# **Preface**

Both novice users and those familar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question "What does it do?" The man pages in general comprise a reference manual. They are not intended to be a tutorial.

# Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

**NAME** 

This section gives the names of the commands or functions documented, followed by a brief description of what they do.

**SYNOPSIS** 

This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

- [ ] Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
- . . . Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . . " .
- Separator. Only one of the arguments separated by this character can be specified at a time.
- { } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

**PROTOCOL** 

This section occurs only in subsection 3R to indicate the protocol description file.

**DESCRIPTION** 

This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are

described under USAGE.

**IOCTL** 

This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device). ioctl calls are used for a particular class of devices all of which have an io ending, such as mtio(7I).

**OPTIONS** 

This secton lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

**OPERANDS** 

This section lists the command operands and describes how they affect the actions of the command.

**OUTPUT** 

This section describes the output - standard output, standard error, or output files - generated by the

**RETURN VALUES** 

If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or –1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in

RETURN VALUES.

**ERRORS** 

On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the

conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph

under the error code.

**USAGE** This section lists special rules, features, and

> commands that require in-depth explanations. The subsections listed here are used to explain built-in

functionality:

Commands Modifiers Variables Expressions Input Grammar

**EXAMPLES** This section provides examples of usage or of how

to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as example%, or if the user must be superuser, example#. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.

**ENVIRONMENT VARIABLES** This section lists any environment variables that

the command or function affects, followed by a

brief description of the effect.

**EXIT STATUS** This section lists the values the command returns to

> the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.

**FILES** This section lists all file names referred to by the

man page, files of interest, and files created or required by commands. Each is followed by a

descriptive summary or explanation.

**ATTRIBUTES** This section lists characteristics of commands,

> utilities, and device drivers by defining the attribute type and its corresponding value. See

attributes(5) for more information.

SEE ALSO This section lists references to other man pages,

in-house documentation, and outside publications.

DIAGNOSTICS This section lists diagnostic messages with a brief

explanation of the condition causing the error.

WARNINGS This section lists warnings about special conditions

which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES This section lists additional information that does

not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never

covered here.

BUGS This section describes known bugs and, wherever

possible, suggests workarounds.

# Introduction

# Intro(5)

**NAME** | Intro – introduction to miscellany

**DESCRIPTION** Among the topics presented in this section are:

Standards The POSIX (IEEE) Standards and the X/Open Specifications are

described on the standards page.

Environments The user environment (environ), the subset of the user

environment that depends on language and cultural conventions (locale), the large file compilation environment (lfcompile), and the transitional compilation environment (lfcompile64) are

described.

Macros The macros to format Reference Manual pages (man and mansun)

as well as other text format macros (me, mm, and ms) are described.

Characters Tables of character sets (ascii, charmap, eqnchar, and iconv),

file format notation (formats), file name pattern matching (fnmatch), and regular expressions (regex and regexp) are

presented.

# Standards, Environments, and Macros

NAME | ascii – map of ASCII character set

**SYNOPSIS** 

cat /usr/pub/ascii

# **DESCRIPTION**

/usr/pub/ascii is a map of the ASCII character set, to be printed as needed. It contains octal and hexadecimal values for each character. While not included in that file, a chart of decimal values is also shown here.

# attributes(5)

**NAME** 

attributes, architecture, availability, CSI, stability, MT-Level – attributes of interfaces

# **DESCRIPTION**

The ATTRIBUTES section of a manual page contains a table (see below) defining attribute types and their corresponding values.

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	SPARC
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Unstable
MT-Level	Safe

# Architecture

Architecture defines processor or specific hardware. See -p option of uname(1). In some cases, it may indicate required adapters or peripherals.

# Availability

This refers to the software package which contains the command or component being described on the man page. To be able to use the command, the indicated package must have been installed. For information on how to add a package see pkgadd(1M).

