| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lsasl [ library ... ] #include &lt;sasl/sasl.h&gt;  int sasl_decode(sasl_conn_t *conn, const char *input, unsigned                inputlen, const char **output, unsigned *outputlen);</pre>                                                                                                                                                                                                                                                                                                                                                                                                               |                |                              |              |                |                     |                            |               |                                                                            |                  |                               |
| <b>DESCRIPTION</b>   | <p>Use the <code>sasl_decode()</code> interface to decode data received. After authentication, call this function on all data received. The data is decoded from encrypted or signed form to plain data. If no security layer is negotiated, the output is identical to the input.</p> <p>Do not give <code>sasl_decode()</code> more data than the negotiated <code>maxbufsize</code>. See <a href="#">sasl_getprop(3SASL)</a>.</p> <p><code>sasl_decode()</code> can complete successfully although the value of <code>outputlen</code> is zero. If this is the case, wait for more data and call <code>sasl_decode()</code> again.</p> |                |                              |              |                |                     |                            |               |                                                                            |                  |                               |

**NAME** sasl\_decode64 – decode base64 string

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslutil.h>

int sasl_decode64(const char *in, unsigned inlen, char *out,
 unsigned outmax, unsigned *outlen);
```

**DESCRIPTION** Use the `sasl_decode64()` interface to decode a base64 encoded buffer.

**PARAMETERS**

|               |                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <i>in</i>     | Input data.                                                                                                  |
| <i>inlen</i>  | The length of the input data.                                                                                |
| <i>out</i>    | The output data. The value of <i>out</i> can be the same as <i>in</i> . However, there must be enough space. |
| <i>outlen</i> | The length of the actual output.                                                                             |
| <i>outmax</i> | The maximum size of the output buffer.                                                                       |

**RETURN VALUES** `sasl_decode64()` returns an integer that corresponds to a SASL error code.

**ERRORS** SASL\_OK The call to `sasl_decode64()` was successful.

See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

## sasl\_dispose(3SASL)

**NAME** sasl\_dispose – dispose of a SASL connection object

**SYNOPSIS** `cc [ flag ... ] file ... -lsasl [ library ... ]  
#include <sasl/sasl.h>`

```
void sasl_dispose(sasl_conn_t **pconn);
```

**DESCRIPTION** Use the `sasl_dispose()` interface when a SASL connection object is no longer needed. Generally, the SASL connection object is no longer needed when the protocol session is completed, not when authentication is completed, as a security layer may have been negotiated.

**PARAMETERS** *pconn* The SASL connection context

**RETURN VALUES** `sasl_dispose()` has no return values.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | Safe            |

**SEE ALSO** `attributes(5)`

- NAME** sasl\_done – dispose of all SASL plug-ins
- SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

void sasl_encode(void);
```
- DESCRIPTION** Make a call to the `sasl_done()` interface when the application is completely done with the SASL library. You must call `sasl_dispose(3SASL)` before you make a call to `sasl_done()`.
- RETURN VALUES** `sasl_done()` has no return values.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | Safe            |

**SEE ALSO** `sasl_dispose(3SASL)`, `attributes(5)`

sasl\_encode(3SASL)

**NAME** sasl\_encode, sasl\_encodev – encode data for transport to an authenticated host

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_encode(sasl_conn_t *conn, const char *input, unsigned
 inputlen, const char **output, unsigned *outputlen);

int sasl_encodev(sasl_conn_t *conn, const struct iovec *invec,
 unsigned numiov, const char *outputlen);
```

**DESCRIPTION** The sasl\_encode() interface encodes data to be sent to a remote host for which there has been a successful authentication session. If there is a negotiated security, the data is signed or encrypted, and the output is sent without modification to the remote host. If there is no security layer, the output is identical to the input.

The sasl\_encodev() interface functions the same as the sasl\_encode() interface, but operates on a struct iovec instead of a character buffer.

**PARAMETERS**

|                  |                                                                            |
|------------------|----------------------------------------------------------------------------|
| <i>conn</i>      | The SASL connection context.                                               |
| <i>input</i>     | Data.                                                                      |
| <i>inputlen</i>  | <i>input</i> length.                                                       |
| <i>output</i>    | The encoded data. <i>output</i> must be allocated or freed by the library. |
| <i>outputlen</i> | The length of <i>output</i> .                                              |
| <i>invec</i>     | A pointer to set of iovec structures.                                      |
| <i>numiov</i>    | The number of iovec structures in the <i>invec</i> set.                    |

**RETURN VALUES** sasl\_encode() returns an integer that corresponds to a SASL error code.

**ERRORS** SASL\_OK The call to sasl\_encode() or sasl\_encodev() was successful.

See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | Safe            |

**SEE ALSO** [attributes\(5\)](#)

**NAME** sasl\_encode64 – encode base64 string

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslutil.h>

int sasl_encode64(const char *in, unsigned inlen, char *out,
 unsigned outmax, unsigned *outlen);
```

**DESCRIPTION** Use the `sasl_encode64()` interface to convert an octet string into a base64 string. This routine is useful for SASL profiles that use base64, such as the IMAP (IMAP4) and POP (POP\_AUTH) profiles. The output is null-terminated. If `outlen` is non-NULL, the length is placed in the `outlen`.

**PARAMETERS**

|               |                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <i>in</i>     | Input data.                                                                                                  |
| <i>inlen</i>  | The length of the input data.                                                                                |
| <i>out</i>    | The output data. The value of <i>out</i> can be the same as <i>in</i> . However, there must be enough space. |
| <i>outlen</i> | The length of the actual output.                                                                             |
| <i>outmax</i> | The maximum size of the output buffer.                                                                       |

**RETURN VALUES** `sasl_encode64()` returns an integer that corresponds to a SASL error code.

**ERRORS**

|              |                                                          |
|--------------|----------------------------------------------------------|
| SASL_OK      | The call to <code>sasl_encode64()</code> was successful. |
| SASL_BUFOVER | The output buffer was too small.                         |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

**SEE ALSO** `sasl_errors(3SASL)`, `attributes(5)`

## sasl\_erasebuffer(3SASL)

**NAME** | sasl\_erasebuffer – erase buffer

**SYNOPSIS** | `cc [ flag ... ] file ... -lsasl [ library ... ]`  
| `#include <sasl/saslutil.h>`  
| `void sasl_erasebuffer(char *pass, unsigned len);`

**DESCRIPTION** | Use the `sasl_erasebuffer()` interface to erase a security sensitive buffer or password. The implementation may use recovery-resistant erase logic.

**PARAMETERS** | *pass*        A password  
| *len*         The length of the password

**RETURN VALUES** | The `sasl_erasebuffer()` interface returns no return values.

**ERRORS**        | None.

**ATTRIBUTES**   | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

**SEE ALSO**       | `attributes(5)`

|                      |                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | sasl_errdetail – retrieve detailed information about an error                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>      | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lsasl [ <i>library</i> ... ] #include &lt;sasl/sasl.h&gt;  const char * <b>sasl_errdetail</b>(sasl_conn_t *<i>conn</i>);</pre>                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>   | The <code>sasl_errdetail()</code> interface returns an internationalized string that is a message that describes the error that occurred on a SASL connection. The <code>sasl_errdetail()</code> interface provides a more user friendly error message than the SASL error code returned when SASL indicates that an error has occurred on a connection. See <a href="#">sasl_errors(3SASL)</a> . |
| <b>PARAMETERS</b>    | <i>conn</i> The SASL connection context for which the inquiry is made.                                                                                                                                                                                                                                                                                                                            |
| <b>RETURN VALUES</b> | <code>sasl_errdetail()</code> returns the string that describes the error that occurred, or NULL, if there was an error retrieving it.                                                                                                                                                                                                                                                            |
| <b>ATTRIBUTES</b>    | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>                     | sasl_errors – SASL error codes                                                                                                                                                                                     |                                                                                |
| <b>SYNOPSIS</b>                 | #include <sasl/sasl.h>                                                                                                                                                                                             |                                                                                |
| <b>DESCRIPTION</b>              | This man page describes the general error codes that may be returned by calls into the SASL library. The meaning of the error code may vary slightly based upon the context of the call from which it is returned. |                                                                                |
| <b>ERRORS</b>                   |                                                                                                                                                                                                                    |                                                                                |
| <b>Common Result Codes</b>      | SASL_OK                                                                                                                                                                                                            | The call was successful.                                                       |
|                                 | SASL_CONTINUE                                                                                                                                                                                                      | Another step is required for authentication.                                   |
|                                 | SASL_FAILURE                                                                                                                                                                                                       | Generic failure.                                                               |
|                                 | SASL_NOMEM                                                                                                                                                                                                         | Memory shortage failure.                                                       |
|                                 | SASL_BUFOVER                                                                                                                                                                                                       | Overflowed buffer.                                                             |
|                                 | SASL_NOMECH                                                                                                                                                                                                        | The mechanism was not supported, or no mechanisms matched the requirements.    |
|                                 | SASL_BADPROT                                                                                                                                                                                                       | The protocol was bad, invalid or cancelled.                                    |
|                                 | SASL_NOT_DONE                                                                                                                                                                                                      | Cannot request information. Not applicable until later in the exchange.        |

| <b>DESCRIPTION</b>   | <p>The <code>sasl_errstring()</code> interface is called to convert a SASL return code from an integer into a human readable string.</p> <p>You should not use the <code>sasl_errstring()</code> interface to extract error code information from SASL. Applications should use <code>sasl_errdetail(3SASL)</code> instead, which contains this error information and more.</p> <p>The <code>sasl_errstring()</code> interface supports only <code>i-default</code> and <code>i-local</code> at this time.</p> |                |                                    |                 |                                                                                                                                                                                    |                     |                                                                                                                            |          |      |

**NAME** sasl\_getcallback\_t – callback function to lookup a sasl\_callback\_t for a connection

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sasl_getcallback_t(sasl_conn_t *conn, unsigned long callbacknum,
 int (**proc)(), void **pcontext);
```

**DESCRIPTION** The sasl\_getcallback\_t() function is a callback to lookup a sasl\_callback\_t for a connection.

**PARAMETERS**

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <i>conn</i>        | The connection to lookup a callback for.                                                   |
| <i>callbacknum</i> | The number of the callback.                                                                |
| <i>proc</i>        | Pointer to the callback function. The value of <i>proc</i> is set to NULL upon failure.    |
| <i>pcontext</i>    | Pointer to the callback context. The value of <i>pcontext</i> is set to NULL upon failure. |

**RETURN VALUES** Like other SASL callback functions, sasl\_getcallback\_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.

**ERRORS**

|               |                                                  |
|---------------|--------------------------------------------------|
| SASL_OK       | The call to sasl_getcallback_t() was successful. |
| SASL_FAIL     | Unable to find a callback of the requested type. |
| SASL_INTERACT | The caller must use interaction to get data.     |

## sasl\_getopt\_t(3SASL)

**NAME** sasl\_getopt\_t – the SASL get option callback function

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_getopt_t(void *context, const char *plugin_name, const char
 *option, const char **result, unsigned *len);
```

**DESCRIPTION** The `sasl_getopt_t()` function allows a SASL configuration to be encapsulated in the caller's configuration system. Some implementations may use default configuration file(s) if this function is omitted. Configuration items are arbitrary strings and are plug-in specific.

**PARAMETERS**

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>context</i>     | The option context from the callback record.                                                                                                                                                  |
| <i>plugin_name</i> | The name of the plug-in. If the value of <i>plugin_name</i> is NULL, the the plug-in is a general SASL option.                                                                                |
| <i>option</i>      | The name of the option.                                                                                                                                                                       |
| <i>result</i>      | The value of <i>result</i> is set and persists until the next call to <code>sasl_getopt_t()</code> in the same thread. The value of <i>result</i> is unchanged if <i>option</i> is not found. |
| <i>len</i>         | The length of <i>result</i> . The value of <i>result</i> can be NULL.                                                                                                                         |

**RETURN VALUES** Like other SASL callback functions, `sasl_getopt_t()` returns an integer that corresponds to a SASL error code. See `<sasl.h>` for a complete list of SASL error codes.

**ERRORS** SASL\_OK The call to `sasl_getopt_t()` was successful.  
See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

**SEE ALSO** [sasl\\_errors\(3SASL\)](#), [attributes\(5\)](#)

**NAME** sas1\_getpath\_t – the SASL callback function to indicate location of the security mechanism drivers

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sas1_getpath_t(void *context, char **path);
```

**DESCRIPTION** Use the sas1\_getpath\_t() function to enable the application to use a different location for the SASL security mechanism drivers, which are shared library files. If the sas1\_getpath\_t() callback is not used, SASL uses /usr/lib/sasl by default.

**PARAMETERS**

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <i>context</i> | The getpath context from the callback record                                                                         |
| <i>path</i>    | The path(s) for the location of the SASL security mechanism drivers. The values for <i>path</i> are colon-separated. |

**RETURN VALUES** Like other SASL callback functions, sas1\_getpath\_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.

**ERRORS** SASL\_OK The call to sas1\_getpath\_t() was successful.

See sas1\_errors(3SASL) for information on SASL error codes.

| <b>DESCRIPTION</b>   | <p>Use the <code>sasl_getrealm_t()</code> function when there is an interaction with <code>SASL_CB_GETREALM</code> as the type.</p> <p>If a mechanism would use this callback, but it is not present, then the first realm listed is automatically selected. A mechanism can still force the existence of a getrealm callback by <code>SASL_CB_GETREALM</code> to its <code>required_prompts</code> list.</p>                                                                                     |                |                                      |              |                                                   |                     |                                                                                                          |               |                                                              |

| <b>DESCRIPTION</b>   | Use the <code>sasl_getsecret_t()</code> function to retrieve the secret from the application. Allocate a <code>sasl_secret_t</code> to length <code>sizeof(sasl_secret_t)+&lt;length of secret&gt;</code> . <code>sasl_secret_t</code> has two fields of <code>len</code> which contain the length of <code>secret</code> in bytes and the data contained in <code>secret</code> . The <code>secret</code> string does not need to be null-terminated.                                                                                                                                     |                |                                                             |                |                                         |                     |                 |                |                                                                                                                                                                                                                                                                            |

| <i>psecret</i>       | To cancel, set the value of <i>psecret</i> to NULL. Otherwise, set the value to the password structure. The structure must persist until the next call to <code>sasl_getsecret_t()</code> in the same connection. Middleware erases password data when it is done with it.                                                                                                                                                                                                                                                                                                                 |                |                                                             |                |                                         |                     |                 |                |                                                                                                                                                                                                                                                                            |
| <b>RETURN VALUES</b> | Like other SASL callback functions, <code>sasl_getsecret_t()</code> returns an integer that corresponds to a SASL error code. See <code>&lt;sasl.h&gt;</code> for a complete list of SASL error codes.                                                                                                                                                                                                                                                                                                                                                                                     |                |                                                             |                |                                         |                     |                 |                |                                                                                                                                                                                                                                                                            |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lsasl [ library ... ] #include &lt;sasl/sasl.h&gt;  int sasl_getsimple_t(void *context, int id, const char **result,     unsigned *len);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                                             |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                     |                                                         |                  |                                                             |                  |                                                         |                |                                                             |               |                                                                                                                                                  |            |                               |
| <b>DESCRIPTION</b>   | Use the <code>sasl_getsimple_t()</code> callback function to retrieve simple data from the application such as the authentication name, the authorization name, and the realm. The <code>id</code> parameter indicates which value is requested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                                                             |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                     |                                                         |                  |                                                             |                  |                                                         |                |                                                             |               |                                                                                                                                                  |            |                               |

**NAME** | sasl\_global\_listmech – retrieve a list of the supported SASL mechanisms

**SYNOPSIS** | `cc [ flag ... ] file ... -lsasl [ library ... ]`  
`#include <sasl/sasl.h>`  
`const char ** sasl_global_listmech( );`

**DESCRIPTION** | The `sasl_global_listmech()` interface to returns a null-terminated array of strings that lists all of the mechanisms that are loaded by either the client or server side of the library.

**RETURN VALUES** | A successful call to `sasl_global_listmech()` returns a pointer the array. On failure, NULL is returned. The SASL library is uninitialized.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Obsolete        |
| MT-Level            | MT-Safe         |

## sasl\_idle(3SASL)

**NAME** sasl\_idle – perform precalculations during an idle period

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_idle(sasl_conn_t *conn);
```

**DESCRIPTION** Use the sasl\_idle() interface during an idle period to allow the SASL library or any mechanisms to perform any necessary precalculation.

**PARAMETERS** *conn* The SASL connection context. The value of *conn* can be NULL in order to complete a precalculation before the connection takes place.

**RETURN VALUES** sasl\_idle() returns the following values:

- 1 Indicates action was taken
- 0 Indicates no action was taken

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

| <b>DESCRIPTION</b>   | The sasl_listmech() interface returns a string listing the SASL names of all the mechanisms available to the specified user. This call is typically given to the client through a capability command or initial server response. Client applications need this list so that they know what mechanisms the server supports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                                                                                                                               |              |                                                                                                                                                              |                     |                                              |            |                              |               |                                        |               |                                                                                           |             |                                                                                          |               |                                                                                                                                     |

sasl\_log\_t(3SASL)

**NAME** sasl\_log\_t – the SASL logging callback function

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_log_t(void *context, int level, const char *message);
```

**DESCRIPTION** Use the sasl\_log\_t() function to log warning and error messages from the SASL library. syslog(3C) is used, unless another logging function is specified.

**PARAMETERS**

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <i>context</i> | The logging context from the callback record.                            |
| <i>level</i>   | The logging level. Possible values for <i>level</i> include:             |
|                | SASL_LOG_NONE Do not log anything.                                       |
|                | SASL_LOG_ERR Log unusual errors. This is the default log level.          |
|                | SASL_LOG_FAIL Log all authentication failures.                           |
|                | SASL_LOG_WARN Log non-fatal warnings.                                    |
|                | SASL_LOG_NOTE Log non-fatal warnings (more verbose than SASL_LOG_WARN).  |
|                | SASL_LOG_DEBUG Log non-fatal warnings (more verbose than SASL_LOG_NOTE). |
|                | SASL_LOG_TRACE Log traces of internal protocols.                         |
|                | SASL_LOG_PASS Log traces of internal protocols, including passwords.     |
| <i>message</i> | The message to log                                                       |

**RETURN VALUES** Like other SASL callback functions, sasl\_log\_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.

**ERRORS** SASL\_OK The call to sasl\_log\_t() was successful.

See sasl\_errors(3SASL) for information on SASL error codes.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

**NAME** sas\_server\_add\_plugin – add a SASL server plug-in

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sasl_server_add_plugin(const char *plugname,
 sasl_server_plug_init_t *cplugfunc);
```

**DESCRIPTION** Use the `sasl_server_add_plugin()` interface to add a server plug-in to the current list of client plug-ins in the SASL library.

**PARAMETERS**

|                  |                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------|
| <i>plugname</i>  | The name of the server plug-in.                                                                   |
| <i>cplugfunc</i> | The value of <i>cplugfunc</i> is filled in by the <code>sasl_server_plug_init_t</code> structure. |

**RETURN VALUES** `sasl_server_add_plugin()` returns an integer that corresponds to a SASL error code.

**ERRORS**

|              |                                                                   |
|--------------|-------------------------------------------------------------------|
| SASL_OK      | The call to <code>sasl_client_add_plugin()</code> was successful. |
| SASL_BADVERS | Version mismatch with plug-in.                                    |

| <b>DESCRIPTION</b>   | Use the <code>sasl_server_init()</code> interface to initialize SASL. You must call <code>sasl_server_init()</code> before you make a call to <code>sasl_server_start()</code> . <code>sasl_server_init()</code> may be called only once per process. A call to <code>sasl_server_init()</code> initializes all SASL mechanism drivers, that is, the authentication mechanisms. The SASL mechanism drivers are usually found in the <code>/usr/lib/sasl</code> directory. |                  |                                                             |                |                                                                                                                                                                               |                     |          |          |        |

| <b>NAME</b>          | sasldb_server_new – create a new server authentication object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lsasldb  [ library ... ] #include &lt;sasldb/sasldb.h&gt;  int <b>sasldb_server_new</b>(const char *service, const char *serverFQDN,     const char *user_realm, const char *iplocalport, const char     *ipremoteport, const sasldb_callback_t *callbacks, unsigned flags,     sasldb_conn_t **pconn);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>   | Use the <code>sasldb_server_new()</code> interface to create a new SASL context. This context will be used for all SASL calls for one connection. The new SASL context handles both authentication and integrity or encryption layers after authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>PARAMETERS</b>    | <p><i>service</i>            The registered name of the service that uses SASL. The registered name is usually the protocol name, for example, IMAP.</p> <p><i>serverFQDN</i>        The fully-qualified server domain name. If the value of <i>serverFQDN</i> is NULL, use <code>gethostname(3C)</code>. The <i>serverFQDN</i> parameter is useful for multi-homed servers.</p> <p><i>user_realm</i>        The domain of the user agent. The <i>user_realm</i> is usually not necessary. The default value of <i>user_realm</i> is NULL.</p> <p><i>iplocalport</i>      The IP address and port of the local side of the connection. The value of <i>iplocalport</i> may be NULL. If <i>iplocalport</i> is NULL, mechanisms that require IP address information are disabled. The <i>iplocalport</i> string must be in one of the following formats:</p> <ul style="list-style-type: none"> <li>■ a.b.c.d:port (IPv4)</li> <li>■ [e:f:g:h:i:j:k:l]:port (IPv6)</li> <li>■ [e:f:g:h:i:j:a.b.c.d]:port (IPv6)</li> </ul> <p>The following older formats are also supported:</p> <ul style="list-style-type: none"> <li>■ a.b.c.d;port (IPv4)</li> <li>■ e:f:g:h:i:j:k:l;port (IPv6)</li> <li>■ e:f:g:h:i:j:a.b.c.d;port (IPv6)</li> </ul> <p><i>ipremoteport</i>    The IP address and port of the remote side of the connection. The value of <i>ipremoteport</i> may be NULL. See <i>iplocalport</i>.</p> <p><i>callbacks</i>        Callbacks, for example: authorization, lang, and new getopt context.</p> <p><i>flags</i>            Usage flags. For servers, the flags <code>SASL_NEED_PROXY</code> and <code>SASL_SUCCESS_DATA</code> are available.</p> <p><i>pconn</i>            A pointer to the connection context allocated by the library. This structure will be used for all future SASL calls for this connection.</p> |
| <b>RETURN VALUES</b> | <code>sasldb_server_new()</code> returns an integer that corresponds to a SASL error code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ERRORS</b>        | <code>SASL_OK</code> The call to <code>sasldb_server_new()</code> was successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

sasl\_server\_new(3SASL)

All other error codes indicate an error situation that must be handled, or the authentication session should be quit. See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |

**NAME** sasl\_server\_plug\_init\_t – server plug-in entry point

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslplug.h>

int sasl_server_plug_init_t(const sasl_utils_t *utils, int
 max_version, int *out_version, sasl_client_plug_t **pluglist, int
 *plugcount);
```

**DESCRIPTION** The sasl\_server\_plug\_init\_t() callback function is the server plug-in entry point.

**PARAMETERS**

|                    |                                               |
|--------------------|-----------------------------------------------|
| <i>utils</i>       | The utility callback functions.               |
| <i>max_version</i> | The highest server plug-in version supported. |
| <i>out_version</i> | The server plug-in version of the result.     |
| <i>pluglist</i>    | The list of server mechanism plug-ins.        |
| <i>plugcount</i>   | The number of server mechanism plug-ins.      |

**RETURN VALUES** Like other SASL callback functions, sasl\_server\_plug\_init\_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.

**ERRORS** SASL\_OK The call to sasl\_server\_plug\_init\_t() was successful.

See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| <b>DESCRIPTION</b>   | The sasl_server_start() interface begins the authentication with the mechanism specified by the <i>mech</i> parameter. sasl_server_start() fails if the mechanism is not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |             |                     |          |          |         |
| <b>PARAMETERS</b>    | <p><i>conn</i>                    The SASL context for this connection.</p> <p><i>mech</i>                    The mechanism name that the client requested.</p> <p><i>clientin</i>                The initial response from the client. The value of <i>clientin</i> is NULL if the protocol lacks support for the client-send-first or if the other end did not have an initial send. No initial client send is distinct from an initial send of a null string. The protocol must account for this difference.</p> <p><i>clientinlen</i>            The length of the initial response.</p> <p><i>serverout</i>                Created by the plugin library. The value of <i>serverout</i> is the initial server response to send to the client. <i>serverout</i> is allocated or freed by the library. It is the job of the client to send it over the network to the server. Protocol specific encoding, for example base64 encoding, must be done by the server.</p> <p><i>serveroutlen</i>            The length of the initial server challenge.</p> |                |                 |              |             |                     |          |          |         |
| <b>RETURN VALUES</b> | sasl_server_start() returns an integer that corresponds to a SASL error code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |             |                     |          |          |         |

**NAME** | sasl\_server\_userdb\_checkpass\_t – plaintext password verification callback function

**SYNOPSIS** | 

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_sasl_server_userdb_checkpass_t(sasl_conn_t *conn, void
 *context, const char *user, const char *pass, unsigned passlen,
 struct propctx *propctx);
```

**DESCRIPTION** | Use the sasl\_sasl\_server\_userdb\_checkpass\_t() callback function to verify a plaintext password against the callback supplier's user database. Verification allows additional ways to encode the userPassword property.

**PARAMETERS** | *conn*                   The SASL connection context.  
*context*                   The context from the callback record.  
*user*                      A null-terminated user name with user@realm syntax.  
*pass*                      The password to check. This string cannot be null-terminated.  
*passlen*                  The length of *pass*.  
*propctx*                  The property context to fill in with userPassword.

**RETURN VALUES** | Like other SASL callback functions, sasl\_server\_userdb\_checkpass\_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.

**ERRORS** | SASL\_OK                  The call to sasl\_server\_userdb\_checkpass\_t() was successful.  
  
See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** | See [attributes\(5\)](#) for descriptions of the following attributes:

**NAME** sas1\_set\_alloc – set the memory allocation functions used by the SASL library

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

void sas1_set_alloc(sas1_malloc_t *m, sas1_calloc_t *c,
 sas1_realloc_t *r, sas1_free_t *f);
```

**DESCRIPTION** Use the `sas1_set_alloc()` interface to set the memory allocation routines that the SASL library and plug-ins will use.

**PARAMETERS**

*c* A pointer to a `calloc()` function

*f* A pointer to a `free()` function

*m* A pointer to a `malloc()` function

*r* A pointer to a `realloc()` function

**RETURN VALUES** `sas1_set_alloc()` has no return values.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Obsolete        |
| MT-Level            | Unsafe          |

**SEE ALSO** `attributes(5)`

**NOTES** While most of `libsasl` is MT-Safe, `sas1_set_*` modifies the global state and should be considered Unsafe.

sasl\_seterror(3SASL)

**NAME** sasl\_seterror – set the error string

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

void sasl_seterror(sasl_conn_t *conn, unsigned flags, const char
 *fmt, ...);
```

**DESCRIPTION** The sasl\_seterror() interface sets the error string that will be returned by sasl\_errdetail(3SASL). Use syslog(3C) style formatting, that is, use printf()—style with %m as the most recent errno error.

The sasl\_seterror() interface is primarily used by server callback functions and internal plug-ins, for example, with the sasl\_authorize\_t callback. The sasl\_seterror() interface triggers a call to the SASL logging callback, if any, with a level of SASL\_LOG\_FAIL, unless the SASL\_NOLOG flag is set.

Make the message string sensitive to the current language setting. If there is no SASL\_CB\_LANGUAGE callback, message strings must be i-default. Otherwise, UTF-8 is used. Use of RFC 2482 for mixed-language text is encouraged.

If the value of conn is NULL, the sasl\_seterror() interface fails.

**PARAMETERS** *conn* The sasl\_conn\_t for which the call to sasl\_seterror() applies.  
*flags* If set to SASL\_NOLOG, the call to sasl\_seterror() is not logged.  
*fmt* A syslog(3C) style format string.

**RETURN VALUES** sasl\_seterror() has no return values.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |
| MT-Level            | MT-Safe         |

Whistler, K. and Adams, G. RFC 2482, Language Tagging in Unicode Plain Text. Network Working Group. January 1999.

**NAME** sasl\_set\_mutex – set the mutex lock functions used by the SASL library

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

void sasl_set_mutex(sasl_mutex_alloc_t *a, sasl_mutex_lock_t *l,
 sasl_mutex_unlock_t *u, sasl_mutex_free_t *f);
```

**DESCRIPTION** Use the `sasl_set_mutex()` interface to set the mutex lock routines that the SASL library and plug-ins will use.

**PARAMETERS**

- a* A pointer to the mutex lock allocation function
- f* A pointer to the mutex free or destroy function
- l* A pointer to the mutex lock function
- u* A pointer to the mutex unlock function

**RETURN VALUES** `sasl_set_mutex()` has no return values.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Obsolete        |
| MT-Level            | Unsafe          |

**SEE ALSO** `attributes(5)`

**NOTES** While most of `libsasl` is MT-Safe, `sasl_set_*` modifies the global state and should be considered Unsafe.

## sasl\_setpass(3SASL)

**NAME** sasl\_setpass – set the password for a user

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

int sasl_setpass(sasl_conn_t *conn, const char *user, const char
 *pass, unsigned passlen, const char *oldpass, unsigned oldpasslen,
 unsigned flags);
```

**DESCRIPTION** Use the `sasl_setpass()` interface to set passwords. `sasl_setpass()` uses the `SASL_CB_SERVER_USERDB_SETPASS` callback, if one is supplied. Additionally, if any server mechanism plugins supply a `setpass` callback, the `setpass` callback would be called. None of the server mechanism plugins currently supply a `setpass` callback.

**PARAMETERS**

|                   |                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>conn</i>       | The SASL connection context                                                                                                                  |
| <i>user</i>       | The username for which the password is set                                                                                                   |
| <i>pass</i>       | The password to set                                                                                                                          |
| <i>passlen</i>    | The length of <i>pass</i>                                                                                                                    |
| <i>oldpass</i>    | The old password, which is optional                                                                                                          |
| <i>oldpasslen</i> | The length of <i>oldpass</i> , which is optional                                                                                             |
| <i>flags</i>      | Refers to flags, including, <code>SASL_SET_CREATE</code> and <code>SASL_SET_DISABLE</code> . Use these flags to create and disable accounts. |

**RETURN VALUES** `sasl_setpass()` returns an integer that corresponds to a SASL error code.

**ERRORS** `SASL_OK` The call to `sasl_setpass()` was successful.

See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

**NAME** sasl\_utf8verify – encode base64 string

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/saslutil.h>

int sasl_utf8verify(const char *str, unsigned len);
```

**DESCRIPTION** Use the `sasl_utf8verify()` interface to verify that a string is valid UTF-8 and does not contain NULL, a carriage return, or a linefeed. If `len == 0`, `strlen(str)` will be used.

**PARAMETERS**

*str*            A string

*len*            The length of the string

**RETURN VALUES** `sasl_utf8verify()` returns an integer that corresponds to a SASL error code.

**ERRORS**

SASL\_OK            The call to `sasl_utf8verify()` was successful.

SASL\_BADPROT      There was invalid UTF-8, or an error was found.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

## sasl\_verifyfile\_t(3SASL)

**NAME** | sasl\_verifyfile\_t – the SASL file verification callback function

**SYNOPSIS** | 

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

typedef enum {
 SASL_VRFY_PLUGIN, /* a DLL/shared library plugin */
 SASL_VRFY_CONF, /* a configuration file */
 SASL_VRFY_PASSWD, /* a password storage file */
 SASL_VRFY_OTHER /* some other file type */
} sasl_verify_ttype_t;

int sasl_verifyfile_t(void *context, const char *file,
 sasl_verify_ttype_t type);
```

**DESCRIPTION** | Use the sasl\_verifyfile\_t() callback function check whether a given file can be used by the SASL library. Applications use sasl\_verifyfile\_t() to check the environment to ensure that plugins or configuration files cannot be written to.

**PARAMETERS** | *context*            The context from the callback record  
*file*                    The full path of the file to verify  
*type*                    The type of the file

**RETURN VALUES** | Like other SASL callback functions, sasl\_verifyfile\_t() returns an integer that corresponds to a SASL error code. See <sasl.h> for a complete list of SASL error codes.

**ERRORS** | SASL\_OK                The call to sasl\_verifyfile\_t() was successful.  
See [sasl\\_errors\(3SASL\)](#) for information on SASL error codes.

**ATTRIBUTES** | See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |
| Interface Stability | Evolving        |

**NAME** sasl\_version – get SASL library version information

**SYNOPSIS**

```
cc [flag ...] file ... -lsasl [library ...]
#include <sasl/sasl.h>

void sasl_version(const char **implementation, int *version);
```

**DESCRIPTION** Use the sasl\_version() interface to obtain the version of the SASL library.

**PARAMETERS** *implementation* A vendor-defined string that describes the implementation. The value of *implementation* returned is Sun SASL.

*version* A vendor-defined representation of the version number.

**RETURN VALUES** The sasl\_version() interface has no return values.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlibsasl     |

| <b>DESCRIPTION</b>   | <p>The <code>sctp_bindx()</code> function adds or removes addresses to or from an SCTP socket. If <code>sock</code> is an Internet Protocol Version 4 (IPv4) socket, <code>addrs</code> should be an array of <code>sockaddr_in</code> structures containing IPv4 addresses. If <code>sock</code> is an Internet Protocol Version 6 (IPv6) socket, <code>addrs</code> should be an array of <code>sockaddr_in6</code> structures containing IPv6 or IPv4-mapped IPv6 addresses. The <code>addrcnt</code> is the number of array elements in <code>addrs</code>. The family of the address type is used with <code>addrcnt</code> to determine the size of the array.</p> <p>The <code>flags</code> parameter is a bitmask that indicates whether addresses are to be added or removed from a socket. The <code>flags</code> parameter is formed by bitwise OR of zero or more of the following flags:</p> <table><tr><td>SCTP_BINDX_ADD_ADDR</td><td>Indicates that addresses from <code>addrs</code> should be added to the SCTP socket.</td></tr><tr><td>SCTP_BINDX_REM_ADDR</td><td>Indicates that addresses from <code>addrs</code> should be removed from the SCTP socket.</td></tr></table> <p>These two flags are mutually exclusive. If <code>flags</code> is formed by a bitwise OR of both <code>SCTP_BINDX_ADD_ADDR</code> and <code>SCTP_BINDX_REM_ADDR</code>, the <code>sctp_bindx()</code> function will fail.</p> <p>Prior to calling <code>sctp_bindx()</code> on an SCTP endpoint, the endpoint should be bound using <code>bind(3SOCKET)</code>. On a listening socket, a special <code>INADDR_ANY</code> value for IP or an unspecified address of all zeros for IPv6 can be used in <code>addrs</code> to add all IPv4 or IPv6 addresses on the system to the socket. The <code>sctp_bindx()</code> function can also be used to add or remove addresses to or from an established association. In such a case, messages are exchanged between the SCTP endpoints to update the address lists for that association if both endpoints support dynamic address reconfiguration.</p> | SCTP_BINDX_ADD_ADDR | Indicates that addresses from <code>addrs</code> should be added to the SCTP socket. | SCTP_BINDX_REM_ADDR | Indicates that addresses from <code>addrs</code> should be removed from the SCTP socket. |
| SCTP_BINDX_ADD_ADDR  | Indicates that addresses from <code>addrs</code> should be added to the SCTP socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                     |                                                                                      |                     |                                                                                          |
| SCTP_BINDX_REM_ADDR  | Indicates that addresses from <code>addrs</code> should be removed from the SCTP socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                     |                                                                                      |                     |                                                                                          |
| <b>RETURN VALUES</b> | Upon successful completion, the <code>sctp_bindx()</code> function returns 0. Otherwise, the function returns -1 and sets <code>errno</code> to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                     |                                                                                      |                     |                                                                                          |
| <b>ERRORS</b>        | The <code>sctp_bindx()</code> call fails under the following conditions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                     |                                                                                      |                     |                                                                                          |

| <b>DESCRIPTION</b>   | <p>The sctp_getladdr() function queries addresses to which an SCTP socket is bound. The sctp_freeladdr() function releases resources that are allocated to hold the addresses.</p> <p>The sctp_getladdr() function returns all the locally bound addresses on the SCTP socket <i>sock</i>. On completion <i>addr</i> points to a dynamically allocated array of sockaddr_in structures for an Internet Protocol (IPv4) socket or an array of sockaddr_in6 structures for an Internet Protocol Version 6 (IPv6) socket. The <i>addr</i> parameter must not be NULL. For an IPv4 SCTP socket, the addresses returned in the sockaddr_in structures are IPv4 addresses. For an IPv6 SCTP socket, the addresses in the sockaddr_in6 structures can be IPv6 addresses or IPv4-mapped IPv6 addresses.</p> <p>If <i>sock</i> is a one-to-many style SCTP socket, <i>id</i> specifies the association of interest. A value of 0 to <i>id</i> returns locally-bound addresses regardless of a particular association. If <i>sock</i> is a one-to-one style SCTP socket, <i>id</i> is ignored.</p> <p>The sctp_freeladdr() function frees the resources allocated by sctp_getladdr(). The <i>addr</i> parameter is the array of addresses allocated by sctp_getladdr().</p> |
| <b>RETURN VALUES</b> | Upon successful completion, the sctp_getladdr() function returns the number of addresses in the <i>addr</i> array. Otherwise, the function returns -1 and sets <i>errno</i> to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ERRORS</b>        | The sctp_getladdr() call fails under the following conditions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>DESCRIPTION</b>   | <p>The sctp_getpaddrs() queries the peer addresses in an SCTP association. The sctp_freepaddrs() function releases resources that are allocated to hold the addresses.</p> <p>The sctp_getpaddrs() function returns all the peer addresses in the SCTP association identified by <i>sock</i>. On completion <i>addrs</i> points to a dynamically allocated array of sockaddr_in structures for an Internet Protocol (IPv4) socket or an array of sockaddr_in6 structures for an Internet Protocol Version 6 (IPv6) socket. The <i>addrs</i> parameter must not be NULL. For an IPv4 SCTP socket, the addresses returned in the sockaddr_in structures are IPv4 addresses. For an IPv6 SCTP socket, the addresses in the sockaddr_in6 structures can be IPv6 addresses or IPv4-mapped IPv6 addresses.</p> <p>If <i>sock</i> is a one-to-many style SCTP socket, <i>id</i> specifies the association of interest. If <i>sock</i> is a one-to-one style SCTP socket, <i>id</i> is ignored.</p> <p>The sctp_freepaddrs() function frees the resources allocated by sctp_getpaddrs(). The <i>addrs</i> parameter is the array of addresses allocated by sctp_getpaddrs().</p> |
| <b>RETURN VALUES</b> | Upon successful completion, the sctp_getpaddrs() function returns the number of addresses in the <i>addrs</i> array. Otherwise, the function returns -1 and sets errno to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ERRORS</b>        | The sctp_getpaddrs() succeeds unless one of the following conditions exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| EBADF                | The <i>sock</i> argument is an invalid file descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>                                 | sctp_opt_info – examine SCTP level options for an SCTP endpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                            |                                        |                           |                   |                       |                           |                       |                           |                            |                                        |                               |                                                  |                                             |                                  |
| <b>SYNOPSIS</b>                             | <pre>cc [ flag... ] file... -lsocket -lnsl -lsctp [ library... ] #include &lt;sys/types.h&gt; #include &lt;sys/socket.h&gt; #include &lt;netinet/sctp.h&gt;  int sctp_opt_info(int sock, sctp_assoc_t id, int opt, void *arg,                  socklen_t *len);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                            |                                        |                           |                   |                       |                           |                       |                           |                            |                                        |                               |                                                  |                                             |                                  |
| <b>DESCRIPTION</b>                          | <p>The <code>sctp_opt_info()</code> returns SCTP level options associated with the SCTP socket <code>sock</code>. If <code>sock</code> is a one-to-many style socket, <code>id</code> refers to the association of interest. If <code>sock</code> is a one-to-one socket or if <code>sock</code> is a branched-off one-to-many style socket, <code>id</code> is ignored. The <code>opt</code> parameter specifies the SCTP option to get. The <code>arg</code> structure is an option-specific structure buffer allocated by the caller. The <code>len</code> parameter is the length of the option specified.</p> <p>Following are the currently supported values for the <code>opt</code> parameter. When one of the options below specifies an association <code>id</code>, the <code>id</code> is relevant for only one-to-many style SCTP sockets. The association <code>id</code> can be ignored for one-to-one style or branched-off one-to-many style SCTP sockets.</p> <p><b>SCTP_RTOINFO</b></p> <p>Returns the protocol parameters used to initialize and bind retransmission timeout (RTO) tunable. The following structure is used to access these parameters:</p> <pre>struct sctp_rtoinfo {     sctp_assoc_t      srto_assoc_id;     uint32_t          srto_initial;     uint32_t          srto_max;     uint32_t          srto_min; };</pre> <p>where:</p> <table><tr><td><code>srto_assoc_id</code></td><td>Association ID specified by the caller</td></tr><tr><td><code>srto_initial</code></td><td>Initial RTO value</td></tr><tr><td><code>srto_max</code></td><td>Maximum value for the RTO</td></tr><tr><td><code>srto_min</code></td><td>Minimum value for the RTO</td></tr></table> <p><b>SSCTP_ASSOCINFO</b></p> <p>Returns association-specific parameters. The following structure is used to access the parameters:</p> <pre>struct sctp_assocparams {     sctp_assoc_t      sasoc_assoc_id;     uint16_t          sasoc_asocmaxrxt;     uint16_t          sasoc_number_peer_destinations;     uint32_t          sasoc_peer_rwnd;     uint32_t          sasoc_local_rwnd;     uint32_t          sasoc_cookie_life; };</pre> <p>where:</p> <table><tr><td><code>srto_assoc_id</code></td><td>Association ID specified by the caller</td></tr><tr><td><code>sasoc_asocmaxrxt</code></td><td>Maximum retransmission count for the association</td></tr><tr><td><code>sasoc_number_peer_destinations</code></td><td>Number of addresses the peer has</td></tr></table> | <code>srto_assoc_id</code> | Association ID specified by the caller | <code>srto_initial</code> | Initial RTO value | <code>srto_max</code> | Maximum value for the RTO | <code>srto_min</code> | Minimum value for the RTO | <code>srto_assoc_id</code> | Association ID specified by the caller | <code>sasoc_asocmaxrxt</code> | Maximum retransmission count for the association | <code>sasoc_number_peer_destinations</code> | Number of addresses the peer has |

| sasoc_cookie_life | Association cookie lifetime used when issuing cookies |

All parameters with time values are in milliseconds.

### SCTP\_DEFAULT\_SEND\_PARAM

Returns the default set of parameters used by the `sendto()` function on this association. The following structure is used to access the parameters:

```
struct sctp_sndrcvinfo {
 uint16_t sinfo_stream;
 uint16_t sinfo_ssn;
 uint16_t sinfo_flags;
 uint32_t sinfo_ppid;
 uint32_t sinfo_context;
 uint32_t sinfo_timetolive;
 uint32_t sinfo_tsn;
 uint32_t sinfo_cumtsn;
 sctp_assoc_t sinfo_assoc_id;
};
```

where:

| sinfo_timetolive | Time to live in milliseconds for a message on the sending side. The message expires if the sending side does not start the first transmission for the message within the specified time period. If the sending side starts the first transmission before the time period expires, the message is sent as a normal reliable message. A value of 0 indicates that the message does not expire. When <code>MSG_PR_SCTP</code> is set in <code>sinfo_flags</code> , the message expires if it is not acknowledged within the time period. |

| sinfo_assoc_id   | Association ID specified by the caller                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### SCTP\_PEER\_ADDR\_PARAMS

Returns the parameters for a specified peer address of the association. The following structure is used to access the parameters:

## sctp\_opt\_info(3SOCKET)

```
struct sctp_paddrparams {
 sctp_assoc_t spp_assoc_id;
 struct sockaddr_storage spp_address;
 uint32_t spp_hbinterval;
 uint16_t spp_pathmaxrxt;
};
where:
 spp_assoc_id Association ID specified by the caller
 spp_address Peer's address
 spp_hbinterval Heartbeat interval in milliseconds
 spp_pathmaxrxt Maximum number of retransmissions
 to an address before it is
 considered unreachable
```

### SCTP\_STATUS

Returns the current status information about the association. The following structure is used to access the parameters:

```
struct sctp_status {
 sctp_assoc_t sstat_assoc_id;
 int32_t sstat_state;
 uint32_t sstat_rwnd;
 uint16_t sstat_unackdata;
 uint16_t sstat_penddata;
 uint16_t sstat_instrms;
 uint16_t sstat_outstrms;
 uint16_t sstat_fragmentation_point;
 struct sctp_paddrinfo sstat_primary;
};
where:
 sstat_assoc_id Association ID specified by the caller
 sstat_state Current state of the association
 which might be one of the following:
 SCTP_IDLE
 SCTP_CLOSED
 SCTP_BOUND
 SCTP_LISTEN
 SCTP_COOKIE_WAIT
 SCTP_COOKIE_ECHOED
 SCTP_ESTABLISHED
 SCTP_SHUTDOWN_PENDING
 SCTP_SHUTDOWN_SEND
 SCTP_SHUTDOWN_RECEIVED
 SCTP_SHUTDOWN_ACK_SEND
 sstat_rwnd Current receive window of the
 association peer
 sstat_unackdata Number of unacked DATA chunks
 sstat_penddata Number of DATA chunks pending
 receipt
 sstat_instrms Number of inbound streams
 sstat_outstrms Number of outbound streams
 sstat_fragmentation_point
 Size at which SCTP fragmentation occurs
 sstat_primary Information about the primary
 peer address

 sstat_primary has the following structure
```

## sctp\_opt\_info(3SOCKET)

```

struct sctp_paddrinfo {
 sctp_assoc_t spinfo_assoc_id;
 struct sockaddr_storage spinfo_address;
 int32_t spinfo_state;
 uint32_t spinfo_cwnd;
 uint32_t spinfo_srtt;
 uint32_t spinfo_rto;
 uint32_t spinfo_mtu;
};

```

where:

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| spinfo_assoc_id | Association ID specified by the caller                                   |
| spinfo_address  | Primary peer address                                                     |
| spinfo_state    | State of the peer address:<br>SCTP_ACTIVE or<br>SCTP_INACTIVE            |
| spinfo_cwnd     | Congestion window of the peer address                                    |
| spinfo_srtt     | Smoothed round-trip time calculation of the peer address                 |
| spinfo_rto      | Current retransmission timeout value of the peer address in milliseconds |
| spinfo_mtu      | P-MTU of the address                                                     |

**RETURN VALUES** Upon successful completion, the `sctp_opt_info()` function returns 0. Otherwise, the function returns -1 and sets `errno` to indicate the error.

