structure</p> |

## rpcbind(3NSL)

should correspond to a connectionless transport. The parameter *\*svcaddr* will be modified to the server's address if the procedure succeeds. See `rpc_call()` and `clnt_call()` in `rpc_clnt_calls(3NSL)` for the definitions of other parameters.

This procedure should normally be used for a "ping" and nothing else. This routine allows programs to do lookup and call, all in one step.

Note: Even if the server is not running `rpcbind` does not return any error messages to the caller. In such a case, the caller times out.

Note: `rpcb_rmtcall()` is only available for connectionless transports.

### `rpcb_set()`

An interface to the `rpcbind` service, which establishes a mapping between the triple [*prognum, versnum, netconf->nc\_netid*] and *svcaddr* on the machine's `rpcbind` service. The value of *nc\_netid* must correspond to a network identifier that is defined by the `netconf` database. This routine returns `TRUE` if it succeeds, `FALSE` otherwise. See also `svc_reg()` in `rpc_svc_calls(3NSL)`. If there already exists such an entry with `rpcbind`, `rpcb_set()` will fail.

### `rpcb_unset()`

An interface to the `rpcbind` service, which destroys the mapping between the triple [*prognum, versnum, netconf->nc\_netid*] and the address on the machine's `rpcbind` service. If *netconf* is `NULL`, `rpcb_unset()` destroys all mapping between the triple [*prognum, versnum, all-transport*] and the addresses on the machine's `rpcbind` service. This routine returns `TRUE` if it succeeds, `FALSE` otherwise. Only the owner of the service or the super-user can destroy the mapping. See also `svc_unreg()` in `rpc_svc_calls(3NSL)`.

| <b>DESCRIPTION</b> | <p>These routines are part of the RPC library that allows C language programs to make procedure calls on other machines across the network, with desired authentication.</p> <p>These routines are normally called after creating the CLIENT handle. The <code>cl_auth</code> field of the CLIENT structure should be initialized by the AUTH structure returned by some of the following routines. The client's authentication information is passed to the server when the RPC call is made.</p> <p>Only the NULL and the SYS style of authentication is discussed here. For the DES style authentication, please refer to <a href="#">secure_rpc(3NSL)</a>.</p> <p>The NULL and SYS style of authentication are safe in multithreaded applications. For the MT-level of the DES style, see its pages.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Routines</b>    | <p>The following routines require that the header <code>&lt;rpc/rpc.h&gt;</code> be included (see <a href="#">rpc(3NSL)</a> for the definition of the AUTH data structure).</p> <pre>#include &lt;rpc/rpc.h&gt;<br/><br/>auth_destroy()<br/>A function macro that destroys the authentication information associated with <i>auth</i>.<br/>Destruction usually involves deallocation of private data structures. The use of <i>auth</i><br/>is undefined after calling <code>auth_destroy()</code>.<br/><br/>authnone_create()<br/>Create and return an RPC authentication handle that passes nonusable<br/>authentication information with each remote procedure call. This is the default<br/>authentication used by RPC.<br/><br/>authsys_create()<br/>Create and return an RPC authentication handle that contains AUTH_SYS<br/>authentication information. The parameter <i>host</i> is the name of the machine on<br/>which the information was created; <i>uid</i> is the user's user ID; <i>gid</i> is the user's current<br/>group ID; <i>len</i> and <i>aup_gids</i> refer to a counted array of groups to which the user<br/>belongs.<br/><br/>authsys_create_default<br/>Call <code>authsys_create()</code> with the appropriate parameters.</pre> |

| <b>DESCRIPTION</b> | <p>RPC library routines allow C language programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a request to the server. Upon receipt of the request, the server calls a dispatch routine to perform the requested service and then sends back a reply.</p> <p>The <code>clnt_call()</code>, <code>rpc_call()</code>, and <code>rpc_broadcast()</code> routines handle the client side of the procedure call. The remaining routines deal with error handling.</p> <p>Some of the routines take a <code>CLIENT</code> handle as one of the parameters. A <code>CLIENT</code> handle can be created by an RPC creation routine such as <code>clnt_create()</code>. See <a href="#">rpc_clnt_create(3NSL)</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

These routines are safe for use in multithreaded applications. CLIENT handles can be shared between threads; however, in this implementation requests by different threads are serialized. In other words, the first request will receive its results before the second request is sent.

**Routines** See [rpc\(3NSL\)](#) for the definition of the CLIENT data structure.

`clnt_call()`

A function macro that calls the remote procedure *procnum* associated with the client handle, *clnt*, which is obtained with an RPC client creation routine such as `clnt_create()`. See [rpc\\_clnt\\_create\(3NSL\)](#). The parameter *inproc* is the XDR function used to encode the procedure's parameters, and *outproc* is the XDR function used to decode the procedure's results. *in* is the address of the procedure's argument(s), and *out* is the address of where to place the result(s). *tout* is the time allowed for results to be returned, which is overridden by a time-out set explicitly through `clnt_control()`. See [rpc\\_clnt\\_create\(3NSL\)](#).

If the remote call succeeds, the status returned is `RPC_SUCCESS`. Otherwise, an appropriate status is returned.

`clnt_send()`

Use the `clnt_send()` function to call a remote asynchronous function.

The `clnt_send()` function calls the remote function `procnum()` associated with the client handle, *clnt*, which is obtained with an RPC client creation routine such as `clnt_create()`. See [rpc\\_clnt\\_create\(3NSL\)](#). The parameter *proc* is the XDR function used to encode the procedure's parameters. The parameter *in* is the address of the procedure's argument(s).

By default, the blocking I/O mode is used. See the [clnt\\_control\(3NSL\)](#) man page for more information on I/O modes.

The `clnt_send()` function does not check if the program version number supplied to `clnt_create()` is registered with the `rpcbind` service. Use `clnt_create_vers()` instead of `clnt_create()` to check on incorrect version number registration. `clnt_create_vers()` will return a valid handle to the client only if a version within the range supplied to `clnt_create_vers()` is supported by the server.

`RPC_SUCCESS` is returned when a request is successfully delivered to the transport layer. This does not mean that the request was received. If an error is returned, use the `clnt_getterr()` routine to find the failure status or the `clnt_perrno()` routine to translate the failure status into error messages.

`clnt_freeres()`

A function macro that frees any data allocated by the RPC/XDR system when it decoded the results of an RPC call. The parameter *out* is the address of the results, and *outproc* is the XDR routine describing the results. This routine returns 1 if the results were successfully freed; otherwise it returns 0.

## rpc\_clnt\_calls(3NSL)

`clnt_geterr()`

A function macro that copies the error structure out of the client handle to the structure at address *errp*.

`clnt_perrno()`

Prints a message to standard error corresponding to the condition indicated by *stat*. A newline is appended. It is normally used after a procedure call fails for a routine for which a client handle is not needed, for instance `rpc_call()`

`clnt_perror()`

Prints a message to the standard error indicating why an RPC call failed; *clnt* is the handle used to do the call. The message is prepended with string *s* and a colon. A newline is appended. This routine is normally used after a remote procedure call fails for a routine that requires a client handle, for instance `clnt_call()`.

`clnt_sperrno()`

Takes the same arguments as `clnt_perrno()`, but instead of sending a message to the standard error indicating why an RPC call failed, returns a pointer to a string that contains the message.

`clnt_sperrno()` is normally used instead of `clnt_perrno()` when the program does not have a standard error, as a program running as a server quite likely does not. `clnt_sperrno()` is also used if the programmer does not want the message to be output with `printf()`, or if a message format different than that supported by `clnt_perrno()` is to be used. See `printf(3C)`. Unlike `clnt_sperror()` and `clnt_spcreaterror()`, `clnt_sperrno()` does not return a pointer to static data. Therefore, the result is not overwritten on each call. See `rpc_clnt_create(3NSL)`.

`clnt_sperror()`

Similar to `clnt_perror()`, except that like `clnt_sperrno()`, it returns a string instead of printing to standard error. However, `clnt_sperror()` does not append a newline at the end of the message.

`clnt_sperror()` returns a pointer to a buffer that is overwritten on each call. In multithreaded applications, this buffer is implemented as thread-specific data.

`rpc_broadcast()`

Similar to `rpc_call()`, except that the call message is broadcast to all the connectionless transports specified by *nettype*. If *nettype* is `NULL`, it defaults to `netpath`. Each time it receives a response, this routine calls `eachresult()`, whose form is:

```
bool_t eachresult(caddr_t out, const struct netbuf *addr,
const struct netconfig *netconf);
```

where *out* is the same as *out* passed to `rpc_broadcast()`, except that the remote procedure's output is decoded there. *addr* points to the address of the machine that sent the results, and *netconf* is the netconfig structure of the transport on which the remote server responded. If `eachresult()` returns 0, `rpc_broadcast()` waits for more replies; otherwise, it returns with appropriate status.

The broadcast file descriptors are limited in size to the maximum transfer size of that transport. For Ethernet, this value is 1500 bytes. `rpc_broadcast()` uses `AUTH_SYS` credentials by default. See `rpc_clnt_auth(3NSL)`.

#### `rpc_broadcast_exp()`

Similar to `rpc_broadcast()`, except that the initial timeout, *inittime* and the maximum timeout, *waittime*, are specified in milliseconds.

*inittime* is the initial time that `rpc_broadcast_exp()` waits before resending the request. After the first resend, the retransmission interval increases exponentially until it exceeds *waittime*.

#### `rpc_call()`

Calls the remote procedure associated with *prognum*, *versnum*, and *procnum* on the machine, *host*. The parameter *inproc* is used to encode the procedure's parameters, and *outproc* is used to decode the procedure's results. *in* is the address of the procedure's argument(s), and *out* is the address of where to place the result(s). *nettype* can be any of the values listed on `rpc(3NSL)`. This routine returns `RPC_SUCCESS` if it succeeds, or it returns an appropriate status. Use the `clnt_perrno()` routine to translate failure status into error messages.

The `rpc_call()` function uses the first available transport belonging to the class *nettype* on which it can create a connection. You do not have control of timeouts or authentication using this routine.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|---------------------|-------------------|
| Architecture        | All               |
| Availability        | SUNWcsl (32-bit)  |
|                     | SUNWcslx (64-bit) |
| Interface Stability | Evolving          |
| MT-Level            | MT-Safe           |

| <b>DESCRIPTION</b> | <pre>CLIENT *clnt_door_create(const rpcprog_t prognum, const rpcvers_t     versnum, const uint_t sendsz);</pre> <p>RPC library routines allow C language programs to make procedure calls on other machines across the network. First a CLIENT handle is created and then the client calls a procedure to send a request to the server. On receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends a reply.</p> <p>These routines are MT-Safe. In the case of multithreaded applications, the <code>-mt</code> option must be specified on the command line at compilation time. When the <code>-mt</code> option is specified, <code>rpc_createerr()</code> becomes a macro that enables each thread to have its own <code>rpc_createerr()</code>. See <code>threads(5)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Routines</b>    | <p>See <a href="#">rpc(3NSL)</a> for the definition of the CLIENT data structure.</p> <pre>clnt_control()</pre> <p>A function macro to change or retrieve various information about a client object. <i>req</i> indicates the type of operation, and <i>info</i> is a pointer to the information. For both connectionless and connection-oriented transports, the supported values of <i>req</i> and their argument types and what they do are:</p> <pre>CLSET_TIMEOUT struct timeval * set total timeout CLGET_TIMEOUT struct timeval *  get total timeout</pre> <p>If the timeout is set using <code>clnt_control()</code>, the timeout argument passed by <code>clnt_call()</code> is ignored in all subsequent calls. If the timeout value is set to 0, <code>clnt_control()</code> immediately returns <code>RPC_TIMEDOUT</code>. Set the timeout parameter to 0 for batching calls.</p> <pre>CLGET_SERVER_ADDR struct netbuf * get server's address CLGET_SVC_ADDR   struct netbuf *  get server's address CLGET_FD         int *           get associated file descriptor CLSET_FD_CLOSE   void           close the file descriptor when                                 destroying the client handle                                 (see clnt_destroy()) CLSET_FD_NCLOSE  void           do not close the file                                 descriptor when destroying the client handle CLGET_VERS       rpcvers_t      get the RPC program's version                                 number associated with the                                 client handle CLSET_VERS       rpcvers_t      set the RPC program's version                                 number associated with the                                 client handle. This assumes                                 that the RPC server for this                                 new version is still listening                                 at the address of the previous                                 version. CLGET_XID        uint32_t       get the XID of the previous                                 remote procedure call CLSET_XID        uint32_t       set the XID of the next                                 remote procedure call CLGET_PROG       rpcprog_t      get program number CLSET_PROG       rpcprog_t      set program number</pre> <p>The following operations are valid for connection-oriented transports only:</p> |

## rpc\_clnt\_create(3NSL)

CLSET\_IO\_MODE rpciomode\_t\* set the IO mode used to send one-way requests. The argument for this operation can be either:

- RPC\_CL\_BLOCKING all sending operations block until the underlying transport protocol has accepted requests. If you specify this argument you cannot use flush and getting and setting buffer size is meaningless.
- RPC\_CL\_NONBLOCKING sending operations do not block and return as soon as requests enter the buffer. You can now use non-blocking I/O. The requests in the buffer are pending. The requests are sent to the server as soon as a two-way request is sent or a flush is done. You are responsible for flushing the buffer. When you choose RPC\_CL\_NONBLOCKING argument you have a choice of flush modes as specified by CLSET\_FLUSH\_MODE.

CLGET\_IO\_MODE rpciomode\_t\* get the current IO mode

CLSET\_FLUSH\_MODE rpcflushmode\_t\* set the flush mode. The flush mode can only be used in non-blocking I/O mode. The argument can be either of the following:

- RPC\_CL\_BESTEFFORT\_FLUSH: All flushes send requests in the buffer until the transport end-point blocks. If the transport connection is congested, the call returns directly.
- RPC\_CL\_BLOCKING\_FLUSH: Flush blocks until the underlying transport protocol accepts all pending requests into the queue.

CLGET\_FLUSH\_MODE rpcflushmode\_t\* get the current flush mode.

CLFLUSH rpcflushmode\_t flush the pending requests. This command can only be used in non-blocking I/O mode. The flush policy depends on which of the following parameters is specified:

- RPC\_CL\_DEFAULT\_FLUSH, or NULL: The flush is done according to the current flush mode policy (see CLSET\_FLUSH\_MODE option).
- RPC\_CL\_BESTEFFORT\_FLUSH: The flush tries to send pending requests without blocking; the call returns directly. If the transport connection is congested, this call could return without the request being sent.
- RPC\_CL\_BLOCKING\_FLUSH: The flush sends all pending requests. This call will block until all the requests have been accepted by the transport layer.

CLSET\_CONNMAXREC\_SIZE int\* set the buffer size. It is not possible to dynamically resize the buffer if it contains data. The default size of the buffer is 16 kilobytes.

CLGET\_CONNMAXREC\_SIZE int\* get the current size of the buffer

CLGET\_CURRENT\_REC\_SIZE int\* get the size of the pending requests stored in the buffer. Use of this command is only recommended when you are in non-blocking I/O mode. The current size of the buffer is always zero when the handle is in blocking mode as the buffer is not used in this mode.

The following operations are valid for connectionless transports only:

## rpc\_clnt\_create(3NSL)

```
CLSET_RETRY_TIMEOUT struct timeval * set the retry timeout
CLGET_RETRY_TIMEOUT struct timeval * get the retry timeout
```

The retry timeout is the time that RPC waits for the server to reply before retransmitting the request.

`clnt_control()` returns TRUE on success and FALSE on failure.

### `clnt_create()`

Generic client creation routine for program *prognum* and version *versnum*. *host* identifies the name of the remote host where the server is located. *nettype* indicates the class of transport protocol to use. The transports are tried in left to right order in NETPATH variable or in top to bottom order in the netconfig database.

`clnt_create()` tries all the transports of the *nettype* class available from the NETPATH environment variable and the netconfig database, and chooses the first successful one. A default timeout is set and can be modified using `clnt_control()`. This routine returns NULL if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure.

Note that `clnt_create()` returns a valid client handle even if the particular version number supplied to `clnt_create()` is not registered with the `rpcbind` service. This mismatch will be discovered by a `clnt_call` later (see [rpc\\_clnt\\_calls\(3NSL\)](#)).

### `clnt_create_timed()`

Generic client creation routine which is similar to `clnt_create()` but which also has the additional parameter *timeout* that specifies the maximum amount of time allowed for each transport class tried. In all other respects, the `clnt_create_timed()` call behaves exactly like the `clnt_create()` call.

### `clnt_create_vers()`

Generic client creation routine which is similar to `clnt_create()` but which also checks for the version availability. *host* identifies the name of the remote host where the server is located. *nettype* indicates the class transport protocols to be used. If the routine is successful it returns a client handle created for the highest version between *vers\_low* and *vers\_high* that is supported by the server. *vers\_outp* is set to this value. That is, after a successful return  $vers\_low \leq *vers\_outp \leq vers\_high$ . If no version between *vers\_low* and *vers\_high* is supported by the server then the routine fails and returns NULL. A default timeout is set and can be modified using `clnt_control()`. This routine returns NULL if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure.

Note: `clnt_create()` returns a valid client handle even if the particular version number supplied to `clnt_create()` is not registered with the `rpcbind` service. This mismatch will be discovered by a `clnt_call` later (see [rpc\\_clnt\\_calls\(3NSL\)](#)). However, `clnt_create_vers()` does this for you and returns a valid handle only if a version within the range supplied is supported by the server.