# Code Set Independence (CSI)

OS utilities and libraries which are free of dependencies on the properties of any code sets are said to have Code Set Independence (CSI). They have the attribute of being CSI enabled. This is in contrast to many commands and utilities, for example, that work only with Extended Unix Codesets (EUC), an encoding method that allows concurrent support for up to four code sets and is commonly used to represent Asian character sets.

However, for practical reasons, this independence is not absolute. Certain assumptions are still applied to the current CSI implementation:

- File code is a superset of ASCII.
- To support multi-byte characters and null-terminated UNIX file names, the NULL and / (slash) characters cannot be part of any multi-byte characters.
- Only "stateless" file code encodings are supported. Stateless encoding avoids shift, locking shift, designation, invocation, and so forth, although single shift is not excluded.
- Process code (wchar\_t values) is implementation dependent and can change over time or between implementations or between locales.
- Not every object can have names composed of arbitrary characters. The names of the following objects must be composed of ASCII characters:
  - User names, group name, and passwords
  - System name
  - Names of printers and special devices
  - Names of terminals (/dev/tty\*)
  - Process ID numbers

- Message queues, semaphores, and shared memory labels.
- The following may be composed of ISO Latin-1 or EUC characters:
  - File names
  - Directory names
  - Command names
  - Shell variables and environmental variable names
  - Mount points for file systems
  - NIS key names and domain names
- The names of NFS shared files should be composed of ASCII characters. Although files and directories may have names and contents composed of characters from non-ASCII code sets, using only the ASCII codeset allows NFS mounting across any machine, regardless of localization. For the commands and utilities that are CSI enabled, all can handle single-byte and multi-byte locales released in 2.6. For applications to get full support of internationalization services, dynamic binding has to be applied. Statically bound programs will only get support for C and POSIX locales.

# **Interface Stability**

Sun often provides developers with early access to new technologies, which allows developers to evaluate with them as soon as possible. Unfortunately, new technologies are prone to changes and standardization often results in interface incompatibility from previous versions.

To make reasonable risk assessments, developers need to know how likely an interface is to change in future releases. To aid developers in making these assessments, interface stability information is included on some manual pages for commands, entry-points, and file formats.

The more stable interfaces can safely be used by nearly all applications, because Sun will endeavor to ensure that these continue to work in future minor releases. Applications that depend only on Standard and Stable interfaces should reliably continue to function correctly on future minor releases (but not necessarily on earlier major releases).

The less stable interfaces allow experimentation and prototyping, but should be used only with the understanding that they might change incompatibly or even be dropped or replaced with alternatives in future minor releases.

"Interfaces" that Sun does not document (for example, most kernel data structures and some symbols in system header files) may be implementation artifacts. Such internal interfaces are not only subject to incompatible change or removal, but we are unlikely to mention such a change in release notes.

# **Release Levels**

Products are given release levels, as well as names, to aid compatibility discussions. Each release level may also include changes suitable for lower levels.

# attributes(5)

Release	Version	Significance
Major	x.0	Likely to contain major feature additions; adhere to different, possibly incompatible Standard revisions; and though unlikely, could change, drop, or replace Standard or Stable interfaces. Initial product releases are usually 1.0.
Minor	x.y	Compared to an x.0 or earlier release (y!=0), it's likely to contain: minor feature additions, compatible Standard and Stable interfaces, possibly incompatible Evolving interfaces, or likely incompatible Unstable interfaces.
Micro	x.y.z	Intended to be interface compatible with the previous release (z!=0), but likely to add bug fixes, performance enhancements, and support for additional hardware.

# Classifications

The following table summarizes how stability level classifications relate to release level. The first column lists the Stability Level. The second column lists the Release Level for Incompatable Changes, and the third column lists other comments. For a complete discussion of individual classifications, see the appropriate subsection below.

Stability	Release	Comments
Standard	Major (x.0)	Actual or de facto.
Stable	Major (x.0)	Incompatibilities are exceptional.
Evolving	Minor (x.y)	Migration advice might accompany an incompatibility.
Unstable	Minor (x.y)	Experimental or transitional: incompatibilities are common.
External	Micro (x.y.z)	Not controlled by Sun: intrarelease incompatibilities are common.