**ERRORS** The `sctp_opt_info()` call fails under the following conditions.

|              |                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------|
| EBADF        | The <i>sock</i> argument is an invalid file descriptor.                                                 |
| ENOTSOCK     | The <i>sock</i> argument is not a socket.                                                               |
| EINVAL       | The association <i>id</i> is invalid for a one-to-many style SCTP socket.                               |
| EINVAL       | The input buffer length is insufficient for the option specified.                                       |
| EINVAL       | The peer address is invalid or does not belong to the association.                                      |
| EAFNOSUPPORT | The address family for the peer's address is other than <code>AF_INET</code> or <code>AF_INET6</code> . |

| <b>NAME</b>          | sctp_peeloff – branch off existing association from a one-to-many Sctp socket to create a one-to-one Stp socket                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|---------------------|----------|----------|------|
| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lsocket -lnsl -lsctp [ library... ] #include &lt;sys/types.h&gt; #include &lt;sys/socket.h&gt; #include &lt;netinet/sctp.h&gt;  int sctp_peeloff(int sock, sctp_assoc_t id);</pre>                                                                                                                                                                                                        |                |                 |                     |          |          |      |
| <b>DESCRIPTION</b>   | <p>The sctp_peeloff() function branches off an existing association from a one-to-many style Sctp socket into a separate socket file descriptor. The resulting branched-off socket is a one-to-one style Sctp socket and is confined to operations allowed on a one-to-one style Sctp socket.</p> <p>The sock argument is a one-to-many socket. The association specified by the id argument is branched off sock.</p> |                |                 |                     |          |          |      |
| <b>RETURN VALUES</b> | Upon successful completion, the sctp_peeloff() function returns the file descriptor that references the branched-off socket. The function returns -1 if an error occurs.                                                                                                                                                                                                                                               |                |                 |                     |          |          |      |
| <b>ERRORS</b>        | <p>The sctp_peeloff() function fails under the following conditions.</p> <p>EOPTNOTSUPP      The sock argument is not a one-to-many style Sctp socket.</p> <p>EINVAL            The id is 0 or greater than the maximum number of associations for sock.</p> <p>EMFILE            Failure to create a new user file descriptor or file structure.</p>                                                                  |                |                 |                     |          |          |      |
| <b>ATTRIBUTES</b>    | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                        |                |                 |                     |          |          |      |

| <b>DESCRIPTION</b>   | <p>The sctp_send() function sends messages from one-to-one and one-to-many style SCTP endpoints. The following parameters can be set:</p> <p><i>s</i>                      Socket created by socket(3SOCKET)</p> <p><i>msg</i>                    Message to be sent</p> <p><i>len</i>                    Size of the message to be sent in bytes</p> <p>The caller completes the <i>sinfo</i> parameter with values used to send a message. Such values might include the stream number, payload protocol identifier, time to live, and the SCTP message flag and context. For a one-to-many socket, the association ID can be specified in the <i>sinfo</i> parameter to send a message to the association represented in the ID.</p> <p>Flags supported for sctp_send() are reserved for future use.</p>                                                                                                                                                                                                                                                          |
| <b>RETURN VALUES</b> | Upon successful completion, the sctp_send() function returns the number of bytes sent. The function returns -1 if an error occurs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ERRORS</b>        | <p>The sctp_send() function fails under the following conditions.</p> <p>EBADF                    The <i>s</i> argument is an invalid file descriptor.</p> <p>ENOTSOCK                The <i>s</i> argument is not a socket.</p> <p>EOPNOTSUPP              MSG_ABORT or MSG_EOF is set in the <i>sinfo_flags</i> field of <i>sinfo</i> for a one-to-one style SCTP socket.</p> <p>EPIPE                    The socket is shutting down and no more writes are allowed.</p> <p>EAGAIN                   The socket is non-blocking and the transmit queue is full.</p> <p>ENOTCONN                There is no established association.</p> <p>EINVAL                   Control message length is incorrect.</p> <p>EINVAL                   Specified destination address does not belong to the association.</p> <p>EINVAL                   The <i>stream_no</i> is outside the number of outbound streams supported by the association.</p> <p>EAFNOSUPPORT            Address family of the specified destination address is other than AF_INET or AF_INET6.</p> |

| <b>DESCRIPTION</b> | <p>The sctp_sendmsg() function sends a message from the SCTP endpoint <i>s</i>.</p> <p>In addition to specifying <i>msg</i> as the message buffer and <i>len</i> as the length of the buffer, the following parameters can be set:</p> <table><tr><td><i>to</i></td><td>Destination address</td></tr><tr><td><i>tolen</i></td><td>Length of the destination address</td></tr><tr><td><i>ppid</i></td><td>Application-specified payload protocol identifier</td></tr><tr><td><i>stream_no</i></td><td>Target stream for the message</td></tr><tr><td><i>timetolive</i></td><td>Time period in milliseconds after which the message expires if transmission for the message has not been started. A value of 0 indicates that the message does not expire. When the MSG_PR_SCTP flag is set the message expires, even if transmission has started, unless the entire message is transmitted within the <i>timetolive</i> period.</td></tr><tr><td><i>context</i></td><td>Value returned when an error occurs in sending a message</td></tr></table> <p>The <i>flags</i> parameter is formed from the bitwise OR of zero or more of the following flags:</p> <table><tr><td>MSG_UNORDERED</td><td>This flag requests un-ordered delivery of the message. If this flag is clear the message is considered an ordered send.</td></tr><tr><td>MSG_ADDR_OVER</td><td>In a one-to-many style SCTP socket, this flag requests that the address passed in <i>to</i> be used in lieu of the primary destination address of the association.</td></tr><tr><td>MSG_ABORT</td><td>When set, this flag causes the specified association to abort by sending an ABORT to the peer. The flag is used only for one-to-many style SCTP socket associations.</td></tr><tr><td>MSG_EOF</td><td>When set, this flag invokes a graceful shutdown on a specified association. The flag is used only for one-to-many style SCTP socket associations.</td></tr></table> | <i>to</i> | Destination address | <i>tolen</i> | Length of the destination address | <i>ppid</i> | Application-specified payload protocol identifier | <i>stream_no</i> | Target stream for the message | <i>timetolive</i> | Time period in milliseconds after which the message expires if transmission for the message has not been started. A value of 0 indicates that the message does not expire. When the MSG_PR_SCTP flag is set the message expires, even if transmission has started, unless the entire message is transmitted within the <i>timetolive</i> period. | <i>context</i> | Value returned when an error occurs in sending a message | MSG_UNORDERED | This flag requests un-ordered delivery of the message. If this flag is clear the message is considered an ordered send. | MSG_ADDR_OVER | In a one-to-many style SCTP socket, this flag requests that the address passed in <i>to</i> be used in lieu of the primary destination address of the association. | MSG_ABORT | When set, this flag causes the specified association to abort by sending an ABORT to the peer. The flag is used only for one-to-many style SCTP socket associations. | MSG_EOF | When set, this flag invokes a graceful shutdown on a specified association. The flag is used only for one-to-many style SCTP socket associations. |

| <i>timetolive</i>  | Time period in milliseconds after which the message expires if transmission for the message has not been started. A value of 0 indicates that the message does not expire. When the MSG_PR_SCTP flag is set the message expires, even if transmission has started, unless the entire message is transmitted within the <i>timetolive</i> period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |           |                     |              |                                   |             |                                                   |                  |                               |                   |                                                                                                                                                                                                                                                                                                                                                  |                |                                                          |               |                                                                                                                         |               |                                                                                                                                                                    |           |                                                                                                                                                                      |         |                                                                                                                                                   |
| <i>context</i>     | Value returned when an error occurs in sending a message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |           |                     |              |                                   |             |                                                   |                  |                               |                   |                                                                                                                                                                                                                                                                                                                                                  |                |                                                          |               |                                                                                                                         |               |                                                                                                                                                                    |           |                                                                                                                                                                      |         |                                                                                                                                                   |
| MSG_UNORDERED      | This flag requests un-ordered delivery of the message. If this flag is clear the message is considered an ordered send.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |           |                     |              |                                   |             |                                                   |                  |                               |                   |                                                                                                                                                                                                                                                                                                                                                  |                |                                                          |               |                                                                                                                         |               |                                                                                                                                                                    |           |                                                                                                                                                                      |         |                                                                                                                                                   |
| MSG_ADDR_OVER      | In a one-to-many style SCTP socket, this flag requests that the address passed in <i>to</i> be used in lieu of the primary destination address of the association.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |           |                     |              |                                   |             |                                                   |                  |                               |                   |                                                                                                                                                                                                                                                                                                                                                  |                |                                                          |               |                                                                                                                         |               |                                                                                                                                                                    |           |                                                                                                                                                                      |         |                                                                                                                                                   |
| MSG_ABORT          | When set, this flag causes the specified association to abort by sending an ABORT to the peer. The flag is used only for one-to-many style SCTP socket associations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                     |              |                                   |             |                                                   |                  |                               |                   |                                                                                                                                                                                                                                                                                                                                                  |                |                                                          |               |                                                                                                                         |               |                                                                                                                                                                    |           |                                                                                                                                                                      |         |                                                                                                                                                   |
| MSG_EOF            | When set, this flag invokes a graceful shutdown on a specified association. The flag is used only for one-to-many style SCTP socket associations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |           |                     |              |                                   |             |                                                   |                  |                               |                   |                                                                                                                                                                                                                                                                                                                                                  |                |                                                          |               |                                                                                                                         |               |                                                                                                                                                                    |           |                                                                                                                                                                      |         |                                                                                                                                                   |

sctp\_sendmsg(3SOCKET)

**MSG\_PR\_SCTP** This flag indicates that the message is treated as partially reliable. The message expires unless the entire message is successfully transmitted within the time period specified in the *timetolive* parameter.

**MSG\_PR\_SCTP** implements *timed reliability* service for SCTP messages. As yet, no common standard has been defined for the service and the interface is considered unstable.

**RETURN VALUES** Upon successful completion, the `sctp_sendmsg()` function returns the number of bytes sent. The function returns -1 if an error occurs.

**ERRORS** The `sctp_sendmsg()` function fails under the following conditions.

**EBADF** The *s* argument is an invalid file descriptor.

**ENOTSOCK** The *s* argument is not a socket.

**EOPNOTSUPP** **MSG\_OOB** is set as a *flag*.

**EOPNOTSUPP** **MSG\_ABORT** or **MSG\_EOF** is set on a one-to-one style SCTP socket.

**EPIPE** The socket is shutting down and no more writes are allowed.

**EAGAIN** The socket is non-blocking and the transmit queue is full.

**ENOTCONN** There is no established association.

**EINVAL** Control message length is incorrect.

**EINVAL** Specified destination address does not belong to the association.

**EAFNOSUPPORT** Address family of the specified destination address is other than **AF\_INET** or **AF\_INET6**.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Evolving        |
| MT-Level            | Safe            |

| <b>DESCRIPTION</b> | <p>The RPC library functions allow C programs to make procedure calls on other machines across the network.</p> <p>RPC supports various authentication flavors. Among them are:</p> <table><tr><td>AUTH_NONE</td><td>No authentication (none).</td></tr><tr><td>AUTH_SYS</td><td>Traditional UNIX-style authentication.</td></tr><tr><td>AUTH_DES</td><td>DES encryption-based authentication.</td></tr></table> <p>The <code>authdes_getucred()</code> and <code>authdes_seccreate()</code> functions implement the AUTH_DES authentication style. The keyserver daemon <code>keyserv(1M)</code> must be running for the AUTH_DES authentication system to work and <code>keylogin(1)</code> must have been run. The AUTH_DES style of authentication is discussed here. For information about the AUTH_NONE and AUTH_SYS flavors of authentication, refer to <a href="#">rpc_clnt_auth(3NSL)</a>. See <a href="#">rpc(3NSL)</a> for the definition of the AUTH data structure.</p>                           | AUTH_NONE | No authentication (none). | AUTH_SYS | Traditional UNIX-style authentication. | AUTH_DES | DES encryption-based authentication. |
| AUTH_NONE          | No authentication (none).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |           |                           |          |                                        |          |                                      |
| AUTH_SYS           | Traditional UNIX-style authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |           |                           |          |                                        |          |                                      |
| AUTH_DES           | DES encryption-based authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |           |                           |          |                                        |          |                                      |

The following functions documented on this page are MT-Safe. For the MT-levels of other authentication styles, see relevant man pages.

#### authdes\_getucred()

This is the first of two functions that interface to the RPC secure authentication system AUTH\_DES. The second is the `authdes_seccreate()` function. The `authdes_getucred()` function is used on the server side to convert an AUTH\_DES credential, which is operating system independent, to an AUTH\_SYS credential. The `authdes_getucred()` function returns 1 if it succeeds, 0 if it fails.

The `*uidp` parameter is set to the user's numerical ID associated with `adc`. The `*gidp` parameter is set to the numerical ID of the user's group. The `*gidlist` parameter contains the numerical IDs of the other groups to which the user belongs. The `*gidlenp` parameter is set to the number of valid group ID entries specified by the `*gidlist` parameter.

The `authdes_getucred()` function fails if the `authdes_cred` structure was created with the netname of a host. In such a case, `netname2host()` should be used to get the host name from the host netname in the `authdes_cred` structure.

#### authdes\_seccreate()

The second of two AUTH\_DES authentication functions, the `authdes_seccreate()` function is used on the client side to return an authentication handle that enables the use of the secure authentication system. The first field, `name`, specifies the network name `netname` of the owner of the server process. The field usually represents a hostname derived from the `host2netname()` utility, but the field might also represent a user name converted with the `user2netname()` utility.

The second field, `window`, specifies the validity of the client credential in seconds. If the difference in time between the client's clock and the server's clock exceeds `window`, the server rejects the client's credentials and the clock will have to be resynchronized. A small window is more secure than a large one, but choosing too small a window increases the frequency of resynchronization due to clock drift.

The third parameter, `timehost`, is the host's name and is optional. If `timehost` is NULL, the authentication system assumes that the local clock is always in sync with the `timehost` clock and does not attempt resynchronization. If a `timehost` is supplied, the system consults the remote time service whenever resynchronization is required. The `timehost` parameter is usually the name of the host on which the server is running.

The final parameter, `ckey`, is also optional. If `ckey` is NULL, the authentication system generates a random DES key to be used for the encryption of credentials. If `ckey` is supplied, it is used for encryption.

If `authdes_seccreate()` fails, it returns NULL.

#### getnetname()

This function returns the unique, operating system independent netname of the caller in the fixed-length array `name`. The function returns 1 if it succeeds and 0 if it fails.

## secure\_rpc(3NSL)

### host2netname()

This function converts a domain-specific hostname *host* to an operating system independent netname. The function returns 1 if it succeeds and 0 if it fails. The `host2netname()` function is the inverse of the `netname2host()` function. If the *domain* is NULL, `host2netname()` uses the default domain name of the machine. If *host* is NULL, it defaults to that machine itself. If *domain* is NULL and *host* is an NIS name such as `myhost.sun.example.com`, the `host2netname()` function uses the domain `sun.example.com` rather than the default domain name of the machine.

### key\_decryptsession()

This function is an interface to the keyserver daemon, which is associated with RPC's secure authentication system (AUTH\_DES authentication). User programs rarely need to call `key_decryptsession()` or the associated functions `key_encryptsession()`, `key_gendes()`, and `key_setsecret()`.

The `key_decryptsession()` function takes a server netname *remotename* and a DES key *deskey*, and decrypts the key by using the the public key of the server and the secret key associated with the effective UID of the calling process. The `key_decryptsession()` function is the inverse of `key_encryptsession()` function.

### key\_encryptsession()

This function is a keyserver interface that takes a server netname *remotename* and a DES key *deskey*, and encrypts the key using the public key of the server and the secret key associated with the effective UID of the calling process. If the keyserver does not have a key registered for the UID, it falls back to using the secret key for the netname *nobody* unless this feature has been disabled. See `keyserv(1M)`. The `key_encryptsession()` function is the inverse of `key_decryptsession()` function. The `key_encryptsession()` function returns 0 if it succeeds, -1 if it fails.

### key\_gendes()

This is a keyserver interface function used to ask the keyserver for a secure conversation key. Selecting a conversion key at random is generally not secure because the common ways of choosing random numbers are too easy to guess. The `key_gendes()` function returns 0 if it succeeds, -1 if it fails.

### key\_setsecret()

This is a keyserver interface function used to set the key for the effective UID of the calling process. This function returns 0 if it succeeds, -1 if it fails.

### key\_secretkey\_is\_set()

This is a keyserver interface function used to determine if a key has been set for the effective UID of the calling process. If the keyserver has a key stored for the effective UID of the calling process, the `key_secretkey_is_set()` function returns 1. Otherwise it returns 0.

### netname2host()

This function converts an operating system independent netname *name* to a domain-specific hostname *host*. The *hostlen* parameter is the maximum size of *host*.

The `netname2host()` function returns 1 if it succeeds and 0 if it fails. The function is the inverse of the `host2netname()` function.

#### `netname2user()`

This function converts an operating system independent netname to a domain-specific user ID. The `netname2user()` function returns 1 if it succeeds and 0 if it fails. The function is the inverse of the `user2netname()` function.

The `*uidp` parameter is set to the user's numerical ID associated with `name`. The `*gidp` parameter is set to the numerical ID of the user's group. The `gidlist` parameter contains the numerical IDs of the other groups to which the user belongs. The `*gidlenp` parameter is set to the number of valid group ID entries specified by the `gidlist` parameter.

#### `user2netname()`

This function converts a domain-specific username to an operating system independent netname. The `user2netname()` function returns 1 if it succeeds and 0 if it fails. The function is the inverse of `netname2user()` function.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

| <b>NAME</b>                | send, sendto, sendmsg – send a message from a socket                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                                                                                                                                                                                                                                                                      |                            |                                                                                                                                         |

| <b>DESCRIPTION</b>         | <p>The <code>send()</code>, <code>sendto()</code>, and <code>sendmsg()</code> functions are used to transmit a message to another transport end-point. The <code>send()</code> function can be used only when the socket is in a connected state. See <a href="#">connect(3SOCKET)</a>. The <code>sendto()</code> and <code>sendmsg()</code> functions can be used at any time. The <code>s</code> socket is created with <a href="#">socket(3SOCKET)</a>.</p> <p>The address of the target is supplied by <code>to</code> with a <code>tolen</code> parameter used to specify the size. The length of the message is supplied by the <code>len</code> parameter. For socket types such as <code>SOCK_DGRAM</code> and <code>SOCK_RAW</code> that require atomic messages, the error <code>EMSGSIZE</code> is returned and the message is not transmitted when it is too long to pass atomically through the underlying protocol. The same restrictions do not apply to <code>SOCK_STREAM</code> sockets.</p> <p>A return value <code>-1</code> indicates locally detected errors. It does not imply a delivery failure.</p> <p>If the socket does not have enough buffer space available to hold a message, the <code>send()</code> function blocks the message, unless the socket has been placed in non-blocking I/O mode (see <code>fcntl(2)</code>). The <code>select(3C)</code> or <code>poll(2)</code> call can be used to determine when it is possible to send more data.</p> <p>The <code>flags</code> parameter is formed from the bitwise OR of zero or more of the following:</p> <table><tr><td><code>MSG_OOB</code></td><td>Send <i>out-of-band</i> data on sockets that support this notion. The underlying protocol must also support <i>out-of-band</i> data. Only <code>SOCK_STREAM</code> sockets created in the <code>AF_INET</code> or the <code>AF_INET6</code> address family support out-of-band data.</td></tr><tr><td><code>MSG_DONTROUTE</code></td><td>The <code>SO_DONTROUTE</code> option is turned on for the duration of the operation. It is used only by diagnostic or routing programs.</td></tr></table> <p>See <a href="#">recv(3SOCKET)</a> for a description of the <code>msghdr</code> structure.</p> | <code>MSG_OOB</code> | Send <i>out-of-band</i> data on sockets that support this notion. | <b>RETURN VALUES</b>       | Upon successful completion, these functions return the number of bytes sent. Otherwise, they return <code>-1</code> and set <code>errno</code> to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                      |                                                                                                                                                                                                                                                                                      |                            |                                                                                                                                         |
| <b>ERRORS</b>              | The <code>send()</code> , <code>sendto()</code> , and <code>sendmsg()</code> functions return errors under the following conditions:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                                                                                                                                                                                                                                                                      |                            |                                                                                                                                         |

|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EINTR        | The operation was interrupted by delivery of a signal before any data could be buffered to be sent.                                                                                                                                            |
| EMSGSIZE     | The socket requires that the message be sent atomically and the message is too long.                                                                                                                                                           |
| ENOMEM       | Insufficient memory is available to complete the operation.                                                                                                                                                                                    |
| ENOSR        | Insufficient STREAMS resources are available for the operation to complete.                                                                                                                                                                    |
| ENOTSOCK     | <i>s</i> is not a socket.                                                                                                                                                                                                                      |
| EWOULDBLOCK  | The socket is marked non-blocking and the requested operation would block. EWOULDBLOCK is also returned when sufficient memory is not immediately available to allocate a suitable buffer. In such a case, the operation can be retried later. |
| ECONNREFUSED | The requested connection was refused by the peer. For connected IPv4 and IPv6 datagram sockets, this indicates that the system received an ICMP Destination Port Unreachable message from the peer in response to some prior transmission.     |

The `send()` and `sendto()` functions return errors under the following conditions:

|        |                                                            |
|--------|------------------------------------------------------------|
| EINVAL | The <i>len</i> argument overflows a <code>ssize_t</code> . |
|--------|------------------------------------------------------------|

The `sendto()` function returns errors under the following conditions:

|        |                                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------|
| EINVAL | The value specified for the <i>to</i> len parameter is not the size of a valid address for the specified address family. |
| EISCON | A destination address was specified and the socket is already connected.                                                 |

The `sendmsg()` function returns errors under the following conditions:

|        |                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EINVAL | The <code>msg_iovlen</code> member of the <code>msg_hdr</code> structure pointed to by <i>msg</i> is less than or equal to 0, or the sum of the <i>iov_len</i> values in the <code>msg_iov</code> array overflows a <code>ssize_t</code> .                         |
| EINVAL | One of the <i>iov_len</i> values in the <code>msg_iov</code> array member of the <code>msg_hdr</code> structure pointed to by <i>msg</i> is negative, or the sum of the <i>iov_len</i> values in the <code>msg_iov</code> array overflows a <code>ssize_t</code> . |

The `send()` function returns errors under the following conditions:

|       |                                                                                                                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EPIPE | The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, if the socket is of type <code>SOCK_STREAM</code> , the <code>SIGPIPE</code> signal is generated to the calling thread. |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

send(3SOCKET)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| MSG_OOB              | Sends out-of-band data on sockets that support out-of-band communications. The significance and semantics of out-of-band data are protocol-specific.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |               |                                                    |               |                                                                                                                                                      |               |                                               |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |         |                                                    |         |                                                                                                                                                      |
| <b>DESCRIPTION</b>   | <p>The <code>send()</code> function initiates transmission of a message from the specified socket to its peer. The <code>send()</code> function sends a message only when the socket is connected (including when the peer of a connectionless socket has been set via <a href="#">connect(3XNET)</a>).</p> <p>The length of the message to be sent is specified by the <i>length</i> argument. If the message is too long to pass through the underlying protocol, <code>send()</code> fails and no data is transmitted.</p> <p>Successful completion of a call to <code>send()</code> does not guarantee delivery of the message. A return value of <code>-1</code> indicates only locally-detected errors.</p> <p>If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have <code>O_NONBLOCK</code> set, <code>send()</code> blocks until space is available. If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does have <code>O_NONBLOCK</code> set, <code>send()</code> will fail. The <code>select(3C)</code> and <code>poll(2)</code> functions can be used to determine when it is possible to send more data.</p> <p>The socket in use may require the process to have appropriate privileges to use the <code>send()</code> function.</p> |               |                                                    |               |                                                                                                                                                      |               |                                               |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |         |                                                    |         |                                                                                                                                                      |
| <b>USAGE</b>         | The <code>send()</code> function is identical to <a href="#">sendto(3XNET)</a> with a null pointer <i>dest_len</i> argument, and to <code>write()</code> if no flags are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |               |                                                    |               |                                                                                                                                                      |               |                                               |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |         |                                                    |         |                                                                                                                                                      |
| <b>RETURN VALUES</b> | Upon successful completion, <code>send()</code> returns the number of bytes sent. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |               |                                                    |               |                                                                                                                                                      |               |                                               |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |         |                                                    |         |                                                                                                                                                      |

## send(3XNET)

### ERRORS

The `send()` function will fail if:

|              |                                                                                                                                                                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EAGAIN       |                                                                                                                                                                                                                                                   |
| EWOULDBLOCK  | The socket's file descriptor is marked <code>O_NONBLOCK</code> and the requested operation would block.                                                                                                                                           |
| EBADF        | The <i>socket</i> argument is not a valid file descriptor.                                                                                                                                                                                        |
| ECONNRESET   | A connection was forcibly closed by a peer.                                                                                                                                                                                                       |
| EDESTADDRREQ | The socket is not connection-mode and no peer address is set.                                                                                                                                                                                     |
| EFAULT       | The <i>buffer</i> parameter can not be accessed.                                                                                                                                                                                                  |
| EINTR        | A signal interrupted <code>send()</code> before any data was transmitted.                                                                                                                                                                         |
| EMSGSIZE     | The message is too large to be sent all at once, as the socket requires.                                                                                                                                                                          |
| ENOTCONN     | The socket is not connected or otherwise has not had the peer prespecified.                                                                                                                                                                       |
| ENOTSOCK     | The <i>socket</i> argument does not refer to a socket.                                                                                                                                                                                            |
| EOPNOTSUPP   | The <i>socket</i> argument is associated with a socket that does not support one or more of the values set in <i>flags</i> .                                                                                                                      |
| EPIPE        | The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type <code>SOCK_STREAM</code> , the <code>SIGPIPE</code> signal is generated to the calling thread. |

The `send()` function may fail if:

|             |                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------|
| EACCES      | The calling process does not have the appropriate privileges.                                   |
| EIO         | An I/O error occurred while reading from or writing to the file system.                         |
| ENETDOWN    | The local interface used to reach the destination is down.                                      |
| ENETUNREACH | No route to the network is present.                                                             |
| ENOBUFS     | Insufficient resources were available in the system to perform the operation.                   |
| ENOSR       | There were insufficient <code>STREAMS</code> resources available for the operation to complete. |

| <b>NAME</b>        | sendmsg – send a message on a socket using a message structure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>cc [ flag ... ] file ... -lxnet [ library ... ] #include &lt;sys/socket.h&gt;  ssize_t <b>sendmsg</b>(int <i>socket</i>, const struct msghdr *<i>message</i>, int <i>flags</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| <b>PARAMETERS</b>  | <p>The function takes the following arguments:</p> <table><tr><td><i>socket</i></td><td>Specifies the socket file descriptor.</td></tr><tr><td><i>message</i></td><td>Points to a <code>msghdr</code> structure, containing both the destination address and the buffers for the outgoing message. The length and format of the address depend on the address family of the socket. The <code>msg_flags</code> member is ignored.</td></tr><tr><td><i>flags</i></td><td>Specifies the type of message transmission. The application may specify 0 or the following flag:</td></tr><tr><td>MSG_EOR</td><td>Terminates a record (if supported by the protocol)</td></tr><tr><td>MSG_OOB</td><td>Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <i>socket</i> | Specifies the socket file descriptor. | <i>message</i> | Points to a <code>msghdr</code> structure, containing both the destination address and the buffers for the outgoing message. The length and format of the address depend on the address family of the socket. The <code>msg_flags</code> member is ignored. | <i>flags</i> | Specifies the type of message transmission. The application may specify 0 or the following flag: | MSG_EOR | Terminates a record (if supported by the protocol) | MSG_OOB | Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific. |
| <i>socket</i>      | Specifies the socket file descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| <i>message</i>     | Points to a <code>msghdr</code> structure, containing both the destination address and the buffers for the outgoing message. The length and format of the address depend on the address family of the socket. The <code>msg_flags</code> member is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| <i>flags</i>       | Specifies the type of message transmission. The application may specify 0 or the following flag:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| MSG_EOR            | Terminates a record (if supported by the protocol)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| MSG_OOB            | Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>sendmsg()</code> function sends a message through a connection-mode or connectionless-mode socket. If the socket is connectionless-mode, the message will be sent to the address specified by <code>msghdr</code>. If the socket is connection-mode, the destination address in <code>msghdr</code> is ignored.</p> <p>The <code>msg_iov</code> and <code>msg_iovlen</code> fields of message specify zero or more buffers containing the data to be sent. <code>msg_iov</code> points to an array of <code>iovec</code> structures; <code>msg_iovlen</code> must be set to the dimension of this array. In each <code>iovec</code> structure, the <code>iov_base</code> field specifies a storage area and the <code>iov_len</code> field gives its size in bytes. Some of these sizes can be zero. The data from each storage area indicated by <code>msg_iov</code> is sent in turn.</p> <p>Successful completion of a call to <code>sendmsg()</code> does not guarantee delivery of the message. A return value of <code>-1</code> indicates only locally-detected errors.</p> <p>If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have <code>O_NONBLOCK</code> set, <code>sendmsg()</code> function blocks until space is available. If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does have <code>O_NONBLOCK</code> set, <code>sendmsg()</code> function will fail.</p> <p>If the socket protocol supports broadcast and the specified address is a broadcast address for the socket protocol, <code>sendmsg()</code> will fail if the <code>SO_BROADCAST</code> option is not set for the socket.</p> |               |                                       |                |                                                                                                                                                                                                                                                             |              |                                                                                                  |         |                                                    |         |                                                                                                                                            |

| <b>DESCRIPTION</b> | <p>The <code>sendto()</code> function sends a message through a connection-mode or connectionless-mode socket. If the socket is connectionless-mode, the message will be sent to the address specified by <code>dest_addr</code>. If the socket is connection-mode, <code>dest_addr</code> is ignored.</p> <p>If the socket protocol supports broadcast and the specified address is a broadcast address for the socket protocol, <code>sendto()</code> will fail if the <code>SO_BROADCAST</code> option is not set for the socket.</p> <p>The <code>dest_addr</code> argument specifies the address of the target. The <code>length</code> argument specifies the length of the message.</p> <p>Successful completion of a call to <code>sendto()</code> does not guarantee delivery of the message. A return value of <code>-1</code> indicates only locally-detected errors.</p> <p>If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have <code>O_NONBLOCK</code> set, <code>sendto()</code> blocks until space is available. If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does have <code>O_NONBLOCK</code> set, <code>sendto()</code> will fail.</p> <p>The socket in use may require the process to have appropriate privileges to use the <code>sendto()</code> function.</p> |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |
| <b>PARAMETERS</b>  | <p>The function takes the following arguments:</p> <table><tr><td><i>socket</i></td><td>Specifies the socket file descriptor.</td></tr><tr><td><i>message</i></td><td>Points to a buffer containing the message to be sent.</td></tr><tr><td><i>length</i></td><td>Specifies the size of the message in bytes.</td></tr><tr><td><i>flags</i></td><td>Specifies the type of message transmission. Values of this argument are formed by logically OR'ing zero or more of the following flags:</td></tr><tr><td>MSG_EOR</td><td>Terminates a record (if supported by the protocol)</td></tr><tr><td>MSG_OOB</td><td>Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <i>socket</i> | Specifies the socket file descriptor. | <i>message</i> | Points to a buffer containing the message to be sent. | <i>length</i> | Specifies the size of the message in bytes. | <i>flags</i> | Specifies the type of message transmission. Values of this argument are formed by logically OR'ing zero or more of the following flags: | MSG_EOR | Terminates a record (if supported by the protocol) | MSG_OOB | Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific. |
| <i>socket</i>      | Specifies the socket file descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |
| <i>message</i>     | Points to a buffer containing the message to be sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |
| <i>length</i>      | Specifies the size of the message in bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |
| <i>flags</i>       | Specifies the type of message transmission. Values of this argument are formed by logically OR'ing zero or more of the following flags:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |
| MSG_EOR            | Terminates a record (if supported by the protocol)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |
| MSG_OOB            | Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |               |                                       |                |                                                       |               |                                             |              |                                                                                                                                         |         |                                                    |         |                                                                                                                                            |

|                      |                                                 |                                                                                                                                                                                                                                                   |

|                      | <i>dest_addr</i>                                | Points to a <code>sockaddr</code> structure containing the destination address. The length and format of the address depend on the address family of the socket.                                                                                  |
|                      | <i>dest_len</i>                                 | Specifies the length of the <code>sockaddr</code> structure pointed to by the <i>dest_addr</i> argument.                                                                                                                                          |
| <b>USAGE</b>         |                                                 | The <code>select(3C)</code> and <code>poll(2)</code> functions can be used to determine when it is possible to send more data.                                                                                                                    |
| <b>RETURN VALUES</b> |                                                 | Upon successful completion, <code>sendto()</code> returns the number of bytes sent. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.                                                                   |
| <b>ERRORS</b>        |                                                 | The <code>sendto()</code> function will fail if:                                                                                                                                                                                                  |
|                      | <code>EAFNOSUPPORT</code>                       | Addresses in the specified address family cannot be used with this socket.                                                                                                                                                                        |
|                      | <code>EAGAIN</code><br><code>EWouldBlock</code> | The socket's file descriptor is marked <code>O_NONBLOCK</code> and the requested operation would block.                                                                                                                                           |
|                      | <code>EBADF</code>                              | The <i>socket</i> argument is not a valid file descriptor.                                                                                                                                                                                        |
|                      | <code>ECONNRESET</code>                         | A connection was forcibly closed by a peer.                                                                                                                                                                                                       |
|                      | <code>EFAULT</code>                             | The <i>message</i> or <i>destaddr</i> parameter cannot be accessed.                                                                                                                                                                               |
|                      | <code>EINTR</code>                              | A signal interrupted <code>sendto()</code> before any data was transmitted.                                                                                                                                                                       |
|                      | <code>EMSGSIZE</code>                           | The message is too large to be sent all at once, as the socket requires.                                                                                                                                                                          |
|                      | <code>ENOTCONN</code>                           | The socket is connection-mode but is not connected.                                                                                                                                                                                               |
|                      | <code>ENOTSOCK</code>                           | The <i>socket</i> argument does not refer to a socket.                                                                                                                                                                                            |
|                      | <code>EOPNOTSUPP</code>                         | The <i>socket</i> argument is associated with a socket that does not support one or more of the values set in <i>flags</i> .                                                                                                                      |
|                      | <code>EPIPE</code>                              | The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type <code>SOCK_STREAM</code> , the <code>SIGPIPE</code> signal is generated to the calling thread. |
|                      |                                                 | If the address family of the socket is <code>AF_UNIX</code> , then <code>sendto()</code> will fail if:                                                                                                                                            |
|                      | <code>EIO</code>                                | An I/O error occurred while reading from or writing to the file system.                                                                                                                                                                           |
|                      | <code>ELOOP</code>                              | Too many symbolic links were encountered in translating the pathname in the socket address.                                                                                                                                                       |

| <b>DESCRIPTION</b>        | <p>The <code>setsockopt()</code> function sets the option specified by the <code>option_name</code> argument, at the protocol level specified by the <code>level</code> argument, to the value pointed to by the <code>option_value</code> argument for the socket associated with the file descriptor specified by the <code>socket</code> argument.</p> <p>The <code>level</code> argument specifies the protocol level at which the option resides. To set options at the socket level, specify the <code>level</code> argument as <code>SOL_SOCKET</code>. To set options at other levels, supply the appropriate protocol number for the protocol controlling the option. For example, to indicate that an option will be interpreted by the TCP (Transport Control Protocol), set <code>level</code> to the protocol number of TCP, as defined in the <code>&lt;netinet/in.h&gt;</code> header, or as determined by using <code>getprotobyname(3XNET)</code>.</p> <p>The <code>option_name</code> argument specifies a single option to set. The <code>option_name</code> argument and any specified options are passed uninterpreted to the appropriate protocol module for interpretations. The <code>&lt;sys/socket.h&gt;</code> header defines the socket level options. The options are as follow</p> <table><tr><td><code>SO_DEBUG</code></td><td>Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an <code>int</code> value. This is a boolean option.</td></tr><tr><td><code>SO_BROADCAST</code></td><td>Permits sending of broadcast messages, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option.</td></tr><tr><td><code>SO_REUSEADDR</code></td><td>Specifies that the rules used in validating addresses supplied to <code>bind(3XNET)</code> should allow reuse of local addresses, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option.</td></tr><tr><td><code>SO_KEEPALIVE</code></td><td>Keeps connections active by enabling the periodic transmission of messages, if this is supported by the protocol. This option takes an <code>int</code> value.</td></tr><tr><td></td><td>If the connected socket fails to respond to these messages, the connection is broken and threads writing to that socket are notified with a <code>SIGPIPE</code> signal.</td></tr><tr><td></td><td>This is a boolean option.</td></tr><tr><td><code>SO_LINGER</code></td><td>Lingers on a <code>close(2)</code> if data is present. This option controls the action taken when unsent messages queue on a socket and <code>close(2)</code> is performed. If <code>SO_LINGER</code></td></tr></table> | <code>SO_DEBUG</code> | Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an <code>int</code> value. This is a boolean option. | <code>SO_BROADCAST</code> | Permits sending of broadcast messages, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option. | <code>SO_REUSEADDR</code> | Specifies that the rules used in validating addresses supplied to <code>bind(3XNET)</code> should allow reuse of local addresses, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option. | <code>SO_KEEPALIVE</code> | Keeps connections active by enabling the periodic transmission of messages, if this is supported by the protocol. This option takes an <code>int</code> value. |  | If the connected socket fails to respond to these messages, the connection is broken and threads writing to that socket are notified with a <code>SIGPIPE</code> signal. |  | This is a boolean option. | <code>SO_LINGER</code> | Lingers on a <code>close(2)</code> if data is present. This option controls the action taken when unsent messages queue on a socket and <code>close(2)</code> is performed. If <code>SO_LINGER</code> |
| <code>SO_DEBUG</code>     | Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an <code>int</code> value. This is a boolean option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                       |                                                                                                                                                                                                   |                           |                                                                                                                                                     |                           |                                                                                                                                                                                                                                                |                           |                                                                                                                                                                |  |                                                                                                                                                                          |  |                           |                        |                                                                                                                                                                                                       |
| <code>SO_BROADCAST</code> | Permits sending of broadcast messages, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                       |                                                                                                                                                                                                   |                           |                                                                                                                                                     |                           |                                                                                                                                                                                                                                                |                           |                                                                                                                                                                |  |                                                                                                                                                                          |  |                           |                        |                                                                                                                                                                                                       |
| <code>SO_REUSEADDR</code> | Specifies that the rules used in validating addresses supplied to <code>bind(3XNET)</code> should allow reuse of local addresses, if this is supported by the protocol. This option takes an <code>int</code> value. This is a boolean option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                                                                                                                                                                                                   |                           |                                                                                                                                                     |                           |                                                                                                                                                                                                                                                |                           |                                                                                                                                                                |  |                                                                                                                                                                          |  |                           |                        |                                                                                                                                                                                                       |
| <code>SO_KEEPALIVE</code> | Keeps connections active by enabling the periodic transmission of messages, if this is supported by the protocol. This option takes an <code>int</code> value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                                                                                                                                                                                                   |                           |                                                                                                                                                     |                           |                                                                                                                                                                                                                                                |                           |                                                                                                                                                                |  |                                                                                                                                                                          |  |                           |                        |                                                                                                                                                                                                       |
|                           | If the connected socket fails to respond to these messages, the connection is broken and threads writing to that socket are notified with a <code>SIGPIPE</code> signal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                                                                                                   |                           |                                                                                                                                                     |                           |                                                                                                                                                                                                                                                |                           |                                                                                                                                                                |  |                                                                                                                                                                          |  |                           |                        |                                                                                                                                                                                                       |

| <code>SO_LINGER</code>    | Lingers on a <code>close(2)</code> if data is present. This option controls the action taken when unsent messages queue on a socket and <code>close(2)</code> is performed. If <code>SO_LINGER</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                       |                                                                                                                                                                                                   |                           |                                                                                                                                                     |                           |                                                                                                                                                                                                                                                |                           |                                                                                                                                                                |  |                                                                                                                                                                          |  |                           |                        |                                                                                                                                                                                                       |

## setsockopt(3XNET)

is set, the system blocks the process during `close(2)` until it can transmit the data or until the time expires. If `SO_LINGER` is not specified, and `close(2)` is issued, the system handles the call in a way that allows the process to continue as quickly as possible. This option takes a `linger` structure, as defined in the `<sys/socket.h>` header, to specify the state of the option and linger interval.

|                           |                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>SO_OOBINLINE</code> | Leaves received out-of-band data (data marked urgent) in line. This option takes an <code>int</code> value. This is a boolean option.                                                                                                                                                                                                                                               |
| <code>SO_SNDBUF</code>    | Sets send buffer size. This option takes an <code>int</code> value.                                                                                                                                                                                                                                                                                                                 |
| <code>SO_RCVBUF</code>    | Sets receive buffer size. This option takes an <code>int</code> value.                                                                                                                                                                                                                                                                                                              |
| <code>SO_DONTROUTE</code> | Requests that outgoing messages bypass the standard routing facilities. The destination must be on a directly-connected network, and messages are directed to the appropriate network interface according to the destination address. The effect, if any, of this option depends on what protocol is in use. This option takes an <code>int</code> value. This is a boolean option. |

For boolean options, 0 indicates that the option is disabled and 1 indicates that the option is enabled.

Options at other protocol levels vary in format and name.

**USAGE** The `setsockopt()` function provides an application program with the means to control socket behavior. An application program can use `setsockopt()` to allocate buffer space, control timeouts, or permit socket data broadcasts. The `<sys/socket.h>` header defines the socket-level options available to `setsockopt()`.

Options may exist at multiple protocol levels. The `SO_` options are always present at the uppermost socket level.

**RETURN VALUES** Upon successful completion, `setsockopt()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

**ERRORS** The `setsockopt()` function will fail if:

|                     |                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <code>EBADF</code>  | The <i>socket</i> argument is not a valid file descriptor.                                              |
| <code>EDOM</code>   | The send and receive timeout values are too big to fit into the timeout fields in the socket structure. |
| <code>EFAULT</code> | The <i>option_value</i> parameter can not be accessed or written.                                       |

## setsockopt(3XNET)

|             |                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------|
| EINVAL      | The specified option is invalid at the specified socket level or the socket has been shut down.       |
| EISCONN     | The socket is already connected, and a specified option can not be set while the socket is connected. |
| ENOPROTOOPT | The option is not supported by the protocol.                                                          |
| ENOTSOCK    | The <i>socket</i> argument does not refer to a socket.                                                |

The `setsockopt()` function may fail if:

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| ENOMEM  | There was insufficient memory available for the operation to complete.             |
| ENOBUFS | Insufficient resources are available in the system to complete the call.           |
| ENOSR   | There were insufficient STREAMS resources available for the operation to complete. |

| <b>SYNOPSIS</b>      | <pre>cc [ flag... ] file... -lsocket -lnsl [ library... ] #include &lt;sys/socket.h&gt;  int shutdown(int s, int how);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                                    |          |                                                                      |       |                                                                             |          |                                        |          |                                     |
| <b>DESCRIPTION</b>   | <p>The shutdown() call shuts down all or part of a full-duplex connection on the socket associated with <i>s</i>. If <i>how</i> is SHUT_RD, further receives are disallowed. If <i>how</i> is SHUT_WR, further sends are disallowed. If <i>how</i> is SHUT_RDWR, further sends and receives are disallowed.</p> <p>The <i>how</i> values should be defined constants.</p>                                                                                                                                                                                                                             |                |                                                    |          |                                                                      |       |                                                                             |          |                                        |          |                                     |
| <b>RETURN VALUES</b> | <p>0 is returned if the call succeeds.</p> <p>-1 is returned if the call fails.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                                    |          |                                                                      |       |                                                                             |          |                                        |          |                                     |
| <b>ERRORS</b>        | <p>The call succeeds unless one of the following conditions exists:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EBADF</td> <td>The <i>s</i> value is not a valid file descriptor.</td> </tr> <tr> <td>ENOMEM</td> <td>Insufficient user memory is available for the operation to complete.</td> </tr> <tr> <td>ENOSR</td> <td>Insufficient STREAMS resources are available for the operation to complete.</td> </tr> <tr> <td>ENOTCONN</td> <td>The specified socket is not connected.</td> </tr> <tr> <td>ENOTSOCK</td> <td>The <i>s</i> value is not a socket.</td> </tr> </table> | EBADF          | The <i>s</i> value is not a valid file descriptor. | ENOMEM   | Insufficient user memory is available for the operation to complete. | ENOSR | Insufficient STREAMS resources are available for the operation to complete. | ENOTCONN | The specified socket is not connected. | ENOTSOCK | The <i>s</i> value is not a socket. |

| <b>DESCRIPTION</b>   | The shutdown() function disables subsequent send() and receive() operations on a socket, depending on the value of the how argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                                                            |                     |                                     |           |                                               |          |                                                        |         |                                                                               |       |                                                                                    |

| <b>DESCRIPTION</b>                  | <p>The <code>slp_api</code> is a C language binding that maps directly into the Service Location Protocol (“SLP”) defined by <i>RFC 2614</i>. This implementation requires minimal overhead. With the exception of the <code>SLPDereg()</code> and <code>SLPDelAttrs()</code> functions, which map into different uses of the SLP deregister request, there is one C language function per protocol request. Parameters are for the most part character buffers. Memory management is kept simple because the client allocates most memory and client callback functions are required to copy incoming parameters into memory allocated by the client code. Any memory returned directly from the API functions is deallocated using the <code>SLPFree()</code> function.</p> <p>To conform with standard C practice, all character strings passed to and returned through the API are null-terminated, even though the SLP protocol does not use null-terminated strings. Strings passed as parameters are UTF-8 but they may still be passed as a C string (a null-terminated sequence of bytes.) Escaped characters must be encoded by the API client as UTF-8. In the common case of US-ASCII, the usual one byte per character C strings work. API functions assist in escaping and unescaping strings.</p> <p>Unless otherwise noted, parameters to API functions and callbacks are non-NULL. Some parameters may have other restrictions. If any parameter fails to satisfy the restrictions on its value, the operation returns a <code>PARAMETER_BAD</code> error.</p> |
| <b>Syntax for String Parameters</b> | <p>Query strings, attribute registration lists, attribute deregistration lists, scope lists, and attribute selection lists follow the syntax described in <i>RFC 2608</i>. The API reflects the strings passed from clients directly into protocol requests, and reflects out strings returned from protocol replies directly to clients. As a consequence, clients are responsible for formatting request strings, including escaping and converting opaque values to escaped byte-encoded strings. Similarly, on output, clients are required to unescape strings and convert escaped string-encoded opaques to binary. The <code>SLPEscape()</code> and <code>SLPUnescape()</code> functions can be used for escaping SLP reserved characters, but they perform no opaque processing.</p> <p>Opaque values consist of a character buffer that contains a UTF-8-encoded string, the first characters of which are the non UTF-8 encoding “<code>\xff</code>”. Subsequent characters are the escaped values for the original bytes in the opaque. The escape convention is relatively simple. An escape consists of a backslash followed by the two hexadecimal digits encoding the byte. An example is “<code>\2c</code>” for the byte <code>0x2c</code>. Clients handle opaque processing themselves, since the algorithm is relatively simple and uniform.</p>                                                                                                                                                                                                              |
| <b>System Properties</b>            | <p>The system properties established in <code>slp.conf(4)</code>, the configuration file, are accessible through the <code>SLPGetProperty()</code> and <code>SLPSetProperty()</code> functions. The <code>SLPSetProperty()</code> function modifies properties only in the running process, not in the configuration file. Errors are checked when the property is used and, as with parsing the configuration file, are logged at the <code>LOG_INFO</code> priority. Program execution continues without interruption by substituting the default for the erroneous</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

slp\_api(3SLP)

parameter. In general, individual agents should rarely be required to override these properties, since they reflect properties of the SLP network that are not of concern to individual agents. If changes are required, system administrators should modify the configuration file.

Properties are global to the process, affecting all threads and all handles created with `SLPOpen()`.

### Memory Management

The only API functions that return memory specifically requiring deallocation on the part of the client are `SLPParseSrvURL()`, `SLPFindScope()`, `SLPEscape()`, and `SLPUnescape()`. Free this memory with `SLPFree()` when it is no longer needed. Do not free character strings returned by means of the `SLPGetProperty()` function.

Any memory passed to callbacks belongs to the library, and it must not be retained by the client code. Otherwise, crashes are possible. Clients must copy data out of the callback parameters. No other use of the memory in callback parameters is allowed.