## rpc\_clnt\_create(3NSL)

`clnt_create_vers_timed()`

Generic client creation routine similar to `clnt_create_vers()` but with the additional parameter *timeout*, which specifies the maximum amount of time allowed for each transport class tried. In all other respects, the `clnt_create_vers_timed()` call behaves exactly like the `clnt_create_vers()` call.

`clnt_destroy()`

A function macro that destroys the client's RPC handle. Destruction usually involves deallocation of private data structures, including *clnt* itself. Use of *clnt* is undefined after calling `clnt_destroy()`. If the RPC library opened the associated file descriptor, or `CLSET_FD_CLOSE` was set using `clnt_control()`, the file descriptor will be closed.

The caller should call `auth_destroy(clnt->cl_auth)` (before calling `clnt_destroy()`) to destroy the associated AUTH structure (see [rpc\\_clnt\\_auth\(3NSL\)](#)).

`clnt_dg_create()`

This routine creates an RPC client for the remote program *prognum* and version *versnum*; the client uses a connectionless transport. The remote program is located at address *svcaddr*. The parameter *fdes* is an open and bound file descriptor. This routine will resend the call message in intervals of 15 seconds until a response is received or until the call times out. The total time for the call to time out is specified by `clnt_call()` (see `clnt_call()` in [rpc\\_clnt\\_calls\(3NSL\)](#)). The retry time out and the total time out periods can be changed using `clnt_control()`. The user may set the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. This routine returns NULL if it fails.

`clnt_pcreateerror()`

Print a message to standard error indicating why a client RPC handle could not be created. The message is prepended with the string *s* and a colon, and appended with a newline.

`clnt_raw_create()`

This routine creates an RPC client handle for the remote program *prognum* and version *versnum*. The transport used to pass messages to the service is a buffer within the process's address space, so the corresponding RPC server should live in the same address space; (see `svc_raw_create()` in [rpc\\_svc\\_create\(3NSL\)](#)). This allows simulation of RPC and measurement of RPC overheads, such as round trip times, without any kernel or networking interference. This routine returns NULL if it fails. `clnt_raw_create()` should be called after `svc_raw_create()`.

`clnt_spccreateerror()`

Like `clnt_pcreateerror()`, except that it returns a string instead of printing to the standard error. A newline is not appended to the message in this case.

Warning: returns a pointer to a buffer that is overwritten on each call. In multithread applications, this buffer is implemented as thread-specific data.

`clnt_tli_create()`

This routine creates an RPC client handle for the remote program *prognum* and version *versnum*. The remote program is located at address *svcaddr*. If *svcaddr* is NULL and it is connection-oriented, it is assumed that the file descriptor is connected. For connectionless transports, if *svcaddr* is NULL, RPC\_UNKOWNADDR error is set. *fildev* is a file descriptor which may be open, bound and connected. If it is RPC\_ANYFD, it opens a file descriptor on the transport specified by *netconf*. If *fildev* is RPC\_ANYFD and *netconf* is NULL, a RPC\_UNKOWNPROTO error is set. If *fildev* is unbound, then it will attempt to bind the descriptor. The user may specify the size of the buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. Depending upon the type of the transport (connection-oriented or connectionless), `clnt_tli_create()` calls appropriate client creation routines. This routine returns NULL if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure. The remote `rpcbind` service (see `rpcbind(1M)`) is not consulted for the address of the remote service.

`clnt_tp_create()`

Like `clnt_create()` except `clnt_tp_create()` tries only one transport specified through *netconf*.

`clnt_tp_create()` creates a client handle for the program *prognum*, the version *versnum*, and for the transport specified by *netconf*. Default options are set, which can be changed using `clnt_control()` calls. The remote `rpcbind` service on the host *host* is consulted for the address of the remote service. This routine returns NULL if it fails. The `clnt_pcreateerror()` routine can be used to print the reason for failure.

`clnt_tp_create_timed()`

Like `clnt_tp_create()` except `clnt_tp_create_timed()` has the extra parameter *timeout* which specifies the maximum time allowed for the creation attempt to succeed. In all other respects, the `clnt_tp_create_timed()` call behaves exactly like the `clnt_tp_create()` call.

`clnt_vc_create()`

This routine creates an RPC client for the remote program *prognum* and version *versnum*; the client uses a connection-oriented transport. The remote program is located at address *svcaddr*. The parameter *fildev* is an open and bound file descriptor. The user may specify the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. This routine returns NULL if it fails.

The address *svcaddr* should not be NULL and should point to the actual address of the remote program. `clnt_vc_create()` does not consult the remote `rpcbind` service for this information.

`rpc_createerr()`

A global variable whose value is set by any RPC client handle creation routine that fails. It is used by the routine `clnt_pcreateerror()` to print the reason for the failure.

## rpc\_clnt\_create(3NSL)

In multithreaded applications, `rpc_createerr` becomes a macro which enables each thread to have its own `rpc_createerr`.

### clnt\_door\_create()

This routine creates an RPC client handle over doors for the given program *prognum* and version *versnum*. Doors is a transport mechanism that facilitates fast data transfer between processes on the same machine. The user may set the size of the send buffer with the parameter *sendsz*. If *sendsz* is 0, the corresponding default buffer size is 16 Kbyte. The `clnt_door_create()` routine returns `NULL` if it fails and sets a value for `rpc_createerr`.

| <b>NAME</b>            | rpc_control – library routine for manipulating global RPC attributes for client and server applications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                             |       |                      |                    |       |                      |                    |       |                               |                    |       |                               |                      |       |                              |                        |       |                               |                       |       |                                    |                    |       |                                             |                        |       |                               |                        |       |                               |                 |                      |           |                 |                   |  |                 |              |  |
| <b>SYNOPSIS</b>        | <code>bool_t rpc_control(int op, void *info);</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                             |       |                      |                    |       |                      |                    |       |                               |                    |       |                               |                      |       |                              |                        |       |                               |                       |       |                                    |                    |       |                                             |                        |       |                               |                        |       |                               |                 |                      |           |                 |                   |  |                 |              |  |
| <b>DESCRIPTION</b>     | <p>This RPC library routine allows applications to set and modify global RPC attributes that apply to clients as well as servers. At present, it supports only server side operations. This function allows applications to set and modify global attributes that apply to client as well as server functions. <i>op</i> indicates the type of operation, and <i>info</i> is a pointer to the operation specific information. The supported values of <i>op</i> and their argument types, and what they do are:</p> <table border="0" style="margin-left: 20px;"> <tr><td>RPC_SVC_MTMODE_SET</td><td>int *</td><td>set multithread mode</td></tr> <tr><td>RPC_SVC_MTMODE_GET</td><td>int *</td><td>get multithread mode</td></tr> <tr><td>RPC_SVC_THRMAX_SET</td><td>int *</td><td>set maximum number of threads</td></tr> <tr><td>RPC_SVC_THRMAX_GET</td><td>int *</td><td>get maximum number of threads</td></tr> <tr><td>RPC_SVC_THRTOTAL_GET</td><td>int *</td><td>get number of active threads</td></tr> <tr><td>RPC_SVC_THRCREATES_GET</td><td>int *</td><td>get number of threads created</td></tr> <tr><td>RPC_SVC_THRERRORS_GET</td><td>int *</td><td>get number of thread create errors</td></tr> <tr><td>RPC_SVC_USE_POLLFD</td><td>int *</td><td>set number of file descriptors to unlimited</td></tr> <tr><td>RPC_SVC_CONNMAXREC_SET</td><td>int *</td><td>set non-blocking max rec size</td></tr> <tr><td>RPC_SVC_CONNMAXREC_GET</td><td>int *</td><td>get non-blocking max rec size</td></tr> </table> <p>There are three multithread (MT) modes. These are:</p> <table border="0" style="margin-left: 20px;"> <tr><td>RPC_SVC_MT_NONE</td><td>Single threaded mode</td><td>(default)</td></tr> <tr><td>RPC_SVC_MT_AUTO</td><td>Automatic MT mode</td><td></td></tr> <tr><td>RPC_SVC_MT_USER</td><td>User MT mode</td><td></td></tr> </table> <p>Unless the application sets the Automatic or User MT modes, it will stay in the default (single threaded) mode. See the <i>Network Interfaces Programmer's Guide</i> for the meanings of these modes and programming examples. Once a mode is set, it cannot be changed.</p> <p>By default, the maximum number of threads that the server will create at any time is 16. This allows the service developer to put a bound on thread resources consumed by a server. If a server needs to process more than 16 client requests concurrently, the maximum number of threads must be set to the desired number. This parameter may be set at any time by the server.</p> <p>Set and get operations will succeed even in modes where the operations don't apply. For example, you can set the maximum number of threads in any mode, even though it makes sense only for the Automatic MT mode. All of the get operations except <code>RPC_SVC_MTMODE_GET</code> apply only to the Automatic MT mode, so values returned in other modes may be undefined.</p> <p>By default, RPC servers are limited to a maximum of 1024 file descriptors or connections due to limitations in the historical interfaces <code>svc_fdset(3NSL)</code> and <code>svc_getreqset(3NSL)</code>. Applications written to use the preferred interfaces of <code>svc_pollfd(3NSL)</code> and <code>svc_getreq_poll(3NSL)</code> can use an unlimited number of file descriptors. Setting <i>info</i> to point to a non-zero integer and <i>op</i> to <code>RPC_SVC_USE_POLLFD</code> removes the limitation.</p> <p>Connection oriented RPC transports read RPC requests in blocking mode by default. Thus, they may be adversely affected by network delays and broken clients. <code>RPC_SVC_CONNMAXREC_SET</code> enables non-blocking mode and establishes the</p> | RPC_SVC_MTMODE_SET                          | int * | set multithread mode | RPC_SVC_MTMODE_GET | int * | get multithread mode | RPC_SVC_THRMAX_SET | int * | set maximum number of threads | RPC_SVC_THRMAX_GET | int * | get maximum number of threads | RPC_SVC_THRTOTAL_GET | int * | get number of active threads | RPC_SVC_THRCREATES_GET | int * | get number of threads created | RPC_SVC_THRERRORS_GET | int * | get number of thread create errors | RPC_SVC_USE_POLLFD | int * | set number of file descriptors to unlimited | RPC_SVC_CONNMAXREC_SET | int * | set non-blocking max rec size | RPC_SVC_CONNMAXREC_GET | int * | get non-blocking max rec size | RPC_SVC_MT_NONE | Single threaded mode | (default) | RPC_SVC_MT_AUTO | Automatic MT mode |  | RPC_SVC_MT_USER | User MT mode |  |

## rpc\_control(3NSL)

maximum record size (in bytes) for RPC requests; RPC responses are not affected. Buffer space is allocated as needed up to the specified maximum, starting at the maximum or `RPC_MAXDATASIZE`, whichever is smaller.

The value established by `RPC_SVC_CONNMAXREC_SET` is used when a connection is created, and it remains in effect for that connection until it is closed. To change the value for existing connections on a per-connection basis, see [svc\\_control\(3NSL\)](#).

`RPC_SVC_CONNMAXREC_GET` retrieves the current maximum record size. A zero value means that no maximum is in effect, and that the connections are in blocking mode.

*info* is a pointer to an argument of type `int`. Non-connection RPC transports ignore `RPC_SVC_CONNMAXREC_SET` and `RPC_SVC_CONNMAXREC_GET`.

### RETURN VALUES

This routine returns `TRUE` if the operation was successful and returns `FALSE` otherwise.

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

| <b>DESCRIPTION</b>   | <p>rpc_gss_getcred() is used by a server to fetch the credentials of a client. These credentials may either be network credentials (in the form of a rpc_gss_rawcred_t structure) or UNIX credentials.</p> <p>For more information on RPCSEC_GSS data types, see the <a href="#">rpcsec_gss(3NSL)</a> man page.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>PARAMETERS</b>    | <p>Essentially, rpc_gss_getcred() passes a pointer to a request (svc_req) as well as pointers to two credential structures and a user-defined cookie; if rpc_gss_getcred() is successful, at least one credential structure is "filled out" with values, as is, optionally, the cookie.</p> <p><i>req</i>                      Pointer to the received service request. svc_req is an RPC structure containing information on the context of an RPC invocation, such as program, version, and transport information.</p> <p><i>rcred</i>                     A pointer to an rpc_gss_rawcred_t structure pointer. This structure contains the version number of the RPCSEC_GSS protocol being used; the security mechanism and QOPs for this session (as strings); principal names for the client (as a rpc_gss_principal_t structure) and server (as a string); and the security service (integrity, privacy, etc., as an enum). If an application is not interested in these values, it may pass NULL for this parameter.</p> <p><i>ucred</i>                     The caller's UNIX credentials, in the form of a pointer to a pointer to a rpc_gss_ucred_t structure, which includes the client's uid and gids. If an application is not interested in these values, it may pass NULL for this parameter.</p> <p><i>cookie</i>                    A four-byte quantity that an application may use in any manner it wants to; RPC does not interpret it. (For example, a cookie may be a pointer or index to a structure that represents a context initiator.) See also <a href="#">rpc_gss_set_callback(3NSL)</a>.</p> |
| <b>RETURN VALUES</b> | rpc_gss_getcred() returns TRUE if it is successful; otherwise, use rpc_gss_get_error() to get the error associated with the failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>          | rpc_gss_get_error – get error codes on failure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |          |         |              |                  |  |                   |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|----------|---------|--------------|------------------|--|-------------------|
| <b>SYNOPSIS</b>      | <pre>#include &lt;rpc/rpcsec_gss.h&gt;  bool_t <b>rpc_gss_get_error</b>(rpc_gss_error_t*error);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |          |         |              |                  |  |                   |
| <b>DESCRIPTION</b>   | <p>rpc_gss_get_error() fetches an error code when an RPCSEC_GSS routine fails.</p> <p>rpc_gss_get_error() uses a rpc_gss_error_t structure of the following form:</p> <pre>typedef struct {     int    rpc_gss_error;          <i>RPCSEC_GSS error</i>     int    system_error;          <i>system error</i> } rpc_gss_error_t;</pre> <p>Currently the only error codes defined for this function are</p> <pre>#define RPC_GSS_ER_SUCCESS      0    /* no error */ #define RPC_GSS_ER_SYSTEMERROR  1    /* system error */</pre> |                |                 |          |         |              |                  |  |                   |
| <b>PARAMETERS</b>    | <p>Information on RPCSEC_GSS data types for parameters may be found on the <a href="#">rpcsec_gss(3NSL)</a> man page.</p> <p><b>error</b>            A rpc_gss_error_t structure. If the rpc_gss_error field is equal to RPC_GSS_ER_SYSTEMERROR, the system_error field will be set to the value of errno.</p>                                                                                                                                                                                                                   |                |                 |          |         |              |                  |  |                   |
| <b>RETURN VALUES</b> | Unless there is a failure indication from an invoked RPCSEC_GSS function, rpc_gss_get_error() does not set error to a meaningful value.                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |         |              |                  |  |                   |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |          |         |              |                  |  |                   |

| <b>DESCRIPTION</b>       | <p>These "convenience functions" return information on available security mechanisms and versions of RPCSEC_GSS.</p> <table><tr><td>rpc_gss_get_mechanisms()</td><td>Returns a list of supported security mechanisms as a null-terminated list of character strings.</td></tr><tr><td>rpc_gss_get_mech_info()</td><td>Takes two arguments: an ASCII string representing a mechanism type, for example, kerberosv5, and a pointer to a rpc_gss_service_t enum. rpc_gss_get_mech_info() will return NULL upon error or if no /etc/gss/qop file is present. Otherwise, it returns a null-terminated list of character strings of supported Quality of Protections (QOPs) for this mechanism. NULL or empty list implies only that the default QOP is available and can be specified to routines that need to take a QOP string parameter as NULL or as an empty string.</td></tr><tr><td>rpc_gss_get_versions()</td><td>Returns the highest and lowest versions of RPCSEC_GSS supported.</td></tr><tr><td>rpc_gss_is_installed()</td><td>Takes an ASCII string representing a mechanism, and returns TRUE if the mechanism is installed.</td></tr></table> | rpc_gss_get_mechanisms() | Returns a list of supported security mechanisms as a null-terminated list of character strings.                        | rpc_gss_get_mech_info() | Takes two arguments: an ASCII string representing a mechanism type, for example, kerberosv5, and a pointer to a rpc_gss_service_t enum. rpc_gss_get_mech_info() will return NULL upon error or if no /etc/gss/qop file is present. Otherwise, it returns a null-terminated list of character strings of supported Quality of Protections (QOPs) for this mechanism. NULL or empty list implies only that the default QOP is available and can be specified to routines that need to take a QOP string parameter as NULL or as an empty string. | rpc_gss_get_versions() | Returns the highest and lowest versions of RPCSEC_GSS supported. | rpc_gss_is_installed() | Takes an ASCII string representing a mechanism, and returns TRUE if the mechanism is installed. |
| rpc_gss_get_mechanisms() | Returns a list of supported security mechanisms as a null-terminated list of character strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                          |                                                                                                                        |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |                                                                  |                        |                                                                                                 |
| rpc_gss_get_mech_info()  | Takes two arguments: an ASCII string representing a mechanism type, for example, kerberosv5, and a pointer to a rpc_gss_service_t enum. rpc_gss_get_mech_info() will return NULL upon error or if no /etc/gss/qop file is present. Otherwise, it returns a null-terminated list of character strings of supported Quality of Protections (QOPs) for this mechanism. NULL or empty list implies only that the default QOP is available and can be specified to routines that need to take a QOP string parameter as NULL or as an empty string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                          |                                                                                                                        |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |                                                                  |                        |                                                                                                 |
| rpc_gss_get_versions()   | Returns the highest and lowest versions of RPCSEC_GSS supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                          |                                                                                                                        |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |                                                                  |                        |                                                                                                 |
| rpc_gss_is_installed()   | Takes an ASCII string representing a mechanism, and returns TRUE if the mechanism is installed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                          |                                                                                                                        |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |                                                                  |                        |                                                                                                 |