### Asynchronous and Incremental Return Semantics

If a handle parameter to an API function is opened asynchronously, the API function calls on the handle to check the other parameters, opens the appropriate operation, and returns immediately. If an error occurs in the process of starting the operation, the error code is returned. If the handle parameter is opened synchronously, the function call is blocked until all results are available, and it returns only after the results are reported through the callback function. The return code indicates whether any errors occurred during the operation.

The callback function is called whenever the API library has results to report. The callback code is required to check the error code parameter before looking at the other parameters. If the error code is not `SLP_OK`, the other parameters may be `NULL` or otherwise invalid. The API library can terminate any outstanding operation on which an error occurs. The callback code can similarly indicate that the operation should be terminated by passing back `SLP_FALSE` to indicate that it is not interested in receiving more results. Callback functions are not permitted to recursively call into the API on the same `SLPHandle`. If an attempt is made to call into the API, the API function returns `SLP_HANDLE_IN_USE`. Prohibiting recursive callbacks on the same handle simplifies implementation of thread safe code, since locks held on the handle will not be in place during a second outcall on the handle.

The total number of results received can be controlled by setting the `net.slp.maxResults` parameter.

On the last call to a callback, whether asynchronous or synchronous, the status code passed to the callback has value `SLP_LAST_CALL`. There are four reasons why the call can terminate:

DA reply received

A reply from a DA has been received and therefore nothing more is expected.

Multicast terminated

The multicast convergence time has elapsed and the API library multicast code is giving up.

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                 |

|                            | <p>Multicast null results</p> <p>Maximum results</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <p>Nothing new has been received during multicast for awhile and the API library multicast code is giving up on that (as an optimization).</p> <p>The user has set the <code>net.slp.maxResults</code> property and that number of replies has been collected and returned.</p> |
| <b>Configuration Files</b> | <p>The API library reads <code>slp.conf(4)</code>, the default configuration file, to obtain the operating parameters. You can specify the location of this file with the <code>SLP_CONF_FILE</code> environment variable. If you do not set this variable, or the file it refers to is invalid, the API will use the default configuration file at <code>/etc/inet/slp.conf</code> instead.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                 |
| <b>Data Structures</b>     | <p>The data structures used by the SLP API are as follows:</p> <p><b>The URL Lifetime Type</b></p> <pre>typedef enum {     SLP_LIFETIME_DEFAULT = 10800,     SLP_LIFETIME_MAXIMUM = 65535 } SLPURLLifetime;</pre> <p>The enumeration <code>SLPURLLifetime</code> contains URL lifetime values, in seconds, that are frequently used. <code>SLP_LIFETIME_DEFAULT</code> is 3 hours, while <code>SLP_LIFETIME_MAXIMUM</code> is 18 hours, which corresponds to the maximum size of the lifetime field in SLP messages. Note that on registration <code>SLP_LIFETIME_MAXIMUM</code> causes the advertisement to be continually reregistered until the process exits.</p> <p><b>The SLPBoolean Type</b></p> <pre>typedef enum {     SLP_FALSE = 0,     SLP_TRUE = 1 } SLPBoolean;</pre> <p>The enumeration <code>SLPBoolean</code> is used as a Boolean flag.</p> <p><b>The Service URL Structure</b></p> <pre>typedef struct srvurl {     char *s_pcSrvType;     char *s_pcHost;     int s_iPort;     char *s_pcNetFamily;     char *s_pcSrvPart; } SLPsrvURL;</pre> <p>The <code>SLPsrvURL</code> structure is filled in by the <code>SLPParseSrvURL()</code> function with information parsed from a character buffer containing a service URL. The fields correspond to different parts of the URL, as follows:</p> |                                                                                                                                                                                                                                                                                 |

## slp\_api(3SLP)

|                            |                                                                                                                                                                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>s_pcSrvType</code>   | A pointer to a character string containing the service type name, including naming authority.                                                                                                                                             |
| <code>s_pcHost</code>      | A pointer to a character string containing the host identification information.                                                                                                                                                           |
| <code>s_iPort</code>       | The port number, or zero, if none. The port is only available if the transport is IP.                                                                                                                                                     |
| <code>s_pcNetFamily</code> | A pointer to a character string containing the network address family identifier. Possible values are "ipx" for the IPX family, "at" for the Appletalk family, and "", the empty string, for the IP address family.                       |
| <code>s_pcSrvPart</code>   | The remainder of the URL, after the host identification.<br><br>The host and port should be sufficient to open a socket to the machine hosting the service; the remainder of the URL should allow further differentiation of the service. |

### The SLPHandle

```
typedef void* SLPHandle;
```

The `SLPHandle` type is returned by `SLPOpen()` and is a parameter to all SLP functions. It serves as a handle for all resources allocated on behalf of the process by the SLP library. The type is opaque.

### Callbacks

Include a function pointer to a callback function specific to a particular API operation in the parameter list when the API function is invoked. The callback function is called with the results of the operation in both the synchronous and asynchronous cases. When the callback function is invoked, the memory included in the callback parameters is owned by the API library, and the client code in the callback must copy out the contents if it wants to maintain the information longer than the duration of the current callback call.

Each callback parameter list contains parameters for reporting the results of the operation, as well as an error code parameter and a cookie parameter. The error code parameter reports the error status of the ongoing (for asynchronous) or completed (for synchronous) operation. The cookie parameter allows the client code that starts the operation by invoking the API function to pass information down to the callback without using global variables. The callback returns an `SLPBoolean` to indicate whether the API library should continue processing the operation. If the value returned from the callback is `SLP_TRUE`, asynchronous operations are terminated. Synchronous operations ignore the return since the operation is already complete.

### SLPRegReport()

```
typedef void SLPRegReport(SLPHandle hSLP,
 SLPError errCode,
 void *pvCookie);
```

`SLPRegReport()` is the callback function to the `SLPReg()`, `SLPDereg()`, and `SLPDelAttrs()` functions. The `SLPRegReport()` callback has the following parameters:

|                 |                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>hSLP</i>     | The <code>SLPHandle()</code> used to initiate the operation.                                                                         |
| <i>errCode</i>  | An error code indicating if an error occurred during the operation.                                                                  |
| <i>pvCookie</i> | Memory passed down from the client code that called the original API function, starting the operation. It may be <code>NULL</code> . |

#### **SLPSrvTypeCallback()**

```
typedef SLPBoolean SLPsrvTypeCallback(SLPHandle hSLP,
 const char* pcSrvTypes,
 SLPError errCode,
 void *pvCookie);
```

The `SLPSrvTypeCallback()` type is the type of the callback function parameter to the `SLPFindSrvTypes()` function. The results are collated when the *hSLP* handle is opened either synchronously or asynchronously. The `SLPSrvTypeCallback()` callback has the following parameters:

|                   |                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hSLP</i>       | The <code>SLPHandle</code> used to initiate the operation.                                                                                                                                                                                                                    |
| <i>pcSrvTypes</i> | A character buffer containing a comma-separated, null-terminated list of service types.                                                                                                                                                                                       |
| <i>errCode</i>    | An error code indicating if an error occurred during the operation. The callback should check this error code before processing the parameters. If the error code is other than <code>SLP_OK</code> , then the API library may choose to terminate the outstanding operation. |
| <i>pvCookie</i>   | Memory passed down from the client code that called the original API function, starting the operation. It can be <code>NULL</code> .                                                                                                                                          |

#### **SLPSrvURLCallback**

```
typedef SLPBoolean SLPsrvURLCallback(SLPHandle hSLP,
 const char* pcSrvURL,
 unsigned short usLifetime,
 SLPError errCode,
 void *pvCookie);
```

The `SLPSrvURLCallback()` type is the type of the callback function parameter to the `SLPFindSrvs()` function. The results are collated, regardless of whether the *hSLP* was opened collated or uncollated. The `SLPSrvURLCallback()` callback has the following parameters:

|                 |                                                            |
|-----------------|------------------------------------------------------------|
| <i>hSLP</i>     | The <code>SLPHandle</code> used to initiate the operation. |
| <i>pcSrvURL</i> | A character buffer containing the returned service URL.    |

## slp\_api(3SLP)

|                   |                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>usLifetime</i> | An unsigned short giving the life time of the service advertisement. The value must be an unsigned integer less than or equal to <code>SLP_LIFETIME_MAXIMUM</code> .                                                                                                          |
| <i>errCode</i>    | An error code indicating if an error occurred during the operation. The callback should check this error code before processing the parameters. If the error code is other than <code>SLP_OK</code> , then the API library may choose to terminate the outstanding operation. |
| <i>pvCookie</i>   | Memory passed down from the client code that called the original API function, starting the operation. It can be <code>NULL</code> .                                                                                                                                          |

### SLPAttrCallback

```
typedef SLPBoolean SLPAttrCallback(SLPHandle hSLP,
 const char* pcAttrList,
 SLPError errCode,
 void *pvCookie);
```

The `SLPAttrCallback()` type is the type of the callback function parameter to the `SLPFindAttrs()` function.

The behavior of the callback differs depending upon whether the attribute request was by URL or by service type. If the `SLPFindAttrs()` operation was originally called with a URL, the callback is called once, in addition to the last call, regardless of whether the handle was opened asynchronously or synchronously. The *pcAttrList* parameter contains the requested attributes as a comma-separated list. It is empty if no attributes match the original tag list.

If the `SLPFindAttrs()` operation was originally called with a service type, the value of *pcAttrList* and the calling behavior depend upon whether the handle was opened asynchronously or synchronously. If the handle was opened asynchronously, the callback is called every time the API library has results from a remote agent. The *pcAttrList* parameter is collated between calls, and contains a comma-separated list of the results from the agent that immediately returned. If the handle was opened synchronously, the results are collated from all returning agents, the callback is called once, and the *pcAttrList* parameter is set to the collated result.

`SLPAttrCallback()` callback has the following parameters:

|                   |                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>hSLP</i>       | The <code>SLPHandle</code> used to initiate the operation.                                                                      |
| <i>pcAttrList</i> | A character buffer containing a comma-separated and null-terminated list of attribute id/value assignments, in SLP wire format. |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>errCode</i>                          | An error code indicating if an error occurred during the operation. The callback should check this error code before processing the parameters. If the error code is other than <code>SLP_OK</code> , then the API library may choose to terminate the outstanding operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>pvCookie</i>                         | Memory passed down from the client code that called the original API function, starting the operation. It can be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ERRORS</b>                           | An interface that is part of the SLP API may return one of the following values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>SLP_LAST_CALL</code>              | The <code>SLP_LAST_CALL</code> code is passed to callback functions when the API library has no more data for them and therefore no further calls will be made to the callback on the currently outstanding operation. The callback uses this to signal the main body of the client code that no more data will be forthcoming on the operation, so that the main body of the client code can break out of data collection loops. On the last call of a callback during both a synchronous and asynchronous call, the error code parameter has value <code>SLP_LAST_CALL</code> , and the other parameters are all <code>NULL</code> . If no results are returned by an API operation, then only one call is made, with the error parameter set to <code>SLP_LAST_CALL</code> . |
| <code>SLP_OK</code>                     | The <code>SLP_OK</code> code indicates that the no error occurred during the operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>SLP_LANGUAGE_NOT_SUPPORTED</code> | No DA or SA has service advertisement information in the language requested, but at least one DA or SA might have information for that service in another language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>SLP_PARSE_ERROR</code>            | The SLP message was rejected by a remote SLP agent. The API returns this error only when no information was retrieved, and at least one SA or DA indicated a protocol error. The data supplied through the API may be malformed or damaged in transit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## slp\_api(3SLP)

|                           |                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SLP_INVALID_REGISTRATION  | The API may return this error if an attempt to register a service was rejected by all DAs because of a malformed URL or attributes. SLP does not return the error if at least one DA accepts the registration.                                                                                              |
| SLP_SCOPE_NOT_SUPPORTED   | The API returns this error if the UA or SA has been configured with the <code>net.slp.useScopes</code> list of scopes and the SA request did not specify one or more of these allowable scopes, and no others. It may also be returned by a DA if the scope included in a request is not supported by a DA. |
| SLP_AUTHENTICATION_ABSENT | This error arises when the UA or SA failed to send an authenticator for requests or registrations when security is enabled and thus required.                                                                                                                                                               |
| SLP_AUTHENTICATION_FAILED | This error arises when a authentication on an SLP message received from a remote SLP agent failed.                                                                                                                                                                                                          |
| SLP_INVALID_UPDATE        | An update for a nonexisting registration was issued, or the update includes a service type or scope different than that in the initial registration.                                                                                                                                                        |
| SLP_REFRESH_REJECTED      | The SA attempted to refresh a registration more frequently than the minimum refresh interval. The SA should call the appropriate API function to obtain the minimum refresh interval to use.                                                                                                                |
| SLP_NOT_IMPLEMENTED       | An outgoing request overflowed the maximum network MTU size. The request should be reduced in size or broken into pieces and tried again.                                                                                                                                                                   |
| SLP_BUFFER_OVERFLOW       | An outgoing request overflowed the maximum network MTU size. The request should be reduced in size or broken into pieces and tried again.                                                                                                                                                                   |
| SLP_NETWORK_TIMED_OUT     | When no reply can be obtained in the time specified by the configured timeout interval, this error is returned.                                                                                                                                                                                             |
| SLP_NETWORK_INIT_FAILED   | If the network cannot initialize properly, this error is returned.                                                                                                                                                                                                                                          |

slp\_api(3SLP)

**LIST OF  
ROUTINES**

|                           |                                                                                                                                                                                                                               |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SLP_MEMORY_ALLOC_FAILED   | If the API fails to allocate memory, the operation is aborted and returns this.                                                                                                                                               |
| SLP_PARAMETER_BAD         | If a parameter passed into an interface is bad, this error is returned.                                                                                                                                                       |
| SLP_NETWORK_ERROR         | The failure of networking during normal operations causes this error to be returned.                                                                                                                                          |
| SLP_INTERNAL_SYSTEM_ERROR | A basic failure of the API causes this error to be returned. This occurs when a system call or library fails. The operation could not recover.                                                                                |
| SLP_HANDLE_IN_USE         | In the C API, callback functions are not permitted to recursively call into the API on the same SLPHandle, either directly or indirectly. If an attempt is made to do so, this error is returned from the called API function |
| SLPOpen ()                | open an SLP handle                                                                                                                                                                                                            |
| SLPClose ()               | close an open SLP handle                                                                                                                                                                                                      |
| SLPReg ()                 | register a service advertisement                                                                                                                                                                                              |
| SLPDereg ()               | deregister a service advertisement                                                                                                                                                                                            |
| SLPDelAttrs ()            | delete attributes                                                                                                                                                                                                             |
| SLPFindSrvTypes ()        | return service types                                                                                                                                                                                                          |
| SLPFindSrvs ()            | return service URLs                                                                                                                                                                                                           |
| SLPFindAttrs ()           | return service attributes                                                                                                                                                                                                     |
| SLPGetRefreshInterval ()  | return the maximum allowed refresh interval for SAs                                                                                                                                                                           |
| SLPFindScopes ()          | return list of configured and discovered scopes                                                                                                                                                                               |
| SLPParseSrvURL ()         | parse service URL                                                                                                                                                                                                             |
| SLPEscape ()              | escape special characters                                                                                                                                                                                                     |
| SLPUnescape ()            | translate escaped characters into UTF-8                                                                                                                                                                                       |
| SLPGetProperty ()         | return SLP configuration property                                                                                                                                                                                             |
| SLPSetProperty ()         | set an SLP configuration property                                                                                                                                                                                             |
| slp_strerror ()           | map SLP error code to message                                                                                                                                                                                                 |
| SLPFree ()                | free memory                                                                                                                                                                                                                   |

| <b>NAME</b>                  | SLPclose – close an open SLP handle                                                                                                                                                                                                                                                                                 |                |                 |              |          |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|
| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  void <b>SLPclose</b>(SLPHandle <i>phSLP</i>);</pre>                                                                                                                                                                                                                                    |                |                 |              |          |
| <b>DESCRIPTION</b>           | The SLPclose() function frees all resources associated with the handle. If the handle is invalid, the function returns silently. Any outstanding synchronous or asynchronous operations are cancelled, so that their callback functions will not be called any further.                                             |                |                 |              |          |
| <b>PARAMETERS</b>            | <i>phSLP</i> An SLPHandle handle returned from a call to SLPOpen().                                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                              |                |                 |              |          |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using SLPclose()</p> <p>The following example will free all resources associated the handle:</p> <pre>SLPHandle hslp     SLPclose(hslp);</pre>                                                                                                                                                  |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | SLP_CONF_FILE When set, use this file for configuration.                                                                                                                                                                                                                                                            |                |                 |              |          |

| <b>DESCRIPTION</b>           | The SLPDelAttrs() function deletes the selected attributes in the locale of the SLPHandle. If no error occurs, the return value is 0. Otherwise, one of the SLPError codes is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                                                                 |              |                                                                                              |                |                                                                           |                 |                                                                            |                 |                                                                        |

| <b>DESCRIPTION</b>           | The SLPDereg() function deregisters the advertisement for URL <i>pcURL</i> in all scopes where the service is registered and in all language locales, not just the locale of the SLPHandle. If no error occurs, the return value is 0. Otherwise, one of the SLPError codes is returned.                                                                                                                                                                                                                                                                            |                |                                                                                       |              |                                                                  |                 |                                                                                       |                 |                                                                                  |

| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  SLPError <b>SLPEscape</b>(const char *pInBuf, char** ppcOutBuf, SLPBoolean     isTag);</pre>                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>DESCRIPTION</b>           | The SLPEscape() function processes the input string in <i>pInBuf</i> and escapes any SLP reserved characters. If the <i>isTag</i> parameter is <i>SLPTrue</i> , it then looks for bad tag characters and signals an error if any are found by returning the <i>SLP_PARSE_ERROR</i> code. The results are put into a buffer allocated by the API library and returned in the <i>ppcOutBuf</i> parameter. This buffer should be deallocated using <i>SLPFree(3SLP)</i> when the memory is no longer needed. |                |                 |              |          |
| <b>PARAMETERS</b>            | <p><i>pInBuf</i>                    Pointer to the input buffer to process for escape characters.</p> <p><i>ppcOutBuf</i>                Pointer to a pointer for the output buffer with the SLP reserved characters escaped. It must be freed using <i>SLPFree()</i> when the memory is no longer needed.</p> <p><i>isTag</i>                     When true, checks the input buffer for bad tag characters.</p>                                                                                         |                |                 |              |          |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <i>slp_api(3SLP)</i> .                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |          |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Converting Attribute Tags</p> <p>The following example shows how to convert the attribute tag , tag-example, to on the wire format:</p> <pre>SLPError err; char* escaped Chars;  err = SLPEscape(",tag-example,", &amp;escapedChars, SLP_TRUE);</pre>                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | <i>SLP_CONF_FILE</i> When set, use this file for configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |          |
| <b>ATTRIBUTES</b>            | See <i>attributes(5)</i> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |          |

| <b>DESCRIPTION</b> | <p>The <code>SLPFindAttrs()</code> function returns service attributes matching the attribute tags for the indicated full or partial URL. If <i>pcURL</i> is a complete URL, the attribute information returned is for that particular service in the language locale of the <code>SLPHandle</code>. If <i>pcURL</i> is a service type, then all attributes for the service type are returned, regardless of the language of registration. Results are returned through the <i>callback</i> parameter.</p> <p>The result is filtered with an SLP attribute request filter string parameter, the syntax of which is described in <i>RFC 2608</i>. If the filter string is the empty string, "", all attributes are returned.</p> <p>If an error occurs in starting the operation, one of the <code>SLPError</code> codes is returned.</p>                                                                                                                                                                                                                   |             |                                                                                                                  |              |                                                                                                       |                    |                                                                                                                              |                  |                                                                                                                                                                                                                                          |                 |                                                                                                               |                 |                                                                                   |

| <i>pcAttrIds</i>   | The filter string indicating which attribute values to return. Use empty string "" to indicate all values. Wildcards matching all attribute ids having a particular prefix or suffix are also possible. It cannot be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                                                                                                                  |              |                                                                                                       |                    |                                                                                                                              |                  |                                                                                                                                                                                                                                          |                 |                                                                                                               |                 |                                                                                   |
| <i>callback</i>    | A callback function through which the results of the operation are reported. It cannot be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                                                                  |              |                                                                                                       |                    |                                                                                                                              |                  |                                                                                                                                                                                                                                          |                 |                                                                                                               |                 |                                                                                   |
| <i>pvCookie</i>    | Memory passed to the callback code from the client. It may be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                                                                  |              |                                                                                                       |                    |                                                                                                                              |                  |                                                                                                                                                                                                                                          |                 |                                                                                                               |                 |                                                                                   |
| <b>ERRORS</b>      | This function or its callback may return any SLP error code. See the <b>ERRORS</b> section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                                                                  |              |                                                                                                       |                    |                                                                                                                              |                  |                                                                                                                                                                                                                                          |                 |                                                                                                               |                 |                                                                                   |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Returning Service Attributes for a Specific URL</p> <p>Use the following example to return the attributes "location" and "dpi" for the URL "service:printer:lpr://serv/queue1" through the callback <code>attrReturn</code>:</p> <pre>SLPHandle hSLP; SLPAttrCallback attrReturn; SLPError err;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                                                                                                  |              |                                                                                                       |                    |                                                                                                                              |                  |                                                                                                                                                                                                                                          |                 |                                                                                                               |                 |                                                                                   |

**EXAMPLE 1** Returning Service Attributes for a Specific URL *(Continued)*

```
err = SLPFindAttrs(hSLP "service:printer:lpr://serv/queue1",
 "default", "location,dpi", attrReturn, err);
```

**EXAMPLE 2** Returning Service Attributes for All URLs of a Specific Type

Use the following example to return the attributes “location” and “dpi” for all service URLs having type “service:printer:lpr”:

```
err = SLPFindAttrs(hSLP, "service:printer:lpr",
 "default", "location, pi",
 attrReturn, NULL);
```

| <b>DESCRIPTION</b>           | <p>The <code>SLPFindScopes()</code> function sets the <code>ppcScopes</code> parameter to a pointer to a comma-separated list including all available scope names. The list of scopes comes from a variety of sources: the configuration file, the <code>net.slp.useScopes</code> property and the <code>net.slp.DAAddresses</code> property, DHCP, or through the DA discovery process. If there is any order to the scopes, preferred scopes are listed before less desirable scopes. There is always at least one string in the array, the default scope, <code>DEFAULT</code>.</p> <p>If no error occurs, <code>SLPFindScopes()</code> returns <code>SLP_OK</code>, otherwise, it returns the appropriate error code.</p> |                |                                                                                                     |                  |                                                                                                                                                                                                                  |

| <b>DESCRIPTION</b>       | <p>The SLPFindSrvTypes () function issues an SLP service type request for service types in the scopes indicated by the <i>pcScopeList</i>. The results are returned through the <i>callback</i> parameter. The service types are independent of language locale, but only for services registered in one of the scopes and for the indicated naming authority.</p> <p>If the naming authority is "*", then results are returned for all naming authorities. If the naming authority is the empty string, "", then the default naming authority, IANA, is used. IANA is not a valid naming authority name. The SLP_PARAMETER_BAD error code will be returned if you include it explicitly.</p> <p>The service type names are returned with the naming authority included in the following format:</p> <pre>service-type "." naming-authority</pre> <p>unless the naming authority is the default, in which case, just the service type name is returned.</p> <p>If an error occurs in starting the operation, one of the SLPError codes is returned.</p> |             |                                                                |                          |                                                                                                                                                              |                    |                                                                                                                                             |                 |                                                                                        |                 |                                                                     |

## SLPFree(3SLP)

| <b>NAME</b>                  | SLPFree – frees memory                                                                                                                                                                                                                                                                                                         |                |                 |              |          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|
| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  SLPError <b>SLPFree</b>(void *pvMem) ;</pre>                                                                                                                                                                                                                                                      |                |                 |              |          |
| <b>DESCRIPTION</b>           | The SLPFree() function frees memory returned from SLPParseSrvURL(), SLPFindScopes(), SLPEscape(), and SLPUnescape().                                                                                                                                                                                                           |                |                 |              |          |
| <b>PARAMETERS</b>            | <i>pvMem</i> A pointer to the storage allocated by the SLPParseSrvURL(), SLPFindScopes(), SLPEscape(), and SLPUnescape() functions. <i>pvMem</i> is ignored if its value is NULL.                                                                                                                                              |                |                 |              |          |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                                         |                |                 |              |          |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using SLPFree()</p> <p>The following example illustrates how to call SLPFree(). It assumes that SrvURL contains previously allocated memory.</p> <pre>SLPError err;  err = SLPFree((void*) SrvURL);</pre>                                                                                                  |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | SLP_CONF_FILE                    When set, use this file for configuration.                                                                                                                                                                                                                                                    |                |                 |              |          |

| <b>NAME</b>                  | SLPGetProperty – return SLP configuration property                                                                                                                                                                                                                                                                                                  |                |                 |              |          |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|
| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  const char* <b>SLPGetProperty</b>(const char* pcName);</pre>                                                                                                                                                                                                                                                           |                |                 |              |          |
| <b>DESCRIPTION</b>           | The SLPGetProperty() function returns the value of the corresponding SLP property name, or NULL, if none. If there is no error, SLPGetProperty() returns a pointer to the property value. If the property was not set, it returns the empty string, "". If an error occurs, SLPGetProperty() returns NULL. The returned string should not be freed. |                |                 |              |          |
| <b>PARAMETERS</b>            | <i>pcName</i> A null-terminated string with the property name. <i>pcName</i> cannot be NULL.                                                                                                                                                                                                                                                        |                |                 |              |          |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                                                              |                |                 |              |          |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using SLPGetProperty()</p> <p>Use the following example to return a list of configured scopes:</p> <pre>const char* useScopes  useScopes = SLPGetProperty("net.slp.useScopes");</pre>                                                                                                                                           |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | SLP_CONF_FILE                      When set, use this file for configuration.                                                                                                                                                                                                                                                                       |                |                 |              |          |
| <b>ATTRIBUTES</b>            | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                     |                |                 |              |          |

## SLPGetRefreshInterval(3SLP)

| <b>NAME</b>                  | SLPGetRefreshInterval – return the maximum allowed refresh interval                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |          |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|
| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  int <b>SLPGetRefreshInterval</b> (void);</pre>                                                                                                                                                                                                                                                                                                                                            |                |                 |              |          |
| <b>DESCRIPTION</b>           | The SLPGetRefreshInterval () function returns the maximum across all DAs of the min-refresh-interval attribute. This value satisfies the advertised refresh interval bounds for all DAs. If this value is used by the SA, it assures that no refresh registration will be rejected. If no DA advertises a min-refresh-interval attribute, a value of 0 is returned. If an error occurs, an SLP error code is returned. |                |                 |              |          |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using SLPGetRefreshInterval ()</p> <p>Use the following example to return the maximum valid refresh interval for SA:</p> <pre>int minrefresh  minrefresh = SLPGetRefreshInterval ( );</pre>                                                                                                                                                                                                        |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | SLP_CONF_FILE                      When set, use this file for configuration.                                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |

| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  SLPError SLPOpen(const char *pcLang, SLPBoolean isAsync, SLPHandle                 *phSLP);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                                                                                                                                                                                        |                |                                                                                                       |              |                                                                                                                       |
| <b>DESCRIPTION</b>           | <p>The SLPOpen() function returns a SLPHandle handle in the <i>phSLP</i> parameter for the language locale passed in as the <i>pcLang</i> parameter. The client indicates if operations on the handle are to be synchronous or asynchronous through the <i>isAsync</i> parameter. The handle encapsulates the language locale for SLP requests issued through the handle, and any other resources required by the implementation. SLP properties are not encapsulated by the handle, they are global. The return value of the function is an SLPError code indicating the status of the operation. Upon failure, the <i>phSLP</i> parameter is NULL.</p> <p>An SLPHandle can only be used for one SLP API operation at a time. If the original operation was started asynchronously, any attempt to start an additional operation on the handle while the original operation is pending results in the return of an SLP_HANDLE_IN_USE error from the API function. The SLPClose() function terminates any outstanding calls on the handle.</p> |                |                                                                                                                                                                                        |                |                                                                                                       |              |                                                                                                                       |
| <b>PARAMETERS</b>            | <table border="0"> <tr> <td style="vertical-align: top;"><i>pcLang</i></td> <td>A pointer to an array of characters containing the language tag set forth in RFC 1766 for the natural language locale of requests issued on the handle. This parameter cannot be NULL.</td> </tr> <tr> <td style="vertical-align: top;"><i>isAsync</i></td> <td>An SLPBoolean indicating whether or not the SLPHandle should be opened for an asynchronous operation.</td> </tr> <tr> <td style="vertical-align: top;"><i>phSLP</i></td> <td>A pointer to an SLPHandle in which the open SLPHandle is returned. If an error occurs, the value upon return is NULL.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                         | <i>pcLang</i>  | A pointer to an array of characters containing the language tag set forth in RFC 1766 for the natural language locale of requests issued on the handle. This parameter cannot be NULL. | <i>isAsync</i> | An SLPBoolean indicating whether or not the SLPHandle should be opened for an asynchronous operation. | <i>phSLP</i> | A pointer to an SLPHandle in which the open SLPHandle is returned. If an error occurs, the value upon return is NULL. |
| <i>pcLang</i>                | A pointer to an array of characters containing the language tag set forth in RFC 1766 for the natural language locale of requests issued on the handle. This parameter cannot be NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                                                                                                                                                                        |                |                                                                                                       |              |                                                                                                                       |
| <i>isAsync</i>               | An SLPBoolean indicating whether or not the SLPHandle should be opened for an asynchronous operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                                                                                                                                                                        |                |                                                                                                       |              |                                                                                                                       |
| <i>phSLP</i>                 | A pointer to an SLPHandle in which the open SLPHandle is returned. If an error occurs, the value upon return is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                                                                                                                                                                        |                |                                                                                                       |              |                                                                                                                       |

| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  SLPError SLPParseSrvURL(const char *pcSrvURL, SLPSrvURL**     ppSrvURL);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |          |
| <b>DESCRIPTION</b>           | <p>The SLPParseSrvURL() routine parses the URL passed in as the argument into a service URL structure and returns it in the ppSrvURL pointer. If a parser error occurs, returns SLP_PARSE_ERROR. The structure returned in ppSrvURL should be freed with SLPFree(). If the URL has no service part, the s_pcSrvPart string is the empty string, "", that is, it is not NULL. If pcSrvURL is not a service: URL, then the s_pcSrvType field in the returned data structure is the URL's scheme, which might not be the same as the service type under which the URL was registered. If the transport is IP, the s_pcNetFamily field is the empty string.</p> <p>If no error occurs, the return value is the SLP_OK. Otherwise, if an error occurs, one of the SLPError codes is returned.</p> |                |                 |              |          |
| <b>PARAMETERS</b>            | <p><i>pcSrvURL</i>            A pointer to a character buffer containing the null terminated URL string to parse. It is destructively modified to produce the output structure. It may not be NULL.</p> <p><i>ppSrvURL</i>            A pointer to a pointer for the SLPSrvURL structure to receive the parsed URL. It may not be NULL.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |          |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |          |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using SLPParseSrvURL()</p> <p>The following example uses the SLPParseSrvURL() function to parse the service URL <code>service:printer:lpr://serv/queue1</code>:</p> <pre>SLPSrvURL* surl; SLPError err;  err = SLPParseSrvURL("service:printer:lpr://serv/queue1", &amp;surl);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | SLP_CONF_FILE            When set, use this file for configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |

| <b>NAME</b>        | SLPReg – register an SLP advertisement                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <b>SYNOPSIS</b>    | <pre>#include &lt;slp.h&gt;  SLPError SLPReg(SLPHandle hSLP, const char *pcSrvURL, const     unsigned short usLifetime, const char *pcSrvType, const char     *pcAttrs, SLPBoolean fresh, SLPRegReport callback, void *pvCookie);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <b>DESCRIPTION</b> | <p>The SLPReg() function registers the URL in <i>pcSrvURL</i> having the lifetime <i>usLifetime</i> with the attribute list in <i>pcAttrs</i>. The <i>pcAttrs</i> list is a comma-separated list of attribute assignments in on-the-wire format (including escaping of reserved characters). The <i>sLifetime</i> parameter must be nonzero and less than or equal to SLP_LIFETIME_MAXIMUM. If the fresh flag is SLP_TRUE, then the registration is new, the SLP protocol <i>fresh</i> flag is set, and the registration replaces any existing registrations.</p> <p>The <i>pcSrvType</i> parameter is a service type name and can be included for service URLs that are not in the service: scheme. If the URL is in the service: scheme, the <i>pcSrvType</i> parameter is ignored. If the fresh flag is SLP_FALSE, then an existing registration is updated. Rules for new and updated registrations, and the format for <i>pcAttrs</i> and <i>pcScopeList</i>, can be found in RFC 2608. Registrations and updates take place in the language locale of the <i>hSLP</i> handle.</p> <p>The API library is required to perform the operation in all scopes obtained through configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                         |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |

If <i>pURL</i> is a service: URL, then this parameter is ignored. <i>pcSrvType</i> cannot be NULL. | <i>pcAttrs</i> | A comma-separated list of attribute assignment expressions for the attributes of the advertisement. <i>pcAttrs</i> cannot be NULL. Use the empty string, "", to indicate no attributes. | <i>fresh</i> | An SLPBoolean that is SLP_TRUE if the registration is new or SLP_FALSE if it is a reregistration. | <i>callback</i> | A callback to report the operation completion status. <i>callback</i> cannot be NULL. | <i>pvCookie</i> | Memory passed to the callback code from the client. <i>pvCookie</i> can be NULL. |
| <i>hSLP</i>        | The language specific SLPHandle on which to register the advertisement. <i>hSLP</i> cannot be NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>pcSrvURL</i>    | The URL to register. The value of <i>pcSrvURL</i> cannot be NULL or the empty string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>usLifetime</i>  | An unsigned short giving the life time of the service advertisement, in seconds. The value must be an unsigned integer less than or equal to SLP_LIFETIME_MAXIMUM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>pcSrvType</i>   | The service type. If <i>pURL</i> is a service: URL, then this parameter is ignored. <i>pcSrvType</i> cannot be NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>pcAttrs</i>     | A comma-separated list of attribute assignment expressions for the attributes of the advertisement. <i>pcAttrs</i> cannot be NULL. Use the empty string, "", to indicate no attributes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>fresh</i>       | An SLPBoolean that is SLP_TRUE if the registration is new or SLP_FALSE if it is a reregistration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>callback</i>    | A callback to report the operation completion status. <i>callback</i> cannot be NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |
| <i>pvCookie</i>    | Memory passed to the callback code from the client. <i>pvCookie</i> can be NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                                                     |                 |                                                                                       |                   |                                                                                                                                                                    |                  |                                                                                                                      |                |                                                                                                                                                                                         |              |                                                                                                   |                 |                                                                                       |                 |                                                                                  |

## SLPReg(3SLP)

**ERRORS** This function or its callback may return any SLP error code. See the **ERRORS** section in [slp\\_api\(3SLP\)](#).

**EXAMPLES** **EXAMPLE 1** An Initial Registration

The following example shows an initial registration for the "service:video://bldg15" camera service for three hours:

```
SLPError err;
SLPHandle hSLP;
SLPRegReport regreport;
err = SLPReg(hSLP, "service:video://bldg15",
 10800, "", "(location=B15-corridor),
 (scan-rate=100)", SLP_TRUE,
 regRpt, NULL);
```

**ENVIRONMENT VARIABLES** **SLP\_CONF\_FILE** When set, use this file for configuration.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWslpu        |

| <b>NAME</b>                  | SLPSetProperty – set an SLP configuration property                                                                                                                                                                                                                                                              |                |                                                                                |                |                                                                                  |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|--------------------------------------------------------------------------------|----------------|----------------------------------------------------------------------------------|
| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  void <b>SLPSetProperty</b>(const char *pcName, const char *pcValue);</pre>                                                                                                                                                                                                         |                |                                                                                |                |                                                                                  |
| <b>DESCRIPTION</b>           | The SLPSetProperty() function sets the value of the SLP property to the new value. The pcValue parameter contains the property value as a string.                                                                                                                                                               |                |                                                                                |                |                                                                                  |
| <b>PARAMETERS</b>            | <table border="0"> <tr> <td style="padding-right: 20px;"><i>pcName</i></td> <td>A null-terminated string with the property name. <i>pcName</i> cannot be NULL.</td> </tr> <tr> <td><i>pcValue</i></td> <td>A null-terminated string with the property value. <i>pcValue</i> cannot be NULL.</td> </tr> </table> | <i>pcName</i>  | A null-terminated string with the property name. <i>pcName</i> cannot be NULL. | <i>pcValue</i> | A null-terminated string with the property value. <i>pcValue</i> cannot be NULL. |
| <i>pcName</i>                | A null-terminated string with the property name. <i>pcName</i> cannot be NULL.                                                                                                                                                                                                                                  |                |                                                                                |                |                                                                                  |
| <i>pcValue</i>               | A null-terminated string with the property value. <i>pcValue</i> cannot be NULL.                                                                                                                                                                                                                                |                |                                                                                |                |                                                                                  |
| <b>ERRORS</b>                | This function or its callback may return any SLP error code. See the ERRORS section in <a href="#">slp_api(3SLP)</a> .                                                                                                                                                                                          |                |                                                                                |                |                                                                                  |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Setting a Configuration Property</p> <p>The following example shows to set the property net.slp.typeHint to service:ftp:</p> <pre>SLPSetProperty ("net.slp.typeHint" "service:ftp");</pre>                                                                                                  |                |                                                                                |                |                                                                                  |
| <b>ENVIRONMENT VARIABLES</b> | SLP_CONF_FILE                      When set, use this file for configuration.                                                                                                                                                                                                                                   |                |                                                                                |                |                                                                                  |

slp\_strerror(3SLP)

**NAME** slp\_strerror – map SLP error codes to messages

**SYNOPSIS**

```
#include <slp.h>

const char* slp_strerror (SLPError err_code);
```

**DESCRIPTION** The slp\_strerror() function maps err\_code to a string explanation of the error. The returned string is owned by the library and must not be freed.

**PARAMETERS** err\_code An SLP error code.

**ERRORS** This function or its callback may return any SLP error code. See the ERRORS section in slp\_api(3SLP).

**EXAMPLES** **EXAMPLE 1** Using slp\_strerror()

The following example returns the message that corresponds to the error code:

```
SLPError error;
const char* msg;
msg = slp_strerror(err);
```

**ENVIRONMENT VARIABLES** SLP\_CONF\_FILE When set, use this file for configuration.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWslpu        |

| <b>SYNOPSIS</b>              | <pre>#include &lt;slp.h&gt;  SLPError SLPUnescape(const char *pcInBuf, char** ppcOutBuf,                     SLPBoolean isTag);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                                                               |                  |                                                                                                                                                                    |              |                                                                |
| <b>DESCRIPTION</b>           | The SLPUnescape() function processes the input string in <i>pcInBuf</i> and unescapes any SLP reserved characters. If the <i>isTag</i> parameter is <i>SLPTrue</i> , then look for bad tag characters and signal an error if any are found with the <i>SLP_PARSE_ERROR</i> code. No transformation is performed if the input string is an opaque. The results are put into a buffer allocated by the API library and returned in the <i>ppcOutBuf</i> parameter. This buffer should be deallocated using <i>SLPFree(3SLP)</i> when the memory is no longer needed. |                |                                                               |                  |                                                                                                                                                                    |              |                                                                |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lxnet [ library ... ] #include &lt;sys/socket.h&gt;  int socketmark(int s);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |                     |          |          |      |
| <b>DESCRIPTION</b>   | The <code>socketmark()</code> function determines whether the socket specified by the descriptor <code>s</code> is at the out-of-band data mark. If the protocol for the socket supports out-of-band data by marking the stream with an out-of-band data mark, the <code>socketmark()</code> function returns 1 when all data preceding the mark has been read and the out-of-band data mark is the first element in the receive queue. The <code>socketmark()</code> function does not remove the mark from the stream.                                                                                                                                                                                                                                                                                                                                                 |                |                 |                     |          |          |      |
| <b>RETURN VALUES</b> | Upon successful completion, the <code>socketmark()</code> function returns a value indicating whether the socket is at an out-of-band data mark. If the protocol has marked the data stream and all data preceding the mark has been read, the return value is 1. If there is no mark, or if data precedes the mark in the receive queue, the <code>socketmark()</code> function returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |                     |          |          |      |
| <b>ERRORS</b>        | The <code>socketmark()</code> function will fail if:<br><br>EBADF                    The <code>s</code> argument is not a valid file descriptor.<br>ENOTTY                   The <code>s</code> argument does not specify a descriptor for a socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |                     |          |          |      |
| <b>USAGE</b>         | The use of this function between receive operations allows an application to determine which received data precedes the out-of-band data and which follows the out-of-band data.<br><br>There is an inherent race condition in the use of this function. On an empty receive queue, the current read of the location might well be at the "mark", but the system has no way of knowing that the next data segment that will arrive from the network will carry the mark, and <code>socketmark()</code> will return false, and the next read operation will silently consume the mark.<br><br>Hence, this function can only be used reliably when the application already knows that the out-of-band data has been seen by the system or that it is known that there is data waiting to be read at the socket, either by <code>SIGURG</code> or <code>select(3C)</code> . |                |                 |                     |          |          |      |

| <b>NAME</b>        | socket – create an endpoint for communication                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                                |         |                                    |          |                                    |        |                                               |
| <b>SYNOPSIS</b>    | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lsocket -lnsl [ <i>library</i> ... ] #include &lt;sys/types.h&gt; #include &lt;sys/socket.h&gt;  int <b>socket</b>(int <i>domain</i>, int <i>type</i>, int <i>protocol</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |                                |         |                                    |          |                                    |        |                                               |
| <b>DESCRIPTION</b> | <p>The <code>socket()</code> function creates an endpoint for communication and returns a descriptor.</p> <p>The <i>domain</i> parameter specifies a communications domain within which communication will take place; this selects the protocol family which should be used. The protocol family generally is the same as the address family for the addresses supplied in later operations on the socket. These families are defined in the include file <code>&lt;sys/socket.h&gt;</code>. There must be an entry in the <code>netconfig(4)</code> file for at least each protocol family and type required. If <i>protocol</i> has been specified, but no exact match for the tuple family, type, protocol is found, then the first entry containing the specified family and type with zero for protocol will be used. The currently understood formats are:</p> <table border="0"> <tr> <td style="padding-right: 20px;">PF_UNIX</td> <td>UNIX system internal protocols</td> </tr> <tr> <td>PF_INET</td> <td>Internet Protocol Version 4 (IPv4)</td> </tr> <tr> <td>PF_INET6</td> <td>Internet Protocol Version 6 (IPv6)</td> </tr> <tr> <td>PF_NCA</td> <td>Network Cache and Accelerator (NCA) protocols</td> </tr> </table> <p>The socket has the indicated <i>type</i>, which specifies the communication semantics. Currently defined types are:</p> <pre>SOCK_STREAM SOCK_DGRAM SOCK_RAW SOCK_SEQPACKET SOCK_RDM</pre> <p>A <code>SOCK_STREAM</code> type provides sequenced, reliable, two-way connection-based byte streams. An out-of-band data transmission mechanism may be supported. A <code>SOCK_DGRAM</code> socket supports datagrams (connectionless, unreliable messages of a fixed (typically small) maximum length). A <code>SOCK_SEQPACKET</code> socket may provide a sequenced, reliable, two-way connection-based data transmission path for datagrams of fixed maximum length; a consumer may be required to read an entire packet with each read system call. This facility is protocol specific, and presently not implemented for any protocol family. <code>SOCK_RAW</code> sockets provide access to internal network interfaces. The types <code>SOCK_RAW</code>, which is available only to the superuser, and <code>SOCK_RDM</code>, for which no implementation currently exists, are not described here.</p> <p>The <i>protocol</i> parameter specifies a particular protocol to be used with the socket. Normally only a single protocol exists to support a particular socket type within a given protocol family. However, multiple protocols may exist, in which case a particular protocol must be specified in this manner. The protocol number to use is</p> | PF_UNIX | UNIX system internal protocols | PF_INET | Internet Protocol Version 4 (IPv4) | PF_INET6 | Internet Protocol Version 6 (IPv6) | PF_NCA | Network Cache and Accelerator (NCA) protocols |

| PF_NCA             | Network Cache and Accelerator (NCA) protocols                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                                |         |                                    |          |                                    |        |                                               |

## socket(3SOCKET)

particular to the “communication domain” in which communication is to take place. If a protocol is specified by the caller, then it will be packaged into a socket level option request and sent to the underlying protocol layers.

Sockets of type `SOCK_STREAM` are full-duplex byte streams, similar to pipes. A stream socket must be in a *connected* state before any data may be sent or received on it. A connection to another socket is created with a `connect(3SOCKET)` call. Once connected, data may be transferred using `read(2)` and `write(2)` calls or some variant of the `send(3SOCKET)` and `recv(3SOCKET)` calls. When a session has been completed, a `close(2)` may be performed. Out-of-band data may also be transmitted as described on the `send(3SOCKET)` manual page and received as described on the `recv(3SOCKET)` manual page.

The communications protocols used to implement a `SOCK_STREAM` insure that data is not lost or duplicated. If a piece of data for which the peer protocol has buffer space cannot be successfully transmitted within a reasonable length of time, then the connection is considered broken and calls will indicate an error with `-1` returns and with `ETIMEDOUT` as the specific code in the global variable `errno`. The protocols optionally keep sockets “warm” by forcing transmissions roughly every minute in the absence of other activity. An error is then indicated if no response can be elicited on an otherwise idle connection for an extended period (for instance 5 minutes). A `SIGPIPE` signal is raised if a thread sends on a broken stream; this causes naive processes, which do not handle the signal, to exit.

`SOCK_SEQPACKET` sockets employ the same system calls as `SOCK_STREAM` sockets. The only difference is that `read(2)` calls will return only the amount of data requested, and any remaining in the arriving packet will be discarded.

`SOCK_DGRAM` and `SOCK_RAW` sockets allow datagrams to be sent to correspondents named in `sendto(3SOCKET)` calls. Datagrams are generally received with `recvfrom(3SOCKET)`, which returns the next datagram with its return address.

An `fcntl(2)` call can be used to specify a process group to receive a `SIGURG` signal when the out-of-band data arrives. It can also enable non-blocking I/O.

The operation of sockets is controlled by socket level *options*. These options are defined in the file `<sys/socket.h>`. `setsockopt(3SOCKET)` and `getsockopt(3SOCKET)` are used to set and get options, respectively.

### RETURN VALUES

A `-1` is returned if an error occurs. Otherwise the return value is a descriptor referencing the socket.