| <b>NAME</b>                | rpc_gss_get_principal_name – Get principal names at server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                            |                                                                                    |             |                                                                                                                                                                                    |             |                                                                                |             |                                                                                           |               |                                                                                      |
| <b>SYNOPSIS</b>            | <pre>#include &lt;rpc/rpcsec_gss.h&gt;  bool_t <b>rpc_gss_get_principal_name</b>(rpc_gss_principal_ *principal,     char *mech, char *name, char *node, char *domain);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                            |                                                                                    |             |                                                                                                                                                                                    |             |                                                                                |             |                                                                                           |               |                                                                                      |
| <b>DESCRIPTION</b>         | <p>Servers need to be able to operate on a client's principal name. Such a name is stored by the server as a <code>rpc_gss_principal_t</code> structure, an opaque byte string which can be used either directly in access control lists or as database indices which can be used to look up a UNIX credential. A server may, for example, need to compare a principal name it has received with the principal name of a known entity, and to do that, it must be able to generate <code>rpc_gss_principal_t</code> structures from known entities.</p> <p><code>rpc_gss_get_principal_name()</code> takes as input a security mechanism, a pointer to a <code>rpc_gss_principal_t</code> structure, and several parameters which uniquely identify an entity on a network: a user or service name, a node name, and a domain name. From these parameters it constructs a unique, mechanism-dependent principal name of the <code>rpc_gss_principal_t</code> structure type.</p>                                                                                                                                                                                                                                  |                            |                                                                                    |             |                                                                                                                                                                                    |             |                                                                                |             |                                                                                           |               |                                                                                      |
| <b>PARAMETERS</b>          | <p>How many of the identifying parameters (<i>name</i>, <i>node</i>, and domain) are necessary to specify depends on the mechanism being used. For example, Kerberos V5 requires only a user name but can accept a node and domain name. An application can choose to set unneeded parameters to <code>NULL</code>.</p> <p>Information on <code>RPCSEC_GSS</code> data types for parameters may be found on the <a href="#">rpcsec_gss(3NSL)</a> man page.</p> <table><tr><td><i>principal</i></td><td>An opaque, mechanism-dependent structure representing the client's principal name.</td></tr><tr><td><i>mech</i></td><td>An ASCII string representing the security mechanism in use. Valid strings may be found in the <code>/etc/gss/mech</code> file, or by using <code>rpc_gss_get_mechanisms()</code>.</td></tr><tr><td><i>name</i></td><td>A UNIX login name (for example, 'gwashington') or service name, such as 'nfs'.</td></tr><tr><td><i>node</i></td><td>A node in a domain; typically, this would be a machine name (for example, 'valleyforge').</td></tr><tr><td><i>domain</i></td><td>A security domain; for example, a DNS, NIS, or NIS+ domain name ('eng.company.com').</td></tr></table> | <i>principal</i>           | An opaque, mechanism-dependent structure representing the client's principal name. | <i>mech</i> | An ASCII string representing the security mechanism in use. Valid strings may be found in the <code>/etc/gss/mech</code> file, or by using <code>rpc_gss_get_mechanisms()</code> . | <i>name</i> | A UNIX login name (for example, 'gwashington') or service name, such as 'nfs'. | <i>node</i> | A node in a domain; typically, this would be a machine name (for example, 'valleyforge'). | <i>domain</i> | A security domain; for example, a DNS, NIS, or NIS+ domain name ('eng.company.com'). |

*ONC+ Developer's Guide*

Linn, J. *RFC 2078, Generic Security Service Application Program Interface, Version 2.*  
Network Working Group. January 1997.

**NOTES** Principal names may be freed up by a call to `free(3C)`. A principal name need only be freed in those instances where it was constructed by the application. (Values returned by other routines point to structures already existing in a context, and need not be freed.)

rpc\_gss\_max\_data\_length(3NSL)

**NAME** | rpc\_gss\_max\_data\_length, rpc\_gss\_svc\_max\_data\_length – get maximum data length for transmission

**SYNOPSIS** | #include <rpc/rpcsec\_gss.h>

```
int rpc_gss_max_data_length(AUTH *handle, int max_tp_unit_len);
int rpc_gss_svc_max_data_length(struct svc_req *req, int
 max_tp_unit_len);
```

**DESCRIPTION** | Performing a security transformation on a piece of data generally produces data with a different (usually greater) length. For some transports, such as UDP, there is a maximum length of data which can be sent out in one data unit. Applications need to know the maximum size a piece of data can be before it's transformed, so that the resulting data will still "fit" on the transport. These two functions return that maximum size.

rpc\_gss\_max\_data\_length() is the client-side version;  
 rpc\_gss\_svc\_max\_data\_length() is the server-side version.

**PARAMETERS**

|                        |                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i>          | An RPC context handle of type AUTH, returned when a context is created (for example, by rpc_gss_seccreate()). Security service and QOP are bound to this handle, eliminating any need to specify them. |
| <i>max_tp_unit_len</i> | The maximum size of a piece of data allowed by the transport.                                                                                                                                          |
| <i>req</i>             | A pointer to an RPC svc_req structure, containing information on the context (for example, program number and credentials).                                                                            |

**RETURN VALUES** | Both functions return the maximum size of untransformed data allowed, as an int.

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| MT-Level       | MT-Safe           |
| Availability   | SUNWrsg (32-bit)  |
|                | SUNWrsgx (64-bit) |

Linn, J. RFC 2078, *Generic Security Service Application Program Interface, Version 2*. Network Working Group. January 1997.

**NAME** | rpc\_gss\_mech\_to\_oid, rpc\_gss\_qop\_to\_num – map mechanism, QOP strings to non-string values

**SYNOPSIS** | 

```
#include <rpc/rpcsec_gss.h>
bool_t rpc_gss_mech_to_oid(charc*mec, rpc_gss_OIDc*oid);
bool_t rpc_gss_qop_to_num(char *qop, char *mec, u_int *num);
```

**DESCRIPTION** | Because in-kernel RPC routines use non-string values for mechanism and Quality of Protection (QOP), these routines exist to map strings for these attributes to their non-string counterparts. (The non-string values for QOP and mechanism are also found in the /etc/gss/qop and /etc/gss/mec files, respectively.)  
rpc\_gss\_mech\_to\_oid() takes a string representing a mechanism, as well as a pointer to a rpc\_gss\_OID object identifier structure. It then gives this structure values corresponding to the indicated mechanism, so that the application can now use the OID directly with RPC routines. rpc\_gss\_qop\_to\_num() does much the same thing, taking strings for QOP and mechanism and returning a number.

**PARAMETERS** | Information on RPCSEC\_GSS data types for parameters may be found on the [rpcsec\\_gss\(3NSL\)](#) man page.

*mec* | An ASCII string representing the security mechanism in use. Valid strings may be found in the /etc/gss/mec file.

*oid* | An object identifier of type rpc\_gss\_OID, whose elements are usable by kernel-level RPC routines.

*qop* | This is an ASCII string which sets the quality of protection (QOP) for the session. Appropriate values for this string may be found in the file /etc/gss/qop.

*num* | The non-string value for the QOP.

**RETURN VALUES** | Both functions return TRUE if they are successful, FALSE otherwise.

**FILES** | /etc/gss/mec | File containing valid security mechanisms  
/etc/gss/qop | File containing valid QOP values

**ATTRIBUTES** | See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| MT-Level       | MT-Safe           |
| Availability   | SUNWrsg (32-bit)  |
|                | SUNWrsgx (64-bit) |

| <b>DESCRIPTION</b>  | <p>rpc_gss_seccreate() is used by an application to create a security context using the RPCSEC_GSS protocol, making use of the underlying GSS-API network layer. rpc_gss_seccreate() allows an application to specify the type of security mechanism (for example, Kerberos v5), the type of service (for example, integrity checking), and the Quality of Protection (QOP) desired for transferring data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <b>PARAMETERS</b>   | <p>Information on RPCSEC_GSS data types for parameters may be found on the <a href="#">rpcsec_gss(3NSL)</a> man page.</p> <table border="0"> <tr> <td style="vertical-align: top;"><i>clnt</i></td> <td>This is the RPC client handle. <i>clnt</i> may be obtained, for example, from <code>clnt_create()</code>.</td> </tr> <tr> <td style="vertical-align: top;"><i>principal</i></td> <td>This is the identity of the server principal, specified in the form <i>service@host</i>, where <i>service</i> is the name of the service the client wishes to access and <i>host</i> is the fully qualified name of the host where the service resides — for example, <code>nfs@mymachine.eng.company.com</code>.</td> </tr> <tr> <td style="vertical-align: top;"><i>mechanism</i></td> <td>This is an ASCII string which indicates which security mechanism to use with this data. Appropriate mechanisms may be found in the file <code>/etc/gss/mech</code>; additionally, <code>rpc_gss_get_mechanisms()</code> returns a list of supported security mechanisms (as null-terminated strings).</td> </tr> <tr> <td style="vertical-align: top;"><i>service_type</i></td> <td>This sets the initial type of service for the session — privacy, integrity, authentication, or none.</td> </tr> <tr> <td style="vertical-align: top;"><i>qop</i></td> <td>This is an ASCII string which sets the quality of protection (QOP) for the session. Appropriate values for this string may be found in the file <code>/etc/gss/qop</code>. Additionally, supported QOPs are returned (as null-terminated strings) by <code>rpc_gss_get_mech_info()</code>.</td> </tr> <tr> <td style="vertical-align: top;"><i>options_req</i></td> <td>This structure contains options which are passed directly to the underlying GSS-API layer. If the caller specifies NULL for this parameter, defaults are used. (See NOTES, below.)</td> </tr> <tr> <td style="vertical-align: top;"><i>options_ret</i></td> <td>These GSS-API options are returned to the caller. If the caller does not need to see these options, then it may specify NULL for this parameter. (See NOTES, below.)</td> </tr> </table> | <i>clnt</i> | This is the RPC client handle. <i>clnt</i> may be obtained, for example, from <code>clnt_create()</code> . | <i>principal</i> | This is the identity of the server principal, specified in the form <i>service@host</i> , where <i>service</i> is the name of the service the client wishes to access and <i>host</i> is the fully qualified name of the host where the service resides — for example, <code>nfs@mymachine.eng.company.com</code> . | <i>mechanism</i> | This is an ASCII string which indicates which security mechanism to use with this data. Appropriate mechanisms may be found in the file <code>/etc/gss/mech</code> ; additionally, <code>rpc_gss_get_mechanisms()</code> returns a list of supported security mechanisms (as null-terminated strings). | <i>service_type</i> | This sets the initial type of service for the session — privacy, integrity, authentication, or none. | <i>qop</i> | This is an ASCII string which sets the quality of protection (QOP) for the session. Appropriate values for this string may be found in the file <code>/etc/gss/qop</code> . If the caller specifies NULL for this parameter, defaults are used. (See NOTES, below.) | <i>options_ret</i> | These GSS-API options are returned to the caller. If the caller does not need to see these options, then it may specify NULL for this parameter. (See NOTES, below.) |
| <i>clnt</i>         | This is the RPC client handle. <i>clnt</i> may be obtained, for example, from <code>clnt_create()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <i>principal</i>    | This is the identity of the server principal, specified in the form <i>service@host</i> , where <i>service</i> is the name of the service the client wishes to access and <i>host</i> is the fully qualified name of the host where the service resides — for example, <code>nfs@mymachine.eng.company.com</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <i>mechanism</i>    | This is an ASCII string which indicates which security mechanism to use with this data. Appropriate mechanisms may be found in the file <code>/etc/gss/mech</code> ; additionally, <code>rpc_gss_get_mechanisms()</code> returns a list of supported security mechanisms (as null-terminated strings).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <i>service_type</i> | This sets the initial type of service for the session — privacy, integrity, authentication, or none.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <i>qop</i>          | This is an ASCII string which sets the quality of protection (QOP) for the session. Appropriate values for this string may be found in the file <code>/etc/gss/qop</code> . Additionally, supported QOPs are returned (as null-terminated strings) by <code>rpc_gss_get_mech_info()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <i>options_req</i>  | This structure contains options which are passed directly to the underlying GSS-API layer. If the caller specifies NULL for this parameter, defaults are used. (See NOTES, below.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |
| <i>options_ret</i>  | These GSS-API options are returned to the caller. If the caller does not need to see these options, then it may specify NULL for this parameter. (See NOTES, below.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                                                                                            |                  |                                                                                                                                                                                                                                                                                                                     |                  |                                                                                                                                                                                                                                                                                                        |                     |                                                                                                      |            |                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                    |                    |                                                                                                                                                                      |

rpc\_gss\_seccreate(3NSL)

**RETURN VALUES** `rpc_gss_seccreate()` returns a security context handle (an RPC authentication handle) of type AUTH. If `rpc_gss_seccreate()` cannot return successfully, the application can get an error number by calling `rpc_gss_get_error()`.

**FILES** `/etc/gss/mech` File containing valid security mechanisms  
`/etc/gss/qop` File containing valid QOP values .

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE    |
|----------------|--------------------|
| MT-Level       | MT-Safe            |
| Availability   | SUNWrsg (32-bits)  |
|                | SUNWrsgx (64-bits) |

| <b>DESCRIPTION</b>   | <p>A server may want to specify a callback routine so that it knows when a context gets first used. This user-defined callback may be specified through the <code>rpc_gss_set_callback()</code> routine. The callback routine is invoked the first time a context is used for data exchanges, after the context is established for the specified program and version.</p> <p>The user-defined callback routine should take the following form:</p> <pre>bool_t callback(struct svc_req *req, gss_cred_id_t deleg,                gss_ctx_id_t gss_context, rpc_gss_lock_t *lock, void **cookie);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |            |                                                                                                                                                                                                    |              |                                                            |                    |                                                                                                                            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                                                                                                                                                                                                         |
| <b>PARAMETERS</b>    | <p><code>rpc_gss_set_callback()</code> takes one argument: a pointer to a <code>rpc_gss_callback_t</code> structure. This structure contains the RPC program and version number as well as a pointer to a user-defined <code>callback()</code> routine. (For a description of <code>rpc_gss_callback_t</code> and other <code>RPCSEC_GSS</code> data types, see the <a href="#">rpcsec_gss(3NSL)</a> man page.)</p> <p>The user-defined <code>callback()</code> routine itself takes the following arguments:</p> <table border="0"> <tr> <td style="vertical-align: top;"><i>req</i></td> <td>Pointer to the received service request. <code>svc_req</code> is an RPC structure containing information on the context of an RPC invocation, such as program, version, and transport information.</td> </tr> <tr> <td style="vertical-align: top;"><i>deleg</i></td> <td>Delegated credentials, if any. (See <i>NOTES</i>, below.)</td> </tr> <tr> <td style="vertical-align: top;"><i>gss_context</i></td> <td>GSS context (allows server to do GSS operations on the context to test for acceptance criteria). See <i>NOTES</i>, below.</td> </tr> <tr> <td style="vertical-align: top;"><i>lock</i></td> <td>This parameter is used to enforce a particular QOP and service for a session. This parameter points to a <code>RPCSEC_GSS rpc_gss_lock_t</code> structure. When the callback is invoked, the <code>rpc_gss_lock_t.locked</code> field is set to <code>TRUE</code>, thus locking the context. A locked context will reject all requests having different values for QOP or service than those specified by the <code>raw_cred</code> field of the <code>rpc_gss_lock_t</code> structure.</td> </tr> <tr> <td style="vertical-align: top;"><i>cookie</i></td> <td>A four-byte quantity that an application may use in any manner it wants to — RPC does not interpret it. (For example, the cookie could be a pointer or index to a structure that represents a context initiator.) The cookie is returned, along with the caller's credentials, with each invocation of <code>rpc_gss_getcred()</code>.</td> </tr> </table> | <i>req</i> | Pointer to the received service request. <code>svc_req</code> is an RPC structure containing information on the context of an RPC invocation, such as program, version, and transport information. | <i>deleg</i> | Delegated credentials, if any. (See <i>NOTES</i> , below.) | <i>gss_context</i> | GSS context (allows server to do GSS operations on the context to test for acceptance criteria). See <i>NOTES</i> , below. | <i>lock</i> | This parameter is used to enforce a particular QOP and service for a session. This parameter points to a <code>RPCSEC_GSS rpc_gss_lock_t</code> structure. When the callback is invoked, the <code>rpc_gss_lock_t.locked</code> field is set to <code>TRUE</code> , thus locking the context. A locked context will reject all requests having different values for QOP or service than those specified by the <code>raw_cred</code> field of the <code>rpc_gss_lock_t</code> structure. | <i>cookie</i> | A four-byte quantity that an application may use in any manner it wants to — RPC does not interpret it. (For example, the cookie could be a pointer or index to a structure that represents a context initiator.) The cookie is returned, along with the caller's credentials, with each invocation of <code>rpc_gss_getcred()</code> . |
| <i>req</i>           | Pointer to the received service request. <code>svc_req</code> is an RPC structure containing information on the context of an RPC invocation, such as program, version, and transport information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |            |                                                                                                                                                                                                    |              |                                                            |                    |                                                                                                                            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                                                                                                                                                                                                         |

| <i>gss_context</i>   | GSS context (allows server to do GSS operations on the context to test for acceptance criteria). See <i>NOTES</i> , below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                    |              |                                                            |                    |                                                                                                                            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                                                                                                                                                                                                         |
| <i>lock</i>          | This parameter is used to enforce a particular QOP and service for a session. This parameter points to a <code>RPCSEC_GSS rpc_gss_lock_t</code> structure. When the callback is invoked, the <code>rpc_gss_lock_t.locked</code> field is set to <code>TRUE</code> , thus locking the context. A locked context will reject all requests having different values for QOP or service than those specified by the <code>raw_cred</code> field of the <code>rpc_gss_lock_t</code> structure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                                                                                                                                                                                    |              |                                                            |                    |                                                                                                                            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                                                                                                                                                                                                         |
| <i>cookie</i>        | A four-byte quantity that an application may use in any manner it wants to — RPC does not interpret it. (For example, the cookie could be a pointer or index to a structure that represents a context initiator.) The cookie is returned, along with the caller's credentials, with each invocation of <code>rpc_gss_getcred()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                                                                                                                                                                                    |              |                                                            |                    |                                                                                                                            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                                                                                                                                                                                                         |
| <b>RETURN VALUES</b> | <code>rpc_gss_set_callback()</code> returns <code>TRUE</code> if the use of the context is accepted; false otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |            |                                                                                                                                                                                                    |              |                                                            |                    |                                                                                                                            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                                                                                                                                                                                                                                                         |

rpc\_gss\_set\_callback(3NSL)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| MT-Level       | MT-Safe           |
| Availability   | SUNWrsg (32-bit)  |
|                | SUNWrsgx (64-bit) |

*ONC+ Developer's Guide*

Linn, J. *RFC 2078, Generic Security Service Application Program Interface, Version 2*. Network Working Group. January 1997.