### ERRORS

The `socket()` function will fail if:

|                           |                                                                            |

| <b>NAME</b>        | socket – create an endpoint for communication                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>cc [ <i>flag</i> ... ] <i>file</i> ... -lxnet [ <i>library</i> ... ] #include &lt;sys/socket.h&gt;  int <b>socket</b>(int <i>domain</i>, int <i>type</i>, int <i>protocol</i>);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>socket()</code> function creates an unbound socket in a communications domain, and returns a file descriptor that can be used in later function calls that operate on sockets.</p> <p>The <code>&lt;sys/socket.h&gt;</code> header defines at least the following values for the <i>domain</i> argument:</p> <table><tr><td>AF_UNIX</td><td>File system pathnames.</td></tr><tr><td>AF_INET</td><td>Internet Protocol version 4 (IPv4) address.</td></tr><tr><td>AF_INET6</td><td>Internet Protocol version 6 (IPv6) address.</td></tr></table> <p>The <i>type</i> argument specifies the socket type, which determines the semantics of communication over the socket. The socket types supported by the system are implementation-dependent. Possible socket types include:</p> <table><tr><td>SOCK_STREAM</td><td>Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.</td></tr><tr><td>SOCK_DGRAM</td><td>Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.</td></tr><tr><td>SOCK_SEQPACKET</td><td>Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.</td></tr></table> <p>If the <i>protocol</i> argument is non-zero, it must specify a protocol that is supported by the address family. The protocols supported by the system are implementation-dependent.</p> <p>The process may need to have appropriate privileges to use the <code>socket()</code> function or to create some sockets.</p> | AF_UNIX       | File system pathnames.                                                  | AF_INET     | Internet Protocol version 4 (IPv4) address. | AF_INET6        | Internet Protocol version 6 (IPv6) address.                                                                                                                                                                  | SOCK_STREAM | Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data. | SOCK_DGRAM | Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length. | SOCK_SEQPACKET | Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag. |

| SOCK_STREAM        | Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| SOCK_DGRAM         | Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| SOCK_SEQPACKET     | Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |

Specifying a <i>protocol</i> of 0 causes <code>socket()</code> to use an unspecified default protocol appropriate for the requested socket type.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <i>domain</i> | Specifies the communications domain in which a socket is to be created. | <i>type</i> | Specifies the type of socket to be created. | <i>protocol</i> | Specifies a particular protocol to be used with the socket. Specifying a <i>protocol</i> of 0 causes <code>socket()</code> to use an unspecified default protocol appropriate for the requested socket type. |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| <i>domain</i>      | Specifies the communications domain in which a socket is to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| <i>type</i>        | Specifies the type of socket to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |
| <i>protocol</i>    | Specifies a particular protocol to be used with the socket. Specifying a <i>protocol</i> of 0 causes <code>socket()</code> to use an unspecified default protocol appropriate for the requested socket type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |               |                                                                         |             |                                             |                 |                                                                                                                                                                                                              |             |                                                                                                                                           |            |                                                                                                 |                |                                                                                                                                                                                                                                                                                                                                                |

The *domain* argument specifies the address family used in the communications domain. The address families supported by the system are implementation-dependent.

**USAGE** The documentation for specific address families specify which protocols each address family supports. The documentation for specific protocols specify which socket types each protocol supports.

The application can determine if an address family is supported by trying to create a socket with *domain* set to the protocol in question.

**RETURN VALUES** Upon successful completion, `socket ()` returns a nonnegative integer, the socket file descriptor. Otherwise a value of -1 is returned and `errno` is set to indicate the error.

**ERRORS** The `socket ()` function will fail if:

|                 |                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------|
| EAFNOSUPPORT    | The implementation does not support the specified address family.                                            |
| EMFILE          | No more file descriptors are available for this process.                                                     |
| ENFILE          | No more file descriptors are available for the system.                                                       |
| EPROTONOSUPPORT | The protocol is not supported by the address family, or the protocol is not supported by the implementation. |
| EPROTOTYPE      | The socket type is not supported by the protocol.                                                            |

The `socket ()` function may fail if:

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| EACCES  | The process does not have appropriate privileges.                                  |
| ENOBUFS | Insufficient resources were available in the system to perform the operation.      |
| ENOMEM  | Insufficient memory was available to fulfill the request.                          |
| ENOSR   | There were insufficient STREAMS resources available for the operation to complete. |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | MT-Safe         |

| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lsocket -lnsl [ library ... ] #include &lt;sys/types.h&gt; #include &lt;sys/socket.h&gt;  int socketpair(int domain, int type, int protocol, int sv[2]);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                                                |          |                                                  |        |                                                                   |       |                                                                          |            |                                                                   |                 |                                                          |        |                                                   |
| <b>DESCRIPTION</b>   | The <code>socketpair()</code> library call creates an unnamed pair of connected sockets in the specified address family <i>domain</i> , of the specified <i>type</i> , that uses the optionally specified <i>protocol</i> . The descriptors that are used in referencing the new sockets are returned in <i>sv</i> [0] and <i>sv</i> [1]. The two sockets are indistinguishable.                                                                                                                                                                                                                                                                                                                                                    |                |                                                                |          |                                                  |        |                                                                   |       |                                                                          |            |                                                                   |                 |                                                          |        |                                                   |
| <b>RETURN VALUES</b> | <code>socketpair()</code> returns <code>-1</code> on failure and <code>0</code> on success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                                                |          |                                                  |        |                                                                   |       |                                                                          |            |                                                                   |                 |                                                          |        |                                                   |
| <b>ERRORS</b>        | The call succeeds unless: <table><tr><td>EAFNOSUPPORT</td><td>The specified address family is not supported on this machine.</td></tr><tr><td>EMFILE</td><td>Too many descriptors are in use by this process.</td></tr><tr><td>ENOMEM</td><td>There was insufficient user memory for the operation to complete.</td></tr><tr><td>ENOSR</td><td>There were insufficient STREAMS resources for the operation to complete.</td></tr><tr><td>EOPNOTSUPP</td><td>The specified protocol does not support creation of socket pairs.</td></tr><tr><td>EPROTONOSUPPORT</td><td>The specified protocol is not supported on this machine.</td></tr><tr><td>EACCES</td><td>The process does not have appropriate privileges.</td></tr></table> | EAFNOSUPPORT   | The specified address family is not supported on this machine. | EMFILE   | Too many descriptors are in use by this process. | ENOMEM | There was insufficient user memory for the operation to complete. | ENOSR | There were insufficient STREAMS resources for the operation to complete. | EOPNOTSUPP | The specified protocol does not support creation of socket pairs. | EPROTONOSUPPORT | The specified protocol is not supported on this machine. | EACCES | The process does not have appropriate privileges. |

| <b>NAME</b>          | socketpair – create a pair of connected sockets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| <b>SYNOPSIS</b>      | <pre>cc [ flag ... ] file ... -lxnet [ library ... ] #include &lt;sys/socket.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| <b>DESCRIPTION</b>   | <p>The <code>socketpair()</code> function creates an unbound pair of connected sockets in a specified <i>domain</i>, of a specified <i>type</i>, under the protocol optionally specified by the <i>protocol</i> argument. The two sockets are identical. The file descriptors used in referencing the created sockets are returned in <i>socket_vector0</i> and <i>socket_vector1</i>.</p> <p>The <i>type</i> argument specifies the socket type, which determines the semantics of communications over the socket. The socket types supported by the system are implementation-dependent. Possible socket types include:</p> <table border="0"> <tr> <td style="padding-right: 20px;">SOCK_STREAM</td> <td>Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.</td> </tr> <tr> <td>SOCK_DGRAM</td> <td>Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.</td> </tr> <tr> <td>SOCK_SEQPACKET</td> <td>Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.</td> </tr> </table> <p>If the <i>protocol</i> argument is non-zero, it must specify a protocol that is supported by the address family. The protocols supported by the system are implementation-dependent.</p> <p>The process may need to have appropriate privileges to use the <code>socketpair()</code> function or to create some sockets.</p> | SOCK_STREAM   | Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data. | SOCK_DGRAM  | Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length. | SOCK_SEQPACKET  | Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag. |                      |                                                                                      |
| SOCK_STREAM          | Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| SOCK_DGRAM           | Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| SOCK_SEQPACKET       | Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |

Specifying a <i>protocol</i> of 0 causes <code>socketpair()</code> to use an unspecified default protocol appropriate for the requested socket type.                                                                                                                              | <i>socket_vector</i> | Specifies a 2-integer array to hold the file descriptors of the created socket pair. |
| <i>domain</i>        | Specifies the communications domain in which the sockets are to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| <i>type</i>          | Specifies the type of sockets to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| <i>protocol</i>      | Specifies a particular protocol to be used with the sockets. Specifying a <i>protocol</i> of 0 causes <code>socketpair()</code> to use an unspecified default protocol appropriate for the requested socket type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |
| <i>socket_vector</i> | Specifies a 2-integer array to hold the file descriptors of the created socket pair.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |               |                                                                                                                                           |             |                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                |                      |                                                                                      |

## socketpair(3XNET)

**USAGE** The documentation for specific address families specifies which protocols each address family supports. The documentation for specific protocols specifies which socket types each protocol supports.

The `socketpair()` function is used primarily with UNIX domain sockets and need not be supported for other domains.

**RETURN VALUES** Upon successful completion, this function returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

**ERRORS** The `socketpair()` function will fail if:

|                              |                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>EAFNOSUPPORT</code>    | The implementation does not support the specified address family.                                            |
| <code>EMFILE</code>          | No more file descriptors are available for this process.                                                     |
| <code>ENFILE</code>          | No more file descriptors are available for the system.                                                       |
| <code>EOPNOTSUPP</code>      | The specified protocol does not permit creation of socket pairs.                                             |
| <code>EPROTONOSUPPORT</code> | The protocol is not supported by the address family, or the protocol is not supported by the implementation. |
| <code>EPROTOTYPE</code>      | The socket type is not supported by the protocol.                                                            |

The `socketpair()` function may fail if:

|                      |                                                                                    |
|----------------------|------------------------------------------------------------------------------------|
| <code>EACCES</code>  | The process does not have appropriate privileges.                                  |
| <code>ENOBUFS</code> | Insufficient resources were available in the system to perform the operation.      |
| <code>ENOMEM</code>  | Insufficient memory was available to fulfill the request.                          |
| <code>ENOSR</code>   | There were insufficient STREAMS resources available for the operation to complete. |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |
| MT-Level            | MT-Safe         |

| <b>NAME</b>        | spray – scatter data in order to test the network                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                    |                 |                                  |               |                                                                                         |
| <b>SYNOPSIS</b>    | <pre>cc [ flag ... ] file ... -lsocket -lnsl [ library ... ] #include &lt;rpcsvc/spray.h&gt;  bool_t xdr_sprayarr(XDR *xdrs, sprayarr *objp); bool_t xdr_spraycumul(XDR *xdrs, spraycumul *objp);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                 |                                    |                 |                                  |               |                                                                                         |
| <b>DESCRIPTION</b> | <p>The spray program sends packets to a given machine to test communications with that machine.</p> <p>The spray program is not a C function interface, per se, but it can be accessed using the generic remote procedure calling interface <code>clnt_call()</code>. See <a href="#">rpc_clnt_calls(3NSL)</a>. The program sends a packet to the called host. The host acknowledges receipt of the packet. The program counts the number of acknowledgments and can return that count.</p> <p>The spray program currently supports the following procedures, which should be called in the order given:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">SPRAYPROC_CLEAR</td> <td>This procedure clears the counter.</td> </tr> <tr> <td>SPRAYPROC_SPRAY</td> <td>This procedure sends the packet.</td> </tr> <tr> <td>SPRAYPROC_GET</td> <td>This procedure returns the count and the amount of time since the last SPRAYPROC_CLEAR.</td> </tr> </table> | SPRAYPROC_CLEAR | This procedure clears the counter. | SPRAYPROC_SPRAY | This procedure sends the packet. | SPRAYPROC_GET | This procedure returns the count and the amount of time since the last SPRAYPROC_CLEAR. |
| SPRAYPROC_CLEAR    | This procedure clears the counter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                                    |                 |                                  |               |                                                                                         |
| SPRAYPROC_SPRAY    | This procedure sends the packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                 |                                    |                 |                                  |               |                                                                                         |
| SPRAYPROC_GET      | This procedure returns the count and the amount of time since the last SPRAYPROC_CLEAR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                 |                                    |                 |                                  |               |                                                                                         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using <code>spray()</code></p> <p>The following code fragment demonstrates how the spray program is used:</p> <pre>#include &lt;rpc/rpc.h&gt; #include &lt;rpcsvc/spray.h&gt; . . . spraycumul    spray_result; sprayarr     spray_data; char         buf[100];          /* arbitrary data */ int          loop = 1000; CLIENT      *clnt; struct timeval timeout0 = {0, 0}; struct timeval timeout25 = {25, 0}; spray_data.sprayarr_len = (uint_t)100; spray_data.sprayarr_val = buf; clnt = clnt_create("somehost", SPRAYPROC, SPRAYVERS, "netpath"); if (clnt == (CLIENT *)NULL) {     /* handle this error */ } if (clnt_call(clnt, SPRAYPROC_CLEAR,              xdr_void, NULL, xdr_void, NULL, timeout25)) {     /* handle this error */ } while (loop- &gt; 0) {     if (clnt_call(clnt, SPRAYPROC_SPRAY,                  xdr_sprayarr, &amp;spray_data, xdr_void, NULL, timeout0)) {         /* handle this error */     } }</pre>                                  |                 |                                    |                 |                                  |               |                                                                                         |

## spray(3SOCKET)

### EXAMPLE 1 Using spray() (Continued)

```
 }
 }
 if (clnt_call(clnt, SPRAYPROC_GET,
 xdr_void, NULL, xdr_spraycumul, &spray_result, timeout25)) {
 /* handle this error */
 }
 printf("Acknowledged %ld of 1000 packets in %d secs %d usecs\n",
 spray_result.counter,
 spray_result.clock.sec,
 spray_result.clock.usec);
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Unsafe          |

**SEE ALSO** spray(1M), rpc\_clnt\_calls(3NSL), attributes(5)

**NOTES** This interface is unsafe in multithreaded applications. Unsafe interfaces should be called only from the main thread.

A spray program is not useful as a networking benchmark as it uses unreliable connectionless transports, for example, udp. It can report a large number of packets dropped, when the drops were caused by the program sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

| <b>NAME</b>        | t_accept – accept a connection request                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_accept(int fd, int resfd, const struct t_call *call);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces that evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, a different header file, <code>tiuser.h</code>, must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is issued by a transport user to accept a connection request. The parameter <i>fd</i> identifies the local transport endpoint where the connection indication arrived; <i>resfd</i> specifies the local transport endpoint where the connection is to be established, and <i>call</i> contains information required by the transport provider to complete the connection. The parameter <i>call</i> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>In <i>call</i>, <i>addr</i> is the protocol address of the calling transport user, <i>opt</i> indicates any options associated with the connection, <i>udata</i> points to any user data to be returned to the caller, and <i>sequence</i> is the value returned by <code>t_listen(3NSL)</code> that uniquely associates the response with a previously received connection indication. The address of the caller, <i>addr</i> may be null (length zero). Where <i>addr</i> is not null then it may optionally be checked by XTI.</p> <p>A transport user may accept a connection on either the same, or on a different, local transport endpoint than the one on which the connection indication arrived. Before the connection can be accepted on the same endpoint (<i>resfd==fd</i>), the user must have responded to any previous connection indications received on that transport endpoint by means of <code>t_accept()</code> or <code>t_snddis(3NSL)</code>. Otherwise, <code>t_accept()</code> will fail and set <code>t_errno</code> to TINDOUT.</p> <p>If a different transport endpoint is specified (<i>resfd!=fd</i>), then the user may or may not choose to bind the endpoint before the <code>t_accept()</code> is issued. If the endpoint is not bound prior to the <code>t_accept()</code>, the endpoint must be in the T_UNBND state before the <code>t_accept()</code> is issued, and the transport provider will automatically bind it to an address that is appropriate for the protocol concerned. If the transport user chooses to bind the endpoint it must be bound to a protocol address with a <i>qlen</i> of zero and must be in the T_IDLE state before the <code>t_accept()</code> is issued.</p> <p>Responding endpoints should be supplied to <code>t_accept()</code> in the state T_UNBND.</p> <p>The call to <code>t_accept()</code> may fail with <code>t_errno</code> set to TLOOK if there are indications (for example connect or disconnect) waiting to be received on endpoint <i>fd</i>. Applications should be prepared for such a failure.</p> |

## t\_accept(3NSL)

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>The <i>udata</i> argument enables the called transport user to send user data to the caller and the amount of user data must not exceed the limits supported by the transport provider as returned in the <i>connect</i> field of the <i>info</i> argument of <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>. If the <i>len</i> field of <i>udata</i> is zero, no data will be sent to the caller. All the <i>maxlen</i> fields are meaningless.</p> <p>When the user does not indicate any option (<i>call</i>→<i>opt.len</i> = 0) the connection shall be accepted with the option values currently set for the responding endpoint <i>resfd</i>.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>VALID STATES</b>  | <code>fd</code> : T_INCON<br><code>resfd</code> ( <code>fd!=resfd</code> ): T_IDLE, T_UNBND                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ERRORS</b>        | On failure, <code>t_errno</code> is set to one of the following:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| TACCES               | The user does not have permission to accept a connection on the responding transport endpoint or to use the specified options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| TBADDATA             | The amount of user data specified was not within the bounds allowed by the transport provider.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| TBADF                | The file descriptor <i>fd</i> or <i>resfd</i> does not refer to a transport endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| TBADOPT              | The specified options were in an incorrect format or contained illegal information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TBADSEQ              | Either an invalid sequence number was specified, or a valid sequence number was specified but the connection request was aborted by the peer. In the latter case, its T_DISCONNECT event will be received on the listening endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| TINDOUT              | The function was called with <i>fd==resfd</i> but there are outstanding connection indications on the endpoint. Those other connection indications must be handled either by rejecting them by means of <code>t_snddis(3NSL)</code> or accepting them on a different endpoint by means of <code>t_accept</code> .                                                                                                                                                                                                                                                                                                                                                     |
| TLOOK                | An asynchronous event has occurred on the transport endpoint referenced by <i>fd</i> and requires immediate attention.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TNOTSUPPORT          | This function is not supported by the underlying transport provider.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

t\_accept(3NSL)

|               |                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOUTSTATE     | The communications endpoint referenced by <i>fd</i> or <i>resfd</i> is not in one of the states in which a call to this function is valid.                                    |
| TPROTO        | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <i>t_errno</i> ). |
| TPROVMISMATCH | The file descriptors <i>fd</i> and <i>resfd</i> do not refer to the same transport provider.                                                                                  |
| TRESADDR      | This transport provider requires both <i>fd</i> and <i>resfd</i> to be bound to the same address. This error results if they are not.                                         |
| TRESQLEN      | The endpoint referenced by <i>resfd</i> (where <i>resfd</i> != <i>fd</i> ) was bound to a protocol address with a <i>qlen</i> that is greater than zero.                      |
| TSYSERR       | A system error has occurred during execution of this function.                                                                                                                |

## TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

### Interface Header

The XTI interfaces use the header file, *xti.h*. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

### Error Description Values

The *t\_errno* values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO  
TINDOUT  
TPROVMISMATCH  
TRESADDR  
TRESQLEN

### Option Buffer

The format of the options in an *opt* buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not specify the buffer format.

### ATTRIBUTES

See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

t\_accept(3NSL)

**SEE ALSO** t\_connect(3NSL), t\_getinfo(3NSL), t\_getstate(3NSL), t\_listen(3NSL), t\_open(3NSL), t\_optmgmt(3NSL), t\_rcvconnect(3NSL), t\_snddis(3NSL), attributes(5)

**WARNINGS** There may be transport provider-specific restrictions on address binding.

Some transport providers do not differentiate between a connection indication and the connection itself. If the connection has already been established after a successful return of t\_listen(3NSL), t\_accept() will assign the existing connection to the transport endpoint specified by *resfd*.

| <b>NAME</b>        | t_alloc – allocate a library structure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |        |                                                                                                                                      |       |                                                                                                                                        |         |                                                                                                                  |       |                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  void *t_alloc(int fd, int struct_type, int fields);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |        |                                                                                                                                      |       |                                                                                                                                        |         |                                                                                                                  |       |                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, a different header file, <code>tiuser.h</code>, must be used. Refer to the section, <b>TLI COMPATIBILITY</b>, for a description of differences between the two interfaces.</p> <p>The <code>t_alloc()</code> function dynamically allocates memory for the various transport function argument structures as specified below. This function will allocate memory for the specified structure, and will also allocate memory for buffers referenced by the structure.</p> <p>The structure to allocate is specified by <i>struct_type</i> and must be one of the following:</p> <table border="0"> <tr> <td>T_BIND</td> <td>struct</td> <td>t_bind</td> </tr> <tr> <td>T_CALL</td> <td>struct</td> <td>t_call</td> </tr> <tr> <td>T_OPTMGMT</td> <td>struct</td> <td>t_optmgmt</td> </tr> <tr> <td>T_DIS</td> <td>struct</td> <td>t_discon</td> </tr> <tr> <td>T_UNITDATA</td> <td>struct</td> <td>t_unitdata</td> </tr> <tr> <td>T_UDERROR</td> <td>struct</td> <td>t_uderr</td> </tr> <tr> <td>T_INFO</td> <td>struct</td> <td>t_info</td> </tr> </table> <p>where each of these structures may subsequently be used as an argument to one or more transport functions.</p> <p>Each of the above structures, except <code>T_INFO</code>, contains at least one field of type <code>struct netbuf</code>. For each field of this type, the user may specify that the buffer for that field should be allocated as well. The length of the buffer allocated will be equal to or greater than the appropriate size as returned in the <i>info</i> argument of <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>. The relevant fields of the <i>info</i> argument are described in the following list. The <i>fields</i> argument specifies which buffers to allocate, where the argument is the bitwise-or of any of the following:</p> <table border="0"> <tr> <td>T_ADDR</td> <td>The <i>addr</i> field of the <code>t_bind</code>, <code>t_call</code>, <code>t_unitdata</code> or <code>t_uderr</code> structures.</td> </tr> <tr> <td>T_OPT</td> <td>The <i>opt</i> field of the <code>t_optmgmt</code>, <code>t_call</code>, <code>t_unitdata</code> or <code>t_uderr</code> structures.</td> </tr> <tr> <td>T_UDATA</td> <td>The <i>udata</i> field of the <code>t_call</code>, <code>t_discon</code> or <code>t_unitdata</code> structures.</td> </tr> <tr> <td>T_ALL</td> <td>All relevant fields of the given structure. Fields which are not supported by the transport provider specified by <i>fd</i> will not be allocated.</td> </tr> </table> <p>For each relevant field specified in <i>fields</i>, <code>t_alloc()</code> will allocate memory for the buffer associated with the field, and initialize the <i>len</i> field to zero and the <i>buf</i> pointer and <i>maxlen</i> field accordingly. Irrelevant or unknown values passed in <i>fields</i> are</p> | T_BIND     | struct | t_bind | T_CALL | struct | t_call | T_OPTMGMT | struct | t_optmgmt | T_DIS | struct | t_discon | T_UNITDATA | struct | t_unitdata | T_UDERROR | struct | t_uderr | T_INFO | struct | t_info | T_ADDR | The <i>addr</i> field of the <code>t_bind</code> , <code>t_call</code> , <code>t_unitdata</code> or <code>t_uderr</code> structures. | T_OPT | The <i>opt</i> field of the <code>t_optmgmt</code> , <code>t_call</code> , <code>t_unitdata</code> or <code>t_uderr</code> structures. | T_UDATA | The <i>udata</i> field of the <code>t_call</code> , <code>t_discon</code> or <code>t_unitdata</code> structures. | T_ALL | All relevant fields of the given structure. Fields which are not supported by the transport provider specified by <i>fd</i> will not be allocated. |

Fields which are not supported by the transport provider specified by <i>fd</i> will not be allocated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |        |                                                                                                                                      |       |                                                                                                                                        |         |                                                                                                                  |       |                                                                                                                                                    |

## t\_alloc(3NSL)

ignored. Since the length of the buffer allocated will be based on the same size information that is returned to the user on a call to [t\\_open\(3NSL\)](#) and [t\\_getinfo\(3NSL\)](#), *fd* must refer to the transport endpoint through which the newly allocated structure will be passed. In the case where a T\_INFO structure is to be allocated, *fd* may be set to any value. In this way the appropriate size information can be accessed. If the size value associated with any specified field is T\_INVALID, `t_alloc()` will be unable to determine the size of the buffer to allocate and will fail, setting `t_errno` to TSYSERR and `errno` to EINVAL. See [t\\_open\(3NSL\)](#) or [t\\_getinfo\(3NSL\)](#). If the size value associated with any specified field is T\_INFINITE, then the behavior of `t_alloc()` is implementation-defined. For any field not specified in *fields*, *buf* will be set to the null pointer and *len* and *maxlen* will be set to zero. See [t\\_open\(3NSL\)](#) or [t\\_getinfo\(3NSL\)](#).

The pointer returned if the allocation succeeds is suitably aligned so that it can be assigned to a pointer to any type of object and then used to access such an object or array of such objects in the space allocated.

Use of `t_alloc()` to allocate structures will help ensure the compatibility of user programs with future releases of the transport interface functions.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RETURN VALUES</b>            | On successful completion, <code>t_alloc()</code> returns a pointer to the newly allocated structure. On failure, a null pointer is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>VALID STATES</b>             | ALL - apart from T_UNINIT                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ERRORS</b>                   | On failure, <code>t_errno</code> is set to one of the following:<br><br>TBADF <code>struct_type</code> is other than T_INFO and the specified file descriptor does not refer to a transport endpoint.<br><br>TNOSTRUCTYPE        Unsupported <i>struct_type</i> requested. This can include a request for a structure type which is inconsistent with the transport provider type specified, that is, connection-mode or connectionless-mode.<br><br>TPROTO               This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).<br><br>TSYSERR              A system error has occurred during execution of this function. |
| <b>TLI COMPATIBILITY</b>        | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Interface Header</b>         | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><br><pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Error Description Values</b> | The <code>t_errno</code> values that can be set by the XTI interface and cannot be set by the TLI interface are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

TPROTO

TNOSTRUCTYPE

**Special Buffer Sizes**

Assume that the value associated with any field of `struct t_info` (argument returned by `t_open()` or `t_getinfo()`) that describes buffer limits is `-1`. Then the underlying service provider can support a buffer of unlimited size. If this is the case, `t_alloc()` will allocate a buffer with the default size 1024 bytes, which may be handled as described in the next paragraph.

If the underlying service provider supports a buffer of unlimited size in the `netbuf` structure (see `t_connect(3NSL)`), `t_alloc()` will return a buffer of size 1024 bytes. If a larger size buffer is required, it will need to be allocated separately using a memory allocation routine such as `malloc(3C)`. The `buf` and `maxlen` fields of the `netbuf` data structure can then be updated with the address of the new buffer and the 1024 byte buffer originally allocated by `t_alloc()` can be freed using `free(3C)`.

Assume that the value associated with any field of `struct t_info` (argument returned by `t_open()` or `t_getinfo()`) that describes `nbuffer` limits is `-2`. Then `t_alloc()` will set the buffer pointer to `NULL` and the buffer maximum size to `0`, and then will return success (see `t_open(3NSL)` or `t_getinfo(3NSL)`).

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO**

| <b>NAME</b>        | t_bind – bind an address to a transport endpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_bind(int fd, const struct t_bind *req, struct t_bind *ret);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces that evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function associates a protocol address with the transport endpoint specified by <i>fd</i> and activates that transport endpoint. In connection mode, the transport provider may begin enqueueing incoming connect indications, or servicing a connection request on the transport endpoint. In connectionless-mode, the transport user may send or receive data units through the transport endpoint.</p> <p>The <i>req</i> and <i>ret</i> arguments point to a <code>t_bind</code> structure containing the following members:</p> <pre>struct netbuf    addr; unsigned        qlen;</pre> <p>The <i>addr</i> field of the <code>t_bind</code> structure specifies a protocol address, and the <i>qlen</i> field is used to indicate the maximum number of outstanding connection indications.</p> <p>The parameter <i>req</i> is used to request that an address, represented by the <code>netbuf</code> structure, be bound to the given transport endpoint. The parameter <i>len</i> specifies the number of bytes in the address, and <i>buf</i> points to the address buffer. The parameter <i>maxlen</i> has no meaning for the <i>req</i> argument. On return, <i>ret</i> contains an encoding for the address that the transport provider actually bound to the transport endpoint; if an address was specified in <i>req</i>, this will be an encoding of the same address. In <i>ret</i>, the user specifies <i>maxlen</i>, which is the maximum size of the address buffer, and <i>buf</i> which points to the buffer where the address is to be placed. On return, <i>len</i> specifies the number of bytes in the bound address, and <i>buf</i> points to the bound address. If <i>maxlen</i> equals zero, no address is returned. If <i>maxlen</i> is greater than zero and less than the length of the address, <code>t_bind()</code> fails with <code>t_errno</code> set to <code>TBUFOVFLW</code>.</p> <p>If the requested address is not available, <code>t_bind()</code> will return <code>-1</code> with <code>t_errno</code> set as appropriate. If no address is specified in <i>req</i> (the <i>len</i> field of <i>addr</i> in <i>req</i> is zero or <i>req</i> is <code>NULL</code>), the transport provider will assign an appropriate address to be bound, and will return that address in the <i>addr</i> field of <i>ret</i>. If the transport provider could not allocate an address, <code>t_bind()</code> will fail with <code>t_errno</code> set to <code>TNOADDR</code>.</p> |

t\_bind(3NSL)

The parameter *req* may be a null pointer if the user does not wish to specify an address to be bound. Here, the value of *qlen* is assumed to be zero, and the transport provider will assign an address to the transport endpoint. Similarly, *ret* may be a null pointer if the user does not care what address was bound by the provider and is not interested in the negotiated value of *qlen*. It is valid to set *req* and *ret* to the null pointer for the same call, in which case the provider chooses the address to bind to the transport endpoint and does not return that information to the user.

The *qlen* field has meaning only when initializing a connection-mode service. It specifies the number of outstanding connection indications that the transport provider should support for the given transport endpoint. An outstanding connection indication is one that has been passed to the transport user by the transport provider but which has not been accepted or rejected. A value of *qlen* greater than zero is only meaningful when issued by a passive transport user that expects other users to call it. The value of *qlen* will be negotiated by the transport provider and may be changed if the transport provider cannot support the specified number of outstanding connection indications. However, this value of *qlen* will never be negotiated from a requested value greater than zero to zero. This is a requirement on transport providers; see WARNINGS below. On return, the *qlen* field in *ret* will contain the negotiated value.

If *fd* refers to a connection-mode service, this function allows more than one transport endpoint to be bound to the same protocol address. but it is not possible to bind more than one protocol address to the same transport endpoint. However, the transport provider must also support this capability. If a user binds more than one transport endpoint to the same protocol address, only one endpoint can be used to listen for connection indications associated with that protocol address. In other words, only one t\_bind() for a given protocol address may specify a value of *qlen* greater than zero. In this way, the transport provider can identify which transport endpoint should be notified of an incoming connection indication. If a user attempts to bind a protocol address to a second transport endpoint with a value of *qlen* greater than zero, t\_bind() will return -1 and set t\_errno to TADDRBUSY. When a user accepts a connection on the transport endpoint that is being used as the listening endpoint, the bound protocol address will be found to be busy for the duration of the connection, until a t\_unbind(3NSL) or t\_close(3NSL) call has been issued. No other transport endpoints may be bound for listening on that same protocol address while that initial listening endpoint is active (in the data transfer phase or in the T\_IDLE state). This will prevent more than one transport endpoint bound to the same protocol address from accepting connection indications.

If *fd* refers to connectionless mode service, this function allows for more than one transport endpoint to be associated with a protocol address, where the underlying transport provider supports this capability (often in conjunction with value of a protocol-specific option). If a user attempts to bind a second transport endpoint to an already bound protocol address when such capability is not supported for a transport provider, t\_bind() will return -1 and set t\_errno to TADDRBUSY.

#### RETURN VALUES

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and t\_errno is set to indicate an error.

#### VALID STATES

T\_UNBND

t\_bind(3NSL)

**ERRORS** On failure, `t_errno` is set to one of the following:

|           |                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TACCES    | The user does not have permission to use the specified address.                                                                                                                                                                                                              |
| TADDRBUSY | The requested address is in use.                                                                                                                                                                                                                                             |
| TBADADDR  | The specified protocol address was in an incorrect format or contained illegal information.                                                                                                                                                                                  |
| TBADF     | The specified file descriptor does not refer to a transport endpoint.                                                                                                                                                                                                        |
| TBUFOVFLW | The number of bytes allowed for an incoming argument ( <i>maxlen</i> ) is greater than 0 but not sufficient to store the value of that argument. The provider's state will change to <code>T_IDLE</code> and the information to be returned in <i>ret</i> will be discarded. |
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                   |
| TNOADDR   | The transport provider could not allocate an address.                                                                                                                                                                                                                        |
| TPROTO    | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                                                          |
| TSYSERR   | A system error has occurred during execution of this function.                                                                                                                                                                                                               |

**TLI COMPATIBILITY** The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

**Interface Header** The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Address Bound** The user can compare the addresses in *req* and *ret* to determine whether the transport provider bound the transport endpoint to a different address than that requested.

**Error Description Values** The `t_errno` values `TPROTO` and `TADDRBUSY` can be set by the XTI interface but cannot be set by the TLI interface.

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is `TBUFOVFLW`. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

t\_bind(3NSL)

**SEE ALSO** t\_accept(3NSL), t\_alloc(3NSL), t\_close(3NSL), t\_connect(3NSL),  
t\_unbind(3NSL), attributes(5)

**WARNINGS** The requirement that the value of *qlen* never be negotiated from a requested value greater than zero to zero implies that transport providers, rather than the XTI implementation itself, accept this restriction.

An implementation need not allow an application explicitly to bind more than one communications endpoint to a single protocol address, while permitting more than one connection to be accepted to the same protocol address. That means that although an attempt to bind a communications endpoint to some address with *qlen=0* might be rejected with TADDRBUSY, the user may nevertheless use this (unbound) endpoint as a responding endpoint in a call to t\_accept(3NSL). To become independent of such implementation differences, the user should supply unbound responding endpoints to t\_accept(3NSL).

The local address bound to an endpoint may change as result of a t\_accept(3NSL) or t\_connect(3NSL) call. Such changes are not necessarily reversed when the connection is released.

## t\_close(3NSL)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |

| <b>NAME</b>              | t_close – close a transport endpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>SYNOPSIS</b>          | <pre>#include &lt;xti.h&gt;  int t_close(int fd);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>DESCRIPTION</b>       | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_close()</code> function informs the transport provider that the user is finished with the transport endpoint specified by <code>fd</code>, and frees any local library resources associated with the endpoint. In addition, <code>t_close()</code> closes the file associated with the transport endpoint.</p> <p>The function <code>t_close()</code> should be called from the <code>T_UNBND</code> state. See <code>t_getstate(3NSL)</code>. However, this function does not check state information, so it may be called from any state to close a transport endpoint. If this occurs, the local library resources associated with the endpoint will be freed automatically. In addition, <code>close(2)</code> will be issued for that file descriptor; if there are no other descriptors in this process or in another process which references the communication endpoint, any connection that may be associated with that endpoint is broken. The connection may be terminated in an orderly or abortive manner.</p> <p>A <code>t_close()</code> issued on a connection endpoint may cause data previously sent, or data not yet received, to be lost. It is the responsibility of the transport user to ensure that data is received by the remote peer.</p> |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>RETURN VALUES</b>     | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |

| <b>TLI COMPATIBILITY</b> | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>Interface Header</b>  | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |
|                          | <pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                                       |                     |                                                                                                                                                                                     |                      |                                                                |

t\_close(3NSL)

**Error Description Values**

The t\_errno value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO**

| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces. This function enables a transport user to request a connection to the specified destination transport user.</p> <p>This function can only be issued in the <code>T_IDLE</code> state. The parameter <i>fd</i> identifies the local transport endpoint where communication will be established, while <i>sndcall</i> and <i>rcvcall</i> point to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>The parameter <i>sndcall</i> specifies information needed by the transport provider to establish a connection and <i>rcvcall</i> specifies information that is associated with the newly established connection.</p> <p>In <i>sndcall</i>, <i>addr</i> specifies the protocol address of the destination transport user, <i>opt</i> presents any protocol-specific information that might be needed by the transport provider, <i>udata</i> points to optional user data that may be passed to the destination transport user during connection establishment, and <i>sequence</i> has no meaning for this function.</p> <p>On return, in <i>rcvcall</i>, <i>addr</i> contains the protocol address associated with the responding transport endpoint, <i>opt</i> represents any protocol-specific information associated with the connection, <i>udata</i> points to optional user data that may be returned by the destination transport user during connection establishment, and <i>sequence</i> has no meaning for this function.</p> <p>The <i>opt</i> argument permits users to define the options that may be passed to the transport provider. The user may choose not to negotiate protocol options by setting the <i>len</i> field of <i>opt</i> to zero. In this case, the provider uses the option values currently set for the communications endpoint.</p> <p>If used, <i>sndcall</i>→<i>opt.buf</i> must point to a buffer with the corresponding options, and <i>sndcall</i>→<i>opt.len</i> must specify its length. The <i>maxlen</i> and <i>buf</i> fields of the <code>netbuf</code> structure pointed by <i>rcvcall</i>→<i>addr</i> and <i>rcvcall</i>→<i>opt</i> must be set before the call.</p> |

The *udata* argument enables the caller to pass user data to the destination transport user and receive user data from the destination user during connection establishment. However, the amount of user data must not exceed the limits supported by the transport provider as returned in the *connect* field of the *info* argument of [t\\_open\(3NSL\)](#) or [t\\_getinfo\(3NSL\)](#). If the *len* of *udata* is zero in *sndcall*, no data will be sent to the destination transport user.

On return, the *addr*, *opt* and *udata* fields of *rcvcall* will be updated to reflect values associated with the connection. Thus, the *maxlen* field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, *maxlen* can be set to zero, in which case no information to this specific argument is given to the user on the return from [t\\_connect\(\)](#). If *maxlen* is greater than zero and less than the length of the value, [t\\_connect\(\)](#) fails with *t\_errno* set to `TBUFOVFLW`. If *rcvcall* is set to `NULL`, no information at all is returned.

By default, [t\\_connect\(\)](#) executes in synchronous mode, and will wait for the destination user's response before returning control to the local user. A successful return (that is, return value of zero) indicates that the requested connection has been established. However, if `O_NONBLOCK` is set by means of [t\\_open\(3NSL\)](#) or [fcntl\(2\)](#), [t\\_connect\(\)](#) executes in asynchronous mode. In this case, the call will not wait for the remote user's response, but will return control immediately to the local user and return `-1` with *t\_errno* set to `TNODATA` to indicate that the connection has not yet been established. In this way, the function simply initiates the connection establishment procedure by sending a connection request to the destination transport user. The [t\\_rcvconnect\(3NSL\)](#) function is used in conjunction with [t\\_connect\(\)](#) to determine the status of the requested connection.

When a synchronous [t\\_connect\(\)](#) call is interrupted by the arrival of a signal, the state of the corresponding transport endpoint is `T_OUTCON`, allowing a further call to either [t\\_rcvconnect\(3NSL\)](#), [t\\_rcvdis\(3NSL\)](#) or [t\\_snddis\(3NSL\)](#). When an asynchronous [t\\_connect\(\)](#) call is interrupted by the arrival of a signal, the state of the corresponding transport endpoint is `T_IDLE`.

|                        |                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RETURN VALUES</b>   | Upon successful completion, a value of 0 is returned. Otherwise, a value of <code>-1</code> is returned and <i>t_errno</i> is set to indicate an error.        |
| <b>VALID STATES</b>    | <code>T_IDLE</code>                                                                                                                                            |
| <b>ERRORS</b>          | On failure, <i>t_errno</i> is set to one of the following:                                                                                                     |
| <code>TACCES</code>    | The user does not have permission to use the specified address or options.                                                                                     |
| <code>TADDRBUSY</code> | This transport provider does not support multiple connections with the same local and remote addresses. This error indicates that a connection already exists. |
| <code>TBADADDR</code>  | The specified protocol address was in an incorrect format or contained illegal information.                                                                    |
| <code>TBADDATA</code>  | The amount of user data specified was not within the bounds allowed by the transport provider.                                                                 |

## t\_connect(3NSL)

|                                 |             |                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | TBADF       | The specified file descriptor does not refer to a transport endpoint.                                                                                                                                                                                                                                                                               |
|                                 | TBADOPT     | The specified protocol options were in an incorrect format or contained illegal information.                                                                                                                                                                                                                                                        |
|                                 | TBUFOVFLW   | The number of bytes allocated for an incoming argument ( <i>maxlen</i> ) is greater than 0 but not sufficient to store the value of that argument. If executed in synchronous mode, the provider's state, as seen by the user, changes to T_DATAXFER, and the information to be returned in <i>rcvcall</i> is discarded.                            |
|                                 | TLOOK       | An asynchronous event has occurred on this transport endpoint and requires immediate attention.                                                                                                                                                                                                                                                     |
|                                 | TNODATA     | O_NONBLOCK was set, so the function successfully initiated the connection establishment procedure, but did not wait for a response from the remote user.                                                                                                                                                                                            |
|                                 | TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                                                                                                                                                                                |
|                                 | TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                                                                          |
|                                 | TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <i>t_errno</i> ).                                                                                                                                                                       |
|                                 | TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                      |
| <b>TLI COMPATIBILITY</b>        |             | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                     |
| <b>Interface Header</b>         |             | The XTI interfaces use the header file, <i>xti.h</i> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><br><pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                    |
| <b>Error Description Values</b> |             | The TPROTO and TADDRBUSY <i>t_errno</i> values can be set by the XTI interface but not by the TLI interface.<br><br>A <i>t_errno</i> value that this routine can return under different circumstances than its XTI counterpart is TBUFOVFLW. It can be returned even when the <i>maxlen</i> field of the corresponding buffer has been set to zero. |
| <b>Option Buffers</b>           |             | The format of the options in an <i>opt</i> buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.                                                                                                                                                                                |

| <b>NAME</b>                     | t_errno – XTI error return value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>                 | <pre>#include &lt;xti.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b>              | <p>This error return value is part of the XTI interfaces that evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI interface that has the same name as an XTI interfaces, a different headerfile, &lt;tiuser.h&gt;, must be used. Refer the the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>t_errno is used by XTI functions to return error values.</p> <p>XTI functions provide an error number in t_errno which has type <i>int</i> and is defined in &lt;xti.h&gt;. The value of t_errno will be defined only after a call to a XTI function for which it is explicitly stated to be set and until it is changed by the next XTI function call. The value of t_errno should only be examined when it is indicated to be valid by a function's return value. Programs should obtain the definition of t_errno by the inclusion of &lt;xti.h&gt;. The practice of defining t_errno in program as <code>extern int t_errno</code> is obsolescent. No XTI function sets t_errno to 0 to indicate an error.</p> <p>It is unspecified whether t_errno is a macro or an identifier with external linkage. It represents a modifiable lvalue of type <i>int</i>. If a macro definition is suppressed in order to access an actual object or a program defines an identifier with name <i>t_errno</i>, the behavior is undefined.</p> <p>The symbolic values stored in t_errno by an XTI function are defined in the ERRORS sections in all relevant XTI function definition pages.</p> |
| <b>TLI COMPATIBILITY</b>        | <p>t_errno is also used by TLI functions to return error values.</p> <p>The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Interface Header</b>         | <p>The XTI interfaces use the header file, &lt;xti.h&gt;. TLI interfaces should <i>not</i> use this header. They should use the header:</p> <pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Error Description Values</b> | <p>The t_errno values that can be set by the XTI interface but cannot be set by the TLI interface are:</p> <pre>TNOSTRUCTYPE TBADNAME TBADQLEN TADDRBUSY TINDOUT</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>NAME</b>              | t_error – produce error message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>          | <pre>#include &lt;xti.h&gt;  int t_error(const char *errmsg);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>       | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_error()</code> function produces a message on the standard error output which describes the last error encountered during a call to a transport function. The argument string <code>errmsg</code> is a user-supplied error message that gives context to the error.</p> <p>The error message is written as follows: first (if <code>errmsg</code> is not a null pointer and the character pointed to by <code>errmsg</code> is not the null character) the string pointed to by <code>errmsg</code> followed by a colon and a space; then a standard error message string for the current error defined in <code>t_errno</code>. If <code>t_errno</code> has a value different from <code>TSYSERR</code>, the standard error message string is followed by a newline character. If, however, <code>t_errno</code> is equal to <code>TSYSERR</code>, the <code>t_errno</code> string is followed by the standard error message string for the current error defined in <code>errno</code> followed by a newline.</p> <p>The language for error message strings written by <code>t_error()</code> is that of the current locale. If it is English, the error message string describing the value in <code>t_errno</code> may be derived from the comments following the <code>t_errno</code> codes defined in <code>xti.h</code>. The contents of the error message strings describing the value in <code>errno</code> are the same as those returned by the <code>strerror(3C)</code> function with an argument of <code>errno</code>.</p> <p>The error number, <code>t_errno</code>, is only set when an error occurs and it is not cleared on successful calls.</p> |
| <b>EXAMPLES</b>          | <p>If a <code>t_connect(3NSL)</code> function fails on transport endpoint <code>fd2</code> because a bad address was given, the following call might follow the failure:</p> <pre>t_error("t_connect failed on fd2");</pre> <p>The diagnostic message to be printed would look like:</p> <pre>t_connect failed on fd2: incorrect addr format</pre> <p>where <i>incorrect addr format</i> identifies the specific error that occurred, and <i>t_connect failed on fd2</i> tells the user which function failed on which transport endpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>RETURN VALUES</b>     | Upon completion, a value of 0 is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>ERRORS</b>            | No errors are defined for the <code>t_error()</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>TLI COMPATIBILITY</b> | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Interface Header** The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description Values** The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `t_errno(3NSL)`, `strerror(3C)`, `attributes(5)`

## t\_free(3NSL)

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |

| <b>NAME</b>          | t_free – free a library structure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_free(void *ptr, int struct_type);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |
| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_free()</code> function frees memory previously allocated by <code>t_alloc(3NSL)</code>. This function will free memory for the specified structure, and will also free memory for buffers referenced by the structure.</p> <p>The argument <code>ptr</code> points to one of the seven structure types described for <code>t_alloc(3NSL)</code>, and <code>struct_type</code> identifies the type of that structure which must be one of the following:</p> <table><tr><td>T_BIND</td><td>struct</td><td>t_bind</td></tr><tr><td>T_CALL</td><td>struct</td><td>t_call</td></tr><tr><td>T_OPTMGMT</td><td>struct</td><td>t_optmgmt</td></tr><tr><td>T_DIS</td><td>struct</td><td>t_discon</td></tr><tr><td>T_UNITDATA</td><td>struct</td><td>t_unitdata</td></tr><tr><td>T_UDERROR</td><td>struct</td><td>t_uderr</td></tr><tr><td>T_INFO</td><td>struct</td><td>t_info</td></tr></table> <p>where each of these structures is used as an argument to one or more transport functions.</p> <p>The function <code>t_free()</code> will check the <code>addr</code>, <code>opt</code> and <code>udata</code> fields of the given structure, as appropriate, and free the buffers pointed to by the <code>buf</code> field of the <code>netbuf</code> structure. If <code>buf</code> is a null pointer, <code>t_free()</code> will not attempt to free memory. After all buffers are freed, <code>t_free()</code> will free the memory associated with the structure pointed to by <code>ptr</code>.</p> <p>Undefined results will occur if <code>ptr</code> or any of the <code>buf</code> pointers points to a block of memory that was not previously allocated by <code>t_alloc(3NSL)</code>.</p> | T_BIND     | struct | t_bind | T_CALL | struct | t_call | T_OPTMGMT | struct | t_optmgmt | T_DIS | struct | t_discon | T_UNITDATA | struct | t_unitdata | T_UDERROR | struct | t_uderr | T_INFO | struct | t_info |

| TPROTO               | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |
| TSYSERR              | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |            |        |        |        |        |        |           |        |           |       |        |          |            |        |            |           |        |         |        |        |        |

t\_free(3NSL)

**TLI COMPATIBILITY** The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

**Interface Header** The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description Values** The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `t_alloc(3NSL)`, `attributes(5)`

| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_getinfo(int fd, struct t_info *info);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                                                                                                                                                                                     |                |                                                                                                                                                                                                                                                  |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function returns the current characteristics of the underlying transport protocol and/or transport connection associated with file descriptor <i>fd</i>. The <i>info</i> pointer is used to return the same information returned by <code>t_open(3NSL)</code>, although not necessarily precisely the same values. This function enables a transport user to access this information during any phase of communication.</p> <p>This argument points to a <code>t_info</code> structure which contains the following members:</p> <pre>t_scalar_t addr; /*max size in octets of the transport protocol address*/ t_scalar_t options; /*max number of bytes of protocol-specific options */ t_scalar_t tsdu; /*max size in octets of a transport service data unit */ t_scalar_t etsdu; /*max size in octets of an expedited transport service*/ /*data unit (ETSDU) */ t_scalar_t connect; /*max number of octets allowed on connection */ /*establishment functions */ t_scalar_t discon; /*max number of octets of data allowed on t_snddis() */ /*and t_rcvdis() functions */ t_scalar_t servtype; /*service type supported by the transport provider */ t_scalar_t flags; /*other info about the transport provider */</pre> <p>The values of the fields have the following meanings:</p> <table><tr><td><i>addr</i></td><td>A value greater than zero indicates the maximum size of a transport protocol address and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not provide user access to transport protocol addresses.</td></tr><tr><td><i>options</i></td><td>A value greater than zero indicates the maximum number of bytes of protocol-specific options supported by the provider, and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not support user-settable options.</td></tr><tr><td><i>tsdu</i></td><td>A value greater than zero specifies the maximum size in octets of a transport service data unit (TSDU); a value of <code>T_NULL (zero)</code> specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a datastream with no logical boundaries preserved across a connection; a value of <code>T_INFINITE (-1)</code> specifies that there is no limit on the size in octets of a TSDU; and a value of <code>T_INVALID (-2)</code> specifies that the transfer of normal data is not supported by the transport provider.</td></tr><tr><td><i>etsdu</i></td><td>A value greater than zero specifies the maximum size in octets of an expedited transport service data unit (ETSDU); a value of</td></tr></table> | <i>addr</i> | A value greater than zero indicates the maximum size of a transport protocol address and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not provide user access to transport protocol addresses. | <i>options</i> | A value greater than zero indicates the maximum number of bytes of protocol-specific options supported by the provider, and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not support user-settable options. | <i>tsdu</i> | A value greater than zero specifies the maximum size in octets of a transport service data unit (TSDU); a value of <code>T_NULL (zero)</code> specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a datastream with no logical boundaries preserved across a connection; a value of <code>T_INFINITE (-1)</code> specifies that there is no limit on the size in octets of a TSDU; and a value of <code>T_INVALID (-2)</code> specifies that the transfer of normal data is not supported by the transport provider. | <i>etsdu</i> | A value greater than zero specifies the maximum size in octets of an expedited transport service data unit (ETSDU); a value of |
| <i>addr</i>        | A value greater than zero indicates the maximum size of a transport protocol address and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not provide user access to transport protocol addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |             |                                                                                                                                                                                                                                     |                |                                                                                                                                                                                                                                                  |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                                                                                                |
| <i>options</i>     | A value greater than zero indicates the maximum number of bytes of protocol-specific options supported by the provider, and a value of <code>T_INVALID (-2)</code> specifies that the transport provider does not support user-settable options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                                                                                                                                                                                                                     |                |                                                                                                                                                                                                                                                  |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                                                                                                |
| <i>tsdu</i>        | A value greater than zero specifies the maximum size in octets of a transport service data unit (TSDU); a value of <code>T_NULL (zero)</code> specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a datastream with no logical boundaries preserved across a connection; a value of <code>T_INFINITE (-1)</code> specifies that there is no limit on the size in octets of a TSDU; and a value of <code>T_INVALID (-2)</code> specifies that the transfer of normal data is not supported by the transport provider.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                                                                                                                                                                                                                                     |                |                                                                                                                                                                                                                                                  |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                                                                                                |
| <i>etsdu</i>       | A value greater than zero specifies the maximum size in octets of an expedited transport service data unit (ETSDU); a value of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                                                                                                                                                                                     |                |                                                                                                                                                                                                                                                  |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                                                                                                |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | T_NULL (zero) specifies that the transport provider does not support the concept of ETSDU, although it does support the sending of an expedited data stream with no logical boundaries preserved across a connection; a value of T_INFINITE (-1) specifies that there is no limit on the size (in octets) of an ETSDU; and a value of T_INVALID (-2) specifies that the transfer of expedited data is not supported by the transport provider. Note that the semantics of expedited data may be quite different for different transport providers.                                                                                      |
| <i>connect</i>  | A value greater than zero specifies the maximum number of octets that may be associated with connection establishment functions and a value of T_INVALID (-2) specifies that the transport provider does not allow data to be sent with connection establishment functions.                                                                                                                                                                                                                                                                                                                                                             |
| <i>discon</i>   | If the T_ORDRELDATA bit in flags is clear, a value greater than zero specifies the maximum number of octets that may be associated with the <code>t_snddis(3NSL)</code> and <code>t_rcvdis(3NSL)</code> functions, and a value of T_INVALID (-2) specifies that the transport provider does not allow data to be sent with the abortive release functions. If the T_ORDRELDATA bit is set in flags, a value greater than zero specifies the maximum number of octets that may be associated with the <code>t_sndreldata()</code> , <code>t_rcvreldata()</code> , <code>t_snddis(3NSL)</code> and <code>t_rcvdis(3NSL)</code> functions. |
| <i>serotype</i> | This field specifies the service type supported by the transport provider, as described below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>flags</i>    | This is a bit field used to specify other information about the communications provider. If the T_ORDRELDATA bit is set, the communications provider supports sending user data with an orderly release. If the T_SENDZERO bit is set in flags, this indicates that the underlying transport provider supports the sending of zero-length TSDUs.                                                                                                                                                                                                                                                                                        |

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the `t_allloc(3NSL)` function may be used to allocate these buffers. An error will result if a transport user exceeds the allowed data size on any function. The value of each field may change as a result of protocol option negotiation during connection establishment (the `t_optmgmt(3NSL)` call has no effect on the values returned by `t_getinfo()`). These values will only change from the values presented to `t_open(3NSL)` after the endpoint enters the T\_DATAXFER state.

The *serotype* field of *info* specifies one of the following values on return:

|        |                                                                                                                       |
|--------|-----------------------------------------------------------------------------------------------------------------------|
| T_COTS | The transport provider supports a connection-mode service but does not support the optional orderly release facility. |
|--------|-----------------------------------------------------------------------------------------------------------------------|

## t\_getinfo(3NSL)

|                                 |            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>TLI COMPATIBILITY</b>        |            | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Interface Header</b>         |            | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Error Description Values</b> |            | The <code>t_errno</code> value <code>TPROTO</code> can be set by the XTI interface but not by the TLI interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>The t_info Structure</b>     |            | For TLI, the <code>t_info</code> structure referenced by <i>info</i> lacks the following structure member:<br><pre>t_scalar_t flags; /* other info about the transport provider */</pre> This member was added to <code>struct t_info</code> in the XTI interfaces.<br><br>When a value of -1 is observed as the return value in various <code>t_info</code> structure members, it signifies that the transport provider can handle an infinite length buffer for a corresponding attribute, such as address data, option data, TSDU (octet size), ETSDU (octet size), connection data, and disconnection data. The corresponding structure members are <code>addr</code> , <code>options</code> , <code>tsdu</code> , <code>estdu</code> , <code>connect</code> , and <code>discon</code> , respectively. |
| <b>ATTRIBUTES</b>               |            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>NAME</b>                         | t_getprotaddr – get the protocol addresses                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |                                                                       |           |                                                                                                                                                          |        |                                                                                                                                                                                     |         |                                                                |
| <b>SYNOPSIS</b>                     | <pre>#include &lt;xti.h&gt;  int t_getprotaddr(int fd, struct t_bind *boundaddr, struct t_bind                  *peeraddr);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                       |           |                                                                                                                                                          |        |                                                                                                                                                                                     |         |                                                                |
| <b>DESCRIPTION</b>                  | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_getprotaddr()</code> function returns local and remote protocol addresses currently associated with the transport endpoint specified by <code>fd</code>. In <code>boundaddr</code> and <code>peeraddr</code> the user specifies <code>maxlen</code>, which is the maximum size (in bytes) of the address buffer, and <code>buf</code> which points to the buffer where the address is to be placed. On return, the <code>buf</code> field of <code>boundaddr</code> points to the address, if any, currently bound to <code>fd</code>, and the <code>len</code> field specifies the length of the address. If the transport endpoint is in the <code>T_UNBND</code> state, zero is returned in the <code>len</code> field of <code>boundaddr</code>. The <code>buf</code> field of <code>peeraddr</code> points to the address, if any, currently connected to <code>fd</code>, and the <code>len</code> field specifies the length of the address. If the transport endpoint is not in the <code>T_DATAXFER</code>, <code>T_INREL</code>, <code>T_OUTCON</code> or <code>T_OUTREL</code> states, zero is returned in the <code>len</code> field of <code>peeraddr</code>. If the <code>maxlen</code> field of <code>boundaddr</code> or <code>peeraddr</code> is set to zero, no address is returned.</p> |       |                                                                       |           |                                                                                                                                                          |        |                                                                                                                                                                                     |         |                                                                |
| <b>RETURN VALUES</b>                | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                       |           |                                                                                                                                                          |        |                                                                                                                                                                                     |         |                                                                |

| <b>NAME</b>              | t_getstate – get the current state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |                                                                       |        |                                                                                                                                                                                     |            |                                                                |         |                                                                |            |                |          |                                          |         |                                              |
| <b>SYNOPSIS</b>          | <pre>#include &lt;xti.h&gt;  int t_getstate(int fd);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                                                                       |        |                                                                                                                                                                                     |            |                                                                |         |                                                                |            |                |          |                                          |         |                                              |
| <b>DESCRIPTION</b>       | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_getstate()</code> function returns the current state of the provider associated with the transport endpoint specified by <i>fd</i>.</p>                                                                                                                                                                               |         |                                                                       |        |                                                                                                                                                                                     |            |                                                                |         |                                                                |            |                |          |                                          |         |                                              |
| <b>RETURN VALUES</b>     | <p>State is returned upon successful completion. Otherwise, a value of <code>-1</code> is returned and <code>t_errno</code> is set to indicate an error. The current state is one of the following:</p> <table><tr><td>T_UNBND</td><td>Unbound.</td></tr><tr><td>T_IDLE</td><td>Idle.</td></tr><tr><td>T_OUTCON</td><td>Outgoing connection pending.</td></tr><tr><td>T_INCON</td><td>Incoming connection pending.</td></tr><tr><td>T_DATAXFER</td><td>Data transfer.</td></tr><tr><td>T_OUTREL</td><td>Outgoing direction orderly release sent.</td></tr><tr><td>T_INREL</td><td>Incoming direction orderly release received.</td></tr></table> <p>If the provider is undergoing a state transition when <code>t_getstate()</code> is called, the function will fail.</p> | T_UNBND | Unbound.                                                              | T_IDLE | Idle.                                                                                                                                                                               | T_OUTCON   | Outgoing connection pending.                                   | T_INCON | Incoming connection pending.                                   | T_DATAXFER | Data transfer. | T_OUTREL | Outgoing direction orderly release sent. | T_INREL | Incoming direction orderly release received. |

| TSYSERR                  | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                                                                       |        |                                                                                                                                                                                     |            |                                                                |         |                                                                |            |                |          |                                          |         |                                              |
| <b>TLI COMPATIBILITY</b> | <p>The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |         |                                                                       |        |                                                                                                                                                                                     |            |                                                                |         |                                                                |            |                |          |                                          |         |                                              |
| <b>Interface Header</b>  | <p>The XTI interfaces use the header file, <code>xti.h</code>. TLI interfaces should <i>not</i> use this header. They should use the header:</p> <pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |                                                                       |        |                                                                                                                                                                                     |            |                                                                |         |                                                                |            |                |          |                                          |         |                                              |

t\_getstate(3NSL)

**Error Description  
Values**

The t\_errno value that can be set by the XTI interface and cannot be set by the TLI interface is:

TPROTO

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

| <b>NAME</b>            | t_listen – listen for a connection indication                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                                                       |                       |                                                                           |                        |                                                                                                                                          |
| <b>SYNOPSIS</b>        | <pre>#include &lt;xti.h&gt;  int t_listen(int fd, struct t_call *call);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                                                       |                       |                                                                           |                        |                                                                                                                                          |
| <b>DESCRIPTION</b>     | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function listens for a connection indication from a calling transport user. The argument <i>fd</i> identifies the local transport endpoint where connection indications arrive, and on return, <i>call</i> contains information describing the connection indication. The parameter <i>call</i> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>In <i>call</i>, <i>addr</i> returns the protocol address of the calling transport user. This address is in a format usable in future calls to <code>t_connect(3NSL)</code>. Note, however that <code>t_connect(3NSL)</code> may fail for other reasons, for example <code>TADDRBUSY</code>. <i>opt</i> returns options associated with the connection indication, <i>udata</i> returns any user data sent by the caller on the connection request, and <i>sequence</i> is a number that uniquely identifies the returned connection indication. The value of <i>sequence</i> enables the user to listen for multiple connection indications before responding to any of them.</p> <p>Since this function returns values for the <i>addr</i>, <i>opt</i> and <i>udata</i> fields of <i>call</i>, the <i>maxlen</i> field of each must be set before issuing the <code>t_listen()</code> to indicate the maximum size of the buffer for each. If the <i>maxlen</i> field of <i>call</i>→<i>addr</i>, <i>call</i>→<i>opt</i> or <i>call</i>→<i>udata</i> is set to zero, no information is returned for this parameter.</p> <p>By default, <code>t_listen()</code> executes in synchronous mode and waits for a connection indication to arrive before returning to the user. However, if <code>O_NONBLOCK</code> is set via <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_listen()</code> executes asynchronously, reducing to a poll for existing connection indications. If none are available, it returns <code>-1</code> and sets <code>t_errno</code> to <code>TNODATA</code>.</p> |                    |                                                                       |                       |                                                                           |                        |                                                                                                                                          |
| <b>RETURN VALUES</b>   | Upon successful completion, a value of 0 is returned. Otherwise, a value of <code>-1</code> is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                                                       |                       |                                                                           |                        |                                                                                                                                          |

| <code>TPROTO</code>             | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                                                                                                                                                                                                                  |
| <code>TQFULL</code>             | The maximum number of outstanding connection indications has been reached for the endpoint referenced by <i>fd</i> . Note that a subsequent call to <code>t_listen()</code> may block until another incoming connection indication is available. This can only occur if at least one of the outstanding connection indications becomes no longer outstanding, for example through a call to <code>t_accept(3NSL)</code> .            |
| <code>TSYSERR</code>            | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>TLI COMPATIBILITY</b>        | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                      |
| <b>Interface Header</b>         | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><br><pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                               |
| <b>Error Description Values</b> | The <code>t_errno</code> values <code>TPROTO</code> , <code>TBADQLEN</code> , and <code>TQFULL</code> can be set by the XTI interface but not by the TLI interface.<br><br>A <code>t_errno</code> value that this routine can return under different circumstances than its XTI counterpart is <code>TBUFOVFLW</code> . It can be returned even when the <code>maxlen</code> field of the corresponding buffer has been set to zero. |
| <b>Option Buffers</b>           | The format of the options in an <code>opt</code> buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.                                                                                                                                                                                                                                                           |

t\_listen(3NSL)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `fcntl(2)`, `t_accept(3NSL)`, `t_alloc(3NSL)`, `t_bind(3NSL)`, `t_connect(3NSL)`, `t_open(3NSL)`, `t_optmgmt(3NSL)`, `t_rcvconnect(3NSL)`, `t_snddis(3NSL)`, `attributes(5)`

**WARNINGS** Some transport providers do not differentiate between a connection indication and the connection itself. If this is the case, a successful return of `t_listen()` indicates an existing connection.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |          |                                                                       |           |                                |        |                       |          |                          |              |                         |         |                            |          |                             |          |                                                                                                                          |            |                                                                                                                                |

| <b>NAME</b>          | t_look – look at the current event on a transport endpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |          |                                                                       |           |                                |        |                       |          |                          |              |                         |         |                            |          |                             |          |                                                                                                                          |            |                                                                                                                                |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt; int t_look(int fd);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |          |                                                                       |           |                                |        |                       |          |                          |              |                         |         |                            |          |                             |          |                                                                                                                          |            |                                                                                                                                |
| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function returns the current event on the transport endpoint specified by <i>fd</i>. This function enables a transport provider to notify a transport user of an asynchronous event when the user is calling functions in synchronous mode. Certain events require immediate notification of the user and are indicated by a specific error, TLOOK, on the current or next function to be executed.</p> <p>This function also enables a transport user to poll a transport endpoint periodically for asynchronous events.</p>                                                                                                                                                                                         |          |                                                                       |           |                                |        |                       |          |                          |              |                         |         |                            |          |                             |          |                                                                                                                          |            |                                                                                                                                |
| <b>RETURN VALUES</b> | <p>Upon success, <code>t_look()</code> returns a value that indicates which of the allowable events has occurred, or returns zero if no event exists. One of the following events is returned:</p> <table border="0"> <tr> <td style="padding-right: 20px;">T_LISTEN</td> <td>Connection indication received.</td> </tr> <tr> <td>T_CONNECT</td> <td>Connect confirmation received.</td> </tr> <tr> <td>T_DATA</td> <td>Normal data received.</td> </tr> <tr> <td>T_EXDATA</td> <td>Expedited data received.</td> </tr> <tr> <td>T_DISCONNECT</td> <td>Disconnection received.</td> </tr> <tr> <td>T_UDERR</td> <td>Datagram error indication.</td> </tr> <tr> <td>T_ORDREL</td> <td>Orderly release indication.</td> </tr> <tr> <td>T_GODATA</td> <td>Flow control restrictions on normal data flow that led to a TFLOW error have been lifted. Normal data may be sent again.</td> </tr> <tr> <td>T_GOEXDATA</td> <td>Flow control restrictions on expedited data flow that led to a TFLOW error have been lifted. ## t\_look(3NSL)

**TPROTO** This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (`t_errno`).

**TSYSERR** A system error has occurred during execution of this function.

### TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

#### Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

#### Return Values

The return values that are defined by the XTI interface and cannot be returned by the TLI interface are:

`T_GODATA`  
`T_GOEXDATA`

#### Error Description Values

The `t_errno` value that can be set by the XTI interface and cannot be set by the TLI interface is:

`TPROTO`

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

#### SEE ALSO

| <b>NAME</b>        | t_open – establish a transport endpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt; #include &lt;fcntl.h&gt;  int t_open(const char *name, int oflag, struct t_info *info);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_open()</code> function must be called as the first step in the initialization of a transport endpoint. This function establishes a transport endpoint by supplying a transport provider identifier that indicates a particular transport provider, that is, transport protocol, and returning a file descriptor that identifies that endpoint.</p> <p>The argument <i>name</i> points to a transport provider identifier and <i>oflag</i> identifies any open flags, as in <code>open(2)</code>. The argument <i>oflag</i> is constructed from <code>O_RDWR</code> optionally bitwise inclusive-OR'ed with <code>O_NONBLOCK</code>. These flags are defined by the header <code>&lt;fcntl.h&gt;</code>. The file descriptor returned by <code>t_open()</code> will be used by all subsequent functions to identify the particular local transport endpoint.</p> <p>This function also returns various default characteristics of the underlying transport protocol by setting fields in the <code>t_info</code> structure. This argument points to a <code>t_info</code> which contains the following members:</p> <pre>t_scalar_t addr;          /* max size of the transport protocol address */ t_scalar_t options;      /* max number of bytes of protocol-specific options */ t_scalar_t tsdu;         /* max size of a transport service data unit (TSDU) */ t_scalar_t etsdu;        /* max size of an expedited transport service data unit (ETSDU) */ t_scalar_t connect;      /* max amount of data allowed on connection establishment functions */ t_scalar_t discon;       /* max amount of data allowed on t_snddis() and t_rcvdis() functions */ t_scalar_t servtype;     /* service type supported by the transport provider */ t_scalar_t flags;        /* other info about the transport provider */</pre> <p>The values of the fields have the following meanings:</p> <p><i>addr</i>                   A value greater than zero (<code>T_NULL</code>) indicates the maximum size of a transport protocol address and a value of <code>-2</code> (<code>T_INVALID</code>) specifies that the transport provider does not provide user access to transport protocol addresses.</p> <p><i>options</i>                 A value greater than zero (<code>T_NULL</code>) indicates the maximum number of bytes of protocol-specific options supported by the provider, and a value of <code>-2</code> (<code>T_INVALID</code>) specifies that the transport provider does not support user-settable options.</p> |

## t\_open(3NSL)

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>tsdu</i>     | A value greater than zero ( <code>T_NULL</code> ) specifies the maximum size of a transport service data unit (TSDU); a value of zero ( <code>T_NULL</code> ) specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a data stream with no logical boundaries preserved across a connection; a value of <code>-1</code> ( <code>T_INFINITE</code> ) specifies that there is no limit to the size of a TSDU; and a value of <code>-2</code> ( <code>T_INVALID</code> ) specifies that the transfer of normal data is not supported by the transport provider.                                                                                                                                              |
| <i>etsdu</i>    | A value greater than zero ( <code>T_NULL</code> ) specifies the maximum size of an expedited transport service data unit (ETSDU); a value of zero ( <code>T_NULL</code> ) specifies that the transport provider does not support the concept of ETSDU, although it does support the sending of an expedited data stream with no logical boundaries preserved across a connection; a value of <code>-1</code> ( <code>T_INFINITE</code> ) specifies that there is no limit on the size of an ETSDU; and a value of <code>-2</code> ( <code>T_INVALID</code> ) specifies that the transfer of expedited data is not supported by the transport provider. Note that the semantics of expedited data may be quite different for different transport providers.             |
| <i>connect</i>  | A value greater than zero ( <code>T_NULL</code> ) specifies the maximum amount of data that may be associated with connection establishment functions, and a value of <code>-2</code> ( <code>T_INVALID</code> ) specifies that the transport provider does not allow data to be sent with connection establishment functions.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>discon</i>   | If the <code>T_ORDRELDATA</code> bit in <code>flags</code> is clear, a value greater than zero ( <code>T_NULL</code> ) specifies the maximum amount of data that may be associated with the <code>t_snddis(3NSL)</code> and <code>t_rcvdis(3NSL)</code> functions, and a value of <code>-2</code> ( <code>T_INVALID</code> ) specifies that the transport provider does not allow data to be sent with the abortive release functions. If the <code>T_ORDRELDATA</code> bit is set in <code>flags</code> , a value greater than zero ( <code>T_NULL</code> ) specifies the maximum number of octets that may be associated with the <code>t_sndreldata()</code> , <code>t_rcvreldata()</code> , <code>t_snddis(3NSL)</code> and <code>t_rcvdis(3NSL)</code> functions. |
| <i>serotype</i> | This field specifies the service type supported by the transport provider, as described below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>flags</i>    | This is a bit field used to specify other information about the communications provider. If the <code>T_ORDRELDATA</code> bit is set, the communications provider supports user data to be sent with an orderly release. If the <code>T_SENDZERO</code> bit is set in <code>flags</code> , this indicates the underlying transport provider supports the sending of zero-length TSDUs.                                                                                                                                                                                                                                                                                                                                                                                 |

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the `t_alloc(3NSL)` function may be used to allocate these buffers. An error will result if a transport user exceeds the allowed data size on any function.

The `servtype` field of `info` specifies one of the following values on return:

|            |                                                                                                                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T_COTS     | The transport provider supports a connection-mode service but does not support the optional orderly release facility.                                                                                                                      |
| T_COTS_ORD | The transport provider supports a connection-mode service with the optional orderly release facility.                                                                                                                                      |
| T_CLTS     | The transport provider supports a connectionless-mode service. For this service type, <code>t_open()</code> will return <code>-2</code> ( <code>T_INVALID</code> ) for <code>etsdu</code> , <code>connect</code> and <code>discon</code> . |

A single transport endpoint may support only one of the above services at one time.

If `info` is set to a null pointer by the transport user, no protocol information is returned by `t_open()`.

**RETURN VALUES** A valid file descriptor is returned upon successful completion. Otherwise, a value of `-1` is returned and `t_errno` is set to indicate an error.

**VALID STATES** T\_UNINIT.

**ERRORS** On failure, `t_errno` is set to the following:

|          |                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TBADFLAG | An invalid flag is specified.                                                                                                                                                       |
| TBADNAME | Invalid transport provider name.                                                                                                                                                    |
| TPROTO   | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ). |
| TSYSERR  | A system error has occurred during execution of this function.                                                                                                                      |

**TLI COMPATIBILITY** The XTI and TLI interface definitions have common names but use different header files. This and other semantic differences between the two interfaces are described in the subsections below.

**Interface Header** The XTI interfaces use the `xti.h` TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description Values** The `t_errno` values `TPROTO` and `TBADNAME` can be set by the XTI interface but cannot be set by the TLI interface.

## t\_open(3NSL)

**Notes** For TLI, the `t_info` structure referenced by *info* lacks the following structure member:

```
t_scalar_t flags; /* other info about the transport provider */
```

This member was added to `struct t_info` in the XTI interfaces.

When a value of `-1` is observed as the return value in various `t_info` structure members, it signifies that the transport provider can handle an infinite length buffer for a corresponding attribute, such as address data, option data, TSDU (octet size), ETSDU (octet size), connection data, and disconnection data. The corresponding structure members are `addr`, `options`, `tsdu`, `estdu`, `connect`, and `discon`, respectively.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `open(2)`, `attributes(5)`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | t_optmgmt – manage options for a transport endpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_optmgmt(int fd, const struct t_optmgmt *req, struct t_optmgmt              *ret);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_optmgmt()</code> function enables a transport user to retrieve, verify or negotiate protocol options with the transport provider. The argument <code>fd</code> identifies a transport endpoint.</p> <p>The <code>req</code> and <code>ret</code> arguments point to a <code>t_optmgmt</code> structure containing the following members:</p> <pre>struct netbuf opt; t_scalar_t    flags;</pre> <p>The <code>opt</code> field identifies protocol options and the <code>flags</code> field is used to specify the action to take with those options.</p> <p>The options are represented by a <code>netbuf</code> structure in a manner similar to the address in <code>t_bind(3NSL)</code>. The argument <code>req</code> is used to request a specific action of the provider and to send options to the provider. The argument <code>len</code> specifies the number of bytes in the options, <code>buf</code> points to the options buffer, and <code>maxlen</code> has no meaning for the <code>req</code> argument. The transport provider may return options and flag values to the user through <code>ret</code>. For <code>ret</code>, <code>maxlen</code> specifies the maximum size of the options buffer and <code>buf</code> points to the buffer where the options are to be placed. If <code>maxlen</code> in <code>ret</code> is set to zero, no options values are returned. On return, <code>len</code> specifies the number of bytes of options returned. The value in <code>maxlen</code> has no meaning for the <code>req</code> argument, but must be set in the <code>ret</code> argument to specify the maximum number of bytes the options buffer can hold.</p> <p>Each option in the options buffer is of the form <code>struct t_opthdr</code> possibly followed by an option value.</p> <p>The <code>level</code> field of <code>struct t_opthdr</code> identifies the XTI level or a protocol of the transport provider. The <code>name</code> field identifies the option within the level, and <code>len</code> contains its total length; that is, the length of the option header <code>t_opthdr</code> plus the length of the option value. If <code>t_optmgmt()</code> is called with the action <code>T_NEGOTIATE</code> set, the <code>status</code> field of the returned options contains information about the success or failure of a negotiation.</p> <p>Several options can be concatenated. The option user has, however to ensure that each options header and value part starts at a boundary appropriate for the architecture-specific alignment rules. The macros <code>T_OPT_FIRSTHDR(nbp)</code>, <code>T_OPT_NEXTHDR(nbp,tohp)</code>, <code>T_OPT_DATA(tohp)</code> are provided for that purpose.</p> |

## t\_optmgmt(3NSL)

T\_OPT\_DATA (nhp)

If argument is a pointer to a `t_opthdr` structure, this macro returns an unsigned character pointer to the data associated with the `t_opthdr`.

T\_OPT\_NEXTHDR (nbp, tohp)

If the first argument is a pointer to a `netbuf` structure associated with an option buffer and second argument is a pointer to a `t_opthdr` structure within that option buffer, this macro returns a pointer to the next `t_opthdr` structure or a null pointer if this `t_opthdr` is the last `t_opthdr` in the option buffer.

T\_OPT\_FIRSTHDR (tohp)

If the argument is a pointer to a `netbuf` structure associated with an option buffer, this macro returns the pointer to the first `t_opthdr` structure in the associated option buffer, or a null pointer if there is no option buffer associated with this `netbuf` or if it is not possible or the associated option buffer is too small to accommodate even the first aligned option header.

`T_OPT_FIRSTHDR` is useful for finding an appropriately aligned start of the option buffer. `T_OPT_NEXTHDR` is useful for moving to the start of the next appropriately aligned option in the option buffer. Note that `OPT_NEXTHDR` is also available for backward compatibility requirements. `T_OPT_DATA` is useful for finding the start of the data part in the option buffer where the contents of its values start on an appropriately aligned boundary.

If the transport user specifies several options on input, all options must address the same level.

If any option in the options buffer does not indicate the same level as the first option, or the level specified is unsupported, then the `t_optmgmt()` request will fail with `TBADOPT`. If the error is detected, some

t\_optmgmt(3NSL)

options have possibly been successfully negotiated. The transport user can check the current status by calling `t_optmgmt()` with the `T_CURRENT` flag set.

The *flags* field of *req* must specify one of the following actions:

T\_NEGOTIATE

This action enables the transport user to negotiate option values.

The user specifies the options of interest and their values in the buffer specified by *req*→*opt.buf* and *req*→*opt.len*. The negotiated option values are returned in the buffer pointed to by *ret*→*opt.buf*. The *status* field of each returned option is set to indicate the result of the negotiation. The value is `T_SUCCESS` if the proposed value was negotiated, `T_PARTSUCCESS` if a degraded value was negotiated, `T_FAILURE` if the negotiation failed (according to the negotiation rules), `T_NOTSUPPORT` if the transport provider does not support this option or illegally requests negotiation of a privileged option, and `T_READONLY` if modification of a read-only option was requested. If the status is `T_SUCCESS`, `T_FAILURE`, `T_NOTSUPPORT` or `T_READONLY`, the returned option value is the same as the one requested on input.

The overall result of the negotiation is returned in *ret*→*flags*.

This field contains the worst single result, whereby the rating is done according to the order `T_NOTSUPPORT`, `T_READONLY`, `T_FAILURE`, `T_PARTSUCCESS`, `T_SUCCESS`. The value `T_NOTSUPPORT` is the worst result and `T_SUCCESS` is the best.

For each level, the option `T_ALLOPT` can be requested on input. No value is given with this option; only the `t_opthdr` part is specified. This input requests to negotiate all supported options of this level to their default values. The result is returned option

## t\_optmgmt(3NSL)

T\_CHECK

by option in *ret*→*opt.buf*. Note that depending on the state of the transport endpoint, not all requests to negotiate the default value may be successful.

This action enables the user to verify whether the options specified in *req* are supported by the transport provider. If an option is specified with no option value (it consists only of a *t\_opthdr* structure), the option is returned with its *status* field set to T\_SUCCESS if it is supported, T\_NOTSUPPORT if it is not or needs additional user privileges, and T\_READONLY if it is read-only (in the current XTI state). No option value is returned.

If an option is specified with an option value, the *status* field of the returned option has the same value, as if the user had tried to negotiate this value with T\_NEGOTIATE. If the status is T\_SUCCESS, T\_FAILURE, T\_NOTSUPPORT or T\_READONLY, the returned option value is the same as the one requested on input.

The overall result of the option checks is returned in *ret*→*flags*. This field contains the worst single result of the option checks, whereby the rating is the same as for T\_NEGOTIATE.

Note that no negotiation takes place. All currently effective option values remain unchanged.

T\_DEFAULT

This action enables the transport user to retrieve the default option values. The user specifies the options of interest in *req*→*opt.buf*. The option values are irrelevant and will be ignored; it is sufficient to specify the *t\_opthdr* part of an option only. The default values are then returned in *ret*→*opt.buf*.

## t\_optmgmt(3NSL)

The *status* field returned is `T_NOTSUPPORT` if the protocol level does not support this option or the transport user illegally requested a privileged option, `T_READONLY` if the option is read-only, and set to `T_SUCCESS` in all other cases. The overall result of the request is returned in *ret→flags*. This field contains the worst single result, whereby the rating is the same as for `T_NEGOTIATE`.

For each level, the option `T_ALLOPT` can be requested on input. All supported options of this level with their default values are then returned. In this case, *ret→opt.maxlen* must be given at least the value *info→options* before the call. See [t\\_getinfo\(3NSL\)](#) and [t\\_open\(3NSL\)](#).

### T\_CURRENT

This action enables the transport user to retrieve the currently effective option values. The user specifies the options of interest in *req→opt.buf*. The option values are irrelevant and will be ignored; it is sufficient to specify the *t\_opthdr* part of an option only. The currently effective values are then returned in *req→opt.buf*.

The *status* field returned is `T_NOTSUPPORT` if the protocol level does not support this option or the transport user illegally requested a privileged option, `T_READONLY` if the option is read-only, and set to `T_SUCCESS` in all other cases. The overall result of the request is returned in *ret→flags*. This field contains the worst single result, whereby the rating is the same as for `T_NEGOTIATE`.

For each level, the option `T_ALLOPT` can be requested on input. All supported options of this level with their currently effective values are then returned.

The option `T_ALLOPT` can only be used with `t_optmgmt()` and the actions `T_NEGOTIATE`, `T_DEFAULT` and `T_CURRENT`. It can be used with any

## t\_optmgmt(3NSL)

supported level and addresses all supported options of this level. The option has no value; it consists of a `t_opthdr` only. Since in a `t_optmgmt()` call only options of one level may be addressed, this option should not be requested together with other options. The function returns as soon as this option has been processed.

Options are independently processed in the order they appear in the input option buffer. If an option is multiply input, it depends on the implementation whether it is multiply output or whether it is returned only once.

Transport providers may not be able to provide an interface capable of supporting `T_NEGOTIATE` and/or `T_CHECK` functionalities. When this is the case, the error `TNOTSUPPORT` is returned.

The function `t_optmgmt()` may block under various circumstances and depending on the implementation. The function will block, for instance, if the protocol addressed by the call resides on a separate controller. It may also block due to flow control constraints; that is, if data sent previously across this transport endpoint has not yet been fully processed. If the function is interrupted by a signal, the option negotiations that have been done so far may remain valid. The behavior of the function is not changed if `O_NONBLOCK` is set.

|                       |                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RETURN VALUES</b>  | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error. |
| <b>VALID STATES</b>   | ALL - apart from <code>T_UNINIT</code> .                                                                                                         |
| <b>ERRORS</b>         | On failure, <code>t_errno</code> is set to one of the following:                                                                                 |
| <code>TBADF</code>    | The specified file descriptor does not refer to a transport endpoint.                                                                            |
| <code>TBADFLAG</code> | An invalid flag was specified.                                                                                                                   |
| <code>TBADOPT</code>  | The specified options were in an incorrect format or contained illegal information.                                                              |

|                                 |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | TBUFOVFLW   | The number of bytes allowed for an incoming argument ( <i>maxlen</i> ) is greater than 0 but not sufficient to store the value of that argument. The information to be returned in <i>ret</i> will be discarded.                                                                                                                                                                                                                                                                          |
|                                 | TNOTSUPPORT | This action is not supported by the transport provider.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                 | TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                                                                                                                                                                                                                |
|                                 | TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <i>t_errno</i> ).                                                                                                                                                                                                                                                                                                             |
|                                 | TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>TLI COMPATIBILITY</b>        |             | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                           |
| <b>Interface Header</b>         |             | The XTI interfaces use the header file, <i>xti.h</i> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><br><pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                          |
| <b>Error Description Values</b> |             | The <i>t_errno</i> value TPROTO can be set by the XTI interface but not by the TLI interface.<br><br>The <i>t_errno</i> values that this routine can return under different circumstances than its XTI counterpart are TACCES and TBUFOVFLW.<br><br>TACCES can be returned to indicate that the user does not have permission to negotiate the specified options.<br><br>TBUFOVFLW can be returned even when the <i>maxlen</i> field of the corresponding buffer has been set to zero.    |
| <b>Option Buffers</b>           |             | The format of the options in an <i>opt</i> buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format. The macros T_OPT_DATA, T_OPT_NEXTHDR, and T_OPT_FIRSTHDR described for XTI are not available for use by TLI interfaces.                                                                                                                                                                                              |
| <b>Actions</b>                  |             | The semantic meaning of various action values for the <i>flags</i> field of <i>req</i> differs between the TLI and XTI interfaces. TLI interface users should heed the following descriptions of the actions:<br><br>T_NEGOTIATE This action enables the user to negotiate the values of the options specified in <i>req</i> with the transport provider. The provider will evaluate the requested options and negotiate the values, returning the negotiated values through <i>ret</i> . |

## t\_optmgmt(3NSL)

- T\_CHECK** This action enables the user to verify whether the options specified in *req* are supported by the transport provider. On return, the *flags* field of *ret* will have either **T\_SUCCESS** or **T\_FAILURE** set to indicate to the user whether the options are supported. These flags are only meaningful for the **T\_CHECK** request.
- T\_DEFAULT** This action enables a user to retrieve the default options supported by the transport provider into the *opt* field of *ret*. In *req*, the *len* field of *opt* must be zero and the *buf* field may be **NULL**.

**Connectionless Mode** If issued as part of the connectionless mode service, `t_optmgmt()` may block due to flow control constraints. The function will not complete until the transport provider has processed all previously sent data units.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| <b>NAME</b>        | t_rcv – receive data or expedited data sent over a connection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_rcv(int fd, void *buf, unsigned int nbytes, int *flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function receives either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint through which data will arrive, <i>buf</i> points to a receive buffer where user data will be placed, and <i>nbytes</i> specifies the size of the receive buffer. The argument <i>flags</i> may be set on return from <code>t_rcv()</code> and specifies optional flags as described below.</p> <p>By default, <code>t_rcv()</code> operates in synchronous mode and will wait for data to arrive if none is currently available. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_rcv()</code> will execute in asynchronous mode and will fail if no data is available. See <code>TNODATA</code> below.</p> <p>On return from the call, if <code>T_MORE</code> is set in <i>flags</i>, this indicates that there is more data, and the current transport service data unit (TSDU) or expedited transport service data unit (ETSDU) must be received in multiple <code>t_rcv()</code> calls. In the asynchronous mode, or under unusual conditions (for example, the arrival of a signal or <code>T_EXDATA</code> event), the <code>T_MORE</code> flag may be set on return from the <code>t_rcv()</code> call even when the number of bytes received is less than the size of the receive buffer specified. Each <code>t_rcv()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_rcv()</code> must follow to get more data for the current TSDU. The end of the TSDU is identified by the return of a <code>t_rcv()</code> call with the <code>T_MORE</code> flag not set. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>, the <code>T_MORE</code> flag is not meaningful and should be ignored. If <i>nbytes</i> is greater than zero on the call to <code>t_rcv()</code>, <code>t_rcv()</code> will return 0 only if the end of a TSDU is being returned to the user.</p> <p>On return, the data is expedited if <code>T_EXPEDITED</code> is set in <i>flags</i>. If <code>T_MORE</code> is also set, it indicates that the number of expedited bytes exceeded <i>nbytes</i>, a signal has interrupted the call, or that an entire ETSDU was not available (only for transport protocols that support fragmentation of ETSDUs). The rest of the ETSDU will be returned by subsequent calls to <code>t_rcv()</code> which will return with <code>T_EXPEDITED</code> set in <i>flags</i>. The end of the ETSDU is identified by the return of a <code>t_rcv()</code> call with <code>T_EXPEDITED</code> set and <code>T_MORE</code> cleared. If the entire ETSDU is not available it is possible for normal data fragments to be returned between the initial and final fragments of an ETSDU.</p> <p>If a signal arrives, <code>t_rcv()</code> returns, giving the user any data currently available. If no data is available, <code>t_rcv()</code> returns -1, sets <code>t_errno</code> to <code>TSYSERR</code> and <code>errno</code> to <code>EINTR</code>. If some data is available, <code>t_rcv()</code> returns the number of bytes received and <code>T_MORE</code> is set in <i>flags</i>.</p> |

t\_rcv(3NSL)

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |        |                                                                       |       |                                                                                                 |         |                                                                                     |             |                                                                      |           |                                                                                                                            |        |                                                                                                                                                                      |         |                                                                |

| <b>NAME</b>          | t_rcvconnect – receive the confirmation from a connection request                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_rcvconnect(int fd, struct t_call *call);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function enables a calling transport user to determine the status of a previously sent connection request and is used in conjunction with <code>t_connect(3NSL)</code> to establish a connection in asynchronous mode, and to complete a synchronous <code>t_connect(3NSL)</code> call that was interrupted by a signal. The connection will be established on successful completion of this function.</p> <p>The argument <i>fd</i> identifies the local transport endpoint where communication will be established, and <i>call</i> contains information associated with the newly established connection. The argument <i>call</i> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>In <i>call</i>, <i>addr</i> returns the protocol address associated with the responding transport endpoint, <i>opt</i> presents any options associated with the connection, <i>udata</i> points to optional user data that may be returned by the destination transport user during connection establishment, and <i>sequence</i> has no meaning for this function.</p> <p>The <i>maxlen</i> field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, <i>maxlen</i> can be set to zero, in which case no information to this specific argument is given to the user on the return from <code>t_rcvconnect()</code>. If <i>call</i> is set to NULL, no information at all is returned. By default, <code>t_rcvconnect()</code> executes in synchronous mode and waits for the connection to be established before returning. On return, the <i>addr</i>, <i>opt</i> and <i>udata</i> fields reflect values associated with the connection.</p> <p>If <code>O_NONBLOCK</code> is set by means of <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_rcvconnect()</code> executes in asynchronous mode, and reduces to a poll for existing connection confirmations. If none are available, <code>t_rcvconnect()</code> fails and returns immediately without waiting for the connection to be established. See <code>TNODATA</code> below. In this case, <code>t_rcvconnect()</code> must be called again to complete the connection establishment phase and retrieve the information returned in <i>call</i>.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>ERRORS</b>        | On failure, <code>t_errno</code> is set to one of the following:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|             |                                                                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TBADF       | The specified file descriptor does not refer to a transport endpoint.                                                                                                                                                                                                                                        |
| TBUFOVFLW   | The number of bytes allocated for an incoming argument ( <i>maxlen</i> ) is greater than 0 but not sufficient to store the value of that argument, and the connection information to be returned in <i>call</i> will be discarded. The provider's state, as seen by the user, will be changed to T_DATAXFER. |
| TLOOK       | An asynchronous event has occurred on this transport connection and requires immediate attention.                                                                                                                                                                                                            |
| TNODATA     | O_NONBLOCK was set, but a connection confirmation has not yet arrived.                                                                                                                                                                                                                                       |
| TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                                                                                                                                         |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                                   |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <i>t_errno</i> ).                                                                                                                                |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                                                                                               |

**TLI  
COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

**Interface Header**

The XTI interfaces use the header file, *xti.h*. TLI interfaces should *not* use this header. They should use the header:

```
#include<tiuser.h>
```

**Error Description  
Values**

The *t\_errno* value TPROTO can be set by the XTI interface but not by the TLI interface.

A *t\_errno* value that this routine can return under different circumstances than its XTI counterpart is TBUFOVFLW. It can be returned even when the *maxlen* field of the corresponding buffer has been set to zero.

**ATTRIBUTES**

See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to identify the cause of a disconnection and to retrieve any user data sent with the disconnection. The argument <i>fd</i> identifies the local transport endpoint where the connection existed, and <i>discon</i> points to a <code>t_discon</code> structure containing the following members:</p> <pre>struct netbuf udata; int reason; int sequence;</pre> <p>The field <i>reason</i> specifies the reason for the disconnection through a protocol-dependent reason code, <i>udata</i> identifies any user data that was sent with the disconnection, and <i>sequence</i> may identify an outstanding connection indication with which the disconnection is associated. The field <i>sequence</i> is only meaningful when <code>t_rcvdis()</code> is issued by a passive transport user who has executed one or more <code>t_listen(3NSL)</code> functions and is processing the resulting connection indications. If a disconnection indication occurs, <i>sequence</i> can be used to identify which of the outstanding connection indications is associated with the disconnection.</p> <p>The <i>maxlen</i> field of <i>udata</i> may be set to zero, if the user does not care about incoming data. If, in addition, the user does not need to know the value of <i>reason</i> or <i>sequence</i>, <i>discon</i> may be set to NULL and any user data associated with the disconnection indication shall be discarded. However, if a user has retrieved more than one outstanding connection indication by means of <code>t_listen(3NSL)</code>, and <i>discon</i> is a null pointer, the user will be unable to identify with which connection indication the disconnection is associated.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| TBUFOVFLW            | The number of bytes allocated for incoming data ( <i>maxlen</i> ) is greater than 0 but not sufficient to store the data. If <i>fd</i> is a passive endpoint with <i>ocnt</i> > 1, it remains in state T_INCON; otherwise, the endpoint state is set to T_IDLE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TNODIS               | No disconnection indication currently exists on the specified transport endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|             |                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                          |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ). |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                      |

**TLI COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

**Interface Header**

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description Values**

The `t_errno` values TPROTO and TOUTSTATE can be set by the XTI interface but not by the TLI interface.

A failure return, and a `t_errno` value that this routine can set under different circumstances than its XTI counterpart is TBUFOVFLW. It can be returned even when the `maxlen` field of the corresponding buffer has been set to zero.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

| <b>DESCRIPTION</b>       | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to receive an orderly release indication for the incoming direction of data transfer. The argument <i>fd</i> identifies the local transport endpoint where the connection exists. After receipt of this indication, the user may not attempt to receive more data by means of <code>t_rcv(3NSL)</code> or <code>t_rcvv()</code>. Such an attempt will fail with <i>t_error</i> set to TOUTSTATE. However, the user may continue to send data over the connection if <code>t_sndrel(3NSL)</code> has not been called by the user. This function is an optional service of the transport provider, and is only supported if the transport provider returned service type <code>T_COTS_ORD</code> on <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>. Any user data that may be associated with the orderly release indication is discarded when <code>t_rcvrel()</code> is called.</p> |       |                                                                       |       |                                                                                                 |        |                                                                                     |             |                                                                      |           |                                                                                                                            |        |                                                                                                                                                                               |         |                                                                |
| <b>RETURN VALUES</b>     | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <i>t_errno</i> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |       |                                                                       |       |                                                                                                 |        |                                                                                     |             |                                                                      |           |                                                                                                                            |        |                                                                                                                                                                               |         |                                                                |

| <b>TLI COMPATIBILITY</b> | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |       |                                                                       |       |                                                                                                 |        |                                                                                     |             |                                                                      |           |                                                                                                                            |        |                                                                                                                                                                               |         |                                                                |

t\_rcvrel(3NSL)

**Interface Header** The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include<tiuser.h>
```

**Error Description Values** The `t_errno` values that can be set by the XTI interface and cannot be set by the TLI interface are:

```
TPROTO
TOUTSTATE
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `t_getinfo(3NSL)`, `t_open(3NSL)`, `t_sndrel(3NSL)`, `attributes(5)`

| <b>NAME</b>          | t_rcvreldata – receive an orderly release indication or confirmation containing user data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |              |                                                                       |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_rcvreldata(int fd, struct t_discon *discon);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |              |                                                                       |
| <b>DESCRIPTION</b>   | <p>This function is used to receive an orderly release indication for the incoming direction of data transfer and to retrieve any user data sent with the release. The argument <i>fd</i> identifies the local transport endpoint where the connection exists, and <i>discon</i> points to a <i>t_discon</i> structure containing the following members:</p> <pre>struct netbuf udata; int reason; int sequence;</pre> <p>After receipt of this indication, the user may not attempt to receive more data by means of <i>t_rcv(3NSL)</i> or <i>t_rcvv(3NSL)</i>. Such an attempt will fail with <i>t_error</i> set to <i>TOUTSTATE</i>. However, the user may continue to send data over the connection if <i>t_sndrel(3NSL)</i> or <i>t_sndreldata(3N)</i> has not been called by the user.</p> <p>The field <i>reason</i> specifies the reason for the disconnection through a protocol-dependent <i>reason code</i>, and <i>udata</i> identifies any user data that was sent with the disconnection; the field <i>sequence</i> is not used.</p> <p>If a user does not care if there is incoming data and does not need to know the value of <i>reason</i>, <i>discon</i> may be a null pointer, and any user data associated with the disconnection will be discarded.</p> <p>If <i>discon-&gt;udata.maxlen</i> is greater than zero and less than the length of the value, <i>t_rcvreldata()</i> fails with <i>t_errno</i> set to <i>TBUFOVFLW</i>.</p> <p>This function is an optional service of the transport provider, only supported by providers of service type <i>T_COTS_ORD</i>. The flag <i>T_ORDRELDATA</i> in the <i>info-&gt;flag</i> field returned by <i>t_open(3NSL)</i> or <i>t_getinfo(3NSL)</i> indicates that the provider supports orderly release user data; when the flag is not set, this function behaves like <i>t_rcvrel(3NSL)</i> and no user data is returned.</p> <p>This function may not be available on all systems.</p> |              |                                                                       |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <i>t_errno</i> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |              |                                                                       |

| <i>TBADF</i>         | The specified file descriptor does not refer to a transport endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |              |                                                                       |

|             |                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TBUFOVFLW   | The number of bytes allocated for incoming data (maxlen) is greater than 0 but not sufficient to store the data, and the disconnection information to be returned in <i>discon</i> will be discarded. The provider state, as seen by the user, will be changed as if the data was successfully retrieved. |
| TLOOK       | An asynchronous event has occurred on this transport endpoint and requires immediate attention.                                                                                                                                                                                                           |
| TNOREL      | No orderly release indication currently exists on the specified transport endpoint.                                                                                                                                                                                                                       |
| TNOTSUPPORT | Orderly release is not supported by the underlying transport provider.                                                                                                                                                                                                                                    |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                                |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                                                                                       |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                                                                                            |

**TLI  
COMPATIBILITY  
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `t_getinfo(3NSL)`, `t_open(3NSL)`, `t_sndreldata(3NSL)`, `t_rcvrel(3NSL)`, `t_sndrel(3NSL)`, `attributes(5)`

**NOTES** The interfaces `t_sndreldata(3NSL)` and `t_rcvreldata()` are only for use with a specific transport called "minimal OSI," which is not available on the Solaris platform. These interfaces are not available for use in conjunction with Internet Transports (TCP or UDP).

| <b>NAME</b>          | t_rcvudata – receive a data unit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_rcvudata(int fd, struct t_unitdata *unitdata, int *flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used in connectionless-mode to receive a data unit from another transport user. The argument <i>fd</i> identifies the local transport endpoint through which data will be received, <i>unitdata</i> holds information associated with the received data unit, and <i>flags</i> is set on return to indicate that the complete data unit was not received. The argument <i>unitdata</i> points to a <code>t_unitdata</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata;</pre> <p>The <i>maxlen</i> field of <i>addr</i>, <i>opt</i> and <i>udata</i> must be set before calling this function to indicate the maximum size of the buffer for each. If the <i>maxlen</i> field of <i>addr</i> or <i>opt</i> is set to zero, no information is returned in the <i>buf</i> field of this parameter.</p> <p>On return from this call, <i>addr</i> specifies the protocol address of the sending user, <i>opt</i> identifies options that were associated with this data unit, and <i>udata</i> specifies the user data that was received.</p> <p>By default, <code>t_rcvudata()</code> operates in synchronous mode and will wait for a data unit to arrive if none is currently available. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_rcvudata()</code> will execute in asynchronous mode and will fail if no data units are available.</p> <p>If the buffer defined in the <i>udata</i> field of <i>unitdata</i> is not large enough to hold the current data unit, the buffer will be filled and <code>T_MORE</code> will be set in <i>flags</i> on return to indicate that another <code>t_rcvudata()</code> should be called to retrieve the rest of the data unit. Subsequent calls to <code>t_rcvudata()</code> will return zero for the length of the address and options until the full data unit has been received.</p> <p>If the call is interrupted, <code>t_rcvudata()</code> will return <code>EINTR</code> and no datagrams will have been removed from the endpoint.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                 | TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                                                                                                                                                                                                         |
|                                 | TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                                                                                                   |
|                                 | TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <i>t_errno</i> ).                                                                                                                                                                                                |
|                                 | TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                                               |
| <b>TLI COMPATIBILITY</b>        |             | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                              |
| <b>Interface Header</b>         |             | The XTI interfaces use the header file, <i>xti.h</i> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><br><pre>#include&lt;tiuser.h&gt;</pre>                                                                                                                                                                                              |
| <b>Error Description Values</b> |             | The <i>t_errno</i> values that can be set by the XTI interface and cannot be set by the TLI interface are:<br><br>TPROTO<br>TOUTSTATE<br><br>A <i>t_errno</i> value that this routine can return under different circumstances than its XTI counterpart is TBUFOVFLW. It can be returned even when the <i>maxLen</i> field of the corresponding buffer has been set to zero. |
| <b>Option Buffers</b>           |             | The format of the options in an <i>opt</i> buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.                                                                                                                                                                                                         |

| <b>NAME</b>          | t_rcvuderr – receive a unit data error indication                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_rcvuderr(int fd, struct t_uderr *uderr);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>t_iuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used in connectionless-mode to receive information concerning an error on a previously sent data unit, and should only be issued following a unit data error indication. It informs the transport user that a data unit with a specific destination address and protocol options produced an error. The argument <i>fd</i> identifies the local transport endpoint through which the error report will be received, and <i>uderr</i> points to a <code>t_uderr</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; t_scalar_t error;</pre> <p>The <i>maxlen</i> field of <i>addr</i> and <i>opt</i> must be set before calling this function to indicate the maximum size of the buffer for each. If this field is set to zero for <i>addr</i> or <i>opt</i>, no information is returned in the <i>buf</i> field of this parameter.</p> <p>On return from this call, the <i>addr</i> structure specifies the destination protocol address of the erroneous data unit, the <i>opt</i> structure identifies options that were associated with the data unit, and <i>error</i> specifies a protocol-dependent error code.</p> <p>If the user does not care to identify the data unit that produced an error, <i>uderr</i> may be set to a null pointer, and <code>t_rcvuderr()</code> will simply clear the error indication without reporting any information to the user.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| TNOUDERR             | No unit data error indication currently exists on the specified transport endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## t\_rcvuderr(3NSL)

|           |                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOUTSTATE | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                          |
| TPROTO    | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ). |
| TSYSERR   | A system error has occurred during execution of this function.                                                                                                                      |

### TLI COMPATIBILITY

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

### Interface Header

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

### Error Description Values

The `t_errno` values TPROTO and TOUTSTATE can be set by the XTI interface but not by the TLI interface.

A `t_errno` value that this routine can return under different circumstances than its XTI counterpart is TBUFOVFLW. It can be returned even when the `maxLen` field of the corresponding buffer has been set to zero.

### Option Buffers

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

| <b>NAME</b>        | t_rcvv – receive data or expedited data sent over a connection and put the data into one or more non-contiguous buffers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_rcvv(int fd, struct t_iovec *iov, unsigned int iovcount, int            *flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This function receives either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint through which data will arrive, <i>iov</i> points to an array of buffer address/buffer size pairs (<i>iov_base</i>, <i>iov_len</i>). The <code>t_rcvv()</code> function receives data into the buffers specified by <i>iov0.iov_base</i>, <i>iov1.iov_base</i>, through <i>iov[iovcount-1].iov_base</i>, always filling one buffer before proceeding to the next.</p> <p>Note that the limit on the total number of bytes available in all buffers passed: <i>iov(0).iov_len + . . . + iov(iovcount-1).iov_len</i> may be constrained by implementation limits. If no other constraint applies, it will be limited by <code>INT_MAX</code>. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> <p>The argument <i>iovcount</i> contains the number of buffers which is limited to <code>T_IOV_MAX</code>, which is an implementation-defined value of at least 16. If the limit is exceeded, the function will fail with <code>TBADDATA</code>.</p> <p>The argument <i>flags</i> may be set on return from <code>t_rcvv()</code> and specifies optional flags as described below.</p> <p>By default, <code>t_rcvv()</code> operates in synchronous mode and will wait for data to arrive if none is currently available. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_rcvv()</code> will execute in asynchronous mode and will fail if no data is available. See <code>TNODATA</code> below.</p> <p>On return from the call, if <code>T_MORE</code> is set in <i>flags</i>, this indicates that there is more data, and the current transport service data unit (TSDU) or expedited transport service data unit (ETSDU) must be received in multiple <code>t_rcvv()</code> or <code>t_rcv(3NSL)</code> calls. In the asynchronous mode, or under unusual conditions (for example, the arrival of a signal or <code>T_EXDATA</code> event), the <code>T_MORE</code> flag may be set on return from the <code>t_rcvv()</code> call even when the number of bytes received is less than the total size of all the receive buffers. Each <code>t_rcvv()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_rcvv()</code> must follow to get more data for the current TSDU. The end of the TSDU is identified by the return of a <code>t_rcvv()</code> call with the <code>T_MORE</code> flag not set. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>, the <code>T_MORE</code> flag is not meaningful and should be ignored. If the amount of buffer space passed in <i>iov</i> is greater than zero on the call to <code>t_rcvv()</code>, then <code>t_rcvv()</code> will return 0 only if the end of a TSDU is being returned to the user.</p> <p>On return, the data is expedited if <code>T_EXPEDITED</code> is set in <i>flags</i>. If <code>T_MORE</code> is also set, it indicates that the number of expedited bytes exceeded <i>nbytes</i>, a signal has interrupted the call, or that an entire ETSDU was not available (only for transport</p> |

## t\_rcvv(3NSL)

protocols that support fragmentation of ETSDUs). The rest of the ETSDU will be returned by subsequent calls to `t_rcvv()` which will return with `T_EXPEDITED` set in flags. The end of the ETSDU is identified by the return of a `t_rcvv()` call with `T_EXPEDITED` set and `T_MORE` cleared. If the entire ETSDU is not available it is possible for normal data fragments to be returned between the initial and final fragments of an ETSDU.

If a signal arrives, `t_rcvv()` returns, giving the user any data currently available. If no data is available, `t_rcvv()` returns `-1`, sets `t_errno` to `TSYSERR` and `errno` to `EINTR`. If some data is available, `t_rcvv()` returns the number of bytes received and `T_MORE` is set in flags.

In synchronous mode, the only way for the user to be notified of the arrival of normal or expedited data is to issue this function or check for the `T_DATA` or `T_EXDATA` events using the `t_look(3NSL)` function. Additionally, the process can arrange to be notified via the EM interface.

**RETURN VALUES** On successful completion, `t_rcvv()` returns the number of bytes received. Otherwise, it returns `-1` on failure and `t_errno` is set to indicate the error.

**VALID STATES** `T_DATAXFER`, `T_OUTREL`.

**ERRORS** On failure, `t_errno` is set to one of the following:

|                          |                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TBADDATA</code>    | <code>iovcount</code> is greater than <code>T_IOV_MAX</code> .                                                                                                                      |
| <code>TBADF</code>       | The specified file descriptor does not refer to a transport endpoint.                                                                                                               |
| <code>TLOOK</code>       | An asynchronous event has occurred on this transport endpoint and requires immediate attention.                                                                                     |
| <code>TNODATA</code>     | <code>O_NONBLOCK</code> was set, but no data is currently available from the transport provider.                                                                                    |
| <code>TNOTSUPPORT</code> | This function is not supported by the underlying transport provider.                                                                                                                |
| <code>TOUTSTATE</code>   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                          |
| <code>TPROTO</code>      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ). |
| <code>TSYSERR</code>     | A system error has occurred during execution of this function.                                                                                                                      |

**TLI COMPATIBILITY ATTRIBUTES** In the TLI interface definition, no counterpart of this routine was defined.

| <b>NAME</b>          | t_rcvvudata – receive a data unit into one or more noncontiguous buffers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_rcvvudata(int fd, struct t_unitdata *unitdata, struct t_iovec                 *iov, unsigned int iovcount, int *flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>   | <p>This function is used in connectionless mode to receive a data unit from another transport user. The argument <i>fd</i> identifies the local transport endpoint through which data will be received, <i>unitdata</i> holds information associated with the received data unit, <i>iovcount</i> contains the number of non-contiguous udata buffers which is limited to T_IOV_MAX, which is an implementation-defined value of at least 16, and <i>flags</i> is set on return to indicate that the complete data unit was not received. If the limit on <i>iovcount</i> is exceeded, the function fails with TBADDDATA. The argument <i>unitdata</i> points to a t_unitdata structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; The maxlen field of <i>addr</i> and <i>opt</i> must be set before calling this function to indicate the maximum size of the buffer for each. The <i>udata</i> field of t_unitdata is not used. The <i>iov_len</i> and <i>iov_base</i> fields of "<i>iov0</i>" through <i>iov</i> [<i>iovcount-1</i>] must be set before calling t_rcvvudata() to define the buffer where the userdata will be placed. If the maxlen field of <i>addr</i> or <i>opt</i> is set to zero then no information is returned in the <i>buf</i> field for this parameter.</pre> <p>On return from this call, <i>addr</i> specifies the protocol address of the sending user, <i>opt</i> identifies options that were associated with this data unit, and <i>iov</i>[0].<i>iov_base</i> through <i>iov</i>[<i>iovcount-1</i>].<i>iov_base</i> contains the user data that was received. The return value of t_rcvvudata() is the number of bytes of user data given to the user.</p> <p>Note that the limit on the total number of bytes available in all buffers passed:</p> <pre>iov(0).iov_len + .. + iov(iovcount-1).iov_len</pre> may be constrained by implementation limits. If no other constraint applies, it will be limited by INT_MAX. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions. <p>By default, t_rcvvudata() operates in synchronous mode and waits for a data unit to arrive if none is currently available. However, if O_NONBLOCK is set by means of t_open(3NSL) or fcntl(2), t_rcvvudata() executes in asynchronous mode and fails if no data units are available.</p> <p>If the buffers defined in the <i>iov</i>[] array are not large enough to hold the current data unit, the buffers will be filled and T_MORE will be set in flags on return to indicate that another t_rcvvudata() should be called to retrieve the rest of the data unit. Subsequent calls to t_rcvvudata() will return zero for the length of the address and options, until the full data unit has been received.</p> |
| <b>RETURN VALUES</b> | On successful completion, t_rcvvudata() returns the number of bytes received. Otherwise, it returns -1 on failure and t_errno is set to indicate the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**VALID STATES** T\_IDLE.

**ERRORS** On failure, `t_errno` is set to one of the following:

|             |                                                                                                                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TBADDATA    | <code>iovcount</code> is greater than <code>T_IOV_MAX</code> .                                                                                                                                                                             |
| TBADF       | The specified file descriptor does not refer to a transport endpoint.                                                                                                                                                                      |
| TBUFOVFLW   | The number of bytes allocated for the incoming protocol address or options ( <i>maxlen</i> ) is greater than 0 but not sufficient to store the information. The unit data information to be returned in <i>unitdata</i> will be discarded. |
| TLOOK       | An asynchronous event has occurred on this transport endpoint and requires immediate attention.                                                                                                                                            |
| TNODATA     | <code>O_NONBLOCK</code> was set, but no data units are currently available from the transport provider.                                                                                                                                    |
| TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                                                                       |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                 |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                        |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                             |

**TLI  
COMPATIBILITY  
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

| <b>NAME</b>        | t_snd – send data or expedited data over a connection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_snd(int fd, void *buf, unsigned int nbytes, int flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used to send either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint over which data should be sent, <i>buf</i> points to the user data, <i>nbytes</i> specifies the number of bytes of user data to be sent, and <i>flags</i> specifies any optional flags described below:</p> <p><b>T_EXPEDITED</b>     If set in <i>flags</i>, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.</p> <p><b>T_MORE</b>            If set in <i>flags</i>, this indicates to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit - ETSDU) is being sent through multiple <code>t_snd()</code> calls. Each <code>t_snd()</code> with the <b>T_MORE</b> flag set indicates that another <code>t_snd()</code> will follow with more data for the current TSDU (or ETSDU).</p> <p>The end of the TSDU (or ETSDU) is identified by a <code>t_snd()</code> call with the <b>T_MORE</b> flag not set. Use of <b>T_MORE</b> enables a user to break up large logical data units without losing the boundaries of those units at the other end of the connection. The flag implies nothing about how the data is packaged for transfer below the transport interface. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>, the <b>T_MORE</b> flag is not meaningful and will be ignored if set.</p> <p>The sending of a zero-length fragment of a TSDU or ETSDU is only permitted where this is used to indicate the end of a TSDU or ETSDU; that is, when the <b>T_MORE</b> flag is not set. Some transport providers also forbid zero-length TSDUs and ETSDUs.</p> <p><b>T_PUSH</b>            If set in <i>flags</i>, requests that the provider transmit all data that it has accumulated but not sent. The request is a local action on the provider and does not affect any similarly named protocol flag (for example, the TCP PUSH flag). This effect of setting this flag is protocol-dependent, and it may be ignored entirely by transport providers which do not support the use of this feature.</p> <p>Note that the communications provider is free to collect data in a send buffer until it accumulates a sufficient amount for transmission.</p> |

By default, `t_snd()` operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if `O_NONBLOCK` is set by means of `t_open(3NSL)` or `fcntl(2)`, `t_snd()` will execute in asynchronous mode, and will fail immediately if there are flow control restrictions. The process can arrange to be informed when the flow control restrictions are cleared by means of either `t_look(3NSL)` or the EM interface.

On successful completion, `t_snd()` returns the number of bytes (octets) accepted by the communications provider. Normally this will equal the number of octets specified in `nbytes`. However, if `O_NONBLOCK` is set or the function is interrupted by a signal, it is possible that only part of the data has actually been accepted by the communications provider. In this case, `t_snd()` returns a value that is less than the value of `nbytes`. If `t_snd()` is interrupted by a signal before it could transfer data to the communications provider, it returns `-1` with `t_errno` set to `TSYSERR` and `errno` set to `EINTR`.

If `nbytes` is zero and sending of zero bytes is not supported by the underlying communications service, `t_snd()` returns `-1` with `t_errno` set to `TBADDATA`.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as specified by the current values in the TSDU or ETSDU fields in the *info* argument returned by `t_getinfo(3NSL)`.

The error `TLOOK` is returned for asynchronous events. It is required only for an incoming disconnect event but may be returned for other events.

## RETURN VALUES

On successful completion, `t_snd()` returns the number of bytes accepted by the transport provider. Otherwise, `-1` is returned on failure and `t_errno` is set to indicate the error.

Note that if the number of bytes accepted by the communications provider is less than the number of bytes requested, this may either indicate that `O_NONBLOCK` is set and the communications provider is blocked due to flow control, or that `O_NONBLOCK` is clear and the function was interrupted by a signal.

## ERRORS

On failure, `t_errno` is set to one of the following:

- |                       |                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TBADDATA</code> | Illegal amount of data: <ul style="list-style-type: none"> <li>■ A single send was attempted specifying a TSDU (ETSDU) or fragment TSDU (ETSDU) greater than that specified by the current values of the TSDU or ETSDU fields in the <i>info</i> argument.</li> <li>■ A send of a zero byte TSDU (ETSDU) or zero byte fragment of a TSDU (ETSDU) is not supported by the provider.</li> </ul> |

| TNOTSUPPORT                     | This function is not supported by the underlying transport provider.                                                                                                                                                                                                                                                                      |
| TOUTSTATE                       | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                                                                |
| TPROTO                          | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                                                                                                                       |
| TSYSERR                         | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                            |
| <b>TLI COMPATIBILITY</b>        | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                           |
| <b>Interface Header</b>         | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:<br><br><code>#include &lt;tiuser.h&gt;</code>                                                                                                                                                  |
| <b>Error Description Values</b> | The <code>t_errno</code> values that can be set by the XTI interface and cannot be set by the TLI interface are:<br><br>TPROTO<br>TLOOK<br>TBADFLAG<br>TOUTSTATE<br><br>The <code>t_errno</code> values that this routine can return under different circumstances than its XTI counterpart are:<br><br>TBADDATA                          |

t\_snd(3NSL)

In the TBADDDATA error cases described above, TBADDDATA is returned, only for illegal zero byte TSDU ( ETSDU) send attempts.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** fcntl(2), t\_getinfo(3NSL), t\_look(3NSL), t\_open(3NSL), t\_rcv(3NSL), attributes(5)

**WARNINGS** It is important to remember that the transport provider treats all users of a transport endpoint as a single user. Therefore if several processes issue concurrent t\_snd () calls then the different data may be intermixed.

Multiple sends which exceed the maximum TSDU or ETSDU size may not be discovered by XTI. In this case an implementation-dependent error will result, generated by the transport provider, perhaps on a subsequent XTI call. This error may take the form of a connection abort, a TSYSEERR, a TBADDDATA or a TPROTO error.

If multiple sends which exceed the maximum TSDU or ETSDU size are detected by XTI, t\_snd () fails with TBADDDATA.

## t\_snddis(3NSL)

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |                                                                       |          |                                                                                                |         |                                                                                                                             |       |                                                                |

| <b>NAME</b>          | t_snddis – send user-initiated disconnection request                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                       |          |                                                                                                |         |                                                                                                                             |       |                                                                |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_snddis(int fd, const struct t_call *call);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |       |                                                                       |          |                                                                                                |         |                                                                                                                             |       |                                                                |
| <b>DESCRIPTION</b>   | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the <a href="#">TLI COMPATIBILITY</a> section for a description of differences between the two interfaces.</p> <p>This function is used to initiate an abortive release on an already established connection, or to reject a connection request. The argument <i>fd</i> identifies the local transport endpoint of the connection, and <i>call</i> specifies information associated with the abortive release. The argument <i>call</i> points to a <code>t_call</code> structure which contains the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;</pre> <p>The values in <i>call</i> have different semantics, depending on the context of the call to <code>t_snddis()</code>. When rejecting a connection request, <i>call</i> must be non-null and contain a valid value of <i>sequence</i> to uniquely identify the rejected connection indication to the transport provider. The <i>sequence</i> field is only meaningful if the transport connection is in the <code>T_INCON</code> state. The <i>addr</i> and <i>opt</i> fields of <i>call</i> are ignored. In all other cases, <i>call</i> need only be used when data is being sent with the disconnection request. The <i>addr</i>, <i>opt</i> and <i>sequence</i> fields of the <code>t_call</code> structure are ignored. If the user does not wish to send data to the remote user, the value of <i>call</i> may be a null pointer.</p> <p>The <i>udata</i> structure specifies the user data to be sent to the remote user. The amount of user data must not exceed the limits supported by the transport provider, as returned in the <i>discon</i> field, of the <i>info</i> argument of <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>. If the <i>len</i> field of <i>udata</i> is zero, no data will be sent to the remote user.</p> |       |                                                                       |          |                                                                                                |         |                                                                                                                             |       |                                                                |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |                                                                       |          |                                                                                                |         |                                                                                                                             |       |                                                                |

| TLOOK                | An asynchronous event, which requires attention, has occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |       |                                                                       |          |                                                                                                |         |                                                                                                                             |       |                                                                |

|             |                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                          |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ). |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                      |

**TLI COMPATIBILITY**

The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.

**Interface Header**

The XTI interfaces use the header file, `xti.h`. TLI interfaces should *not* use this header. They should use the header:

```
#include <tiuser.h>
```

**Error Description Values**

The `t_errno` value TPROTO can be set by the XTI interface but not by the TLI interface.

**Option Buffers**

The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO**

[t\\_connect\(3NSL\)](#), [t\\_getinfo\(3NSL\)](#), [t\\_listen\(3NSL\)](#), [t\\_open\(3NSL\)](#), [t\\_snd\(3NSL\)](#), [attributes\(5\)](#)

**WARNINGS**

`t_snddis()` is an abortive disconnection. Therefore a `t_snddis()` issued on a connection endpoint may cause data previously sent by means of [t\\_snd\(3NSL\)](#), or data not yet received, to be lost, even if an error is returned.

| <b>DESCRIPTION</b>       | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>For transport providers of type <code>T_COTS_ORD</code>, this function is used to initiate an orderly release of the outgoing direction of data transfer and indicates to the transport provider that the transport user has no more data to send. The argument <i>fd</i> identifies the local transport endpoint where the connection exists. After calling <code>t_sndrel()</code>, the user may not send any more data over the connection. However, a user may continue to receive data if an orderly release indication has not been received. For transport providers of types other than <code>T_COTS_ORD</code>, this function fails with error <code>TNOTSUPPORT</code>.</p> |                    |                                                                       |                    |                                                                                                                                            |                    |                                                                                                 |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>RETURN VALUES</b>     | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                    |                                                                       |                    |                                                                                                                                            |                    |                                                                                                 |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |

| <b>TLI COMPATIBILITY</b> | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                    |                                                                       |                    |                                                                                                                                            |                    |                                                                                                 |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>Interface Header</b>  | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                                       |                    |                                                                                                                                            |                    |                                                                                                 |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |

t\_sndrel(3NSL)

```
#include <tiuser.h>
```

**Error Description Values**

The t\_errno values that can be set by the XTI interface and cannot be set by the TLI interface are:

TPROTO  
TLOOK  
TOUTSTATE

**Notes**

Whenever this function fails with t\_error set to TFLOW, O\_NONBLOCK must have been set.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO**

t\_error(3NSL), t\_getinfo(3NSL), t\_open(3NSL), t\_rcvrel(3NSL), attributes(5)

| <b>NAME</b>          | t_sndreldata – initiate or respond to an orderly release with user data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>      | <pre>#include &lt;xti.h&gt;  int t_sndreldata(int fd, struct t_discon *discon);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>   | <p>This function is used to initiate an orderly release of the outgoing direction of data transfer and to send user data with the release. The argument <i>fd</i> identifies the local transport endpoint where the connection exists, and <i>discon</i> points to a <code>t_discon</code> structure containing the following members:</p> <pre>struct netbuf udata; int reason; int sequence;</pre> <p>After calling <code>t_sndreldata()</code>, the user may not send any more data over the connection. However, a user may continue to receive data if an orderly release indication has not been received.</p> <p>The field <i>reason</i> specifies the reason for the disconnection through a protocol-dependent <i>reason code</i>, and <i>udata</i> identifies any user data that is sent with the disconnection; the field <i>sequence</i> is not used.</p> <p>The <i>udata</i> structure specifies the user data to be sent to the remote user. The amount of user data must not exceed the limits supported by the transport provider, as returned in the <i>discon</i> field of the <i>info</i> argument of <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>. If the <i>len</i> field of <i>udata</i> is zero or if the provider did not return <code>T_ORDRELDATA</code> in the <code>t_open(3NSL)</code> flags, no data will be sent to the remote user.</p> <p>If a user does not wish to send data and reason code to the remote user, the value of <i>discon</i> may be a null pointer.</p> <p>This function is an optional service of the transport provider, only supported by providers of service type <code>T_COTS_ORD</code>. The flag <code>T_ORDRELDATA</code> in the <i>info</i>→<i>flag</i> field returned by <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code> indicates that the provider supports orderly release user data.</p> <p>This function may not be available on all systems.</p> |
| <b>RETURN VALUES</b> | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|             |                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TLOOK       | An asynchronous event has occurred on this transport endpoint and requires immediate attention.                                                                                     |
| TNOTSUPPORT | Orderly release is not supported by the underlying transport provider.                                                                                                              |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                          |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ). |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                      |

**TLI  
COMPATIBILITY  
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO**

`t_getinfo(3NSL)`, `t_open(3NSL)`, `t_rcvrel(3NSL)`, `t_rcvreldata(3NSL)`, `t_sndrel(3NSL)`, `attributes(5)`

**NOTES**

The interfaces `t_sndreldata()` and `t_rcvreldata(3NSL)` are only for use with a specific transport called "minimal OSI," which is not available on the Solaris platform. These interfaces are not available for use in conjunction with Internet Transports (TCP or UDP).

| <b>NAME</b>        | t_sndudata – send a data unit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_sndudata(int fd, const struct t_unitdata *unitdata);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>This function is used in connectionless-mode to send a data unit to another transport user. The argument <i>fd</i> identifies the local transport endpoint through which data will be sent, and <i>unitdata</i> points to a <code>t_unitdata</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata;</pre> <p>In <i>unitdata</i>, <i>addr</i> specifies the protocol address of the destination user, <i>opt</i> identifies options that the user wants associated with this request, and <i>udata</i> specifies the user data to be sent. The user may choose not to specify what protocol options are associated with the transfer by setting the <i>len</i> field of <i>opt</i> to zero. In this case, the provider uses the option values currently set for the communications endpoint.</p> <p>If the <i>len</i> field of <i>udata</i> is zero, and sending of zero octets is not supported by the underlying transport service, the <code>t_sndudata()</code> will return <code>-1</code> with <code>t_errno</code> set to <code>TBADDATA</code>.</p> <p>By default, <code>t_sndudata()</code> operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_sndudata()</code> will execute in asynchronous mode and will fail under such conditions. The process can arrange to be notified of the clearance of a flow control restriction by means of either <code>t_look(3NSL)</code> or the EM interface.</p> <p>If the amount of data specified in <i>udata</i> exceeds the TSDU size as returned in the <i>tsdu</i> field of the <i>info</i> argument of <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>, a <code>TBADDATA</code> error will be generated. If <code>t_sndudata()</code> is called before the destination user has activated its transport endpoint (see <code>t_bind(3NSL)</code>), the data unit may be discarded.</p> <p>If it is not possible for the transport provider to immediately detect the conditions that cause the errors <code>TBADDADDR</code> and <code>TBADOPT</code>, these errors will alternatively be returned by <code>t_rcvuderr</code>. Therefore, an application must be prepared to receive these errors in both of these ways.</p> <p>If the call is interrupted, <code>t_sndudata()</code> will return <code>EINTR</code> and the datagram will not be sent.</p> |

| <code>TPROTO</code>             | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error ( <code>t_errno</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                       |                                                                                             |                       |                                                                                                                                                                                                |                    |                                                                       |                      |                                                                                     |                    |                                                                                                                                        |                    |                                                                |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |
| <code>TSYSERR</code>            | A system error has occurred during execution of this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                                                                                             |                       |                                                                                                                                                                                                |                    |                                                                       |                      |                                                                                     |                    |                                                                                                                                        |                    |                                                                |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>TLI COMPATIBILITY</b>        | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                       |                                                                                             |                       |                                                                                                                                                                                                |                    |                                                                       |                      |                                                                                     |                    |                                                                                                                                        |                    |                                                                |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>Interface Header</b>         | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header: <pre style="margin-left: 2em;">#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                       |                                                                                             |                       |                                                                                                                                                                                                |                    |                                                                       |                      |                                                                                     |                    |                                                                                                                                        |                    |                                                                |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |
| <b>Error Description Values</b> | The <code>t_errno</code> values that can be set by the XTI interface and cannot be set by the TLI interface are: <table border="0" style="margin-left: 2em;"> <tr><td><code>TPROTO</code></td></tr> <tr><td><code>TBADADDR</code></td></tr> <tr><td><code>TBADOPT</code></td></tr> <tr><td><code>TLOOK</code></td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <code>TPROTO</code>   | <code>TBADADDR</code>                                                                       | <code>TBADOPT</code>  | <code>TLOOK</code>                                                                                                                                                                             |                    |                                                                       |                      |                                                                                     |                    |                                                                                                                                        |                    |                                                                |                          |                                                                      |                        |                                                                                                                            |                     |                                                                                                                                                                                     |                      |                                                                |

## t\_sndudata(3NSL)

TOUTSTATE

**Notes** Whenever this function fails with `t_error` set to `TFLOW`, `O_NONBLOCK` must have been set.

**Option Buffers** The format of the options in an `opt` buffer is dictated by the transport provider. Unlike the XTI interface, the TLI interface does not fix the buffer format.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

**SEE ALSO** `fcntl(2)`, `t_alloc(3NSL)`, `t_bind(3NSL)`, `t_error(3NSL)`, `t_getinfo(3NSL)`, `t_look(3NSL)`, `t_open(3NSL)`, `t_rcvudata(3NSL)`, `t_rcvuderr(3NSL)`, `attributes(5)`

| <b>NAME</b>              | t_sndv – send data or expedited data, from one or more non-contiguous buffers, on a connection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                          |                                                                                                                                        |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>          | <pre>#include &lt;xti.h&gt;  int t_sndv(int fd, const struct t_iovec *iov, unsigned int iovcount,            int flags);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                          |                                                                                                                                        |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b>       | <p>This function is used to send either normal or expedited data. The argument <i>fd</i> identifies the local transport endpoint over which data should be sent, <i>iov</i> points to an array of buffer address/buffer length pairs. <code>t_sndv()</code> sends data contained in buffers <i>iov0</i>, <i>iov1</i>, through <i>iov</i> [<i>iovcount</i>-1]. <i>iovcount</i> contains the number of non-contiguous data buffers which is limited to <code>T_IOV_MAX</code>, an implementation-defined value of at least 16. If the limit is exceeded, the function fails with <code>TBADDATA</code>.</p> <p><i>iov</i>(0).<i>iov_len</i> + . . . + <i>iov</i>(<i>iovcount</i>-1).<i>iov_len</i>)</p> <p>Note that the limit on the total number of bytes available in all buffers passed: may be constrained by implementation limits. If no other constraint applies, it will be limited by <code>INT_MAX</code>. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> <p>The argument <i>flags</i> specifies any optional flags described below:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>T_EXPEDITED</code></td> <td>If set in <i>flags</i>, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.</td> </tr> <tr> <td><code>T_MORE</code></td> <td>If set in <i>flags</i>, this indicates to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit – ETSDU) is being sent through multiple <code>t_sndv()</code> calls. Each <code>t_sndv()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_sndv()</code> or <code>t_snd(3NSL)</code> will follow with more data for the current TSDU (or ETSDU).</td> </tr> </table> <p>The end of the TSDU (or ETSDU) is identified by a <code>t_sndv()</code> call with the <code>T_MORE</code> flag not set. Use of <code>T_MORE</code> enables a user to break up large logical data units without losing the boundaries of those units at the other end of the connection. The flag implies nothing about how the data is packaged for transfer below the transport interface. If the transport provider does not support the concept of a TSDU as indicated in the <i>info</i> argument on return from <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>, the <code>T_MORE</code> flag is not meaningful and will be ignored if set.</p> <p>The sending of a zero-length fragment of a TSDU or ETSDU is only permitted where this is used to indicate the end of a TSDU or ETSDU, that is, when the <code>T_MORE</code> flag is not set. Some transport providers also forbid zero-length TSDUs and ETSDUs.</p> | <code>T_EXPEDITED</code> | If set in <i>flags</i> , the data will be sent as expedited data and will be subject to the interpretations of the transport provider. | <code>T_MORE</code> | If set in <i>flags</i> , this indicates to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit – ETSDU) is being sent through multiple <code>t_sndv()</code> calls. Each <code>t_sndv()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_sndv()</code> or <code>t_snd(3NSL)</code> will follow with more data for the current TSDU (or ETSDU). |

| <code>T_MORE</code>      | If set in <i>flags</i> , this indicates to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit – ETSDU) is being sent through multiple <code>t_sndv()</code> calls. Each <code>t_sndv()</code> with the <code>T_MORE</code> flag set indicates that another <code>t_sndv()</code> or <code>t_snd(3NSL)</code> will follow with more data for the current TSDU (or ETSDU).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                          |                                                                                                                                        |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## t\_sndv(3NSL)

If set in *flags*, requests that the provider transmit all data that it has accumulated but not sent. The request is a local action on the provider and does not affect any similarly named protocol flag (for example, the TCP PUSH flag). This effect of setting this flag is protocol-dependent, and it may be ignored entirely by transport providers which do not support the use of this feature.

The communications provider is free to collect data in a send buffer until it accumulates a sufficient amount for transmission.

By default, `t_sndv()` operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if `O_NONBLOCK` is set by means of `t_open(3NSL)` or `fcntl(2)`, `t_sndv()` executes in asynchronous mode, and will fail immediately if there are flow control restrictions. The process can arrange to be informed when the flow control restrictions are cleared via either `t_look(3NSL)` or the EM interface.

On successful completion, `t_sndv()` returns the number of bytes accepted by the transport provider. Normally this will equal the total number of bytes to be sent, that is,

```
(iov0.iov_len + .. + iov[iovcnt-1].iov_len)
```

However, the interface is constrained to send at most `INT_MAX` bytes in a single send. When `t_sndv()` has submitted `INT_MAX` (or lower constrained value, see the note above) bytes to the provider for a single call, this value is returned to the user. However, if `O_NONBLOCK` is set or the function is interrupted by a signal, it is possible that only part of the data has actually been accepted by the communications provider. In this case, `t_sndv()` returns a value that is less than the value of `nbytes`. If `t_sndv()` is interrupted by a signal before it could transfer data to the communications provider, it returns `-1` with `t_errno` set to `TSYSERR` and `errno` set to `EINTR`.

If the number of bytes of data in the *iov* array is zero and sending of zero octets is not supported by the underlying transport service, `t_sndv()` returns `-1` with `t_errno` set to `TBADDATA`.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as specified by the current values in the TSDU or ETSDU fields in the *info* argument returned by `t_getinfo(3NSL)`.

The error `TLOOK` is returned for asynchronous events. It is required only for an incoming disconnect event but may be returned for other events.

### RETURN VALUES

On successful completion, `t_sndv()` returns the number of bytes accepted by the transport provider. Otherwise, `-1` is returned on failure and `t_errno` is set to indicate the error.

Note that in synchronous mode, if more than `INT_MAX` bytes of data are passed in the *iov* array, only the first `INT_MAX` bytes will be passed to the provider.

If the number of bytes accepted by the communications provider is less than the number of bytes requested, this may either indicate that `O_NONBLOCK` is set and the communications provider is blocked due to flow control, or that `O_NONBLOCK` is clear and the function was interrupted by a signal.

**VALID STATES**

`T_DATAXFER`, `T_INREL`.

**ERRORS**

On failure, `t_errno` is set to one of the following:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**TLI  
COMPATIBILITY  
ATTRIBUTES**

In the TLI interface definition, no counterpart of this routine was defined.

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT Level       | Safe            |

t\_sndv(3NSL)

**SEE ALSO** [t\\_getinfo\(3NSL\)](#), [t\\_open\(3NSL\)](#), [t\\_rcvv\(3NSL\)](#) [t\\_rcv\(3NSL\)](#), [t\\_snd\(3NSL\)](#), [attributes\(5\)](#)

**WARNINGS** It is important to remember that the transport provider treats all users of a transport endpoint as a single user. Therefore if several processes issue concurrent `t_sndv()` or `t_snd(3NSL)` calls, then the different data may be intermixed.

Multiple sends which exceed the maximum TSDU or ETSDU size may not be discovered by XTI. In this case an implementation-dependent error will result (generated by the transport provider), perhaps on a subsequent XTI call. This error may take the form of a connection abort, a `TSYSERR`, a `TBADDATA` or a `TPROTO` error.

If multiple sends which exceed the maximum TSDU or ETSDU size are detected by XTI, `t_sndv()` fails with `TBADDATA`.

| <b>NAME</b>        | t_sndvudata – send a data unit from one or more noncontiguous buffers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>#include &lt;xti.h&gt;  int t_sndvudata(int fd, struct t_unitdata *unitdata, struct t_iovec                 *iov, unsigned int iovcount);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This function is used in connectionless mode to send a data unit to another transport user. The argument <i>fd</i> identifies the local transport endpoint through which data will be sent, <i>iovcount</i> contains the number of non-contiguous <i>udata</i> buffers and is limited to an implementation-defined value given by <code>T_IOV_MAX</code> which is at least 16, and <i>unitdata</i> points to a <code>t_unitdata</code> structure containing the following members:</p> <pre>struct netbuf addr; struct netbuf opt; struct netbuf udata;</pre> <p>If the limit on <i>iovcount</i> is exceeded, the function fails with <code>TBADDATA</code>.</p> <p>In <i>unitdata</i>, <i>addr</i> specifies the protocol address of the destination user, and <i>opt</i> identifies options that the user wants associated with this request. The <i>udata</i> field is not used. The user may choose not to specify what protocol options are associated with the transfer by setting the <i>len</i> field of <i>opt</i> to zero. In this case, the provider may use default options.</p> <p>The data to be sent is identified by <i>iov</i> [0] through <i>iov</i> [<i>iovcount</i>-1].</p> <p>Note that the limit on the total number of bytes available in all buffers passed:</p> <pre>iov(0).iov_len + .. + iov(iovcount-1).iov_len</pre> <p>may be constrained by implementation limits. If no other constraint applies, it will be limited by <code>INT_MAX</code>. In practice, the availability of memory to an application is likely to impose a lower limit on the amount of data that can be sent or received using scatter/gather functions.</p> <p>By default, <code>t_sndvudata()</code> operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if <code>O_NONBLOCK</code> is set by means of <code>t_open(3NSL)</code> or <code>fcntl(2)</code>, <code>t_sndvudata()</code> executes in asynchronous mode and will fail under such conditions. The process can arrange to be notified of the clearance of a flow control restriction by means of either <code>t_look(3NSL)</code> or the EM interface.</p> <p>If the amount of data specified in <i>iov</i> [0] through <i>iov</i> [<i>iovcount</i>-1] exceeds the TSDU size as returned in the <i>tsdu</i> field of the <i>info</i> argument of <code>t_open(3NSL)</code> or <code>t_getinfo(3NSL)</code>, or is zero and sending of zero octets is not supported by the underlying transport service, a <code>TBADDATA</code> error is generated. If <code>t_sndvudata()</code> is called before the destination user has activated its transport endpoint (see <code>t_bind(3NSL)</code>), the data unit may be discarded.</p> |

t\_sndvudata(3NSL)

If it is not possible for the transport provider to immediately detect the conditions that cause the errors TBADDADDR and TBADOPT, these errors will alternatively be returned by t\_rcvuderr(3NSL). An application must therefore be prepared to receive these errors in both of these ways.

**RETURN VALUES** Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and t\_errno is set to indicate an error.

**VALID STATES** T\_IDLE.

**ERRORS** On failure, t\_errno is set to one of the following:

- |             |                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TBADADDR    | The specified protocol address was in an incorrect format or contained illegal information.                                                                                                                                                                                                           |
| TBADDATA    | Illegal amount of data. <ul style="list-style-type: none"><li>■ A single send was attempted specifying a TSDU greater than that specified in the <i>info</i> argument, or a send of a zero byte TSDU is not supported by the provider.</li><li>■ <i>iovcount</i> is greater than T_IOV_MAX.</li></ul> |
| TBADF       | The specified file descriptor does not refer to a transport endpoint.                                                                                                                                                                                                                                 |
| TBADOPT     | The specified options were in an incorrect format or contained illegal information.                                                                                                                                                                                                                   |
| TFLOW       | O_NONBLOCK i was set, but the flow control mechanism prevented the transport provider from accepting any data at this time.                                                                                                                                                                           |
| TLOOK       | An asynchronous event has occurred on this transport endpoint.                                                                                                                                                                                                                                        |
| TNOTSUPPORT | This function is not supported by the underlying transport provider.                                                                                                                                                                                                                                  |
| TOUTSTATE   | The communications endpoint referenced by <i>fd</i> is not in one of the states in which a call to this function is valid.                                                                                                                                                                            |
| TPROTO      | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI error (t_errno).                                                                                                                                  |
| TSYSERR     | A system error has occurred during execution of this function.                                                                                                                                                                                                                                        |

| <b>DESCRIPTION</b>       | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>The <code>t_strerror()</code> function maps the error number in <code>errnum</code> that corresponds to an XTI error to a language-dependent error message string and returns a pointer to the string. The string pointed to will not be modified by the program, but may be overwritten by a subsequent call to the <code>t_strerror</code> function. The string is not terminated by a newline character. The language for error message strings written by <code>t_strerror()</code> is that of the current locale. If it is English, the error message string describing the value in <code>t_errno</code> may be derived from the comments following the <code>t_errno</code> codes defined in <code>&lt;xti.h&gt;</code>. If an error code is unknown, and the language is English, <code>t_strerror()</code> returns the string:</p> <pre>"&lt;error&gt;: error unknown" where &lt;error&gt; is the error number supplied as input. In other languages, an equivalent text is provided.</pre> |                |                 |          |      |
| <b>VALID STATES</b>      | ALL - apart from <code>T_UNINIT</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |          |      |
| <b>RETURN VALUES</b>     | The function <code>t_strerror()</code> returns a pointer to the generated message string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |          |      |
| <b>TLI COMPATIBILITY</b> | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |      |
| <b>Interface Header</b>  | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |          |      |

| <b>NAME</b>             | t_sync – synchronize transport library                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                      |          |                     |       |                       |                              |                      |                              |                         |                |                       |                                                                       |
| <b>SYNOPSIS</b>         | <pre>#include &lt;xti.h&gt;  int t_sync (int fd) ;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                      |          |                     |       |                       |                              |                      |                              |                         |                |                       |                                                                       |
| <b>DESCRIPTION</b>      | <p>This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p>For the transport endpoint specified by <i>fd</i>, <code>t_sync()</code> synchronizes the data structures managed by the transport library with information from the underlying transport provider. In doing so, it can convert an uninitialized file descriptor (obtained by means of a <code>open(2)</code>, <code>dup(2)</code> or as a result of a <code>fork(2)</code> and <code>exec(2)</code>) to an initialized transport endpoint, assuming that the file descriptor referenced a transport endpoint, by updating and allocating the necessary library data structures. This function also allows two cooperating processes to synchronize their interaction with a transport provider.</p> <p>For example, if a process forks a new process and issues an <code>exec(2)</code>, the new process must issue a <code>t_sync()</code> to build the private library data structure associated with a transport endpoint and to synchronize the data structure with the relevant provider information.</p> <p>It is important to remember that the transport provider treats all users of a transport endpoint as a single user. If multiple processes are using the same endpoint, they should coordinate their activities so as not to violate the state of the transport endpoint. The function <code>t_sync()</code> returns the current state of the transport endpoint to the user, thereby enabling the user to verify the state before taking further action. This coordination is only valid among cooperating processes; it is possible that a process or an incoming event could change the endpoint's state <i>after</i> a <code>t_sync()</code> is issued.</p> <p>If the transport endpoint is undergoing a state transition when <code>t_sync()</code> is called, the function will fail.</p> |                      |          |                     |       |                       |                              |                      |                              |                         |                |                       |                                                                       |
| <b>RETURN VALUES</b>    | <p>On successful completion, the state of the transport endpoint is returned. Otherwise, a value of <code>-1</code> is returned and <code>t_errno</code> is set to indicate an error. The state returned is one of the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>T_UNBND</code></td> <td>Unbound.</td> </tr> <tr> <td><code>T_IDLE</code></td> <td>Idle.</td> </tr> <tr> <td><code>T_OUTCON</code></td> <td>Outgoing connection pending.</td> </tr> <tr> <td><code>T_INCON</code></td> <td>Incoming connection pending.</td> </tr> <tr> <td><code>T_DATAXFER</code></td> <td>Data transfer.</td> </tr> <tr> <td><code>T_OUTREL</code></td> <td>Outgoing orderly release (waiting for an orderly release indication).</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <code>T_UNBND</code> | Unbound. | <code>T_IDLE</code> | Idle. | <code>T_OUTCON</code> | Outgoing connection pending. | <code>T_INCON</code> | Incoming connection pending. | <code>T_DATAXFER</code> | Data transfer. | <code>T_OUTREL</code> | Outgoing orderly release (waiting for an orderly release indication). |

| <b>TLI COMPATIBILITY</b>        | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below. |                                                                                                                                                                                                         |                |                 |          |      |
| <b>Interface Header</b>         | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:                                                      |                                                                                                                                                                                                         |                |                 |          |      |
|                                 | <pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                            |                                                                                                                                                                                                         |                |                 |          |      |
| <b>Error Description Values</b> | The <code>t_errno</code> value that can be set by the XTI interface and cannot be set by the TLI interface is:                                                                                  |                                                                                                                                                                                                         |                |                 |          |      |
|                                 | TPROTO                                                                                                                                                                                          |                                                                                                                                                                                                         |                |                 |          |      |

| <b>DESCRIPTION</b>                  | <p>The t_sysconf() function provides a method for the application to determine the current value of configurable and implementation-dependent XTI limits or options.</p> <p>The <i>name</i> argument represents the XTI system variable to be queried. The following table lists the minimal set of XTI system variables from &lt;xti.h&gt; that can be returned by t_sysconf(), and the symbolic constants, defined in &lt;xti.h&gt; that are the corresponding values used for <i>name</i>.</p> <table border="1" data-bbox="461 720 1430 806"> <thead> <tr> <th>Variable</th> <th>Value of Name</th> </tr> </thead> <tbody> <tr> <td>T_IOV_MAX</td> <td>_SC_T_IOV_MAX</td> </tr> </tbody> </table> | Variable       | Value of Name   | T_IOV_MAX | _SC_T_IOV_MAX |
| Variable                            | Value of Name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |           |               |
| T_IOV_MAX                           | _SC_T_IOV_MAX                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |           |               |
| <b>RETURN VALUES</b>                | If <i>name</i> is valid, t_sysconf() returns the value of the requested limit/option, which might be -1, and leaves t_errno unchanged. Otherwise, a value of -1 is returned and t_errno is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |           |               |
| <b>VALID STATES</b>                 | All.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |           |               |
| <b>ERRORS</b>                       | On failure, t_errno is set to the following:<br>TBADFLAG <i>name</i> has an invalid value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |           |               |

| <b>DESCRIPTION</b>              | <p>The This routine is part of the XTI interfaces which evolved from the TLI interfaces. XTI represents the future evolution of these interfaces. However, TLI interfaces are supported for compatibility. When using a TLI routine that has the same name as an XTI routine, the <code>tiuser.h</code> header file must be used. Refer to the TLI COMPATIBILITY section for a description of differences between the two interfaces.</p> <p><code>t_unbind()</code> function disables the transport endpoint specified by <code>fd</code> which was previously bound by <code>t_bind(3NSL)</code>. On completion of this call, no further data or events destined for this transport endpoint will be accepted by the transport provider. An endpoint which is disabled by using <code>t_unbind()</code> can be enabled by a subsequent call to <code>t_bind(3NSL)</code>.</p> |       |                                                                       |       |                                                                |           |                                                                                                                                  |        |                                                                                                                                                                                     |         |                                                                |
| <b>RETURN VALUES</b>            | Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and <code>t_errno</code> is set to indicate an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |                                                                       |       |                                                                |           |                                                                                                                                  |        |                                                                                                                                                                                     |         |                                                                |

| <b>TLI COMPATIBILITY</b>        | The XTI and TLI interface definitions have common names but use different header files. This, and other semantic differences between the two interfaces are described in the subsections below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |                                                                       |       |                                                                |           |                                                                                                                                  |        |                                                                                                                                                                                     |         |                                                                |
| <b>Interface Header</b>         | The XTI interfaces use the header file, <code>xti.h</code> . TLI interfaces should <i>not</i> use this header. They should use the header:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |                                                                       |       |                                                                |           |                                                                                                                                  |        |                                                                                                                                                                                     |         |                                                                |
|                                 | <pre>#include &lt;tiuser.h&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |       |                                                                       |       |                                                                |           |                                                                                                                                  |        |                                                                                                                                                                                     |         |                                                                |
| <b>Error Description Values</b> | The <code>t_errno</code> value that can be set by the XTI interface and cannot be set by the TLI interface is:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |                                                                       |       |                                                                |           |                                                                                                                                  |        |                                                                                                                                                                                     |         |                                                                |

| <b>DESCRIPTION</b>       | XDR routines allow C programmers to describe arbitrary data structures in a machine-independent fashion. Data for remote procedure calls (RPC) are transmitted using these routines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |             |                       |           |                   |          |                  |           |                   |          |                  |             |                 |             |                  |            |                  |          |                  |           |                  |          |                  |            |                 |           |                  |            |                 |         |                  |          |                  |                |                  |            |                   |             |                   |               |                  |               |                   |            |                 |           |                  |            |                 |            |                   |            |                  |

| <b>DESCRIPTION</b> | <p>XDR library routines allow C programmers to describe arbitrary data structures in a machine-independent fashion. Protocols such as remote procedure calls (RPC) use these routines to describe the format of the data.</p> <p>These routines deal specifically with the management of the XDR stream.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Routines</b>    | <p>See <a href="#">rpc(3NSL)</a> for the definition of the XDR data structure. Note that any buffers passed to the XDR routines must be properly aligned. It is suggested either that <code>malloc(3C)</code> be used to allocate these buffers, or that the programmer insure that the buffer address is divisible evenly by four.</p> <pre>#include &lt;rpc/xdr.h&gt;</pre> <p><code>bool_t xdr_control( XDR *xdrs, int req, void *info );</code><br/>A function macro to change or retrieve various information about an XDR stream. <i>req</i> indicates the type of operation and <i>info</i> is a pointer to the information. The supported values of <i>req</i> is <code>XDR_GET_BYTES_AVAIL</code> and its argument type is <code>xdr_bytesrec *</code>. They return the number of bytes left unconsumed in the stream and a flag indicating whether or not this is the last fragment.</p> <p><code>uint_t xdr_getpos( const XDR *xdrs );</code><br/>A macro that invokes the get-position routine associated with the XDR stream, <i>xdrs</i>. The routine returns an unsigned integer, which indicates the position of the XDR byte stream. A desirable feature of XDR streams is that simple arithmetic works with this number, although the XDR stream instances need not guarantee this. Therefore, applications written for portability should not depend on this feature.</p> <p><code>long *xdr_inline( XDR *xdrs, const int len );</code><br/>A macro that invokes the in-line routine associated with the XDR stream, <i>xdrs</i>. The routine returns a pointer to a contiguous piece of the stream's buffer; <i>len</i> is the byte length of the desired buffer. Note: pointer is cast to <code>long *</code>.</p> <p>Warning: <code>xdr_inline()</code> may return <code>NULL (0)</code> if it cannot allocate a contiguous piece of a buffer. Therefore the behavior may vary among stream instances; it exists for the sake of efficiency, and applications written for portability should not depend on this feature.</p> <p><code>bool_t xdrrec_endofrecord( XDR *xdrs, int sendnow );</code><br/>This routine can be invoked only on streams created by <code>xdrrec_create()</code>. See <a href="#">xdr_create(3NSL)</a>. The data in the output buffer is marked as a completed record, and the output buffer is optionally written out if <i>sendnow</i> is non-zero. This routine returns <code>TRUE</code> if it succeeds, <code>FALSE</code> otherwise.</p> <p><code>bool_t xdrrec_eof( XDR *xdrs );</code><br/>This routine can be invoked only on streams created by <code>xdrrec_create()</code>. After consuming the rest of the current record in the stream, this routine returns <code>TRUE</code> if there is no more data in the stream's input buffer. It returns <code>FALSE</code> if there is additional data in the stream's input buffer.</p> |