**NOTES** If a server does not specify a callback, all incoming contexts will be accepted.

Because the GSS-API is not currently exposed, the *deleg* and *gss\_context* arguments are mentioned for informational purposes only, and the user-defined callback function may choose to do nothing with them.

| <b>NAME</b>          | rpc_gss_set_defaults – change service, QOP for a session                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>      | <pre>#include &lt;rpc/rpcsec_gss.h&gt;  bool_t <b>rpc_gss_set_defaults</b>(AUTH *auth, rpc_gss_service_t service,     char *qop);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>   | rpc_gss_set_defaults() allows an application to change the service (privacy, integrity, authentication, or none) and Quality of Protection (QOP) for a transfer session. New values apply to the rest of the session (unless changed again).                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>PARAMETERS</b>    | <p>Information on RPCSEC_GSS data types for parameters may be found on the <a href="#">rpcsec_gss(3NSL)</a> man page.</p> <p><i>auth</i>                    An RPC authentication handle returned by <code>rpc_gss_seccreate()</code>.</p> <p><i>service</i>                 An enum of type <code>rpc_gss_service_t</code>, representing one of the following types of security service: authentication, privacy, integrity, or none.</p> <p><i>qop</i>                      A string representing Quality of Protection. Valid strings may be found in the file <code>/etc/gss/qop</code> or by using <code>rpc_gss_get_mech_info()</code>.</p> |
| <b>RETURN VALUES</b> | <code>rpc_gss_set_svc_name()</code> returns TRUE if it is successful; otherwise, use <code>rpc_gss_get_error()</code> to get the error associated with the failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>FILES</b>         | <code>/etc/gss/qop</code> File containing valid QOPs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ATTRIBUTES</b>    | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| MT-Level       | MT-Safe           |
| Availability   | SUNWrsg (32-bit)  |
|                | SUNWrsgx (64-bit) |

rpc\_gss\_set\_svc\_name(3NSL)

**NAME** | rpc\_gss\_set\_svc\_name – send a principal name to a server

**SYNOPSIS** | #include <rpc/rpcsec\_gss.h>

| bool\_t **rpc\_gss\_set\_svc\_name**(char \*principal, char \*mechanism, u\_int

| req\_time, u\_int program, u\_int version);

**DESCRIPTION** | rpc\_gss\_set\_svc\_name() sets the name of a principal the server is to represent. If a server is going to act as more than one principal, this procedure can be invoked for every such principal.

**PARAMETERS** | Information on RPCSEC\_GSS data types for parameters may be found on the [rpcsec\\_gss\(3NSL\)](#) man page.

| *principal* | An ASCII string representing the server’s principal name, given in the form of *service@host*.

| *mech* | An ASCII string representing the security mechanism in use. Valid strings may be found in the */etc/gss/mech* file, or by using `rpc_gss_get_mechanisms()`.

| *req\_time* | The time, in seconds, for which a credential should be valid. Note that the *req\_time* is a hint to the underlying mechanism. The actual time that the credential will remain valid is mechanism dependent. In the case of kerberos the actual time will be GSS\_C\_INDEFINITE.

| *program* | The RPC program number for this service.

| *version* | The RPC version number for this service.

**RETURN VALUES** | rpc\_gss\_set\_svc\_name() returns TRUE if it is successful; otherwise, use `rpc_gss_get_error()` to get the error associated with the failure.

**FILES** | */etc/gss/mech* | File containing valid security mechanisms

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| MT-Level       | MT-Safe           |
| Availability   | SUNWrsg (32-bit)  |
|                | SUNWrsgx (64-bit) |

| <b>DESCRIPTION</b> | <p>The remote asynchronous calls (RAC) package is a special interface to the RPC library that allows messages to be sent using the RPC protocol without blocking during the time between when the message is sent and the reply is received. To RPC servers, RAC messages are indistinguishable from RPC messages.</p> <p>A client establishes an RPC session in the usual way (see <a href="#">rpc_clnt_create(3NSL)</a>). A RAC message is sent using <code>rac_send()</code>. This routine returns immediately, allowing the client to conduct other processing. When the client wants to determine whether the returned value from the call has been received, <code>rac_poll()</code> is used. <code>rac_recv()</code> is used to collect the returned value; it can also be used to block while waiting for the returned value to arrive. <code>rac_drop()</code> is used to inform the RPC library that the client is no longer interested in the results of a particular RAC message.</p> <p><code>rac_drop()</code>      <code>rac_drop()</code> should be called when the user is no longer interested in the result of a <code>rac_send()</code> currently in progress. No message to the server is generated by this call, but any subsequent reply received for this handle will be silently dropped. It also frees any space occupied by the asynchronous call handle <i>h</i>.</p> <p>                    After a call to <code>rac_drop()</code> the handle referred to by <i>h</i> is invalid. It may no longer be used in any asynchronous operation.</p> <p><code>rac_poll()</code>      <code>rac_poll()</code> returns the status of the call currently in progress on the &lt;CLIENT, asynchronous handle&gt; tuple referred to by <i>cl</i> and <i>h</i>.</p> <p>                    <code>rac_poll()</code> return values are:</p> <table><tr><td>RPC_SUCCESS</td><td>A reply has been received and is available for reading by <code>rac_recv()</code>.</td></tr><tr><td>RPC_INPROGRESS</td><td>No reply has been received. The call referred to by the given handle has not yet timed out.</td></tr></table> | RPC_SUCCESS | A reply has been received and is available for reading by <code>rac_recv()</code> . | RPC_INPROGRESS | No reply has been received. The call referred to by the given handle has not yet timed out. |
| RPC_SUCCESS        | A reply has been received and is available for reading by <code>rac_recv()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |             |                                                                                     |                |                                                                                             |
| RPC_INPROGRESS     | No reply has been received. The call referred to by the given handle has not yet timed out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                                                                     |                |                                                                                             |

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| RPC_TIMEDOUT       | No reply has been received. The call referred to by the given handle has exceeded the maximum timeout value specified in <code>rac_send()</code> . |
| RPC_STALERACHANDLE | Either the handle referred to by <i>h</i> is invalid or no call is currently in progress for the given <CLIENT, asynchronous handle> tuple.        |
| RPC_CANTRECV       | Either the file descriptor associated with the given CLIENT handle is bad, or an error occurred while attempting to receive a packet.              |
| RPC_SYSTEMERROR    | Space could not be allocated to receive a packet.                                                                                                  |

On unreliable transports, a call to `rac_poll()` will trigger a retransmission when necessary (that is, if a `rac_send()` is in progress, no reply has been received, the per-call timeout has expired, and the total timeout has not yet expired).

The return value for `rac_poll()` is independent of the RPC return value in the reply packet. Although a combination of `clnt_control()`'s CLGET\_FD request and `poll(2)` may be used to extract the proper file descriptor and poll for packets, `rac_poll()` is still useful since it will determine whether a reply is available for a specific <CLIENT, asynchronous handle> tuple.

`rac_recv()`

`rac_recv()` retrieves the results of a previous asynchronous RPC call, placing them in the buffer indicated in the `rac_send()` call and using the XDR decode function supplied there. It depends on the application to have ensured that a reply is present (using `rac_poll()`). If `rac_recv()` is called before a reply has been received, it will block awaiting a reply.

All errors normally returned by the RPC client call functions may be returned here. In addition:

|                    |                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| RPC_STALERACHANDLE | Either the handle referred to by <i>h</i> is invalid or no call is currently in progress for the given <CLIENT, asynchronous handle> tuple. |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|

Additionally, if a packet is present and its status is not `RPC_SUCCESS`, it is possible that the client credentials need refreshing. In this

## rpc\_rac(3RAC)

case, `RPC_AUTHERROR` is returned and the client should attempt to resend the call.

When a reply has been received, `rac_recv()` will invoke the XDR decode procedure specified in the `rac_send()` call. After a call to `rac_recv()`, the handle referred to by `h` is invalid. It may no longer be used in any asynchronous operation.

`rac_send()` `rac_send()` initiates (sends to the server) an RPC call to the specified procedure. It does not await a reply from the server. `argsp` is the address of the procedure's arguments, `resultsp` is the address in which to place the results, `xargs` and `xresults` are XDR functions used to encode and decode respectively. Note: `resultsp` must be a valid pointer when `rac_recv()` is called. `timeout` should contain the total amount of time the application is willing to wait for a reply.

Upon success, an opaque handle, known as the asynchronous handle, is returned. This handle is to be used in subsequent asynchronous calls to poll for the status of the call (`rac_poll()`), receive the returned results of the call (`rac_recv()`), or cancel the call (`rac_drop()`).

On failure, `(void *) 0` is returned.

In case of failure, the application may retrieve the RPC failure code by calling `clnt_geterr()` immediately after a `rac_send()` failure (see [rpc\(3NSL\)](#)). Possible errors include both transient problems (such as transport failures) and permanent ones (such as XDR encoding failures).

Multiple `rac_sends` on the same client handle are permitted, but may introduce unpredictable perturbations to the current timeout and retry model used by the RPC library.

The interface imposes a limit on the amount of time a call may be in progress before it is considered to have failed. This method was chosen over limitations on the number of retries because of a desire for transport independence.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** [poll\(2\)](#), [rpc\(3NSL\)](#), [rpc\\_clnt\\_create\(3NSL\)](#), [rpc\\_clnt\\_calls\(3NSL\)](#), [xdr\(3NSL\)](#), [attributes\(5\)](#)

**WARNINGS** The RAC interface is not the recommended interface for having multiple RPC requests outstanding. The preferred method of accomplishing this in the Solaris environment is to use synchronous RPC calls with threads. The RAC interface is provided as a service to developers interested in porting RPC applications to Solaris 2.0. Use of this interface will degrade the performance of normal synchronous RPC calls (see [rpc\\_clnt\\_calls\(3NSL\)](#)). For these reasons, use of this interface is disparaged.

The library `librac` must be linked before `libnsl` to use RAC. If the libraries are not linked in the correct order, then the results are indeterminate.

**NOTES** These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

| <b>NAME</b>            | rpcsec_gss – security flavor incorporating GSS-API protections                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>        | <pre>cc [ flag... ] file... -lnsl [ library... ] #include &lt;rpc/rpcsec_gss.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b>     | <p>RPCSEC_GSS is a security flavor which sits "on top" of the GSS-API (Generic Security Service API) for network transmissions. Applications using RPCSEC_GSS can take advantage of GSS-API security features; moreover, they can use any security mechanism (such as RSA public key or Kerberos) that works with the GSS-API.</p> <p>The GSS-API offers two security services beyond the traditional authentication services (AUTH_DH, AUTH_SYS, and AUTH_KERB): integrity and privacy. With integrity, the system uses cryptographic checksumming to ensure the authenticity of a message (authenticity of originator, recipient, and data); privacy provides additional security by encrypting data. Applications using RPCSEC_GSS specify which service they wish to use. Type of security service is mechanism-independent.</p> <p>Before exchanging data with a peer, an application must establish a context for the exchange. RPCSEC_GSS provides a single function for this purpose, <code>rpc_gss_seccreate()</code>, which allows the application to specify the security mechanism, Quality of Protection (QOP), and type of service at context creation. (The QOP parameter sets the cryptographic algorithms to be used with integrity or privacy, and is mechanism-dependent.) Once a context is established, applications can reset the QOP and type of service for each data unit exchanged, if desired.</p> <p>Valid mechanisms and QOPs may be obtained from configuration files or from the name service. Each mechanism has a default QOP.</p> <p>Contexts are destroyed with the usual RPC <code>auth_destroy()</code> call.</p> |
| <b>Data Structures</b> | <p>Some of the data structures used by the RPCSEC_GSS package are shown below.</p> <p><b>rpc_gss_service_t</b></p> <p>This enum defines the types of security services the context may have. <code>rpc_gss_seccreate()</code> takes this as one argument when setting the service type for a session.</p> <pre>typedef enum {     rpc_gss_svc_default = 0,     rpc_gss_svc_none = 1,     rpc_gss_svc_integrity = 2,     rpc_gss_svc_privacy = 3 } rpc_gss_service_t ;</pre> <p><b>rpc_gss_options_req_t</b></p> <p>Structure containing options passed directly through to the GSS-API. <code>rpc_gss_seccreate()</code> takes this as an argument when creating a context.</p> <pre>typedef struct {     int req_flags; /*GSS request bits */     int time_req; /*requested credential lifetime */</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

```

 gss_cred_id_t my_cred; /*GSS credential struct*/
 gss_channel_bindings_t;
 input_channel_bindings;
} rpc_gss_options_req_t ;

```

### rpc\_gss\_OID

This data type is used by in-kernel RPC routines, and thus is mentioned here for informational purposes only.

```

typedef struct {
 u_int length;
 void *elements
} *rpc_gss_OID;

```

### rpc\_gss\_options\_ret\_t

Structure containing GSS-API options returned to the calling function, `rpc_gss_seccreate()`. `MAX_GSS_MECH` is defined as 128.

```

typedef struct {
 int major_status;
 int minor_status;
 u_int rpcsec_version /*vers. of RPCSEC_GSS */
 int ret_flags
 int time_req
 gss_ctx_id_t gss_context;
 char actual_mechanism[MAX_GSS_MECH]; /*mechanism used*/
} rpc_gss_options_ret_t;

```

### rpc\_gss\_principal\_t

The (mechanism-dependent, opaque) client principal type. Used as an argument to the `rpc_gss_get_principal_name()` function, and in the `gsscred` table. Also referenced by the `rpc_gss_rawcred_t` structure for raw credentials (see below).

```

typedef struct {
 int len;
 char name[1];
} *rpc_gss_principal_t;

```

### rpc\_gss\_rawcred\_t

Structure for raw credentials. Used by `rpc_gss_getcred()` and `rpc_gss_set_callback()`.

```

typedef struct {
 u_int version; /*RPC version # */
 char *mechanism; /*security mechanism*/
 char *qop; /*Quality of Protection*/
 rpc_gss_principal_t client_principal; /*client name*/
 char *svc_principal; /*server name*/
 rpc_gss_service_t service; /*service (integrity, etc.)*/
} rpc_gss_rawcred_t;

```

## rpcsec\_gss(3NSL)

### **rpc\_gss\_ucred\_t**

Structure for UNIX credentials. Used by `rpc_gss_getcred()` as an alternative to `rpc_gss_rawcred_t`.

```
typedef struct {
 uid_t uid; /*user ID*/
 gid_t gid; /*group ID*/
 short gidlen;
 git_t *gidlist; /*list of groups*/
} rpc_gss_ucred_t;
```

### **rpc\_gss\_callback\_t**

Callback structure used by `rpc_gss_set_callback()`.

```
typedef struct {
 u_int program; /*RPC program #*/
 u_int version; /*RPC version #*/
 bool_t (*callback)(); /*user-defined callback routine*/
} rpc_gss_callback_t;
```

### **rpc\_gss\_lock\_t**

Structure used by a callback routine to enforce a particular QOP and service for a session. The `locked` field is normally set to `FALSE`; the server sets it to `TRUE` in order to lock the session. (A locked context will reject all requests having different QOP and service values than those found in the `raw_cred` structure.) For more information, see the `rpc_gss_set_callback(3NSL)` man page.

```
typedef struct {
 bool_t locked;
 rpc_gss_rawcred_t *raw_cred;
} rpc_gss_lock_t;
```

### **rpc\_gss\_error\_t**

Structure used by `rpc_gss_get_error()` to fetch an error code when a RPCSEC\_GSS routine fails.

```
typedef struct {
 int rpc_gss_error;
 int system_error; /*same as errno*/
} rpc_gss_error_t;
```

## **Index to Routines**

The following lists RPCSEC\_GSS routines and the manual reference pages on which they are described. An (S) indicates it is a server-side function:

| Routine (Manual Page)                      | Description                        |
|--------------------------------------------|------------------------------------|
| <a href="#">rpc_gss_seccreate(3NSL)</a>    | Create a secure RPCSEC_GSS context |
| <a href="#">rpc_gss_set_defaults(3NSL)</a> | Switch service, QOP for a session  |

rpcsec\_gss(3NSL)

|                                                |                                                  |
|------------------------------------------------|--------------------------------------------------|
| <code>rpc_gss_max_data_length(3NSL)</code>     | Get maximum data length allowed by transport     |
| <code>rpc_gss_set_svc_name(3NSL)</code>        | Set server's principal name (S)                  |
| <code>rpc_gss_getcred(3NSL)</code>             | Get credentials of caller (S)                    |
| <code>rpc_gss_set_callback(3NSL)</code>        | Specify callback to see context use (S)          |
| <code>rpc_gss_get_principal_name(3NSL)</code>  | Get client principal name (S)                    |
| <code>rpc_gss_svc_max_data_length(3NSL)</code> | Get maximum data length allowed by transport (S) |
| <code>rpc_gss_get_error(3NSL)</code>           | Get error number                                 |
| <code>rpc_gss_get_mechanisms(3NSL)</code>      | Get valid mechanism strings                      |
| <code>rpc_gss_get_mech_info(3NSL)</code>       | Get valid QOP strings, current service           |
| <code>rpc_gss_get_versions(3NSL)</code>        | Get supported RPCSEC_GSS versions                |
| <code>rpc_gss_is_installed(3NSL)</code>        | Checks if a mechanism is installed               |

```

**DESCRIPTION** RPC routines allow C programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a request to the server. Upon receipt of the request, the server calls a dispatch routine to perform the requested service, and then sends back a reply. Finally, the procedure call returns to the client.

The routines described in this manual page have been superseded by other routines. The preferred routine is given after the description of the routine. New programs should use the preferred routines, as support for the older interfaces may be dropped in future releases.

**File Descriptors** Transport independent RPC uses TLI as its transport interface instead of sockets.

Some of the routines described in this section (such as `clnttcp_create()`) take a pointer to a file descriptor as one of the parameters. If the user wants the file descriptor to be a socket, then the application will have to be linked with both `librpcsoc` and `libnsl`. If the user passed `RPC_ANYSOCK` as the file descriptor, and the application is linked with `libnsl` only, then the routine will return a TLI file descriptor and not a socket.

**Routines** The following routines require that the header `<rpc/rpc.h>` be included. The symbol `PORTMAP` should be defined so that the appropriate function declarations for the old interfaces are included through the header files.