```
int xdrrec_readbytes(XDR *xdrs, caddr_t addr, uint_t nbytes);
```

This routine can be invoked only on streams created by `xdrrec_create()`. It attempts to read *nbytes* bytes from the XDR stream into the buffer pointed to by *addr*. Upon success this routine returns the number of bytes read. Upon failure, it returns `-1`. A return value of `0` indicates an end of record.

```
bool_t xdrrec_skiprecord(XDR *xdrs);
```

This routine can be invoked only on streams created by `xdrrec_create()`. See `xdr_create(3NSL)`. It tells the XDR implementation that the rest of the current record in the stream's input buffer should be discarded. This routine returns `TRUE` if it succeeds, `FALSE` otherwise.

```
bool_t xdr_setpos(XDR *xdrs, const uint_t pos);
```

A macro that invokes the set position routine associated with the XDR stream *xdrs*. The parameter *pos* is a position value obtained from `xdr_getpos()`. This routine returns `TRUE` if the XDR stream was repositioned, and `FALSE` otherwise.

Warning: it is difficult to reposition some types of XDR streams, so this routine may fail with one type of stream and succeed with another. Therefore, applications written for portability should not depend on this feature.

```
unsigned long xdr_sizeof(xdrproc_t func, void *data);
```

This routine returns the number of bytes required to encode *data* using the XDR filter function *func*, excluding potential overhead such as RPC headers or record markers. `0` is returned on error. This information might be used to select between transport protocols, or to determine the buffer size for various lower levels of RPC client and server creation routines, or to allocate storage when XDR is used outside of the RPC subsystem.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | Safe            |

| <b>DESCRIPTION</b> | XDR library routines allow C programmers to describe complex data structures in a machine-independent fashion. Protocols such as remote procedure calls (RPC) use these routines to describe the format of the data. These routines are the XDR library routines for complex data structures. They require the creation of XDR streams. See <a href="#">xdr_create(3NSL)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Routines</b>    | <p>See <a href="#">rpc(3NSL)</a> for the definition of the XDR data structure. Note that any buffers passed to the XDR routines must be properly aligned. It is suggested either that <code>malloc()</code> be used to allocate these buffers, or that the programmer insure that the buffer address is divisible evenly by four.</p> <pre>#include &lt;rpc/xdr.h&gt;</pre> <p><code>bool_t xdr_array(XDR *xdrs, caddr_t *arrp, uint_t *sizep, const uint_t maxsize, const uint_t elsize, const xdrproc_t elproc);</code><br/><code>xdr_array()</code> translates between variable-length arrays and their corresponding external representations. The parameter <code>arrp</code> is the address of the pointer to the array, while <code>sizep</code> is the address of the element count of the array; this element count cannot exceed <code>maxsize</code>. The parameter <code>elsize</code> is the size of each of the array's elements, and <code>elproc</code> is an XDR routine that translates between the array elements' C form and their external representation. If <code>*arrp</code> is NULL when decoding, <code>xdr_array()</code> allocates memory and <code>*arrp</code> points to it. This routine returns TRUE if it succeeds, FALSE otherwise.</p> <p><code>bool_t xdr_bytes(XDR *xdrs, char **sp, uint_t *sizep, const uint_t maxsize);</code><br/><code>xdr_bytes()</code> translates between counted byte strings and their external representations. The parameter <code>sp</code> is the address of the string pointer. The length of the string is located at address <code>sizep</code>; strings cannot be longer than <code>maxsize</code>. If <code>*sp</code> is NULL when decoding, <code>xdr_bytes()</code> allocates memory and <code>*sp</code> points to it. This routine returns TRUE if it succeeds, FALSE otherwise.</p> <p><code>bool_t xdr_opaque(XDR *xdrs, caddr_t cp, const uint_t cnt);</code><br/><code>xdr_opaque()</code> translates between fixed size opaque data and its external representation. The parameter <code>cp</code> is the address of the opaque object, and <code>cnt</code> is its size in bytes. This routine returns TRUE if it succeeds, FALSE otherwise.</p> <p><code>bool_t xdr_pointer(XDR *xdrs, char **objpp, uint_t objsize, const xdrproc_t xdrobj);</code><br/>Like <code>xdr_reference()</code> except that it serializes null pointers, whereas <code>xdr_reference()</code> does not. Thus, <code>xdr_pointer()</code> can represent recursive data structures, such as binary trees or linked lists. If <code>*objpp</code> is NULL when decoding, <code>xdr_pointer()</code> allocates memory and <code>*objpp</code> points to it.</p> |

```
bool_t xdr_reference(XDR *xdrs, caddr_t *pp, uint_t size, const xdrproc_t proc);
```

`xdr_reference()` provides pointer chasing within structures. The parameter `pp` is the address of the pointer; `size` is the `sizeof` the structure that `*pp` points to; and `proc` is an XDR procedure that translates the structure between its C form and its external representation. If `*pp` is NULL when decoding, `xdr_reference()` allocates memory and `*pp` points to it. This routine returns 1 if it succeeds, 0 otherwise.

Warning: this routine does not understand null pointers. Use `xdr_pointer()` instead.

```
bool_t xdr_string(XDR *xdrs, char **sp, const uint_t maxsize);
```

`xdr_string()` translates between C strings and their corresponding external representations. Strings cannot be longer than `maxsize`. Note: `sp` is the address of the string's pointer. If `*sp` is NULL when decoding, `xdr_string()` allocates memory and `*sp` points to it. This routine returns TRUE if it succeeds, FALSE otherwise. Note: `xdr_string()` can be used to send an empty string (""), but not a null string.

```
bool_t xdr_union(XDR *xdrs, enum_t *dscmp, char *unp, const struct xdr_discrim
*choices, const xdrproc_t (*defaultarm));
```

`xdr_union()` translates between a discriminated C union and its corresponding external representation. It first translates the discriminant of the union located at `dscmp`. This discriminant is always an `enum_t`. Next the union located at `unp` is translated. The parameter `choices` is a pointer to an array of `xdr_discrim` structures. Each structure contains an ordered pair of [`value`, `proc`]. If the union's discriminant is equal to the associated `value`, then the `proc` is called to translate the union. The end of the `xdr_discrim` structure array is denoted by a routine of value NULL. If the discriminant is not found in the `choices` array, then the `defaultarm` procedure is called (if it is not NULL). It returns TRUE if it succeeds, FALSE otherwise.

```
bool_t xdr_vector(XDR *xdrs, char *arrp, const uint_t size, const uint_t elsize, const
xdrproc_t elproc);
```

`xdr_vector()` translates between fixed-length arrays and their corresponding external representations. The parameter `arrp` is the address of the pointer to the array, while `size` is the element count of the array. The parameter `elsize` is the `sizeof` each of the array's elements, and `elproc` is an XDR routine that translates between the array elements' C form and their external representation. This routine returns TRUE if it succeeds, FALSE otherwise.

```
bool_t xdr_wrapstring(XDR *xdrs, char **sp);
```

A routine that calls `xdr_string(xdrs, sp, maxuint)`; where `maxuint` is the maximum value of an unsigned integer.

Many routines, such as `xdr_array()`, `xdr_pointer()`, and `xdr_vector()` take a function pointer of type `xdrproc_t()`, which takes two arguments.

`xdr_string()`, one of the most frequently used routines, requires three arguments, while `xdr_wrapstring()` only requires two. For these routines, `xdr_wrapstring()` is desirable. This routine returns TRUE if it succeeds, FALSE

xdr\_complex(3NSL)

otherwise.

| <b>DESCRIPTION</b> | <p>The XDR library routines allow C programmers to describe arbitrary data structures in a machine-independent fashion. Protocols such as remote procedure calls (RPC) use these routines to describe the format of the data.</p> <p>These routines deal with the creation of XDR streams, which must be created before any data can be translated into XDR format.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Routines</b>    | <p>See <a href="#">rpc(3NSL)</a> for the definition of the XDR CLIENT and SVCXPRT data structures. Any buffers passed to the XDR routines must be properly aligned. Use <code>malloc(3C)</code> to allocate these buffers or be sure that the buffer address is divisible evenly by four.</p> <p><b>xdr_destroy()</b><br/> A macro that invokes the destroy routine associated with the XDR stream, <i>xdrs</i>. Private data structures associated with the stream are freed. Using <i>xdrs</i> after <code>xdr_destroy()</code> is invoked is undefined.</p> <p><b>xdrmem_create()</b><br/> This routine initializes the XDR stream object pointed to by <i>xdrs</i>. The stream's data is written to or read from a chunk of memory at location <i>addr</i> whose length is no less than <i>size</i> bytes long. The <i>op</i> determines the direction of the XDR stream. The value of <i>op</i> can be either XDR_ENCODE, XDR_DECODE, or XDR_FREE.</p> <p><b>xdrrec_create()</b><br/> This routine initializes the read-oriented XDR stream object pointed to by <i>xdrs</i>. The stream's data is written to a buffer of size <i>sendsz</i>. A value of 0 indicates the system should use a suitable default. The stream's data is read from a buffer of size <i>recvsz</i>. It too can be set to a suitable default by passing a 0 value. When a stream's output buffer is full, <i>writeit</i> is called. Similarly, when a stream's input buffer is empty, <code>xdrrec_create()</code> calls <i>readit</i>. The behavior of these two routines is similar to the system calls <code>read()</code> and <code>write()</code>, except that an appropriate handle, <i>read_handle</i> or <i>write_handle</i>, is passed to the former routines as the first parameter instead of a file descriptor. See <code>read(2)</code> and <code>write(2)</code>, respectively. The XDR stream's <i>op</i> field must be set by the caller.</p> <p>This XDR stream implements an intermediate record stream. Therefore, additional bytes in the stream are provided for record boundary information.</p> |

## xdr\_create(3NSL)

### xdrstdio\_create()

This routine initializes the XDR stream object pointed to by *xdrs*. The XDR stream data is written to or read from the standard I/O stream *file*. The parameter *op* determines the direction of the XDR stream. The value of *op* can be either `XDR_ENCODE`, `XDR_DECODE`, or `XDR_FREE`.

The destroy routine associated with XDR streams calls `fflush()` on the *file* stream, but never `fclose()`. See `fclose(3C)`.

A failure of any of these functions can be detected by first initializing the *x\_ops* field in the XDR structure (*xdrs*-> *x\_ops*) to `NULL` before calling the `xdr*_create()` function. If the *x\_ops* field is still `NULL`, after the return from the `xdr*_create()` function, the call has failed. If the *x\_ops* field contains some other value, assume that the call has succeeded.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| MT-Level       | MT-Safe         |

|              |                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xdr_bool()   | xdr_bool() translates between booleans (C integers) and their external representations. When encoding data, this filter produces values of either 1 or 0. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                              |
| xdr_char()   | xdr_char() translates between C characters and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise. Note: encoded characters are not packed, and occupy 4 bytes each. For arrays of characters, it is worthwhile to consider xdr_bytes(), xdr_opaque(), or xdr_string() (see xdr_complex(3NSL)).                                            |
| xdr_double() | xdr_double() translates between C double precision numbers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                                         |
| xdr_enum()   | xdr_enum() translates between C enums (actually integers) and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                                          |
| xdr_float()  | xdr_float() translates between C floats and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                                                            |
| xdr_free()   | Generic freeing routine. The first argument is the XDR routine for the object being freed. The second argument is a pointer to the object itself. Note: the pointer passed to this routine is not freed, but what it points to is freed (recursively, depending on the XDR routine).                                                                                              |
| xdr_hyper()  | xdr_hyper() translates between ANSI C long long integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                                           |
| xdr_int()    | xdr_int() translates between C integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                                                            |
| xdr_long()   | xdr_long() translates between C long integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.<br><br>In a 64-bit environment, this routine returns an error if the value of <code>lp</code> is outside the range <code>[INT32_MIN, INT32_MAX]</code> . The <code>xdr_int()</code> routine is recommended in place of this routine. |

|                    |                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xdr_longlong_t()   | xdr_longlong_t() translates between ANSI C long long integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise. This routine is identical to xdr_hyper().                                                                                                                                                  |
| xdr_quadruple()    | xdr_quadruple() translates between IEEE quadruple precision floating point numbers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                       |
| xdr_short()        | xdr_short() translates between C short integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                          |
| xdr_u_char()       | xdr_u_char() translates between unsigned C characters and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                                    |
| xdr_u_hyper()      | xdr_u_hyper() translates between unsigned ANSI C long long integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                      |
| xdr_u_int()        | A filter primitive that translates between a C unsigned integer and its external representation. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                             |
| xdr_u_long()       | xdr_u_long() translates between C unsigned long integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.<br><br>In a 64-bit environment, this routine returns an error if the value of <i>ulp</i> is outside the range [0, UINT32_MAX]. The xdr_u_int() routine is recommended in place of this routine. |
| xdr_u_longlong_t() | xdr_u_longlong_t() translates between unsigned ANSI C long long integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise. This routine is identical to xdr_u_hyper().                                                                                                                                     |
| xdr_u_short()      | xdr_u_short() translates between C unsigned short integers and their external representations. This routine returns TRUE if it succeeds, FALSE otherwise.                                                                                                                                                                                               |
| xdr_void()         | This routine always returns TRUE. It may be passed to RPC routines that require a function parameter, where nothing is to be done.                                                                                                                                                                                                                      |

| <b>DESCRIPTION</b> | <p>This package of functions provides an interface to NIS, Network Information Service Version 2, formerly referred to as YP. In this version of SunOS, NIS version 2 is supported only for compatibility with previous versions. The recommended enterprise level information service is NIS+ or NIS version 3. See nis+(1). The current SunOS supports only the client interface to NIS version 2. This client interface will in turn be served either by an existing ypser process running on another machine on the network that has an earlier version of SunOS, or by a NIS+ server running in "YP-compatibility mode." See rpc.nisd(1M). The NOTES section in ypfiles(4) discusses the implications of being an NIS client of an NIS+ server in <i>YP-compatibility mode</i>. For commands used to access NIS from a client machine, see ypbind(1M), ypwhich(1), ypmatch(1), and ypcat(1). The package can be loaded from the standard library, /usr/lib/libnsl.so.1.</p> <p>All input parameter names begin with <i>in</i>. Output parameters begin with <i>out</i>. Output parameters of type char ** should be addresses of uninitialized character pointers. Memory is allocated by the NIS client package using malloc(3C) and can be freed by the user code if it has no continuing need for it. For each <i>outkey</i> and <i>outval</i>, two extra bytes of memory are allocated at the end that contain NEWLINE and null,</p> |

## ypclnt(3NSL)

respectively, but these two bytes are not reflected in *outkeylen* or *outvalen*. The *indomain* and *inmap* strings must be non-null and null-terminated. String parameters that are accompanied by a count parameter may not be null, but they may point to null strings, with the count parameter indicating this. Counted strings need not be null-terminated.

All functions in this package of type *int* return 0 if they succeed. Otherwise, they return a failure code (YPERR\_XXX). Failure codes are described in the ERRORS section.

### Routines

#### yp\_bind()

To use the NIS name services, the client process must be "bound" to an NIS server that serves the appropriate domain using `yp_bind()`. Binding need not be done explicitly by user code. Binding is done automatically whenever an NIS lookup function is called. The `yp_bind()` function can be called directly for processes that make use of a backup strategy, for example, a local file in cases when NIS services are not available. A process should call `yp_unbind()` when it is finished using NIS in order to free up resources.

#### yp\_unbind()

Each binding allocates or uses up one client process socket descriptor. Each bound domain costs one socket descriptor. However, multiple requests to the same domain use that same descriptor. The `yp_unbind()` function is available at the client interface for processes that explicitly manage their socket descriptors while accessing multiple domains. The call to `yp_unbind()` makes the domain *unbound*, and frees all per-process and per-node resources used to bind it.

If an RPC failure results upon use of a binding, that domain will be unbound automatically. At that point, the `ypclnt()` layer will retry a few more times or until the operation succeeds, provided that `rpcbind(1M)` and `ypbind(1M)` are running, and either:

- The client process cannot bind a server for the proper domain; or
- RPC requests to the server fail.

Under the following circumstances, the `ypclnt` layer will return control to the user code, with either an error or success code and the results:

- If an error is not RPC-related.
- If `rpcbind` is not running.
- If `ypbind` is not running.
- If a bound `ypserv` process returns any answer (success or failure).

#### yp\_get\_default\_domain()

NIS lookup calls require a map name and a domain name, at minimum. The client process should know the name of the map of interest. Client processes fetch the node's default domain by calling `yp_get_default_domain()` and use the returned *outdomain* as the *indomain* parameter to successive NIS name service calls. The domain returned is the same as that returned using the `SI_SRPC_DOMAIN` command to the `sysinfo(2)` system call. The value returned in *outdomain* should not be freed.

`yp_match()`

The `yp_match()` function returns the value associated with a passed key. This key must be exact because no pattern matching is available. `yp_match()` requires a full YP map name, such as `hosts.byname`, instead of the nickname `hosts`.

`yp_first()`

The `yp_first()` function returns the first key-value pair from the named map in the named domain.

`yp_next()`

The `yp_next()` function returns the next key-value pair in a named map. The *inkey* parameter must be the *outkey* returned from an initial call to `yp_first()` (to get the second key-value pair) or the one returned from the *n*th call to `yp_next()` (to get the *n*th + second key-value pair). Similarly, the *inkeylen* parameter must be the *outkeylen* returned from the earlier `yp_first()` or `yp_next()` call.

The concept of first and next is particular to the structure of the NIS map being processed. Retrieval order is not related to either the lexical order within any original (non-NIS name service) data base, or to any obvious numerical sorting order on the keys, values, or key-value pairs. The only ordering guarantee is that if the `yp_first()` function is called on a particular map, and then the `yp_next()` function is repeatedly called on the same map at the same server until the call fails with a reason of `YPERR_NOMORE`, every entry in the data base is seen exactly once. Further, if the same sequence of operations is performed on the same map at the same server, the entries are seen in the same order.

Under conditions of heavy server load or server failure, the domain can become unbound, then bound once again (perhaps to a different server) while a client is running. This binding can cause a break in one of the enumeration rules. Specific entries may be seen twice by the client, or not at all. This approach protects the client from error messages that would otherwise be returned in the midst of the enumeration. For a better solution to enumerating all entries in a map, see `yp_all()`.

`yp_all()`

The `yp_all()` function provides a way to transfer an entire map from server to client in a single request using TCP (rather than UDP as with other functions in this package). The entire transaction takes place as a single RPC request and response. The `yp_all()` function can be used just like any other NIS name service procedure to identify the map in the normal manner and to supply the name of a function that will be called to process each key-value pair within the map. The call to `yp_all()` returns only when the transaction is completed (successfully or unsuccessfully), or the `foreach()` function decides that it does not want to see any more key-value pairs.

The third parameter to `yp_all()` is:

```
struct ypsall_callback *incallback {
 int (*foreach)();
 char *data;
};
```

## ypclnt(3NSL)

The function `foreach()` is called:

```
foreach(int instatus, char *inkey,
int inkeylen, char *inval,
int invallen, char *indata);
```

The *instatus* parameter holds one of the return status values defined in `<rpcsvc/yp_prot.h>`, either `YP_TRUE` or an error code. See `ypprot_err()`, for a function that converts an NIS name service protocol error code to a `ypclnt` layer error code.

The key and value parameters are somewhat different than defined in the synopsis section above. First, the memory pointed to by the *inkey* and *inval* parameters is private to the `yp_all()` function, and is overwritten with the arrival of each new key-value pair. The `foreach()` function must do something useful with the contents of that memory, but it does not own the memory itself. Key and value objects presented to the `foreach()` function look exactly as they do in the server's map. If they were not NEWLINE-terminated or null-terminated in the map, they would not be here either.

The *indata* parameter is the contents of the `incallback->data` element passed to `yp_all()`. The *data* element of the callback structure can be used to share state information between the `foreach()` function and the mainline code. Its use is optional, and no part of the NIS client package inspects its contents; cast it to something useful, or ignore it. The `foreach()` function is Boolean. It should return 0 to indicate that it wants to be called again for further received key-value pairs, or non-zero to stop the flow of key-value pairs. If `foreach()` returns a non-zero value, it is not called again. The functional value of `yp_all()` is then 0.

### `yp_order()`

The `yp_order()` function returns the order number for a map. The function is not supported if the `ypbind` process on the client's system is bound to an NIS+ server running in "YP-compatibility mode."

### `yp_master()`

The `yp_master()` function returns the machine name of the master NIS server for a map.

### `yperr_string()`

The `yperr_string()` function returns a pointer to an error message string that is null-terminated but contains no period or NEWLINE.

### `ypprot_err()`

The `ypprot_err()` function takes an NIS name service protocol error code as input, and returns a `ypclnt()` layer error code, which can be used as an input to `yperr_string()`.

## RETURN VALUES

All integer functions return 0 if the requested operation is successful, or one of the following errors if the operation fails:

`YPERR_ACCESS`                      Access violation.

|               |                                        |
|---------------|----------------------------------------|
| YPERR_BADARGS | The arguments to the function are bad. |
| YPERR_BADDB   | The YP database is bad.                |
| YPERR_BUSY    | The database is busy.                  |
| YPERR_DOMAIN  | Cannot bind to server on this domain.  |
| YPERR_KEY     | No such key in map.                    |
| YPERR_MAP     | No such map in server's domain.        |
| YPERR_NODOM   | Local domain name not set.             |
| YPERR_NOMORE  | No more records in map database.       |
| YPERR_PMAP    | Cannot communicate with rpcbind.       |
| YPERR_RESRC   | Resource allocation failure.           |
| YPERR_RPC     | RPC failure; domain has been unbound.  |
| YPERR_YPBIND  | Cannot communicate with ypbind.        |
| YPERR_YPERR   | Internal YP server or client error.    |
| YPERR_YPSESV  | Cannot communicate with ypserv.        |
| YPERR_VERS    | YP version mismatch.                   |

| <b>SYNOPSIS</b>      | <pre>#include &lt;rpcsvc/ypclnt.h&gt;  int <b>yp_update</b>(char *domain, char *map, unsigned ypop, char *key, int     keylen, char *data, int datalen);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |          |        |
| <b>DESCRIPTION</b>   | <p>yp_update() is used to make changes to the NIS database. The syntax is the same as that of yp_match() except for the extra parameter ypop which may take on one of four values. If it is POP_CHANGE then the data associated with the key will be changed to the new value. If the key is not found in the database, then yp_update() will return YPERR_KEY. If ypop has the value YPOP_INSERT then the key-value pair will be inserted into the database. The error YPERR_KEY is returned if the key already exists in the database. To store an item into the database without concern for whether it exists already or not, pass ypop as YPOP_STORE and no error will be returned if the key already or does not exist. To delete an entry, the value of ypop should be YPOP_DELETE.</p> <p>This routine depends upon secure RPC, and will not work unless the network is running secure RPC.</p> |                |                 |          |        |
| <b>RETURN VALUES</b> | <p>If the value of ypop is POP_CHANGE, yp_update() returns the error YPERR_KEY if the key is not found in the database.</p> <p>If the value of ypop is POP_INSERT, yp_update() returns the error YPERR_KEY if the key already exists in the database.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |          |        |

## A

- abandon an LDAP operation in progress —  
  ldap\_abandon, 233
- accept — accept a connection on a socket, 20
- accept a security context initiated by a peer  
  application — gss\_accept\_sec\_context, 126
- acquire a handle for a pre-existing credential by  
  name — gss\_acquire\_cred, 132
- acquire an auxiliary property context —  
  sasl\_auxprop\_getctx, 462
- acquire an auxiliary property context —  
  sasl\_client\_step, 478
- add a credential-element to a credential —  
  gss\_add\_cred, 135
- add a SASL auxiliary property plug-in —  
  sasl\_auxprop\_add\_plugin, 461
- add a SASL client plug-in —  
  sasl\_client\_add\_plugin, 471
- add a SASL server plug-in —  
  sasl\_server\_add\_plugin, 503
- add a SASL user canonicalization plug-in —  
  sasl\_canonuser\_add\_plugin, 464
- add an object identifier to an object identifier set  
  — gss\_add\_oid\_set\_member, 139
- add or remove IP addresses to or from an SCTP  
  socket — sctp\_bindx, 522
- address and name information error description  
  — gai\_strerror, 69
- allow application to determine maximum  
  message size with resulting output token of a  
  specified maximum size —  
  gss\_wrap\_size\_limit, 200

- attach a cryptographic message —  
  gss\_wrap, 198
- auth\_destroy — library routines for client side  
  remote procedure call authentication, 386
- authnone\_create — library routines for client  
  side remote procedure call  
  authentication, 386
- authsys\_create — library routines for client side  
  remote procedure call authentication, 386
- authsys\_create\_default — library routines for  
  client side remote procedure call  
  authentication, 386

## B

- Basic Encoding Rules library decoding  
  functions
  - ber\_alloc\_t, 24
  - ber\_bvdup, 24
  - ber\_bvecfree, 24
  - ber\_bvfree, 24
  - ber\_decode, 24
  - ber\_first\_element, 24
  - ber\_flatten, 24
  - ber\_free, 24
  - ber\_get\_bitstring, 24
  - ber\_get\_boolean, 24
  - ber\_get\_int, 24
  - ber\_get\_next, 24
  - ber\_get\_null, 24
  - ber\_get\_stringa, 24
  - ber\_get\_stringal, 24

Basic Encoding Rules library decoding functions (Continued)

- `ber_get_stringb`, 24
- `ber_init`, 24
- `ber_next_element`, 24
- `ber_peek_tag`, 24
- `ber_scanf`, 24
- `ber_skip_tag`, 24

`ber_alloc` — simplified Basic Encoding Rules library encoding functions, 29

`ber_alloc_t` — Basic Encoding Rules library decoding functions, 24

`ber_bvdup` — Basic Encoding Rules library decoding functions, 24

`ber_bvecfree` — Basic Encoding Rules library decoding functions, 24

`ber_bvfree` — Basic Encoding Rules library decoding functions, 24

`ber_decode` — Basic Encoding Rules library decoding functions, 24

`ber_encode` — simplified Basic Encoding Rules library encoding functions, 29

`ber_first_element` — Basic Encoding Rules library decoding functions, 24

`ber_flatten` — Basic Encoding Rules library decoding functions, 24

`ber_free` — Basic Encoding Rules library decoding functions, 24

`ber_get_bitstring` — Basic Encoding Rules library decoding functions, 24

`ber_get_boolean` — Basic Encoding Rules library decoding functions, 24

`ber_get_int` — Basic Encoding Rules library decoding functions, 24

`ber_get_next` — Basic Encoding Rules library decoding functions, 24

`ber_get_null` — Basic Encoding Rules library decoding functions, 24

`ber_get_stringa` — Basic Encoding Rules library decoding functions, 24

`ber_get_stringal` — Basic Encoding Rules library decoding functions, 24

`ber_get_stringb` — Basic Encoding Rules library decoding functions, 24

`ber_init` — Basic Encoding Rules library decoding functions, 24

`ber_next_element` — Basic Encoding Rules library decoding functions, 24

`ber_peek_tag` — Basic Encoding Rules library decoding functions, 24

`ber_printf` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_bitstring` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_boolean` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_int` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_null` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_ostring` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_seq` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_set` — simplified Basic Encoding Rules library encoding functions, 29

`ber_put_string` — simplified Basic Encoding Rules library encoding functions, 29

`ber_scanf` — Basic Encoding Rules library decoding functions, 24

`ber_skip_tag` — Basic Encoding Rules library decoding functions, 24

`ber_start_seq` — simplified Basic Encoding Rules library encoding functions, 29

`ber_start_set` — simplified Basic Encoding Rules library encoding functions, 29

`bind` — bind a name to a socket, 33

bind an address to a transport endpoint — `t_bind`, 616

branch off existing association from a one-to-many SCTP socket to create a one-to-one STP socket — `sctp_peeloff`, 533

byteorder — convert values between host and network byte order, 38

## C

callback function to lookup a `sasl_callback_t` for a connection — `sasl_getcallback_t`, 491

change QOP, service for session, — `rpc_gss_set_defaults`, 415

check a plaintext password — `sasl_checkpass`, 469

check an APOP challenge or response — `sasl_checkapop`, 468

cldap\_close — dispose of connectionless LDAP pointer, 39  
 cldap\_open — LDAP connectionless communication preparation, 40  
 cldap\_search\_s — connectionless LDAP search, 41  
     Retransmission Algorithm, 41  
 cldap\_setretryinfo — set connectionless LDAP request retransmission parameters, 43  
 client plug-in entry point —  
     sasl\_client\_plug\_init\_t, 475  
 client side remote procedure call authentication, library routines for  
     — auth\_destroy, 386  
     — authnone\_create, 386  
     — authsys\_create, 386  
     — authsys\_create\_default, 386

 clnt\_vc\_create — library routines for dealing with creation and manipulation of CLIENT handles, 392  
 close an open SLP handle — SLPclose, 573  
 communications  
     accept a connection on a socket — accept, 20  
     allocate memory for, 613  
     bind a name to a socket — bind, 33  
     create a pair of connected sockets — socketpair, 604  
     create an endpoint for communication — socket, 599  
     get name of peer connected to socket — getpeername, 104  
     get socket name — getsockname, 117  
     listen for connections on a socket — listen, 304  
     scatter data in order to test the network — spray, 607  
 compare two internal-form names — gss\_compare\_name, 142  
 configuration script, execute — doconfig, 53

- connect — initiate a connection on a socket, 44
- connectionless LDAP search —
  - cldap\_search\_s, 41
- convert IPv4 and IPv6 addresses between binary and text form — inet\_ntop, 220
- convert IPv4 and IPv6 addresses between binary and text form — inet\_pton, 220
- convert values between host and network byte order — byteorder, 38
- convert values between host and network byte order — htonl, 38
- convert values between host and network byte order — htons, 38
- convert values between host and network byte order — ntohl, 38
- convert values between host and network byte order — ntohs, 38
- convert a contiguous string name to GSS\_API internal format — gss\_import\_name, 157
- convert a GSS-API status code to text — gss\_display\_status, 149
- convert a mechanism name to export form — gss\_export\_name, 152
- convert a string to an OID — gss\_str\_to\_oid, 191
- convert an internal name to a mechanism name — gss\_canonicalize\_name, 140
- convert an OID to a string — gss\_oid\_to\_str, 179
- convert internal-form name to text — gss\_display\_name, 147
- create a copy of an internal name — gss\_duplicate\_name, 151
- create a new client authentication object — sasl\_client\_new, 473
- create a new server authentication object — sasl\_server\_new, 505
- create a new server authentication object — sasl\_server\_start, 508
- create a security context using the RPCSEC\_GSS protocol — rpc\_gss\_seccreate, 411
- create an object-identifier set containing no object identifiers — gss\_create\_empty\_oid\_set, 144

## D

- decode base64 string — sasl\_decode64, 481

- decode data received — sasl\_decode, 480
- delete a GSS-API security context — gss\_delete\_sec\_context, 145
- delete attributes — SLPDelAttrs, 574
- deregister the SLP advertisement — SLPDereg, 576
- determine available security mechanisms — gss\_indicate\_mechs, 161
- determine how long a context will remain valid — gss\_context\_time, 143
- determine whether a socket is at the out-of-band mark — socketmark, 598
- dial — establish an outgoing terminal line connection, 50
- discard a credential handle — gss\_release\_cred, 184
- discard an internal-form name — gss\_release\_name, 185
- dispose of a SASL connection object — sasl\_dispose, 482
- dispose of all SASL plug-ins — sasl\_done, 483
- dispose of connectionless LDAP pointer — cldap\_close, 39
- dn\_comp — resolver routines, 366
- dn\_expand — resolver routines, 366
- doconfig — execute a configuration script, 53

## E

- encode data for transport to an authenticated host — sasl\_encode, 484
- encode data for transport to an authenticated host — sasl\_encodev, 484
- encode base64 string — sasl\_encode64, 485
- encode base64 string — sasl\_utf8verify, 519
- endhostent — get network host entry, 76
- endservent — get service entry, 113
- erase buffer — sasl\_erasebuffer, 486
- escapes SLP reserved characters — SLPescape, 577
- establish an outgoing terminal line connection — dial, 50
- establish an outgoing terminal line connection — undial, 50
- Ethernet address mapping operations, — ethers, 63

ethers — Ethernet address mapping operations, 63  
examine SCTP level options for an SCTP endpoint — `sctp_opt_info`, 528  
external data representation, See XDR, 704

## F

find service types — `SLPFindSrvTypes`, 584  
`fp_resstat` — resolver routines, 366  
free a `BerElement` structure from memory — `ldap_ber_free`, 236  
free buffer storage allocated by a GSS-API function — `gss_release_buffer`, 183  
free memory allocated by LDAP API functions — `ldap_memfree`, 281  
free storage associated with a GSS-API-generated `gss_OID_set` object — `gss_release_oid_set`, 187  
`freeaddrinfo` — get address information, 65  
`freeaddrinfo` — translate between node name and address, 70  
`freehostent` — get IP node entry, 83  
`frees` memory — `SLPFree`, 586  
functions to map Internet Protocol network interface names and interface indexes — `if_freenameindex`, 206  
functions to map Internet Protocol network interface names and interface indexes — `if_indextoname`, 206  
functions to map Internet Protocol network interface names and interface indexes — `if_nameindex`, 206  
functions to map Internet Protocol network interface names and interface indexes — `if_nametoindex`, 206

## G

`gai_strerror` — address and name information error description, 69  
`gai_strerror` — translate between node name and address, 70  
generic transport name-to-address translation — `netdir`, 307

generic transport name-to-address translation — `netdir_free`, 307  
generic transport name-to-address translation — `netdir_getbyaddr`, 307  
generic transport name-to-address translation — `netdir_getbyname`, 307  
generic transport name-to-address translation — `netdir_mergeaddr`, 307  
generic transport name-to-address translation — `netdir_options`, 307  
generic transport name-to-address translation — `netdir_perror`, 307  
generic transport name-to-address translation — `netdir_sperror`, 307  
generic transport name-to-address translation — `taddr2uaddr`, 307  
generic transport name-to-address translation — `uaddr2taddr`, 307  
get address information — `freeaddrinfo`, 65  
get address information — `getaddrinfo`, 65  
get IP node entry — `freehostent`, 83  
get IP node entry — `getipnodebyaddr`, 83  
get IP node entry — `getipnodebyname`, 83  
get network host entry — `endhostent`, 76  
get network host entry — `gethostbyaddr`, 76  
get network host entry — `gethostbyaddr_r`, 76  
get network host entry — `gethostbyname`, 76  
get network host entry — `gethostbyname_r`, 76  
get network host entry — `gethostent`, 76  
get network host entry — `gethostent_r`, 76  
get network host entry — `sethostent`, 76  
get or set session preferences in the `ldap` structure. — `ldap_get_option`, 271  
get or set session preferences in the `ldap` structure. — `ldap_set_option`, 271  
get service entry — `getservbyname`, 113  
`endservent`, 113  
`getservbyname_r`, 113  
`getservbyport`, 113  
`getservbyport_r`, 113  
`getservent`, 113  
`getservent_r`, 113  
`setservent`, 113  
get a SASL property — `sasl_getprop`, 494  
get credentials of client — `rpc_gss_getcred`, 401  
get error codes on failure, —  
`rpc_gss_get_error`, 403

get maximum data length for transmission  
   — `rpc_gss_max_data_length`, 408  
   — `rpc_gss_svc_max_data_length`, 408  
 get principal names at server, —  
   `rpc_get_principal_name`, 406  
 get SASL library version information —  
   `sasl_version`, 521  
 getaddrinfo — get address information, 65  
 getaddrinfo — translate between node name  
   and address, 70  
 gethostbyaddr — get network host entry, 76  
 gethostbyaddr\_r — get network host entry, 76  
 gethostbyname — get network host entry, 76  
 gethostbyname\_r — get network host entry, 76  
 gethostent — get network host entry, 76  
 gethostent\_r — get network host entry, 76  
 getipnodebyaddr — get IP node entry, 83  
 getipnodebyname — get IP node entry, 83  
 getnameinfo — translate between node name  
   and address, 70  
 getpeername — get name of peer connected to  
   socket, 104  
 getpublickey — retrieve public or secret  
   key, 109  
 getsecretkey — retrieve public or secret  
   key, 109  
 getservbyname — get service entry, 113  
 getservbyname\_r — get service entry, 113  
 getservbyport — get service entry, 113  
 getservbyport\_r — get service entry, 113  
 getservent — get service entry, 113  
 getservent\_r — get service entry, 113  
 gss\_accept\_sec\_context — accept a security  
   context initiated by a peer application, 126  
 gss\_acquire\_cred — acquire a handle for a  
   pre-existing credential by name, 132  
 gss\_add\_cred — add a credential-element to a  
   credential, 135  
 gss\_add\_oid\_set\_member — add an object  
   identifier to an object identifier set, 139  
 gss\_canonicalize\_name — convert an internal  
   name to a mechanism name, 140  
 gss\_compare\_name — compare two  
   internal-form names, 142  
 gss\_context\_time — determine how long a  
   context will remain valid, 143  
 gss\_create\_empty\_oid\_set — create an  
   object-identifier set containing no object  
   identifiers, 144  
 gss\_delete\_sec\_context — delete a GSS-API  
   security context, 145  
 gss\_display\_name — convert internal-form  
   name to text, 147  
 gss\_display\_status — convert a GSS-API status  
   code to text, 149  
 gss\_duplicate\_name — create a copy of an  
   internal name, 151  
 gss\_export\_name — convert a mechanism name  
   to export form, 152  
 gss\_export\_sec\_context — transfer a security  
   context to another process, 153  
 gss\_import\_name — convert a contiguous  
   string name to GSS-API internal format, 157  
 gss\_import\_sec\_context — import security  
   context established by another process, 159  
 gss\_indicate\_mechs — determine available  
   security mechanisms, 161  
 gss\_init\_sec\_context — initiate a GSS-API  
   security context with a peer application, 162  
 gss\_inquire\_context — obtain information about  
   a security context, 169  
 gss\_inquire\_cred — obtain information about a  
   credential, 172  
 gss\_inquire\_cred\_by\_mech — obtain  
   per-mechanism information about a  
   credential, 174  
 gss\_inquire\_mechs\_for\_name — list  
   mechanisms that support the specified  
   name-type, 176  
 gss\_inquire\_names\_for\_mech — list the  
   name-types supported by the specified  
   mechanism, 178  
 gss\_oid\_to\_str — convert an OID to a  
   string, 179  
 gss\_process\_context\_token — pass  
   asynchronous token to security service, 181  
 gss\_release\_buffer — free buffer storage  
   allocated by a GSS-API function, 183  
 gss\_release\_cred — discard a credential  
   handle, 184  
 gss\_release\_name — discard an internal-form  
   name, 185  
 gss\_release\_oid — release an object  
   identifier, 186

gss\_release\_oid\_set — free storage associated with a GSS-API-generated gss\_OID\_set object, 187  
 gss\_store\_cred — store a credential in the current credential store, 188  
 gss\_str\_to\_oid — convert a string to an OID, 191  
 gss\_test\_oid\_set\_member — interrogate an object identifier set, 193  
 gss\_verify\_mic — verify integrity of a received message, 196  
 gss\_wrap — attach a cryptographic message, 198  
 gss\_wrap — verify a message with attached cryptographic message, 194  
 gss\_wrap\_size\_limit — allow application to determine maximum message size with resulting output token of a specified maximum size, 200

## H

herror — resolver routines, 366  
 host machines, remote, return information about users — rusers, rnusers, 455  
 hstrerror — resolver routines, 366  
 htonl — convert values between host and network byte order, 38  
 htons — convert values between host and network byte order, 38

## I

icmp6\_filter — Variable allocation datatype, 203  
 if\_freenameindex — functions to map Internet Protocol network interface names and interface indexes, 206  
 if\_freenameindex — routines to map Internet Protocol network interface names and interface indexes, 204  
 if\_indextoname — functions to map Internet Protocol network interface names and interface indexes, 206  
 if\_indextoname — routines to map Internet Protocol network interface names and interface indexes, 204  
 if\_nameindex — functions to map Internet Protocol network interface names and interface indexes, 206  
 if\_nameindex — routines to map Internet Protocol network interface names and interface indexes, 204  
 if\_nametoindex — functions to map Internet Protocol network interface names and interface indexes, 206  
 if\_nametoindex — routines to map Internet Protocol network interface names and interface indexes, 204  
 import security context established by another process — gss\_import\_sec\_context, 159  
 inet — Internet address manipulation, 208  
 inet\_addr — Internet address manipulation, 208  
 inet\_lnaof — Internet address manipulation, 208  
 inet\_makeaddr — Internet address manipulation, 208  
 inet\_netof — Internet address manipulation, 208  
 inet\_network — Internet address manipulation, 208  
 inet\_ntoa — Internet address manipulation, 208  
 inet\_ntop — convert IPv4 and IPv6 addresses between binary and text form, 220  
 inet\_ntop — Internet address manipulation, 208  
 inet\_pton — convert IPv4 and IPv6 addresses between binary and text form, 220  
 inet\_pton — Internet address manipulation, 208  
 inet6 — Internet address manipulation, 208  
 inet6\_opt — Option manipulation mechanism, 212  
 inet6\_rth — Routing header manipulation, 215  
 initialize an LDAP session — ldap\_init, 286  
 initialize an LDAP session — ldap\_open, 286  
 initialize SASL client authentication — sasl\_client\_init, 472  
 initiate a connection on a socket — connect, 44  
 initiate a GSS-API security context with a peer application — gss\_init\_sec\_context, 162  
 Internet address manipulation — inet6, 208  
 Internet address manipulation — inet, 208

- Internet address manipulation —  
inet\_addr, 208
- Internet address manipulation —  
inet\_lnaof, 208
- Internet address manipulation —  
inet\_makeaddr, 208
- Internet address manipulation —  
inet\_netof, 208
- Internet address manipulation —  
inet\_network, 208
- Internet address manipulation —  
inet\_ntoa, 208
- Internet address manipulation —  
inet\_ntop, 208
- Internet address manipulation —  
inet\_pton, 208
- interrogate an object identifier set —  
gss\_test\_oid\_set\_member, 193

## L

  ldap\_url\_search\_s, 300

LDAP Uniform Resource Locator functions —  
  ldap\_url\_search\_st, 300

ldap — Lightweight Directory Access Protocol  
  package, Index, 224

ldap\_8859\_to\_t61 — LDAP character set  
  translation functions, 240

ldap\_abandon — abandon an LDAP operation  
  in progress, 233

ldap\_add — perform an LDAP add  
  operation, 234

ldap\_add\_ext — perform an LDAP add  
  operation, 234

ldap\_add\_ext\_s — perform an LDAP add  
  operation, 234

ldap\_add\_s — perform an LDAP add  
  operation, 234

LDAP attribute remapping functions  
  — ldap\_free\_friendlymap, 263  
  — ldap\_friendly\_name, 263

LDAP attribute value handling functions  
  — ldap\_count\_values, 276  
  — ldap\_get\_values, 276  
  — ldap\_get\_values\_len, 276

ldap\_ber\_free — free a BerElement structure  
  from memory, 236

ldap\_bind — LDAP bind functions, 237

ldap\_bind\_s — LDAP bind functions, 237

ldap\_build\_filter — LDAP filter generating  
  functions, 267

LDAP character set translation functions  
  — ldap\_8859\_to\_t61, 240  
  — ldap\_enable\_translation, 240  
  — ldap\_set\_string\_translators, 240  
  — ldap\_t61\_to\_8859, 240

LDAP character set translation functions  
  (Continued)  
  — ldap\_translate\_from\_t61, 240  
  — ldap\_translate\_to\_t61, 240

ldap\_compare — LDAP compare  
  operation, 242

ldap\_compare\_ext — LDAP compare  
  operation, 242

ldap\_compare\_ext\_s — LDAP compare  
  operation, 242

LDAP compare operation  
  — ldap\_compare, 242  
  — ldap\_compare\_ext, 242  
  — ldap\_compare\_ext\_s, 242  
  — ldap\_compare\_s, 242

ldap\_compare\_s — LDAP compare  
  operation, 242

LDAP connectionless communication  
  preparation — cldap\_open, 40

LDAP control disposal  
  — ldap\_control\_free, 244  
  — ldap\_controls\_free, 244

ldap\_control\_free — LDAP control  
  disposal, 244

ldap\_controls\_free — LDAP control  
  disposal, 244

ldap\_count\_entries — LDAP entry parsing and  
  counting functions, 260

ldap\_count\_messages — LDAP message  
  processing functions, 262

ldap\_count\_references — LDAP entry parsing  
  and counting functions, 260

ldap\_count\_values — LDAP attribute value  
  handling functions, 276

ldap\_delete — LDAP delete operation, 245

ldap\_delete\_ext — LDAP delete operation, 245

ldap\_delete\_ext\_s — LDAP delete  
  operation, 245

LDAP delete operation  
  — ldap\_delete, 245  
  — ldap\_delete\_ext, 245  
  — ldap\_delete\_ext\_s, 245  
  — ldap\_delete\_s, 245

ldap\_delete\_s — LDAP delete operation, 245

LDAP display template functions  
  — ldap\_disptmpl, 246  
  — ldap\_first\_disptmpl, 246  
  — ldap\_first\_tmplcol, 246

LDAP display template functions (Continued)

- `ldap_first_tmplrow`, 246
- `ldap_free_templates`, 246
- `ldap_init_templates`, 246
- `ldap_init_templates_buf`, 246
- `ldap_next_disptmpl`, 246
- `ldap_next_tmplcol`, 246
- `ldap_next_tmplrow`, 246
- `ldap_oc2template`, 246
- `ldap_tmplattrs`, 246

`ldap_disptmpl` — LDAP display template functions, 246

- DISPTMPL Structure Elements, 248
- Syntax IDs, 249
- TMLITEM Structure Elements, 249

LDAP DN handling functions

- `ldap_dn2ufn`, 264
- `ldap_dns_to_dn`, 264
- `ldap_explode_dn`, 264
- `ldap_explode_dns`, 264
- `ldap_get_dn`, 264
- `ldap_is_dns_dn`, 264

`ldap_dn_to_url` — LDAP Uniform Resource Locator functions, 300

`ldap_dn2ufn` — LDAP DN handling functions, 264

`ldap_dns_to_dn` — LDAP DN handling functions, 264

`ldap_dns_to_url` — LDAP Uniform Resource Locator functions, 300

`ldap_enable_translation` — LDAP character set translation functions, 240

LDAP entry display functions

- `ldap_entry2text`, 252
- `ldap_entry2text_search`, 252
- `ldap_vals2text`, 252

LDAP entry modification functions

- `ldap_modify`, 282
- `ldap_modify_ext`, 282
- `ldap_modify_ext_s`, 282
- `ldap_modify_s`, 282

LDAP entry sorting functions

- `ldap_sort`, 296
- `ldap_sort_entries`, 296
- `ldap_sort_strcasecmp`, 296
- `ldap_sort_values`, 296

`ldap_entry2text` — LDAP entry display functions, 252

`ldap_entry2text_search` — LDAP entry display functions, 252

`ldap_err2string` — LDAP protocol error handling functions, 255

`ldap_error` — LDAP protocol error handling functions, 255

`ldap_explode_dn` — LDAP DN handling functions, 264

`ldap_explode_dns` — LDAP DN handling functions, 264

`ldap_first_attribute` — step through LDAP entry attributes, 259

`ldap_first_disptmpl` — LDAP display template functions, 246

`ldap_first_entry` — LDAP entry parsing and counting functions, 260

`ldap_first_message` — LDAP message processing functions, 262

`ldap_first_reference` — LDAP entry parsing and counting functions, 260

`ldap_first_searchobj` — LDAP search preference configuration routines, 294

`ldap_first_tmplcol` — LDAP display template functions, 246

`ldap_first_tmplrow` — LDAP display template functions, 246

`ldap_free_friendlymap` — LDAP attribute remapping functions, 263

`ldap_free_searchprefs` — LDAP search preference configuration routines, 294

`ldap_free_templates` — LDAP display template functions, 246

`ldap_free_urldesc` — LDAP Uniform Resource Locator functions, 300

`ldap_friendly_name` — LDAP attribute remapping functions, 263

`ldap_get_dn` — LDAP DN handling functions, 264

`ldap_get_lang_values` — return an attribute's values that matches a specified language subtype, 269

`ldap_get_lang_values_len` — return an attribute's values that matches a specified language subtype, 269

`ldap_get_option` — get or set session preferences in the `ldap` structure., 271

`ldap_get_values` — LDAP attribute value handling functions, 276

ldap\_get\_values\_len — LDAP attribute value handling functions, 276  
 ldap\_getfilter — LDAP filter generating functions, 267  
 ldap\_getfilter\_free — LDAP filter generating functions, 267  
 ldap\_getfirstfilter — LDAP filter generating functions, 267  
 ldap\_getnextfilter — LDAP filter generating functions, 267  
 ldap\_init — initialize an LDAP session, 286  
 ldap\_init\_getfilter — LDAP filter generating functions, 267  
 ldap\_init\_getfilter\_buf — LDAP filter generating functions, 267  
 ldap\_init\_searchprefs — LDAP search preference configuration routines, 294  
 ldap\_init\_searchprefs\_buf — LDAP search preference configuration routines, 294  
 ldap\_init\_templates — LDAP display template functions, 246  
 ldap\_init\_templates\_buf — LDAP display template functions, 246  
 ldap\_is\_dns\_dn — LDAP DN handling functions, 264  
 ldap\_is\_ldap\_url — LDAP Uniform Resource Locator functions, 300  
 ldap\_memcache — LDAP client caching functions, 278  
 ldap\_memcache\_destroy — LDAP client caching functions, 278  
 ldap\_memcache\_flush — LDAP client caching functions, 278  
 ldap\_memcache\_get — LDAP client caching functions, 278  
 ldap\_memcache\_init — LDAP client caching functions, 278  
 ldap\_memcache\_set — LDAP client caching functions, 278  
 ldap\_memcache\_update — LDAP client caching functions, 278  
 ldap\_memfree — free memory allocated by LDAP API functions, 281  
 LDAP message processing functions  
   — ldap\_count\_message, 262  
   — ldap\_first\_message, 262  
   — ldap\_msgtype, 262  
   — ldap\_next\_message, 262  
 LDAP message result parser  
   — ldap\_parse\_extended\_result, 288  
   — ldap\_parse\_result, 288  
   — ldap\_parse\_sasl\_bind\_result, 288  
 ldap\_modify — LDAP entry modification functions, 282  
 ldap\_modify\_ext — LDAP entry modification functions, 282  
 ldap\_modify\_ext\_s — LDAP entry modification functions, 282  
 ldap\_modify\_s — LDAP entry modification functions, 282  
 ldap\_modrdn — modify LDAP entry RDN, 284  
 ldap\_modrdn\_s — modify LDAP entry RDN, 284  
 ldap\_modrdn2 — modify LDAP entry RDN, 284  
 ldap\_modrdn2\_s — modify LDAP entry RDN, 284  
 ldap\_msgfree — wait for and return LDAP operation result, 289  
 ldap\_msgtype — LDAP message processing functions, 262  
 ldap\_next\_attribute — step through LDAP entry attributes, 259  
 ldap\_next\_disptmpl — LDAP display template functions, 246  
 ldap\_next\_entry — LDAP entry parsing and counting functions, 260  
 ldap\_next\_message — LDAP message processing functions, 262  
 ldap\_next\_reference — LDAP entry parsing and counting functions, 260  
 ldap\_next\_searchobj — LDAP search preference configuration routines, 294  
 ldap\_next\_tmplcol — LDAP display template functions, 246  
 ldap\_next\_tmplrow — LDAP display template functions, 246  
 ldap\_oc2template — LDAP display template functions, 246  
 ldap\_open — initialize an LDAP session, 286  
 ldap\_parse\_extended\_result — LDAP message result parser, 288  
 ldap\_parse\_result — LDAP message result parser, 288  
 ldap\_parse\_sasl\_bind\_result — LDAP message result parser, 288

ldap\_perror — LDAP protocol error handling functions, 255  
 ldap\_rename — modify LDAP entry RDN, 284  
 ldap\_rename\_s — modify LDAP entry RDN, 284  
 ldap\_result — wait for and return LDAP operation result, 289  
 ldap\_result2error — LDAP protocol error handling functions, 255  
 ldap\_sasl\_bind — LDAP bind functions, 237  
 ldap\_sasl\_bind\_s — LDAP bind functions, 237  
 ldap\_search — LDAP search operations, 291  
 ldap\_search\_ext — LDAP search operations, 291  
 ldap\_search\_ext\_s — LDAP search operations, 291  
 LDAP search preference configuration routines — ldap\_first\_searchobj, 294  
 — ldap\_free\_searchprefs, 294  
 — ldap\_init\_searchprefs, 294  
 — ldap\_init\_searchprefs\_buf, 294  
 — ldap\_next\_searchobj, 294  
 — ldap\_searchprefs, 294  
 ldap\_search\_s — LDAP search operations, 291  
 ldap\_search\_st — LDAP search operations, 291  
 ldap\_searchprefs — LDAP search preference configuration routines, 294  
 ldap\_set\_option — get or set session preferences in the ldap structure., 271  
 ldap\_set\_rebind\_proc — LDAP bind functions, 237  
 ldap\_set\_string\_translators — LDAP character set translation functions, 240  
 ldap\_setfilteraffixes — LDAP filter generating functions, 267  
 ldap\_simple\_bind — LDAP bind functions, 237  
 ldap\_simple\_bind\_s — LDAP bind functions, 237  
 ldap\_sort — LDAP entry sorting functions, 296  
 ldap\_sort\_entries — LDAP entry sorting functions, 296  
 ldap\_sort\_strcasecmp — LDAP entry sorting functions, 296  
 ldap\_sort\_values — LDAP entry sorting functions, 296  
 ldap\_t61\_to\_8859 — LDAP character set translation functions, 240  
 ldap\_tmplattrs — LDAP display template functions, 246  
 ldap\_translate\_from\_t61 — LDAP character set translation functions, 240  
 ldap\_translate\_to\_t61 — LDAP character set translation functions, 240  
 ldap\_ufn — LDAP user friendly search functions, 298  
 ldap\_ufn\_search\_c — LDAP user friendly search functions, 298  
 ldap\_ufn\_search\_ct — LDAP user friendly search functions, 298  
 ldap\_ufn\_search\_s — LDAP user friendly search functions, 298  
 ldap\_ufn\_setfilter — LDAP user friendly search functions, 298  
 ldap\_ufn\_setprefix — LDAP user friendly search functions, 298  
 ldap\_ufn\_timeout — LDAP user friendly search functions, 298  
 ldap\_unbind — LDAP bind functions, 237  
 ldap\_unbind\_ext — LDAP bind functions, 237  
 ldap\_unbind\_s — LDAP bind functions, 237  
 ldap\_url — LDAP Uniform Resource Locator functions, 300  
 ldap\_url\_parse — LDAP Uniform Resource Locator functions, 300  
 ldap\_url\_parse\_nodn — LDAP Uniform Resource Locator functions, 300  
 ldap\_url\_search — LDAP Uniform Resource Locator functions, 300  
 ldap\_url\_search\_s — LDAP Uniform Resource Locator functions, 300  
 ldap\_url\_search\_st — LDAP Uniform Resource Locator functions, 300  
 LDAP user friendly search functions — ldap\_ufn, 298  
 — ldap\_ufn\_search\_c, 298  
 — ldap\_ufn\_search\_ct, 298  
 — ldap\_ufn\_search\_s, 298  
 — ldap\_ufn\_setfilter, 298  
 — ldap\_ufn\_setprefix, 298  
 — ldap\_ufn\_timeout, 298  
 ldap\_vals2text — LDAP entry display functions, 252  
 library routines for dealing with creation and manipulation of CLIENT handles — clnt\_control, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_create, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_create\_timed, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_create\_vers, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_create\_vers\_timed, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_destroy, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_dg\_create, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_door\_create, 392

library routines for dealing with creation and manipulation of CLIENT handles —  
 clnt\_pcreateerror, 392

library routines for dealing with creation and manipulation of CLIENT handles —

- miscellaneous NIS+ functions — `nis_rmdir`, 334
- miscellaneous NIS+ functions —
  - `nis_server`, 334

- miscellaneous NIS+ functions —
  - `nis_servstate`, 334
- miscellaneous NIS+ functions — `nis_stats`, 334
- modify LDAP entry RDN
  - `ldap_modrdn`, 284
  - `ldap_modrdn_s`, 284
  - `ldap_modrdn2`, 284
  - `ldap_modrdn2_s`, 284
  - `ldap_rename`, 284
  - `ldap_rename_s`, 284

## N

- `netdir` — generic transport name-to-address translation, 307
- `netdir_free` — generic transport name-to-address translation, 307
- `netdir_getbyaddr` — generic transport name-to-address translation, 307
- `netdir_getbyname` — generic transport name-to-address translation, 307
- `netdir_mergeaddr` — generic transport name-to-address translation, 307
- `netdir_options` — generic transport name-to-address translation, 307
- `netdir_perror` — generic transport name-to-address translation, 307
- `netdir_sperror` — generic transport name-to-address translation, 307
- network configuration database entry
  - `endnetconfig`, 100
  - `freenetconfignt`, 100
  - `getnetconfig`, 100
  - `getnetconfignt`, 100
  - `nc_perror`, 100
  - `nc_sperror`, 100
  - `setnetconfig`, 100
- network configuration entry corresponding to NETPATH
  - `endnetpath`, 102
  - `getnetpath`, 102
  - `setnetpath`, 102
- network entry
  - `endnetent`, 96
  - `getnetbyaddr`, 96
  - `getnetbyaddr_r`, 96
  - `getnetbyname`, 96

network entry (Continued)

- getnetbyname\_r, 96
- getnetent, 96
- getnetent\_r, 96
- setnetent, 96

network listener service

- format and send listener service request message — nlsrequest, 350
- get client's data passed via the listener — nlsgetcall, 348
- get name of transport provider — nlsprovider, 349

network protocol entry

- endprotoent, 106
- getprotobyname, 106
- getprotobyname\_r, 106
- getprotobyname\_r, 106
- getprotobyname\_r, 106
- getprotoent, 106
- getprotoent\_r, 106
- setprotoent, 106

NIS Version 2 client interface — ypcnt, 717

NIS Version 2 client interface — yperr\_string, 717

NIS Version 2 client interface — ypprot\_err, 717

NIS Version 2 client interface — yp\_all, 717

NIS Version 2 client interface — yp\_bind, 717

NIS Version 2 client interface — yp\_first, 717

NIS Version 2 client interface — yp\_get\_default\_domain, 717

NIS Version 2 client interface — yp\_master, 717

NIS Version 2 client interface — yp\_match, 717

NIS Version 2 client interface — yp\_next, 717

NIS Version 2 client interface — yp\_order, 717

NIS Version 2 client interface — yp\_unbind, 717

NIS+ table functions — nis\_tables

- nis\_first\_entry, 339
- nis\_modify\_entry, 339
- nis\_next\_entry, 339
- nis\_remove\_entry, 339

NIS, change information, — yp\_update, 722

NIS+ error messages

- nis\_error, 311
- nis\_terror, 311
- nis\_perror, 311
- nis\_sperrno, 311
- nis\_sperror, 311

NIS+ error messages (Continued)

- nis\_sperror\_r, 311

NIS+ group manipulation functions

- nis\_addmember, 313
- nis\_creategroup, 313
- nis\_destroygroup, 313
- nis\_groups, 313
- nis\_ismember, 313
- nis\_print\_group\_entry, 313
- nis\_removemember, 313
- nis\_verifygroup, 313

NIS+ local names

- nis\_freenames, 336
- nis\_getnames, 336
- nis\_local\_directory, 316
- nis\_local\_group, 316
- nis\_local\_host, 316
- nis\_local\_names, 316
- nis\_local\_principal, 316

NIS+ log administration functions

- nis\_checkpoint, 333
- nis\_ping, 333

NIS+ namespace functions

- nis\_add, 318
- nis\_freeresult, 318
- nis\_lookup, 318
- nis\_modify, 318
- nis\_names, 318
- nis\_remove, 318

NIS+ object formats, — nis\_objects, 325

NIS+ subroutines

- nis\_clone\_object, 336
- nis\_destroy\_object, 336
- nis\_dir\_cmp, 336
- nis\_domain\_of, 336
- nis\_leaf\_of, 336
- nis\_name\_of, 336
- nis\_print\_object, 336
- nis\_subr, 336

NIS+ table functions

- nis\_add\_entry, 339
- nis\_first\_entry, 339
- nis\_list, 339
- nis\_modify\_entry, 339
- nis\_next\_entry, 339
- nis\_remove\_entry, 339
- nis\_tables, 339

nis\_freeservlist — miscellaneous NIS+ functions, 334  
 nis\_freetags — miscellaneous NIS+ functions, 334  
 nis\_getservlist — miscellaneous NIS+ functions, 334  
 nis\_mkdir — miscellaneous NIS+ functions, 334  
 nis\_tables — NIS+ table functions, 339  
 nis\_rmdir — miscellaneous NIS+ functions, 334  
 nis\_server — miscellaneous NIS+ functions, 334  
 nis\_servstate — miscellaneous NIS+ functions, 334  
 nis\_stats — miscellaneous NIS+ functions, 334  
 ntohl — convert values between host and network byte order, 38  
 ntohs — convert values between host and network byte order, 38

## O

obtain information about a credential — gss\_inquire\_cred, 172  
 obtain information about a security context — gss\_inquire\_context, 169  
 obtain per-mechanism information about a credential — gss\_inquire\_cred\_by\_mech, 174  
 open an SLP handle — SLPOpen, 589  
 Option manipulation mechanism — inet6\_opt, 212

## P

parse service URL — SLPParseSrvURL, 591  
 pass asynchronous token to security service — gss\_process\_context\_token, 181  
 perform a step in the authentication negotiation — sasl\_client\_start, 476  
 perform a step in the server authentication negotiation — sasl\_server\_step, 510  
 perform an LDAP add operation — ldap\_add, 234  
 — ldap\_add\_ext, 234

perform an LDAP add operation (Continued) — ldap\_add\_ext\_s, 234  
 — ldap\_add\_s, 234  
 perform precalculations during an idle period — sasl\_idle, 500  
 plaintext password verification callback function — sasl\_server\_userdb\_checkpass\_t, 511  
 prompt for input in response to a challenge — sasl\_chalprompt\_t, 467  
 prop\_clear — SASL auxilliary properties, 458  
 prop\_dispose — SASL auxilliary properties, 458  
 prop\_dup — SASL auxilliary properties, 458  
 prop\_erase — SASL auxilliary properties, 458  
 prop\_format — SASL auxilliary properties, 458  
 prop\_get — SASL auxilliary properties, 458  
 prop\_getnames — SASL auxilliary properties, 458  
 prop\_new — SASL auxilliary properties, 458  
 prop\_request — SASL auxilliary properties, 458  
 prop\_set — SASL auxilliary properties, 458  
 prop\_setvals — SASL auxilliary properties, 458  
 publickey — retrieve public or secret key, 109

## R

rac\_drop() — remote asynchronous calls, 418  
 rac\_poll() — remote asynchronous calls, 418  
 rac\_recv() — remote asynchronous calls, 418  
 rac\_send() — remote asynchronous calls, 418  
 rcmd — routines for returning a stream to a remote command, 352  
 rcmd\_af — routines for returning a stream to a remote command, 352  
 receive a message from a socket — recv, 354  
 receive a message from a socket — recvfrom, 354  
 receive a message from a socket — recvmsg, 354  
 receive message from an SCTP socket — sctp\_recvmsg, 534  
 recv — receive a message from a socket, 354  
 recvfrom — receive a message from a socket, 354  
 recvmsg — receive a message from a socket, 354

register an SLP advertisement — SLPReg, 593  
 release an object identifier —  
     gss\_release\_oid, 186  
 remote procedure calls, library routines for —  
     rpc, 375  
 remote system  
     return information about users — rusers,  
         rnusers, 455  
     write to — rstat, 454  
     write to — rwall, 456  
 request auxiliary properties from SASL —  
     sasl\_auxprop\_request, 463  
 res\_getservers — resolver routines, 366  
 res\_hostaliases — resolver routines, 366  
 res\_init — resolver routines, 366  
 res\_mkquery — resolver routines, 366  
 res\_nclose — resolver routines, 366  
 res\_ninit — resolver routines, 366  
 res\_nmquery — resolver routines, 366  
 res\_nquery — resolver routines, 366  
 res\_nquerydomain — resolver routines, 366  
 res\_nsearch — resolver routines, 366  
 res\_nsend — resolver routines, 366  
 res\_nsendsigned — resolver routines, 366  
 res\_query — resolver routines, 366  
 res\_search — resolver routines, 366  
 res\_send — resolver routines, 366  
 res\_setservers — resolver routines, 366  
 resolver — resolver routines, 366  
 resolver routines — dn\_comp, 366  
 resolver routines — dn\_expand, 366  
 resolver routines — fp\_resstat, 366  
 resolver routines — herror, 366  
 resolver routines — hstrerror, 366  
 resolver routines — resolver, 366  
 resolver routines — res\_getservers, 366  
 resolver routines — res\_hostaliases, 366  
 resolver routines — res\_init, 366  
 resolver routines — res\_mkquery, 366  
 resolver routines — res\_nclose, 366  
 resolver routines — res\_ninit, 366  
 resolver routines — res\_nmquery, 366  
 resolver routines — res\_nquery, 366  
 resolver routines — res\_nquerydomain, 366  
 resolver routines — res\_nsearch, 366  
 resolver routines — res\_nsend, 366  
 resolver routines — res\_nsendsigned, 366  
 resolver routines — res\_query, 366  
 resolver routines — res\_search, 366  
 resolver routines — res\_send, 366  
 resolver routines — res\_setservers, 366  
 retrieve public or secret key —  
     getpublickey, 109  
     getsecretkey, 109  
     publickey, 109  
 retrieve a list of the supported SASL  
     mechanisms — sasl\_global\_listmech, 499  
 retrieve a list of the supported SASL  
     mechanisms — sasl\_listmech, 501  
 return an attribute's values that matches a  
     specified language subtype —  
         ldap\_get\_lang\_values, 269  
 return an attribute's values that matches a  
     specified language subtype —  
         ldap\_get\_lang\_values\_len, 269  
 return stream to a remote command —  
     rexec, 373  
 return stream to a remote command —  
     rexec\_af, 373  
 return list of configured and discovered scopes  
     — SLPFindScopes, 580  
 return service attributes — SLPFindAttrs, 578  
 return service URLs — SLPFindSrvs, 582  
 return SLP configuration property —  
     SLPGetProperty, 587  
 return the maximum allowed refresh interval —  
     SLPGetRefreshInterval, 588  
 returns all locally bound addresses on an SCTP  
     socket — sctp\_freeladdr, 524  
 returns all locally bound addresses on an SCTP  
     socket — sctp\_getladdr, 524  
 returns all peer addresses on an SCTP  
     association — sctp\_freepaddr, 526  
 returns all peer addresses on an SCTP  
     association — sctp\_getpaddr, 526  
 rexec — return stream to a remote  
     command, 373  
 rexec\_af — return stream to a remote  
     command, 373  
 rnusers — return information about users on  
     remote machines, 455  
 routines for returning a stream to a remote  
     command — rcmd, 352  
 routines for returning a stream to a remote  
     command — rcmd\_af, 352

routines for returning a stream to a remote command — `rresvport`, 352  
 routines for returning a stream to a remote command — `rresvport_af`, 352  
 routines for returning a stream to a remote command — `ruserok`, 352  
 routines to map Internet Protocol network interface names and interface indexes — `if_freenameindex`, 204  
 routines to map Internet Protocol network interface names and interface indexes — `if_indextoname`, 204  
 routines to map Internet Protocol network interface names and interface indexes — `if_nameindex`, 204  
 routines to map Internet Protocol network interface names and interface indexes — `if_nametoindex`, 204  
 Routing header manipulation — `inet6_rth`, 215  
`rpc` — library routines for remote procedure calls, 375  
 RPC, data transmission using XDR routines — `xdr`, 704  
 RPC, XDR library routines  
   — `rpc_xdr`, 452  
   — `xdr_accepted_reply`, 452  
   — `xdr_authsys_parms`, 452  
   — `xdr_callhdr`, 452  
   — `xdr_callmsg`, 452  
   — `xdr_opaque_auth`, 452  
   — `xdr_rejected_reply`, 452  
   — `xdr_replymsg`, 452  
 RPC bind service library routines  
   — `rpc_getmaps`, 384  
   — `rpcb_getaddr`, 384  
   — `rpcb_gettime`, 384  
   — `rpcb_rmtcall`, 384  
   — `rpcb_set`, 384  
   — `rpcb_unset`, 384  
   — `rpcbind`, 384  
`rpc_broadcast` — library routines for client side calls, 388  
`rpc_broadcast_exp` — library routines for client side calls, 388  
`rpc_call` — library routines for client side calls, 388  
`rpc_clnt_auth` — library routines for client side remote procedure call authentication, 386  
`rpc_clnt_calls` — library routines for client side calls, 388  
   Routines, 388, 389  
`rpc_clnt_create` — library routines for dealing with creation and manipulation of CLIENT handles, 392  
   Routines, 393  
`rpc_createerr` — library routines for dealing with creation and manipulation of CLIENT handles, 392  
 RPC entry  
   — `endrpcent`, 110  
   — `getrpcbyname`, 110  
   — `getrpcbyname_r`, 110  
   — `getrpcbynumber`, 110  
   — `getrpcbynumber_r`, 110  
   — `getrpcent`, 110  
   — `getrpcent_r`, 110  
   — `setrpcent`, 110  
`rpc_gss_getcred` — get credentials of client, 401  
`rpc_gss_seccreate` — create a security context using the RPCSEC\_GSS protocol, 411  
 RPC library routine for manipulating global RPC attributes for client and server applications, — `rpc_control`, 399  
 RPC library routines for registering servers  
   — `rpc_reg`, 450  
   — `rpc_svc_reg`, 450  
   — `svc_auth_reg`, 450  
   — `svc_reg`, 450  
   — `svc_unreg`, 450  
   — `xprt_register`, 450  
   — `xprt_unregister`, 450  
 RPC library routines for server side errors  
   — `rpc_svc_err`, 446  
   — `svcerr_auth`, 446  
   — `svcerr_decode`, 446  
   — `svcerr_noproc`, 446  
   — `svcerr_noprog`, 446  
   — `svcerr_progvers`, 446  
   — `svcerr_systemerr`, 446  
   — `svcerr_weakauth`, 446  
 RPC obsolete library routines  
   — `authdes_create`, 428  
   — `authunix_create_default`, 428  
   — `callrpc`, 428  
   — `clnt_broadcast`, 428  
   — `clntraw_create`, 428

RPC obsolete library routines (Continued)

- clnttcp\_create, 428
- clntudp\_bufcreate, 428
- clntudp\_create, 428
- get\_myaddress, 428
- getrpcport, 428
- pmap\_getmaps, 428
- pmap\_getport, 428
- pmap\_rmtcall, 428
- pmap\_set, 428
- pmap\_unset, 428
- registerrpc, 428
- rpc\_soc, 428
- svc\_fds, 428
- svc\_getcaller, 428
- svc\_getreq, 428
- svc\_register, 428
- svc\_unregister, 428
- svcd\_create, 428
- svcraw\_create, 428
- svctcp\_create, 428
- svcudp\_bufcreate, 428
- svcudp\_create, 428
- xdr\_authunix\_parms, 428

rpc routines

- rac\_drop() — remote asynchronous calls, 418
- rac\_poll() — remote asynchronous calls, 418
- rac\_recv() — remote asynchronous calls, 418
- rac\_send() — remote asynchronous calls, 418

rpc\_svc\_calls — library routines for RPC servers, 437

rpc\_svc\_create — library routines for the creation of server handles, 441

rpc — security flavor incorporating GSS-API onto ONC RPC, 422

resvport — routines for returning a stream to a remote command, 352

resvport\_af — routines for returning a stream to a remote command, 352

rstat — get performance data from remote kernel, 454

ruserok — routines for returning a stream to a remote command, 352

rusers — return information about users on remote machines, 455

xdr\_utmpidlearr, 455

rwall — write to specified remote machines, 456

**S**

SASL auxilliary properties — prop\_clear, 458

SASL auxilliary properties — prop\_dispose, 458

SASL auxilliary properties — prop\_dup, 458

SASL auxilliary properties — prop\_erase, 458

SASL auxilliary properties — prop\_format, 458

SASL auxilliary properties — prop\_get, 458

SASL auxilliary properties — prop\_getnames, 458

SASL auxilliary properties — prop\_new, 458

SASL auxilliary properties — prop\_request, 458

SASL auxilliary properties — prop\_set, 458

SASL auxilliary properties — prop\_setvals, 458

SASL auxilliary properties — sasl\_auxprop, 458

sasl\_authorize\_t — the SASL authorization callback, 457

sasl\_auxprop — SASL auxilliary properties, 458

sasl\_auxprop\_add\_plugin — add a SASL auxiliary property plug-in, 461

sasl\_auxprop\_getctx — acquire an auxiliary property context, 462

sasl\_auxprop\_request — request auxilliary properties from SASL, 463

sasl\_canon\_user\_t — the canon user callback, 465

sasl\_canonuser\_add\_plugin — add a SASL user canonicalization plug-in, 464

sasl\_chalprompt\_t — prompt for input in response to a challenge, 467

sasl\_checkpop — check an APOP challenge or response, 468

sasl\_checkpass — check a plaintext password, 469

sasl\_client\_add\_plugin — add a SASL client plug-in, 471

sasl\_client\_init — initialize SASL client authentication, 472

sasl\_client\_new — create a new client authentication object, 473

**sasl\_client\_plug\_init\_t** — client plug-in entry point, 475  
**sasl\_client\_start** — perform a step in the authentication negotiation, 476  
**sasl\_client\_step** — acquire an auxiliary property context, 478  
**sasl\_decode** — decode data received, 480  
**sasl\_decode64** — decode base64 string, 481  
**sasl\_dispose** — dispose of a SASL connection object, 482  
**sasl\_done** — dispose of all SASL plug-ins, 483  
**sasl\_encode** — encode data for transport to an authenticated host, 484  
**sasl\_encode64** — encode base64 string, 485  
**sasl\_encodev** — encode data for transport to an authenticated host, 484  
**sasl\_erasebuffer** — erase buffer, 486  
**SASL error codes** — **sasl\_errors**, 488  
**sasl\_errors** — SASL error codes, 488  
**sasl\_errstring** — translate a SASL return code to a human-readable form, 490  
**sasl\_getcallback\_t** — callback function to lookup a **sasl\_callback\_t** for a connection, 491  
**sasl\_getopt\_t** — the SASL get option callback function, 492  
**sasl\_getpath\_t** — the SASL callback function to indicate location of the security mechanism drivers, 493  
**sasl\_getprop** — get a SASL property, 494  
**sasl\_getrealm\_t** — the realm acquisition callback function, 496  
**sasl\_getsecret\_t** — the SASL callback function for secrets (passwords), 497  
**sasl\_getsimple\_t** — the SASL callback function for username, authname and realm, 498  
**sasl\_global\_listmech** — retrieve a list of the supported SASL mechanisms, 499  
**sasl\_idle** — perform precalculations during an idle period, 500  
**sasl\_listmech** — retrieve a list of the supported SASL mechanisms, 501  
**sasl\_log\_t** — the SASL logging callback function, 502  
**sasl\_server\_add\_plugin** — add a SASL server plug-in, 503  
**SASL server authentication initialization** — **sasl\_server\_init**, 504  
**sasl\_server\_init** — SASL server authentication initialization, 504  
**sasl\_server\_new** — create a new server authentication object, 505  
**sasl\_server\_plug\_init\_t** — server plug-in entry point, 507  
**sasl\_server\_start** — create a new server authentication object, 508  
**sasl\_server\_step** — perform a step in the server authentication negotiation, 510  
**sasl\_server\_userdb\_checkpass\_t** — plaintext password verification callback function, 511  
**sasl\_server\_userdb\_setpass\_t** — user database plaintext password setting callback function, 512  
**sasl\_set\_alloc** — set the memory allocation functions used by the SASL library, 513  
**sasl\_set\_mutex** — set the mutex lock functions used by the SASL library, 515  
**sasl\_seterror** — set the error string, 514  
**sasl\_setpass** — set the password for a user, 516  
**sasl\_setprop** — set a SASL property, 517  
**sasl\_utf8verify** — encode base64 string, 519  
**sasl\_verifyfile\_t** — the SASL file verification callback function, 520  
**sasl\_version** — get SASL library version information, 521  
**sctp\_bindx** — add or remove IP addresses to or from an SCTP socket, 522  
**sctp\_freeladdrs** — returns all locally bound addresses on an SCTP socket, 524  
**sctp\_freepaddrs** — returns all peer addresses on an SCTP association, 526  
**sctp\_getladdrs** — returns all locally bound addresses on an SCTP socket, 524  
**sctp\_getpaddrs** — returns all peer addresses on an SCTP association, 526  
**sctp\_opt\_info** — examine SCTP level options for an SCTP endpoint, 528  
**sctp\_peeloff** — branch off existing association from a one-to-many SCTP socket to create a one-to-one STP socket, 533  
**sctp\_recvmsg** — receive message from an SCTP socket, 534  
**sctp\_send** — send message from an SCTP socket, 536  
**sctp\_sendmsg** — send message from an SCTP socket, 538

send — send a message from a socket, 544  
 send a message from a socket — send, 544  
 send a message from a socket — sendmsg, 544  
 send a message from a socket — sendto, 544  
 send message from an SCTP socket —  
   sctp\_send, 536  
 send message from an SCTP socket —  
   sctp\_sendmsg, 538  
 sendmsg — send a message from a socket, 544  
 sendto — send a message from a socket, 544  
 server plug-in entry point —  
   sasl\_server\_plug\_init\_t, 507  
 Service Access Facility library function, —  
   doconfig, 53  
 Service Location Protocol Application  
   Programming Interface — slp\_api, 563  
 set a SASL property — sasl\_setprop, 517  
 set an SLP configuration property —  
   SLP SetProperty, 595  
 set connectionless LDAP request retransmission  
   parameters — cldap\_setretryinfo, 43  
 set server principal name, —  
   rpc\_gss\_set\_svc\_name, 416  
 set the error string — sasl\_seterror, 514  
 set the memory allocation functions used by the  
   SASL library — sasl\_set\_alloc, 513  
 set the mutex lock functions used by the SASL  
   library — sasl\_set\_mutex, 515  
 set the password for a user — sasl\_setpass, 516  
 sethostent — get network host entry, 76  
 setservent — get service entry, 113  
 shut down part of a full-duplex connection —  
   shutdown, 561  
 shutdown — shut down part of a full-duplex  
   connection, 561  
 simplified Basic Encoding Rules library  
   encoding functions  
     — ber\_alloc, 29  
     — ber\_encode, 29  
     — ber\_printf, 29  
     — ber\_put\_bitstring, 29  
     — ber\_put\_boolean, 29  
     — ber\_put\_int, 29  
     — ber\_put\_null, 29  
     — ber\_put\_ostring, 29  
     — ber\_put\_seq, 29  
     — ber\_put\_set, 29  
     — ber\_put\_string, 29  
   simplified Basic Encoding Rules library  
   encoding functions (Continued)  
     — ber\_start\_seq, 29  
     — ber\_start\_set, 29  
   slp\_api — Service Location Protocol Application  
     Programming Interface, 563  
   slp\_strerror — map SLP error codes to  
     messages, 596  
   SLPclose — close an open SLP handle, 573  
   SLPDelAttrs — delete attributes, 574  
   SLPDereg — deregister the SLP  
     advertisement, 576  
   SLPEscape — escapes SLP reserved  
     characters, 577  
   SLPFindAttrs — return service attributes, 578  
   SLPFindScopes — return list of configured and  
     discovered scopes, 580  
   SLPFindSrvs — return service URLs, 582  
   SLPFindSrvTypes — find service types, 584  
   SLPFree — frees memory, 586  
   SLPGetProperty — return SLP configuration  
     property, 587  
   SLPGetRefreshInterval — return the maximum  
     allowed refresh interval, 588  
   SLPOpen — open an SLP handle, 589  
   SLPParseSrvURL — parse service URL, 591  
   SLPReg — register an SLP advertisement, 593  
   SLP SetProperty — set an SLP configuration  
     property, 595  
   SLPUnescape — translate escaped characters  
     into UTF-8, 597  
   socketmark — determine whether a socket is at  
     the out-of-band mark, 598  
   socket — create an endpoint for  
     communication, 599  
   socket  
     accept a connection — accept, 20  
     bind a name — bind, 33  
     get options — getsocketopt, 119  
     get name — getsockname, 117  
     get name of connected peer —  
       getpeername, 104  
     listen for connections — listen, 304  
     set options — setsocketopt, 119  
   socketpair — create a pair of connected  
     sockets, 604  
   spray — scatter data in order to test the  
     network, 607

- step through LDAP entry attributes —  
  ldap\_first\_attribute, 259
- step through LDAP entry attributes —  
  ldap\_next\_attribute, 259
- store a credential in the current credential store  
  — gss\_store\_cred, 188
- STREAMS
  - accept a connection on a socket — accept, 20
  - bind a name to a socket — bind, 33
  - create a pair of connected sockets —  
  socketpair, 604
  - create an endpoint for communication —  
  socket, 599
  - get and set socket options — getsockopt,  
  setsockopt, 119
  - get name of peer connected to socket —  
  getpeername, 104
  - get socket name — getsockname, 117
  - listen for connections on a socket —  
  listen, 304
- svc\_control — library routines for the creation  
  of server handles, 441
- svc\_create — library routines for the creation of  
  server handles, 441
- svc\_destroy — library routines for the creation  
  of server handles, 441
- svc\_dg\_create — library routines for the  
  creation of server handles, 441
- svc\_dg\_enablecache — library routines for RPC  
  servers, 437
- svc\_done — library routines for RPC  
  servers, 437
- svc\_door\_create — library routines for the  
  creation of server handles, 441
- svc\_exit — library routines for RPC  
  servers, 437
- svc\_fd\_create — library routines for the creation  
  of server handles, 441
- svc\_fd\_negotiate\_ucred — library routines for  
  RPC servers, 437
- svc\_fdset — library routines for RPC  
  servers, 437
- svc\_freeargs — library routines for RPC  
  servers, 437
- svc\_getargs — library routines for RPC  
  servers, 437
- svc\_getcallerucred — library routines for RPC  
  servers, 437

- svc\_getreq\_common — library routines for RPC  
  servers, 437
- svc\_getreq\_poll — library routines for RPC  
  servers, 437
- svc\_getreqset — library routines for RPC  
  servers, 437
- svc\_getrpccaller — library routines for RPC  
  servers, 437
- svc\_max\_pollfd — library routines for RPC  
  servers, 437
- svc\_pollfd — library routines for RPC  
  servers, 437
- svc\_raw\_create — library routines for the  
  creation of server handles, 441
- svc\_run — library routines for RPC  
  servers, 437
- svc\_sendreply — library routines for RPC  
  servers, 437
- svc\_tli\_create — library routines for the creation  
  of server handles, 441
- svc\_tp\_create — library routines for the creation  
  of server handles, 441
- svc\_vc\_create — library routines for the creation  
  of server handles, 441

## T

- t\_alloc — allocate memory for argument  
  structures, 613
- t\_bind — bind an address to a transport  
  endpoint, 616
- taddr2uaddr — generic transport  
  name-to-address translation, 307
- the canon user callback —  
  sasldb\_canon\_user\_t, 465
- the realm acquisition callback function —  
  sasldb\_getrealm\_t, 496
- the SASL authorization callback —  
  sasldb\_authorize\_t, 457
- the SASL callback function for secrets  
  (passwords) — sasldb\_getsecret\_t, 497
- the SASL callback function for username,  
  authname and realm —  
  sasldb\_getsimple\_t, 498
- the SASL callback function to indicate location  
  of the security mechanism drivers —  
  sasldb\_getpath\_t, 493

- the SASL file verification callback function —  
  sasl\_verifyfile\_t, 520
- the SASL get option callback function —  
  sasl\_getopt\_t, 492
- the SASL logging callback function —  
  sasl\_log\_t, 502
- transfer a security context to another process —  
  gss\_export\_sec\_context, 153
- translate between node name and address —  
  freeaddrinfo, 70
- translate between node name and address —  
  gai\_strerror, 70
- translate between node name and address —  
  getaddrinfo, 70
- translate between node name and address —  
  getnameinfo, 70
- translate a SASL return code to a  
  human-readable form — sasl\_errstring, 490
- translate escaped characters into UTF-8 —  
  SLPUnescape, 597
- transport functions, allocate memory, 613

## U

- uaddr2taddr — generic transport  
  name-to-address translation, 307
- undial — establish an outgoing terminal line  
  connection, 50
- user database plaintext password setting  
  callback function —  
  sasl\_server\_userdb\_setpass\_t, 512
- users, return information from remote machines  
  — rusers, musers, 455

## V

- Variable allocation datatype —  
  icmp6\_filter, 203
- verify a message with attached cryptographic  
  message — gss\_wrap, 194
- verify integrity of a received message —  
  gss\_verify\_mic, 196

## W

- wait for and return LDAP operation result —  
  ldap\_msgfree, 289
- wait for and return LDAP operation result —  
  ldap\_result, 289

## X

- XDR library routines
  - xdr, 704
  - xdr\_admin, 706
  - xdr\_control, 706
  - xdr\_getpos, 706
  - xdr\_inline, 706
  - xdr\_setpos, 706
  - xdr\_sizeof, 706
  - xdrrec\_endofrecord, 706
  - xdrrec\_eof, 706
  - xdrrec\_readbytes, 706
  - xdrrec\_skiprecord, 706
- XDR library routines for complex data  
  structures
  - xdr\_array, 708
  - xdr\_bytes, 708
  - xdr\_complex, 708
  - xdr\_opaque, 708
  - xdr\_pointer, 708
  - xdr\_reference, 708
  - xdr\_string, 708
  - xdr\_union, 708
  - xdr\_vector, 708
  - xdr\_wrapstring, 708
- XDR library routines for RPC
  - rpc\_xdr, 452
  - xdr\_accepted\_reply, 452
  - xdr\_authsys\_parms, 452
  - xdr\_callhdr, 452
  - xdr\_callmsg, 452
  - xdr\_opaque\_auth, 452
  - xdr\_rejected\_reply, 452
  - xdr\_replymsg, 452
- XDR library routines for simple data structures
  - xdr\_bool, 713
  - xdr\_char, 713
  - xdr\_double, 713
  - xdr\_enum, 713
  - xdr\_float, 713

## XDR library routines for simple data structures

(Continued)

- xdr\_free, 713
  - xdr\_hyper, 713
  - xdr\_int, 713
  - xdr\_long, 713
  - xdr\_longlong\_t, 713
  - xdr\_quadruple, 713
  - xdr\_short, 713
  - xdr\_simple, 713
  - xdr\_u\_char, 713
  - xdr\_u\_hyper, 713
  - xdr\_u\_int, 713
  - xdr\_u\_long, 713
  - xdr\_u\_longlong\_t, 713
  - xdr\_u\_short, 713
  - xdr\_void, 713
- xdr\_statstime — get performance data from remote kernel, 454
- xdr\_statsvar — get performance data from remote kernel, 454
- ### XDR stream creation library routines
- xdr\_create, 711
  - xdr\_destroy, 711
  - xdrmem\_create, 711
  - xdrrec\_create, 711
  - xdrstdio\_create, 711

## Y

- yp\_all — NIS Version 2 client interface, 717
- yp\_bind — NIS Version 2 client interface, 717
- yp\_first — NIS Version 2 client interface, 717
- yp\_get\_default\_domain — NIS Version 2 client interface, 717
- yp\_master — NIS Version 2 client interface, 717
- yp\_match — NIS Version 2 client interface, 717
- yp\_next — NIS Version 2 client interface, 717
- yp\_order — NIS Version 2 client interface, 717