```
authdes_create()
 authdes_create() is the first of two routines which interface to the RPC secure
 authentication system, known as DES authentication. The second is
 authdes_getucred(), below. Note: the keyserver daemon keyserv(1M) must
 be running for the DES authentication system to work.
```

`authdes_create()`, used on the client side, returns an authentication handle that will enable the use of the secure authentication system. The first parameter *name* is the network name, or *netname*, of the owner of the server process. This field usually represents a hostname derived from the utility routine `host2netname()`, but could also represent a user name using `user2netname()`. See

[secure\\_rpc\(3NSL\)](#). The second field is window on the validity of the client credential, given in seconds. A small window is more secure than a large one, but choosing too small of a window will increase the frequency of resynchronizations because of clock drift. The third parameter *syncaddr* is optional. If it is `NULL`, then the authentication system will assume that the local clock is always in sync with the server's clock, and will not attempt resynchronizations. If an address is supplied, however, then the system will use the address for consulting the remote time service whenever resynchronization is required. This parameter is usually the address of the RPC server itself. The final parameter *ckey* is also optional. If it is `NULL`, then the authentication system will generate a random DES key to be used for the encryption of credentials. If it is supplied, however, then it will be used instead.

This routine exists for backward compatibility only, and it is made obsolete by `authdes_seccreate()`. See [secure\\_rpc\(3NSL\)](#).

`authunix_create()`

Create and return an RPC authentication handle that contains .UX authentication information. The parameter *host* is the name of the machine on which the information was created; *uid* is the user's user ID; *gid* is the user's current group ID; *grouplen* and *gidlistp* refer to a counted array of groups to which the user belongs.

It is not very difficult to impersonate a user.

This routine exists for backward compatibility only, and it is made obsolete by `authsys_create()`. See [rpc\\_clnt\\_auth\(3NSL\)](#).

`authunix_create_default()`

Call `authunix_create()` with the appropriate parameters.

This routine exists for backward compatibility only, and it is made obsolete by `authsys_create_default()`. See [rpc\\_clnt\\_auth\(3NSL\)](#).

`callrpc()`

Call the remote procedure associated with *prognum*, *versnum*, and *procnum* on the machine, *host*. The parameter *inproc* is used to encode the procedure's parameters, and *outproc* is used to decode the procedure's results; *in* is the address of the procedure's argument, and *out* is the address of where to place the result(s). This routine returns 0 if it succeeds, or the value of `enum clnt_stat` cast to an integer if it fails. The routine `clnt_perrno()` is handy for translating failure statuses into messages. See [rpc\\_clnt\\_calls\(3NSL\)](#).

You do not have control of timeouts or authentication using this routine. This routine exists for backward compatibility only, and is made obsolete by `rpc_call()`. See [rpc\\_clnt\\_calls\(3NSL\)](#).

## rpc\_soc(3NSL)

### clnt\_stat\_clnt\_broadcast()

Like `callrpc()`, except the call message is broadcast to all locally connected broadcast nets. Each time the caller receives a response, this routine calls `eachresult()`, whose form is:

```
eachresult(char *out, struct sockaddr_in *addr);
```

where *out* is the same as *out* passed to `clnt_broadcast()`, except that the remote procedure's output is decoded there; *addr* points to the address of the machine that sent the results. If `eachresult()` returns 0, `clnt_broadcast()` waits for more replies; otherwise it returns with appropriate status. If `eachresult()` is NULL, `clnt_broadcast()` returns without waiting for any replies.

Broadcast packets are limited in size to the maximum transfer unit of the transports involved. For Ethernet, the caller's argument size is approximately 1500 bytes. Since the call message is sent to all connected networks, it may potentially lead to broadcast storms. `clnt_broadcast()` uses SB AUTH\_SYS credentials by default. See `rpc_clnt_auth(3NSL)`. This routine exists for backward compatibility only, and is made obsolete by `rpc_broadcast()`. See `rpc_clnt_calls(3NSL)`.

### clntraw\_create()

This routine creates an internal, memory-based RPC client for the remote program *prognum*, version *versnum*. The transport used to pass messages to the service is actually a buffer within the process's address space, so the corresponding RPC server should live in the same address space. See `svcrw_create()`. This allows simulation of RPC and acquisition of RPC overheads, such as round trip times, without any kernel interference. This routine returns NULL if it fails.

This routine exists for backward compatibility only. It has the same functionality as `clnt_raw_create()`. See `rpc_clnt_create(3NSL)`, which obsoletes it.

### clnttcp\_create()

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses TCP/IP as a transport. The remote program is located at Internet address *addr*. If *addr->sin\_port* is 0, then it is set to the actual port that the remote program is listening on. The remote `rpcbind` service is consulted for this information. The parameter *\*fdp* is a file descriptor, which may be open and bound; if it is `RPC_ANYSOCK`, then this routine opens a new one and sets *\*fdp*. Refer to the File Descriptor section for more information. Since TCP-based RPC uses buffered I/O, the user may specify the size of the send and receive buffers with the parameters *sendsz* and *recvsz*. Values of 0 choose suitable defaults. This routine returns NULL if it fails.

This routine exists for backward compatibility only. `clnt_create()`, `clnt_tli_create()`, or `clnt_vc_create()` should be used instead. See `rpc_clnt_create(3NSL)`.

### clntudp\_bufcreate()

Create a client handle for the remote program *prognum*, on *versnum*; the client uses UDP/IP as the transport. The remote program is located at the Internet address *addr*. If *addr->sin\_port* is 0, it is set to port on which the remote program is listening

on (the remote `rpcbind` service is consulted for this information). The parameter `*fdp` is a file descriptor, which may be open and bound. If it is `RPC_ANYSOCK`, then this routine opens a new one and sets `*fdp`. Refer to the `File Descriptor` section for more information. The UDP transport resends the call message in intervals of `wait` time until a response is received or until the call times out. The total time for the call to time out is specified by `clnt_call()`. See [rpc\\_clnt\\_calls\(3NSL\)](#). If successful it returns a client handle, otherwise it returns `NULL`. The error can be printed using the `clnt_pcreateerror()` routine. See [rpc\\_clnt\\_create\(3NSL\)](#).

The user can specify the maximum packet size for sending and receiving by using `sendsz` and `recvsz` arguments for UDP-based RPC messages.

If `addr->sin_port` is 0 and the requested version number `versnum` is not registered with the remote portmap service, it returns a handle if at least a version number for the given program number is registered. The version mismatch is discovered by a `clnt_call()` later (see [rpc\\_clnt\\_calls\(3NSL\)](#)).

This routine exists for backward compatibility only. `clnt_tli_create()` or `clnt_dg_create()` should be used instead. See [rpc\\_clnt\\_create\(3NSL\)](#).

#### `clntudp_create()`

This routine creates an RPC client handle for the remote program `prognum`, version `versnum`; the client uses UDP/IP as a transport. The remote program is located at Internet address `addr`. If `addr->sin_port` is 0, then it is set to actual port that the remote program is listening on. The remote `rpcbind` service is consulted for this information. The parameter `*fdp` is a file descriptor, which may be open and bound; if it is `RPC_ANYSOCK`, then this routine opens a new one and sets `*fdp`. Refer to the `File Descriptor` section for more information. The UDP transport resends the call message in intervals of `wait` time until a response is received or until the call times out. The total time for the call to time out is specified by `clnt_call()`. See [rpc\\_clnt\\_calls\(3NSL\)](#). `clntudp_create()` returns a client handle on success, otherwise it returns `NULL`. The error can be printed using the `clnt_pcreateerror()` routine. See [rpc\\_clnt\\_create\(3NSL\)](#).

Since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

This routine exists for backward compatibility only. `clnt_create()`, `clnt_tli_create()`, or `clnt_dg_create()` should be used instead. See [rpc\\_clnt\\_create\(3NSL\)](#).

#### `get_myaddress()`

Places the local system's IP address into `*addr`, without consulting the library routines that deal with `/etc/hosts`. The port number is always set to `htons(PMAPPORT)`.

## rpc\_soc(3NSL)

This routine is only intended for use with the RPC library. It returns the local system's address in a form compatible with the RPC library, and should not be taken as the system's actual IP address. In fact, the *\*addr* buffer's host address part is actually zeroed. This address may have only local significance and should not be assumed to be an address that can be used to connect to the local system by remote systems or processes.

This routine remains for backward compatibility only. The routine `netdir_getbyname()` should be used with the name `HOST_SELF` to retrieve the local system's network address as a *netbuf* structure. See `netdir(3NSL)`.

### `getrpcport()`

`getrpcport()` returns the port number for the version *versnum* of the RPC program *prognum* running on *host* and using protocol *proto*. `getrpcport()` returns 0 if the RPC system failed to contact the remote portmap service, the program associated with *prognum* is not registered, or there is no mapping between the program and a port.

This routine exists for backward compatibility only. Enhanced functionality is provided by `rpcb_getaddr()`. See `rpcbind(3NSL)`.

### `pmaplist()`

A user interface to the portmap service, which returns a list of the current RPC program-to-port mappings on the host located at IP address *addr*. This routine can return `NULL`. The command `'rpcinfo -p'` uses this routine.

This routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_getmaps()`. See `rpcbind(3NSL)`.

### `pmap_getport()`

A user interface to the portmap service, which returns the port number on which waits a service that supports program *prognum*, version *versnum*, and speaks the transport protocol associated with *protocol*. The value of *protocol* is most likely `IPPROTO_UDP` or `IPPROTO_TCP`. A return value of 0 means that the mapping does not exist or that the RPC system failed to contact the remote portmap service. In the latter case, the global variable `rpc_createerr` contains the RPC status.

This routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_getaddr()`. See `rpcbind(3NSL)`.

### `pmap_rmtcall()`

Request that the portmap on the host at IP address *\*addr* make an RPC on the behalf of the caller to a procedure on that host. *\*portp* is modified to the program's port number if the procedure succeeds. The definitions of other parameters are discussed in `callrpc()` and `clnt_call()`. See `rpc_clnt_calls(3NSL)`.

This procedure is only available for the UDP transport.

If the requested remote procedure is not registered with the remote portmap then no error response is returned and the call times out. Also, no authentication is done.

This routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_rmtcall()`. See [rpcbind\(3NSL\)](#).

#### `pmap_set()`

A user interface to the portmap service, that establishes a mapping between the triple [*prognum*, *versnum*, *protocol*] and *port* on the machine's portmap service. The value of *protocol* may be `IPPROTO_UDP` or `IPPROTO_TCP`. Formerly, the routine failed if the requested *port* was found to be in use. Now, the routine only fails if it finds that *port* is still bound. If *port* is not bound, the routine completes the requested registration. This routine returns 1 if it succeeds, 0 otherwise. Automatically done by `svc_register()`.

This routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_set()`. See [rpcbind\(3NSL\)](#).

#### `pmap_unset()`

A user interface to the portmap service, which destroys all mapping between the triple [*prognum*, *versnum*, *all-protocols*] and *port* on the machine's portmap service. This routine returns one if it succeeds, 0 otherwise.

This routine exists for backward compatibility only, enhanced functionality is provided by `rpcb_unset()`. See [rpcbind\(3NSL\)](#).

#### `svc_fds()`

A global variable reflecting the RPC service side's read file descriptor bit mask; it is suitable as a parameter to the `select()` call. This is only of interest if a service implementor does not call `svc_run()`, but rather does his own asynchronous event processing. This variable is read-only, yet it may change after calls to `svc_getreq()` or any creation routines. Do not pass its address to `select()`! Similar to `svc_fdset`, but limited to 32 descriptors.

This interface is made obsolete by `svc_fdset`. See [rpc\\_svc\\_calls\(3NSL\)](#).

#### `svc_getcaller()`

This routine returns the network address, represented as a `struct sockaddr_in`, of the caller of a procedure associated with the RPC service transport handle, *xprt*.

This routine exists for backward compatibility only, and is obsolete. The preferred interface is `svc_getrpccaller()`. See [rpc\\_svc\\_reg\(3NSL\)](#), which returns the address as a `struct netbuf`.

#### `svc_getreq()`

This routine is only of interest if a service implementor does not call `svc_run()`, but instead implements custom asynchronous event processing. It is called when the `select()` call has determined that an RPC request has arrived on some RPC file descriptors; *rdfds* is the resultant read file descriptor bit mask. The routine returns when all file descriptors associated with the value of *rdfds* have been serviced. This routine is similar to `svc_getreqset()` but is limited to 32 descriptors.

This interface is made obsolete by `svc_getreqset()`

`svcfcreate()`

Create a service on top of any open and bound descriptor. Typically, this descriptor is a connected file descriptor for a stream protocol. Refer to the `File Descriptor` section for more information. `sendsz` and `recvsz` indicate sizes for the send and receive buffers. If they are 0, a reasonable default is chosen.

This interface is made obsolete by `svc_fd_create()` (see [rpc\\_svc\\_create\(3NSL\)](#)).

`svccraw_create()`

This routine creates an internal, memory-based RPC service transport, to which it returns a pointer. The transport is really a buffer within the process's address space, so the corresponding RPC client should live in the same address space; see `clntraw_create()`. This routine allows simulation of RPC and acquisition of RPC overheads (such as round trip times), without any kernel interference. This routine returns NULL if it fails.

This routine exists for backward compatibility only, and has the same functionality of `svc_raw_create()`. See [rpc\\_svc\\_create\(3NSL\)](#), which obsoletes it.

`svctcp_create()`

This routine creates a TCP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the file descriptor `fd`, which may be `RPC_ANYSOCK`, in which case a new file descriptor is created. If the file descriptor is not bound to a local TCP port, then this routine binds it to an arbitrary port. Refer to the `File Descriptor` section for more information. Upon completion, `xprt->xp_fd` is the transport's file descriptor, and `xprt->xp_port` is the transport's port number. This routine returns NULL if it fails. Since TCP-based RPC uses buffered I/O, users may specify the size of buffers; values of 0 choose suitable defaults.

This routine exists for backward compatibility only. `svc_create()`, `svc_tli_create()`, or `svc_vc_create()` should be used instead. See [rpc\\_svc\\_create\(3NSL\)](#).

`svccudp_bufcreate()`

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the file descriptor `fd`. If `fd` is `RPC_ANYSOCK` then a new file descriptor is created. If the file descriptor is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, `xprt->xp_fd` is the transport's file descriptor, and `xprt->xp_port` is the transport's port number. Refer to the `File Descriptor` section for more information. This routine returns NULL if it fails.

The user specifies the maximum packet size for sending and receiving UDP-based RPC messages by using the `sendsz` and `recvsz` parameters.

This routine exists for backward compatibility only. `svc_tli_create()`, or `svc_dg_create()` should be used instead. See [rpc\\_svc\\_create\(3NSL\)](#).

`svccudp_create()`

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the file descriptor *fd*, which may be `RPC_ANYSOCK`, in which case a new file descriptor is created. If the file descriptor is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, `xprt->xp_fd` is the transport's file descriptor, and `xprt->xp_port` is the transport's port number. This routine returns NULL if it fails.

Since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

This routine exists for backward compatibility only. `svc_create()`, `svc_tli_create()`, or `svc_dg_create()` should be used instead. See [rpc\\_svc\\_create\(3NSL\)](#).

`registerrpc()`

Register program *prognum*, procedure *procname*, and version *versnum* with the RPC service package. If a request arrives for program *prognum*, version *versnum*, and procedure *procnum*, *procname* is called with a pointer to its parameter(s). *procname* should return a pointer to its static result(s). *inproc* is used to decode the parameters while *outproc* is used to encode the results. This routine returns 0 if the registration succeeded, -1 otherwise.

`svc_run()` must be called after all the services are registered.

This routine exists for backward compatibility only, and it is made obsolete by `rpc_reg()`.

`svc_register()`

Associates *prognum* and *versnum* with the service dispatch procedure, *dispatch*. If *protocol* is 0, the service is not registered with the portmap service. If *protocol* is non-zero, then a mapping of the triple [*prognum*, *versnum*, *protocol*] to `xprt->xp_port` is established with the local portmap service (generally *protocol* is 0, `IPPROTO_UDP` or `IPPROTO_TCP`). The procedure *dispatch* has the following form:

```
dispatch(struct svc_req *request, SVCXPRT *xprt);
```

The `svc_register()` routine returns one if it succeeds, and 0 otherwise.

This routine exists for backward compatibility only. Enhanced functionality is provided by `svc_reg()`.

`svc_unregister()`

Remove all mapping of the double [*prognum*, *versnum*] to dispatch routines, and of the triple [*prognum*, *versnum*, *all-protocols*] to port number from portmap.

This routine exists for backward compatibility. Enhanced functionality is provided by `svc_unreg()`.

## rpc\_soc(3NSL)

`xdr_authunix_parms()`

Used for describing UNIX credentials. This routine is useful for users who wish to generate these credentials without using the RPC authentication package.

This routine exists for backward compatibility only, and is made obsolete by `xdr_authsys_parms()`. See [rpc\\_xdr\(3NSL\)](#).

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** [keyserv\(1M\)](#), [rpcbind\(1M\)](#), [rpcinfo\(1M\)](#), [netdir\(3NSL\)](#), [netdir\\_getbyname\(3NSL\)](#), [rpc\(3NSL\)](#), [rpc\\_clnt\\_auth\(3NSL\)](#), [rpc\\_clnt\\_calls\(3NSL\)](#), [rpc\\_clnt\\_create\(3NSL\)](#), [rpc\\_svc\\_calls\(3NSL\)](#), [rpc\\_svc\\_create\(3NSL\)](#), [rpc\\_svc\\_err\(3NSL\)](#), [rpc\\_svc\\_reg\(3NSL\)](#), [rpc\\_xdr\(3NSL\)](#), [rpcbind\(3NSL\)](#), [secure\\_rpc\(3NSL\)](#), [select\(3C\)](#), [xdr\\_authsys\\_parms\(3NSL\)](#), [libnsl\(3LIB\)](#), [librpcsoc\(3LIBUCB\)](#), [attributes\(5\)](#)

**NOTES** These interfaces are unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>DESCRIPTION</b> | <p>These routines are part of the RPC library which allows C language programs to make procedure calls on other machines across the network.</p> <p>These routines are associated with the server side of the RPC mechanism. Some of them are called by the server side dispatch function. Others, such as <code>svc_run()</code>, are called when the server is initiated.</p> <p>Because the service transport handle <code>SVCXPRT</code> contains a single data area for decoding arguments and encoding results, the structure cannot freely be shared between threads that call functions to decode arguments and encode results. When a server is operating in the Automatic or User MT modes, however, a copy of this structure is passed to the service dispatch procedure in order to enable concurrent request processing. Under these circumstances, some routines which would otherwise be Unsafe, become Safe. These are marked as such. Also marked are routines that are Unsafe for multithreaded applications, and are not to be used by such applications. See <code>rpc(3NSL)</code> for the definition of the <code>SVCXPRT</code> data structure.</p> |

## rpc\_svc\_calls(3NSL)

The `svc_dg_enablecache()` function allocates a duplicate request cache for the service endpoint `xprt`, large enough to hold `cache_size` entries. Once enabled, there is no way to disable caching. The function returns 1 if space necessary for a cache of the given size was successfully allocated, and 0 otherwise. This function is Safe in multithreaded applications.

The `svc_done()` function frees resources allocated to service a client request directed to the service endpoint `xprt`. This call pertains only to servers executing in the User MT mode. In the User MT mode, service procedures must invoke this call before returning, either after a client request has been serviced, or after an error or abnormal condition that prevents a reply from being sent. After `svc_done()` is invoked, the service endpoint `xprt` should not be referenced by the service procedure. Server multithreading modes and parameters can be set using the `rpc_control()` call. This function is Safe in multithreaded applications. It will have no effect if invoked in modes other than the User MT mode.

The `svc_exit()` function when called by any of the RPC server procedures or otherwise, destroys all services registered by the server and causes `svc_run()` to return. If RPC server activity is to be resumed, services must be reregistered with the RPC library either through one of the `rpc_svc_create(3NSL)` functions, or using `xprt_register(3NSL)`. The `svc_exit()` function has global scope and ends all RPC server activity.

The `svc_freeargs()` function macro frees any data allocated by the RPC/XDR system when it decoded the arguments to a service procedure using `svc_getargs()`. This routine returns TRUE if the results were successfully freed, and FALSE otherwise. This function macro is Safe in multithreaded applications utilizing the Automatic or User MT modes.

The `svc_getargs()` function macro decodes the arguments of an RPC request associated with the RPC service transport handle `xprt`. The parameter `in` is the address where the arguments will be placed; `inproc` is the XDR routine used to decode the arguments. This routine returns TRUE if decoding succeeds, and FALSE otherwise. This function macro is Safe in multithreaded applications utilizing the Automatic or User MT modes.

The `svc_getreq_common()` function is called to handle a request on a file descriptor.

The `svc_getreq_poll()` function is only of interest if a service implementor does not call `svc_run()`, but instead implements custom asynchronous event processing. It is called when `poll(2)` has determined that an RPC request has arrived on some RPC file descriptors; `pollretval` is the return value from `poll(2)` and `pfds` is the array of `pollfd` structures on which the `poll(2)` was done. It is assumed to be an array large enough to contain the maximal number of descriptors allowed. The `svc_getreq_poll()` function macro is Unsafe in multithreaded applications.

The `svc_getreqset()` function is only of interest if a service implementor does not call `svc_run()`, but instead implements custom asynchronous event processing. It is called when `select(3C)` has determined that an RPC request has arrived on some

RPC file descriptors; *rdfds* is the resultant read file descriptor bit mask. The routine returns when all file descriptors associated with the value of *rdfds* have been serviced. This function macro is Unsafe in multithreaded applications.

The `svc_getrpccaller()` function is the approved way of getting the network address of the caller of a procedure associated with the RPC service transport handle *xprt*. This function macro is Safe in multithreaded applications.

The `svc_run()` function never returns. In single-threaded mode, the function waits for RPC requests to arrive. When an RPC request arrives, the `svc_run()` function calls the appropriate service procedure. This procedure is usually waiting for the `poll(2)` library call to return.

Applications that execute in the Automatic or the User MT mode should invoke the `svc_run()` function exactly once. In the Automatic MT mode, the `svc_run()` function creates threads to service client requests. In the User MT mode, the function provides a framework for service developers to create and manage their own threads for servicing client requests.

The `svc_fdset` global variable reflects the RPC server's read file descriptor bit mask. This is only of interest if service implementors do not call `svc_run()`, but rather do their own asynchronous event processing. This variable is read-only may change after calls to `svc_getreqset()` or after any creation routine. Do not pass its address to `select(3C)`. Instead, pass the address of a copy. multithreaded applications executing in either the Automatic MT mode or the user MT mode should never read this variable. They should use auxiliary threads to do asynchronous event processing. The `svc_fdset` variable is limited to 1024 file descriptors and is considered obsolete. Use of `svc_pollfd` is recommended instead.

The `svc_pollfd` global variable points to an array of `pollfd_t` structures that reflect the RPC server's read file descriptor array. This is only of interest if service implementors do not call `svc_run()` but rather do their own asynchronous event processing. This variable is read-only, and it may change after calls to `svc_getreg_poll()` or any creation routines. Do not pass its address to `poll(2)`. Instead, pass the address of a copy. By default, `svc_pollfd` is limited to 1024 entries. Use `rpc_control(3NSL)` to remove this limitation. multithreaded applications executing in either the Automatic MT mode or the user MT mode should never be read this variable. They should use auxiliary threads to do asynchronous event processing.

The `svc_max_pollfd` global variable contains the maximum length of the `svc_pollfd` array. This variable is read-only, and it may change after calls to `svc_getreg_poll()` or any creation routines.

The `svc_sendreply()` function is called by an RPC service dispatch routine to send the results of a remote procedure call. The *xprt* parameter is the transport handle of the request. The *outproc* parameter is the XDR routine used to encode the results. The *out* parameter is the address of the results. This routine returns TRUE if it succeeds, FALSE otherwise. The `svc_sendreply()` function macro is Safe in multithreaded applications that use the Automatic or the User MT mode.

## rpc\_svc\_calls(3NSL)

The `svc_fd_negotiate_ucred()` function is called by an RPC server to inform the underlying transport that the function wishes to receive `ucreds` for local calls, including those over IP transports.

The `svc_getcallerucred()` function attempts to retrieve the `ucred_t` associated with the caller. The function returns 0 when successful and -1 when not.

When successful, the `svc_getcallerucred()` function stores the pointer to a freshly allocated `ucred_t` in the memory location pointed to by the `ucred` argument if that memory location contains the null pointer. If the memory location is non-null, the function reuses the existing `ucred_t`. When `ucred` is no longer needed, a credential allocated by `svc_getcallerucred()` should be freed with `ucred_free(3C)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of attribute types and values.

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | See below.      |

The `svc_fd_negotiate_ucred()`, `svc_dg_enablecache()`, `svc_getrpccaller()`, and `svc_getcallerucred()` functions are Safe in multithreaded applications. The `svc_freeargs()`, `svc_getargs()`, and `svc_sendreply()` functions are Safe in multithreaded applications that use the Automatic or the User MT mode. The `svc_getreq_common()`, `svc_getreqset()`, and `svc_getreq_poll()` functions are Unsafe in multithreaded applications and should be called only from the main thread.

| <b>DESCRIPTION</b> | These routines are part of the RPC library which allows C language programs to make procedure calls on servers across the network. These routines deal with the creation of service handles. Once the handle is created, the server can be invoked by calling <code>svc_run()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## rpc\_svc\_create(3NSL)

returned. *info* should be a pointer to an integer. Upon successful completion of the SVCGET\_VERSQUIET request, *\*info* contains an integer which describes the server's current behavior: 0 indicates normal server behavior, that is, an RPC\_PROGVERSMISMATCH error will be returned. 1 indicates that the out of range request will be silently ignored.

### SVCSET\_VERSQUIET

If a request is received for a program number served by this server but the version number is outside the range registered with the server, an RPC\_PROGVERSMISMATCH error will normally be returned. It is sometimes desirable to change this behavior. *info* should be a pointer to an integer which is either 0, indicating normal server behavior and an RPC\_PROGVERSMISMATCH error will be returned, or 1, indicating that the out of range request should be silently ignored.

### SVCGET\_XID

Returns the transaction ID of connection-oriented and connectionless transport service calls. The transaction ID assists in uniquely identifying client requests for a given RPC version, program number, procedure, and client. The transaction ID is extracted from the service transport handle *svc*. *info* must be a pointer to an unsigned long. Upon successful completion of the SVCGET\_XID request, *\*info* contains the transaction ID. Note that rendezvous and raw service handles do not define a transaction ID. Thus, if the service handle is of rendezvous or raw type, and the request is of type SVCGET\_XID, *svc\_control()* will return FALSE. Note also that the transaction ID read by the server can be set by the client through the suboption CLSET\_XID in *clnt\_control()*. See *clnt\_create(3NSL)*

### SVCSET\_RECVERRHANDLER

Attaches or detaches a disconnection handler to the service handle, *svc*, that will be called when a transport error arrives during the reception of a request or when the server is waiting for a request and the connection shuts down. This handler is only useful for a connection oriented service handle.

*\*info* contains the address of the error handler to attach, or NULL to detach a previously defined one. The error handler has two arguments. It has a

rpc\_svc\_create(3NSL)

pointer to the erroneous service handle. It also has an integer that indicates if the full service is closed (when equal to zero), or that only one connection on this service is closed (when not equal to zero).

```
void handler (const SVCXPRT *svc, const bool_t isAConnection);
```

With the service handle address, *svc*, the error handler is able to detect which connection has failed and to begin an error recovery process. The error handler can be called by multiple threads and should be implemented in an MT-safe way.

SVCGET\_RECVERRHANDLER

Upon successful completion of the SVCGET\_RECVERRHANDLER request, *\*info* contains the address of the handler for receiving errors. Upon failure, *\*info* contains NULL.

This routine returns TRUE if the operation was successful. Otherwise, it returns false.

svc\_create ()

svc\_create () creates server handles for all the transports belonging to the class *nettype*.

*nettype* defines a class of transports which can be used for a particular application. The transports are tried in left to right order in NETPATH variable or in top to bottom order in the netconfig database. If *nettype* is NULL, it defaults to netpath.

svc\_create () registers itself with the rpcbind service (see rpcbind(1M)). *dispatch* is called when there is a remote procedure call for the given *prognum* and *versnum*; this requires calling svc\_run () (see svc\_run () in rpc\_svc\_reg(3NSL)). If svc\_create () succeeds, it returns the number of server handles it created, otherwise it returns 0 and an error message is logged.

svc\_destroy ()

A function macro that destroys the RPC service handle *xprt*. Destruction usually involves deallocation of private data structures, including *xprt* itself. Use of *xprt* is undefined after calling this routine.

svc\_dg\_create ()

This routine creates a connectionless RPC service handle, and returns a pointer to it. This routine returns NULL if it fails, and an error message is logged. *sendsz* and *recvsz* are parameters used to specify the size of the

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | <p>buffers. If they are 0, suitable defaults are chosen. The file descriptor <i>fildev</i> should be open and bound. The server is not registered with <code>rpcbind(1M)</code>.</p> <p>Warning: since connectionless-based RPC messages can only hold limited amount of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>svc_fd_create()</code>  | <p>This routine creates a service on top of an open and bound file descriptor, and returns the handle to it. Typically, this descriptor is a connected file descriptor for a connection-oriented transport. <i>sendsz</i> and <i>recvsz</i> indicate sizes for the send and receive buffers. If they are 0, reasonable defaults are chosen. This routine returns NULL if it fails, and an error message is logged.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>svc_raw_create()</code> | <p>This routine creates an RPC service handle and returns a pointer to it. The transport is really a buffer within the process's address space, so the corresponding RPC client should live in the same address space; (see <code>clnt_raw_create()</code> in <code>rpc_clnt_create(3NSL)</code>). This routine allows simulation of RPC and acquisition of RPC overheads (such as round trip times), without any kernel and networking interference. This routine returns NULL if it fails, and an error message is logged.</p> <p>Note: <code>svc_run()</code> should not be called when the raw interface is being used.</p>                                                                                                                                                                                                                                                                                                                      |
| <code>svc_tli_create()</code> | <p>This routine creates an RPC server handle, and returns a pointer to it. <i>fildev</i> is the file descriptor on which the service is listening. If <i>fildev</i> is <code>RPC_ANYFD</code>, it opens a file descriptor on the transport specified by <i>netconf</i>. If the file descriptor is unbound and <i>bindaddr</i> is non-null <i>fildev</i> is bound to the address specified by <i>bindaddr</i>, otherwise <i>fildev</i> is bound to a default address chosen by the transport. In the case where the default address is chosen, the number of outstanding connect requests is set to 8 for connection-oriented transports. The user may specify the size of the send and receive buffers with the parameters <i>sendsz</i> and <i>recvsz</i>; values of 0 choose suitable defaults. This routine returns NULL if it fails, and an error message is logged. The server is not registered with the <code>rpcbind(1M)</code> service.</p> |
| <code>svc_tp_create()</code>  | <p><code>svc_tp_create()</code> creates a server handle for the network specified by <i>netconf</i>, and registers itself with the <code>rpcbind</code> service. <i>dispatch</i> is called when there is a</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

rpc\_svc\_create(3NSL)

remote procedure call for the given *prognum* and *versnum*; this requires calling `svc_run()`. `svc_tp_create()` returns the service handle if it succeeds, otherwise a NULL is returned and an error message is logged.

svc\_vc\_create()

This routine creates a connection-oriented RPC service and returns a pointer to it. This routine returns NULL if it fails, and an error message is logged. The users may specify the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of 0 choose suitable defaults. The file descriptor *fdes* should be open and bound. The server is not registered with the `rpcbind(1M)` service.

svc\_door\_create()

This routine creates an RPC server handle over doors and returns a pointer to it. Doors is a transport mechanism that facilitates fast data transfer between processes on the same machine. for the given program The user may set the size of the send buffer with the parameter *sendsz*. If *sendsz* is 0, the corresponding default buffer size is 16 Kbyte. If successful, the `svc_door_create()` routine returns the service handle. Otherwise it returns NULL and sets a value for `rpc_createerr`. The server is not registered with `rpcbind(1M)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|---------------------|-------------------|
| Architecture        | All               |
| Availability        | SUNWcsl (32-bit)  |
|                     | SUNWcslx (64-bit) |
| Interface Stability | Evolving          |
| MT-Level            | MT-Safe           |

rpc\_svc\_err(3NSL)

**NAME** rpc\_svc\_err, svcerr\_auth, svcerr\_decode, svcerr\_noproc, svcerr\_noprogram, svcerr\_progvers, svcerr\_systemerr, svcerr\_weakauth – library routines for server side remote procedure call errors

**DESCRIPTION** These routines are part of the RPC library which allows C language programs to make procedure calls on other machines across the network.

These routines can be called by the server side dispatch function if there is any error in the transaction with the client.

**Routines** See [rpc\(3NSL\)](#) for the definition of the SVCXPRT data structure.

```
#include <rpc/rpc.h>
```

void svcerr\_auth(const SVCXPRT \*xpirt, const enum auth\_stat why);  
Called by a service dispatch routine that refuses to perform a remote procedure call due to an authentication error.

void svcerr\_decode(const SVCXPRT \*xpirt);  
Called by a service dispatch routine that cannot successfully decode the remote parameters (see `svc_getargs()` in [rpc\\_svc\\_reg\(3NSL\)](#)).

void svcerr\_noproc(const SVCXPRT \*xpirt);  
Called by a service dispatch routine that does not implement the procedure number that the caller requests.

void svcerr\_noprogram(const SVCXPRT \*xpirt);  
Called when the desired program is not registered with the RPC package. Service implementors usually do not need this routine.

void svcerr\_progvers(const SVCXPRT \*xpirt, const rpcvers\_t low\_vers, const rpcvers\_t high\_vers);  
Called when the desired version of a program is not registered with the RPC package. *low\_vers* is the lowest version number, and *high\_vers* is the highest version number. Service implementors usually do not need this routine.

void svcerr\_systemerr(const SVCXPRT \*xpirt);  
Called by a service dispatch routine when it detects a system error not covered by any particular protocol. For example, if a service can no longer allocate storage, it may call this routine.

void svcerr\_weakauth(const SVCXPRT \*xpirt);  
Called by a service dispatch routine that refuses to perform a remote procedure call due to insufficient (but correct) authentication parameters. The routine calls `svcerr_auth(xpirt, AUTH_TOOWEAK)`.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

| <b>DESCRIPTION</b> | <p>The following RPC routines are used to declare or remove a callback on a file descriptor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |        |                                                        |        |                                                                                           |        |                      |
| <b>Routines</b>    | <p>See <a href="#">rpc(3NSL)</a> for the definition of the SVCXPRT data structure.</p> <p><b>svc_add_input()</b></p> <p>This function is used to register a <i>callback</i> function on a file descriptor, <i>fd</i>. The file descriptor, <i>fd</i>, is the first parameter to be passed to <i>svc_add_input()</i>. This <i>callback</i> function will be automatically called if any of the events specified in the <i>events</i> parameter occur on this descriptor. The <i>events</i> parameter is used to specify when the callback is invoked. This parameter is a mask of poll events to which the user wants to listen. See <a href="#">poll(2)</a> for further details of the events that can be specified.</p> <p>The callback to be invoked is specified using the <i>callback</i> parameter. The <i>cookie</i> parameter can be used to pass any data to the <i>callback</i> function. This parameter is a user-defined value which is passed as an argument to the <i>callback</i> function, and it is not used by the Sun RPC library itself.</p> <p>Several callbacks can be registered on the same file descriptor as long as each callback registration specifies a separate set of event flags.</p> <p>The <i>callback</i> function is called with the registration <i>id</i>, the <i>fd</i> file descriptor, an <i>revents</i> value, which is a bitmask of all events concerning the file descriptor, and the <i>cookie</i> user-defined value.</p> <p>Upon successful completion, the function returns a unique identifier for this registration, that can be used later to remove this callback. Upon failure, -1 is returned and <i>errno</i> is set to indicate the error.</p> <p>The <i>svc_add_input()</i> function will fail if:</p> <table><tr><td>EINVAL</td><td>The <i>fd</i> or <i>events</i> parameters are invalid.</td></tr><tr><td>EEXIST</td><td>A callback is already registered to the file descriptor with one of the specified events.</td></tr><tr><td>ENOMEM</td><td>Memory is exhausted.</td></tr></table> | EINVAL | The <i>fd</i> or <i>events</i> parameters are invalid. | EEXIST | A callback is already registered to the file descriptor with one of the specified events. | ENOMEM | Memory is exhausted. |
| EINVAL             | The <i>fd</i> or <i>events</i> parameters are invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |        |                                                        |        |                                                                                           |        |                      |

rpc\_svc\_input(3NSL)

svc\_remove\_input ()

This function is used to unregister a callback function on a file descriptor, *fd*. The *id* parameter specifies the registration to be removed.

Upon successful completion, the function returns zero. Upon failure, -1 is returned and *errno* is set to indicate the error.

The `svc_remove_input ()` function will fail if:

EINVAL           The *id* parameter is invalid.

**ATTRIBUTES** See `attributes (5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|---------------------|-------------------|
| Architecture        | All               |
| Availability        | SUNWcsl (32-bit)  |
|                     | SUNWcslx (64-bit) |
| Interface Stability | Evolving          |
| MT-Level            | MT-Safe           |

| <b>NAME</b>        | rpc_svc_reg, rpc_reg, svc_reg, svc_unreg, svc_auth_reg, xprt_register, xprt_unregister<br>– library routines for registering servers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | These routines are a part of the RPC library which allows the RPC servers to register themselves with <code>rpcbind()</code> (see <code>rpcbind(1M)</code> ), and associate the given program and version number with the dispatch function. When the RPC server receives a RPC request, the library invokes the dispatch routine with the appropriate arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Routines</b>    | See <code>rpc(3NSL)</code> for the definition of the <code>SVCXPRT</code> data structure.<br><br><pre>#include &lt;rpc/rpc.h&gt;  bool_t rpc_reg(const rpcprog_t prognum, const rpcvers_t versnum, const rpcproc_t procnum, char *(*procname)(), const xdrproc_t inproc, const xdrproc_t outproc, const char *nettype);</pre> Register program <i>prognum</i> , procedure <i>procname</i> , and version <i>versnum</i> with the RPC service package. If a request arrives for program <i>prognum</i> , version <i>versnum</i> , and procedure <i>procnum</i> , <i>procname</i> is called with a pointer to its parameter(s); <i>procname</i> should return a pointer to its <code>static</code> result(s). The <i>arg</i> parameter to <i>procname</i> is a pointer to the (decoded) procedure argument. <i>inproc</i> is the XDR function used to decode the parameters while <i>outproc</i> is the XDR function used to encode the results. Procedures are registered on all available transports of the class <i>nettype</i> . See <code>rpc(3NSL)</code> . This routine returns 0 if the registration succeeded, -1 otherwise.<br><br><pre>int svc_reg(const SVCXPRT *xprt, const rpcprog_t prognum, const rpcvers_t versnum, const void (*dispatch)(), const struct netconfig *netconf);</pre> Associates <i>prognum</i> and <i>versnum</i> with the service dispatch procedure, <i>dispatch</i> . If <i>netconf</i> is <code>NULL</code> , the service is not registered with the <code>rpcbind</code> service. For example, if a service has already been registered using some other means, such as <code>inetd</code> (see <code>inetd(1M)</code> ), it will not need to be registered again. If <i>netconf</i> is non-zero, then a mapping of the triple [ <i>prognum</i> , <i>versnum</i> , <i>netconf</i> ->] to <i>xprt</i> -> <i>xp_ltaddr</i> is established with the local <code>rpcbind</code> service.<br><br>The <code>svc_reg()</code> routine returns 1 if it succeeds, and 0 otherwise.<br><br><pre>void svc_unreg(const rpcprog_t prognum, const rpcvers_t versnum);</pre> Remove from the <code>rpcbind</code> service, all mappings of the triple [ <i>prognum</i> , <i>versnum</i> , <i>all-transports</i> ] to network address and all mappings within the RPC service package of the double [ <i>prognum</i> , <i>versnum</i> ] to dispatch routines.<br><br><pre>int svc_auth_reg(const int cred_flavor, const enum auth_stat (*handler)());</pre> Registers the service authentication routine <i>handler</i> with the dispatch mechanism so that it can be invoked to authenticate RPC requests received with authentication type <i>cred_flavor</i> . This interface allows developers to add new authentication types to their RPC applications without needing to modify the libraries. Service implementors usually do not need this routine. |

rpc\_svc\_reg(3NSL)

Typical service application would call `svc_auth_reg()` after registering the service and prior to calling `svc_run()`. When needed to process an RPC credential of type `cred_flavor`, the *handler* procedure will be called with two parameters (`struct svc_req *rqst`, `struct rpc_msg *msg`) and is expected to return a valid enum `auth_stat` value. There is no provision to change or delete an authentication handler once registered.

The `svc_auth_reg()` routine returns 0 if the registration is successful, 1 if `cred_flavor` already has an authentication handler registered for it, and -1 otherwise.

`void xprt_register(const SVCXPRT *xprt);`

After RPC service transport handle `xprt` is created, it is registered with the RPC service package. This routine modifies the global variable `svc_fdset` (see [rpc\\_svc\\_calls\(3NSL\)](#)). Service implementors usually do not need this routine.

`void xprt_unregister(const SVCXPRT *xprt);`

Before an RPC service transport handle `xprt` is destroyed, it unregisters itself with the RPC service package. This routine modifies the global variable `svc_fdset` (see [rpc\\_svc\\_calls\(3NSL\)](#)). Service implementors usually do not need this routine.

| <b>DESCRIPTION</b> | These routines are used for describing the RPC messages in XDR language. They should normally be used by those who do not want to use the RPC package directly. These routines return TRUE if they succeed, FALSE otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Routines</b>    | See <a href="#">rpc(3NSL)</a> for the definition of the XDR data structure.<br><pre>#include &lt;rpc/rpc.h&gt;</pre> <p><b>xdr_accepted_reply()</b><br/>Used to translate between RPC reply messages and their external representation. It includes the status of the RPC call in the XDR language format. In the case of success, it also includes the call results.</p> <p><b>xdr_authsys_parms()</b><br/>Used for describing UNIX operating system credentials. It includes machine-name, uid, gid list, etc.</p> <p><b>xdr_callhdr()</b><br/>Used for describing RPC call header messages. It encodes the static part of the call message header in the XDR language format. It includes information such as transaction ID, RPC version number, program and version number.</p> <p><b>xdr_callmsg()</b><br/>Used for describing RPC call messages. This includes all the RPC call information such as transaction ID, RPC version number, program number, version number, authentication information, etc. This is normally used by servers to determine information about the client RPC call.</p> <p><b>xdr_opaque_auth()</b><br/>Used for describing RPC opaque authentication information messages.</p> <p><b>xdr_rejected_reply()</b><br/>Used for describing RPC reply messages. It encodes the rejected RPC message in the XDR language format. The message could be rejected either because of version number mis-match or because of authentication errors.</p> |

rpc\_xdr(3NSL)

xdr\_replmsg()

Used for describing RPC reply messages. It translates between the RPC reply message and its external representation. This reply could be either an acceptance, rejection or NULL.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Safe            |

| <b>DESCRIPTION</b> | <p>These routines require that the <code>rpc.rstatd(1M)</code> daemon be configured and available on the remote system indicated by <i>host</i>. The <code>rstat()</code> protocol is used to gather statistics from remote kernel. Statistics will be available on items such as paging, swapping, and cpu utilization.</p> <p><code>rstat()</code> fills in the <code>statstime</code> structure <i>statp</i> for <i>host</i>. <i>statp</i> must point to an allocated <code>statstime</code> structure. <code>rstat()</code> returns <code>RPC_SUCCESS</code> if it was successful; otherwise a <code>enum clnt_stat</code> is returned which can be displayed using <code>clnt_perrno(3NSL)</code>.</p> <p><code>havedisk()</code> returns 1 if <i>host</i> has disk, 0 if it does not, and -1 if this cannot be determined.</p> <p>The following XDR routines are available in <code>librpcsvc</code>:</p> <pre>xdr_statstime xdr_statsvar</pre> |                |                 |          |         |

| <b>DESCRIPTION</b> | <p>These routines require that the <code>rpc.rusersd(1M)</code> daemon be configured and available on the remote system indicated by <i>host</i>. The <code>rusers()</code> protocol is used to retrieve information about users logged in on the remote system.</p> <p><code>rusers()</code> fills the <code>utmpidlearr</code> structure with data about <i>host</i>, and returns 0 if successful. <i>up</i> must point to an allocated <code>utmpidlearr</code> structure. If <code>rusers()</code> returns successful it will have allocated data structures within the <i>up</i> structure, which should be freed with <code>xdr_free(3NSL)</code> when you no longer need them:</p> <pre>xdr_free(xdr_utmpidlearr, up);</pre> <p>On error, the returned value can be interpreted as an <code>enum clnt_stat</code> and can be displayed with <code>clnt_perror(3NSL)</code> or <code>clnt_sperrno(3NSL)</code>.</p> <p>See the header <code>&lt;rpcsvc/rusers.h&gt;</code> for a definition of <code>struct utmpidlearr</code>.</p> <p><code>rnusers()</code> returns the number of users logged on to <i>host</i> (–1 if it cannot determine that number).</p> <p>The following XDR routines are available in <code>librpcsvc</code>:</p> <pre>xdr_utmpidlearr</pre> |                |                 |          |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |          |         |

| <b>DESCRIPTION</b> | <p>These routines require that the <code>rpc.rwalld(1M)</code> daemon be configured and available on the remote system indicated by <i>host</i>.</p> <p><code>rwall()</code> executes <code>wall(1M)</code> on <i>host</i>. The <code>rpc.rwalld</code> process on <i>host</i> prints <i>msg</i> to all users logged on to that system. <code>rwall()</code> returns <code>RPC_SUCCESS</code> if it was successful; otherwise a <code>enum clnt_stat</code> is returned which can be displayed using <code>clnt_perrno(3NSL)</code>.</p> |                |                 |          |         |

| <b>DESCRIPTION</b>    | <p>sasl_authorize_t() is a typedef function prototype that defines the interface associated with the SASL_CB_PROXY_POLICY callback.</p> <p>Use the sasl_authorize_t() interface to check whether the authorized user <i>auth_identity</i> can act as the user <i>requested_user</i>. For example, the user <i>root</i> may want to authenticate with <i>root</i>'s credentials but as the user <i>tmartin</i>, with all of <i>tmartin</i>'s rights, not <i>root</i>'s. A server application should be very careful when it determines which users may proxy as other users.</p>                                                                                                                                                                                                                                                            |                |                                                |                       |                                                                                  |                     |                                       |                      |                                                                                   |             |                                      |                      |                                                                              |              |                                 |                |                      |

| <b>NAME</b>           | sasl_auxprop, prop_new, prop_dup, prop_request, prop_get, prop_getnames, prop_clear, prop_erase, prop_dispose, prop_format, prop_set, prop_setvals – SASL auxilliary properties                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>       | <pre>cc [ flag ... ] file ... -lsasl [ library ... ] #include &lt;sasl/prop.h&gt;  struct propctx *prop_new(unsigned estimate);  int prop_dup(struct propctx *src_ctx, struct propctx *dst_ctx);  int prop_request(struct propctx *ctx, const char **names);  const struct propval *prop_get(struct propctx *ctx);  int prop_getnames(struct propctx *ctx, const char **names, struct propval *vals);  void prop_clear(struct propctx *ctx, int requests);  void prop_erase(struct propctx *ctx, const char *name);  void prop_dispose(struct propctx *ctx);  int prop_format(struct propctx *ctx, const char *sep, int seplen, char *outbuf, unsigned outmax, unsigned *outlen);  int prop_set(struct propctx *ctx, const char *name, const char *value, int vallen);  int prop_setvals(struct propctx *ctx, const char *name, const char **values);</pre>                                                        |
| <b>DESCRIPTION</b>    | <p>The SASL auxilliary properties are used to obtain properties from external sources during the authentication process. For example, a mechanism might need to query an LDAP server to obtain the authentication secret. The application probably needs other information from the LDAP server as well, such as the home directory of the UID. The auxilliary property interface allows the two to cooperate and results in only a single query against the property sources.</p> <p>Property lookups take place directly after user canonicalization occurs. Therefore, all request should be registered with the context before user canonicalization occurs. Requests can also be registered by using the <code>sasl_auxprop_request(3SASL)</code> function. Most of the auxilliary property functions require a property context that can be obtained by calling <code>sasl_auxprop_getctx(3SASL)</code>.</p> |
| <b>prop_new()</b>     | The <code>prop_new()</code> function creates a new property context. It is unlikely that application developers will use this call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>prop_dup()</b>     | The <code>prop_dup()</code> function duplicates a given property context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>prop_request()</b> | The <code>prop_request()</code> function adds properties to the request list of a given context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>prop_get()</b>     | The <code>prop_get()</code> function returns a null-terminated array of <code>struct propval</code> from the given context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>prop_getnames()</b> | <p>The <code>prop_getnames()</code> function fills in an array of <code>struct propval</code> based on a list of property names. The <code>vals</code> array is at least as long as the <code>names</code> array. The values that are filled in by this call persist until the next call on the context to <code>prop_request()</code>, <code>prop_clear()</code>, or <code>prop_dispose()</code>. If a name specified was never requested, then its associated values entry will be set to <code>NULL</code>.</p> <p>The <code>prop_getnames()</code> function returns the number of matching properties that were found or a SASL error code.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                                                  |            |                       |                 |                                                                                                                      |              |                                                                                                                                                                                  |             |                           |  |                                                                                                                                                                                                                                                          |               |                                                                                                                                               |               |                                                                                                                     |               |                                                                                      |
| <b>prop_clear()</b>    | <p>The <code>prop_clear()</code> function clears <i>values</i> and <i>requests</i> from a property context. If the value of <i>requests</i> is 1, then <i>requests</i> is cleared. Otherwise, the value of <i>requests</i> is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                                                                  |            |                       |                 |                                                                                                                      |              |                                                                                                                                                                                  |             |                           |  |                                                                                                                                                                                                                                                          |               |                                                                                                                                               |               |                                                                                                                     |               |                                                                                      |

|                 |                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------|
| <i>requests</i> | The request list for a given context.                                                                             |
| <i>sep</i>      | The separator to use for the string.                                                                              |
| <i>seplen</i>   | The length of the separator. The the values is less than 0, then <code>strlen</code> will be used as <i>sep</i> . |
| <i>vallen</i>   | The length of the property.                                                                                       |
| <i>vals</i>     | The value string.                                                                                                 |
| <i>value</i>    | A value for the property of length <i>vallen</i> .                                                                |
| <i>values</i>   | A null-terminated array of values to be added to the property.                                                    |

**ERRORS** The `sasl_auxprop()` functions that return an `int` will return a SASL error code. See [sasl\\_errors\(3SASL\)](#). Those `sasl_auxprop()` functions that return a pointer will return a valid pointer upon success and return `NULL` upon failure.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

sasl\_auxprop\_add\_plugin(3SASL)

**NAME** sasl\_auxprop\_add\_plugin – add a SASL auxiliary property plug-in

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sasl_auxprop_add_plugin(const char *plugname,
 sasl_auxprop_plug_init_t *cplugfunc);
```

**DESCRIPTION** Use the `sasl_auxprop_add_plugin()` interface to add a auxiliary property plug-in to the current list of auxiliary property plug-ins in the SASL library.

**PARAMETERS**

|                  |                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------|
| <i>plugname</i>  | The name of the auxiliary property plug-in.                                                        |
| <i>cplugfunc</i> | The value of <i>cplugfunc</i> is filled in by the <code>sasl_auxprop_plug_init_t</code> structure. |

**RETURN VALUES** `sasl_auxprop_add_plugin()` returns an integer that corresponds to a SASL error code.

**ERRORS**

|              |                                                                   |
|--------------|-------------------------------------------------------------------|
| SASL_OK      | The call to <code>sasl_client_add_plugin()</code> was successful. |
| SASL_BADVERS | Version mismatch with plug-in.                                    |
| SASL_NOMEM   | Memory shortage failure.                                          |

See [sasl\\_errors\(3SASL\)](#) for information on other SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

## sasl\_auxprop\_getctx(3SASL)

**NAME** | sasl\_auxprop\_getctx – acquire an auxiliary property context

**SYNOPSIS** | 

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

struct propctx *sasl_auxprop_getctx(sasl_conn_t *conn);
```

**DESCRIPTION** | The sasl\_auxprop\_getctx() interface returns an auxiliary property context for the given sasl\_conn\_t on which the sasl auxiliary property functions can operate. See sasl\_auxprop(3SASL).

**PARAMETERS** | *conn*                      The sasl\_conn\_t for which the request is being made

**RETURN VALUES** | sasl\_auxprop\_getctx() returns a pointer to the context, upon success.  
sasl\_auxprop\_getctx() returns NULL upon failure.

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | Safe            |

|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|-------------|---------------------|----------|----------|------|
| <b>SYNOPSIS</b>     | <pre>cc [ flag ... ] file ... -lsasl [ library ... ] #include &lt;sasl/sasl.h&gt;  int <b>sasl_auxprop_request</b>(sasl_conn_t *conn, const char     **propnames);</pre>                                                                                                                                                                                                                                                                                     |                |                 |              |             |                     |          |          |      |
| <b>DESCRIPTION</b>  | The <code>sasl_auxprop_request()</code> interface requests that the SASL library obtain properties from any auxiliary property plugins that might be installed, for example, the user's home directory from an LDAP server. The lookup occurs just after username canonicalization is complete. Therefore, the request should be made before the call to <code>sasl_server_start(3SASL)</code> , but after the call to <code>sasl_server_new(3SASL)</code> . |                |                 |              |             |                     |          |          |      |
| <b>PARAMETERS</b>   | <p><i>conn</i>                   The <code>sasl_conn_t</code> for which the request is being made</p> <p><i>propnames</i>             A null-terminated array of property names to request. This array must persist until a call to <code>sasl_dispose(3SASL)</code> on the <code>sasl_conn_t</code>.</p>                                                                                                                                                    |                |                 |              |             |                     |          |          |      |
| <b>ERRORS</b>       | <code>sasl_auxprop_request()</code> returns <code>SASL_OK</code> upon success. See <code>sasl_errors(3SASL)</code> for a discussion of other SASL error codes.                                                                                                                                                                                                                                                                                               |                |                 |              |             |                     |          |          |      |
| <b>ATTRIBUTES</b>   | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |             |                     |          |          |      |
|                     | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWlibsasl</td> </tr> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>                                                                                                                                                                         | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWlibsasl | Interface Stability | Evolving | MT-Level | Safe |

## sasl\_canonuser\_add\_plugin(3SASL)

**NAME** | sasl\_canonuser\_add\_plugin – add a SASL user canonicalization plug-in

**SYNOPSIS** | 

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sasl_canonuser_add_plugin(const char *plugname,
 sasl_canonuser_plug_init_t *cplugfunc);
```

**DESCRIPTION** | Use the `sasl_canonuser_add_plugin()` interface to add a user canonicalization plug-in to the current list of user canonicalization plug-ins in the SASL library.

**PARAMETERS** | *plugname*            The name of the user canonicalization plug-in.  
*cplugfunc*            The value of *cplugfunc* is filled in by the `sasl_canonuser_plug_init_t` structure.

**RETURN VALUES** | `sasl_server_add_plugin()` returns an integer that corresponds to a SASL error code.

**ERRORS** | `SASL_OK`            The call to `sasl_client_add_plugin()` was successful.  
`SASL_BADVERS`    Version mismatch with plug-in.  
`SASL_NOMEM`      Memory shortage failure.

See [sasl\\_errors\(3SASL\)](#) for information on other SASL error codes.

**ATTRIBUTES** | See [attributes\(5\)](#) for descriptions of the following attributes:

| <b>DESCRIPTION</b>   | The <code>sasl_canon_user_t()</code> interface is the callback function for an application-supplied user canonical function. This function is subject to the requirements of all canonical functions. It must copy the result into the output buffers, but the output buffers and the input buffers can be the same.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                                                              |                 |                                             |             |                                                      |             |                                                                   |              |                                                                                                                                                                                                                                                                                                |                |                                              |                 |                                             |                   |                          |                 |                                      |                |                                       |                |                                      |

The value of <i>defresult</i> can be NULL                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                                 |              |                                                                                           |                     |                         |               |                        |                  |                                                               |               |                                                                 |            |                                    |
| <i>result</i>        | The user's response. <i>result</i> is a null-terminated string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                                 |              |                                                                                           |                     |                         |               |                        |                  |                                                               |               |                                                                 |            |                                    |
| <i>len</i>           | The length of the user's response.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                                                 |              |                                                                                           |                     |                         |               |                        |                  |                                                               |               |                                                                 |            |                                    |
| <b>RETURN VALUES</b> | Like other SASL callback functions, sasl_chalprompt_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                                 |              |                                                                                           |                     |                         |               |                        |                  |                                                               |               |                                                                 |            |                                    |

| <b>DESCRIPTION</b>   | <p>The <code>sasl_checkpop()</code> interface checks an APOP challenge or response. APOP is an option POP3 authentication command that uses a shared secret password. See <i>RFC 1939</i>.</p> <p>If <code>sasl_checkpop()</code> is called with a NULL challenge, <code>sasl_checkpop()</code> will check to see if the APOP mechanism is enabled.</p>                                                                                     |                |                                                                  |                     |                                  |                     |                                |                 |                     |                 |                               |

| <b>DESCRIPTION</b>   | <p>The <code>sasl_checkpass()</code> interface checks a plaintext password. The <code>sasl_checkpass()</code> interface is used for protocols that had a login method before SASL, for example, the LOGIN command in IMAP. The password is checked with the <code>pwcheck_method</code>.</p> <p>The <code>sasl_checkpass()</code> interface is a server interface. You cannot use it to check passwords from a client.</p> <p>The <code>sasl_checkpass()</code> interface checks the possible repositories until it succeeds or there are no more repositories. If <code>sasl_server_userdb_checkpass_t</code> is registered, <code>sasl_checkpass()</code> tries it first.</p> <p>Use the <code>pwcheck_method</code> SASL option to specify which <code>pwcheck</code> methods to use.</p> <p>The <code>sasl_checkpass()</code> interface supports the transition of passwords if the SASL option <code>auto_transition</code> is on.</p> <p>If <code>user</code> is NULL, check is plaintext passwords are enabled.</p> |             |                                                                  |             |                             |                |                           |             |                                                   |                |                         |

**SEE ALSO** [sasl\\_errors\(3SASL\)](#), [attributes\(5\)](#)

**NAME** sasl\_client\_add\_plugin – add a SASL client plug-in

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sasl_client_add_plugin(const char *plugname,
 sasl_client_plug_init_t *cplugfunc);
```

**DESCRIPTION** Use the `sasl_client_add_plugin()` interface to add a client plug-in to the current list of client plug-ins in the SASL library.

**PARAMETERS**

|                  |                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------|
| <i>plugname</i>  | The name of the client plug-in.                                                                   |
| <i>cplugfunc</i> | The value of <i>cplugfunc</i> is filled in by the <code>sasl_client_plug_init_t</code> structure. |

**RETURN VALUES** `sasl_client_add_plugin()` returns an integer that corresponds to a SASL error code.

**ERRORS**

|              |                                                                   |
|--------------|-------------------------------------------------------------------|
| SASL_OK      | The call to <code>sasl_client_add_plugin()</code> was successful. |
| SASL_BADVERS | Version mismatch with plug-in.                                    |
| SASL_NOMEM   | Memory shortage failure.                                          |

See [sasl\\_errors\(3SASL\)](#) for information on other SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

## sasl\_client\_init(3SASL)

**NAME** sasl\_client\_init – initialize SASL client authentication

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_client_init(const sasl_callback_t *callbacks);
```

**DESCRIPTION** Use the `sasl_client_init()` interface to initialize SASL. The `sasl_client_init()` interface must be called before any calls to `sasl_client_start(3SASL)`. The call to `sasl_client_init()` initializes all SASL client drivers, for example, authentication mechanisms. SASL client drivers are usually found in the `/usr/lib/sasl` directory.

**PARAMETERS** *callbacks* Specifies the base callbacks for all client connections.

**RETURN VALUES** `sasl_client_init()` returns an integer that corresponds to a SASL error code.

**ERRORS**

|               |                                                             |
|---------------|-------------------------------------------------------------|
| SASL_OK       | The call to <code>sasl_client_init()</code> was successful. |
| SASL_BADVERS  | There is a mismatch in the mechanism version.               |
| SASL_BADPARAM | There is an error in the configuration file.                |
| SASL_NOMEM    | There is not enough memory to complete the operation.       |

All other error codes indicate an error situation that must be handled, or the authentication session should be quit. See `sasl_errors(3SASL)` for information on SASL error codes.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | Unsafe          |

**SEE ALSO** `sasl_errors(3SASL)`, `attributes(5)`

**NOTES** While most of `libsasl` is MT-Safe, no other `libsasl` function should be called until this function completes.

| <b>DESCRIPTION</b>         | Use the <code>sasl_client_new()</code> interface to create a new SASL context. This SASL context will be used for all SASL calls for one connection. The context handles both authentication and the integrity and encryption layers after authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                                                                                  |                          |                                                                                 |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                         |                                                                |                    |                                                                                                                                                                                             |              |                                                                               |              |                                                                                                                                    |

For clients, the flag <code>SASL_NEED_PROXY</code> is available. | <i>pconn</i> | The connection context allocated by the library. The <i>pconn</i> structure is used for all future SASL calls for this connection. |
| <i>service</i>             | The registered name of the service that uses SASL, usually the protocol name, for example, IMAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |                                                                                                  |                          |                                                                                 |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                         |                                                                |                    |                                                                                                                                                                                             |              |                                                                               |              |                                                                                                                                    |
| <i>serverFQDN</i>          | The fully qualified domain name of the server, for example, serverhost.cmu.edu.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                      |                                                                                                  |                          |                                                                                 |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                         |                                                                |                    |                                                                                                                                                                                             |              |                                                                               |              |                                                                                                                                    |
| <i>iplocalport</i>         | The IP and port of the local side of the connection, or NULL. If <i>iplocalport</i> is NULL, mechanisms that require IP address information are disabled. The <i>iplocalport</i> string must be in one of the following formats: <ul style="list-style-type: none"> <li>■ a.b.c.d:port (IPv6)</li> <li>■ [e:f:g:h:i:j:k:l]:port (IPv6)</li> <li>■ [e:f:g:h:i:j:a.b.c.d]:port (IPv6)</li> <li>■ a.b.c.d;port (IPv4)</li> <li>■ e:f:g:h:i:j:k:l;port (IPv6)</li> <li>■ e:f:g:h:i:j:a.b.c.d;port (IPv6)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                      |                                                                                                  |                          |                                                                                 |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                         |                                                                |                    |                                                                                                                                                                                             |              |                                                                               |              |                                                                                                                                    |
| <i>ipremoteport</i>        | The IP and port of the remote side of the connection, or NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                      |                                                                                                  |                          |                                                                                 |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                         |                                                                |                    |                                                                                                                                                                                             |              |                                                                               |              |                                                                                                                                    |

**NAME** | `sas_client_plug_init_t` – client plug-in entry point

**SYNOPSIS** | 

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sas_client_plug_init_t(const sasl_utils_t *utils, int
 max_version, int *out_version, sasl_client_plug_t **pluglist, int
 *plugcount) ;
```

**DESCRIPTION** | The `sas_client_plug_init_t()` callback function is the client plug-in entry point.

**PARAMETERS** | *utils*                    The utility callback functions.  
*max\_version*                The highest client plug-in version supported.  
*out\_version*                The client plug-in version of the result..  
*pluglist*                    The list of client mechanism plug-ins.  
*plugcount*                  The number of client mechanism plug-ins.

**RETURN VALUES** | Like other SASL callback functions, `sas_client_plug_init_t()` returns an integer that corresponds to a SASL error code. See `<sasl.h>` for a complete list of SASL error codes.

**ERRORS** | `SASL_OK`                The call to `sas_client_plug_init_t()` was successful.  
See [sas\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** | See [attributes\(5\)](#) for descriptions of the following attributes:

| <b>DESCRIPTION</b>                      | <p>Use the <code>sasl_client_start()</code> interface to select a mechanism for authentication and start the authentication session. The <code>mechlist</code> parameter holds the list of mechanisms that the client might like to use. The mechanisms in the list are not necessarily supported by the client, nor are the mechanisms necessarily valid. SASL determines which of the mechanisms to use based upon the security preferences specified earlier. The list of mechanisms is typically a list of mechanisms that the server supports, acquired from a capability request.</p> <p>If <code>SASL_INTERACT</code> is returned, the library needs some values to be filled in before it can proceed. The <code>prompt_need</code> structure is filled in with requests. The application fulfills these requests and calls <code>sasl_client_start()</code> again with identical parameters. The <code>prompt_need</code> parameter is the same pointer as before, but it is filled in by the application.</p> |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |

Any protocol specific encoding that is necessary, for example base64 encoding, must be done by the client. |  | If the protocol lacks client-send-first capability, then set <i>clientout</i> to NULL. If there is no initial client-send, then <i>clientout</i> will be set to NULL on return. | <i>mech</i> | Contains the name of the chosen SASL mechanism, upon success. |
| <i>conn</i>                             | The SASL connection context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |
| <i>mechlist</i>                         | A list of mechanism that the server has available. Punctuation is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |
| <i>prompt_need</i>                      | A list of prompts that are needed to continue, if necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |
| <i>clientout</i><br><i>clientoutlen</i> | <i>clientout</i> and <i>clientoutlen</i> are created. They contain the initial client response to send to the server. It is the job of the client to send them over the network to the server. Any protocol specific encoding that is necessary, for example base64 encoding, must be done by the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |
|                                         | If the protocol lacks client-send-first capability, then set <i>clientout</i> to NULL. If there is no initial client-send, then <i>clientout</i> will be set to NULL on return.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |
| <i>mech</i>                             | Contains the name of the chosen SASL mechanism, upon success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |
| <b>RETURN VALUES</b>                    | <code>sasl_client_start()</code> returns an integer that corresponds to a SASL error code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                              |                 |                                                                            |                    |                                                              |                                         |                                                                                                                                                                                                                                                                                                           |  |                                                                                                                                                                                 |             |                                                               |

| <b>DESCRIPTION</b>                      | <p>Use the <code>sasl_client_step()</code> interface performs a step in the authentication negotiation. <code>sasl_client_step()</code> returns <code>SASL_OK</code> if the complete negotiation is successful. If the negotiation on step is completed successfully, but at least one more step is required, <code>sasl_client_step()</code> returns <code>SASL_CONTINUE</code>. A client should not assume an authentication negotiaion is successful because the server signaled success through the protocol. For example, if the server signaled <code>OK</code> Authentication succeeded in IMAP, <code>sasl_client_step()</code> should be called one more time with a <code>serverinlen</code> of zero.</p> <p>If a call to <code>sasl_client_step()</code> returns <code>SASL_INTERACT</code>, the library requires some values before <code>sasl_client_step()</code> can proceed. The <code>prompt_need</code> structure will be filled with the requests. The application should fulfill these requests and call <code>sasl_client_step()</code> again with identical parameters. The <code>prompt_need</code> parameter will be the same pointer as before, but it will have been filled in by the application.</p> |                      |                                                                                          |                            |                                                                                                                         |                            |                                                                                      |                                         |                                                                                                                                                                                                                                                                                                                        |                    |                                                              |