Stability	Release	Comments
Obsolete	Minor (x.y)	Deprecated interface: likely to be removed in a future minor release.

The interface stability level classifications described on this manual page apply to both source and binary interfaces unless otherwise stated. All stability level classifications are public, with the exception of the Private classification. The stability level of a documented interface (one that is documented in the manual pages) is unspecified unless explicitly stated. The stability level of an undocumented interface is implicitly Private.

The existence of documentation other than the documentation that is a component of the Solaris product should not be construed to imply any level of stability for interfaces provided by the Solaris product. The only source of stability level information is Solaris manual pages.

Standard[: [organization\_name,] standard\_name, version]

The documented interface complies with the standard listed. If a standard is not specified the interface is defined by several standards. This is usually the hierarchy built up from the C Language (defined by ISO/IEC or K&R), SVID 3 and associated ABIs (defined by AT&T), the POSIX standards (defined by IEEE and ISO/IEC), and the Single UNIX Specifications (defined by The Open Group). See standards(5) for a complete list of these standards.

Most of these interfaces are defined by a formal standard, and controlled by a standards development organization. Changes will usually be made in accordance with approved changes to that standard. This stability level can also apply to interfaces that have been adopted (without a formal standard) by an "industry convention."

Support is provided for only the specified version(s) of a standard; support for later versions is not guaranteed. If the standards development organization approves a non-upward-compatible change to a Standard interface that Sun decides to support, Sun will announce a compatibility and migration strategy.

Programmers producing portable applications should rely on the interface descriptions present in the standard or specification to which the application is intended to conform, rather than the manual page descriptions of Standard interfaces. When the standard or specification allows alternative implementation choices, the manual page usually only describes the alternative implemented by Sun. The manual page also describes any compatible extensions to the base definition of Standard interfaces provided by Sun.

# Stable

A Stable interface is a mature interface under Sun's control. Sun will try to avoid non-upwards-compatible changes to these interfaces, especially in minor or micro releases.

# attributes(5)

If support of a Stable interface must be discontinued, Sun will attempt to provide notification and the stability level changes to Obsolete.

# Evolving

An Evolving interface may eventually become Standard or Stable but is still in transition.

Sun will make reasonable efforts to ensure compatibility with previous releases as it evolves. When non-upwards compatible changes become necessary, they will occur in minor and major releases; such changes will be avoided in micro releases whenever possible. If such a change is necessary, it will be documented in the release notes for the affected release, and when feasible, Sun will provide migration aids for binary compatibility and continued source development.

## External

An External interface is controlled by an entity other than Sun. At Sun's discretion, Sun can deliver as part of any release updated and possibly incompatible versions of such interfaces, subject to their availability from the controlling entity. This classification is typically applied to publicly available "freeware" and similar objects.

For External interfaces, Sun makes no claims regarding either source or binary compatibility between any two releases. Applications based on these interfaces might not work in future releases, including patches that contain External interfaces.

# Unstable

An Unstable interface is provided to give developers early access to new or rapidly changing technology or as an interim solution to a problem for which a more stable solution is anticipated in the future.

For Unstable interfaces, Sun makes no claims about either source or binary compatibility from one minor release to another. Applications developed based on these interfaces may not work in future minor releases.

# Obsolete: Scheduled for removal after event

An Obsolete interface is supported in the current release, but is scheduled to be removed in a future (minor) release. When support of an interface is to be discontinued, Sun will attempt to provide notification before discontinuing support. Use of an Obsolete interface may produce warning messages.

# Private

A Private interface is an interface provided by a component (or product) intended only for the use of that component. A Private interface might still be visible to or accessible by other components. Because the use of interfaces private to another component carries great stability risks, such use is explicitly not supported. Components not supplied by Sun Microsystems should not use Private interfaces.

Most Private interfaces are not documented. It is an exceptional case when a Private interface is documented. Reasons for documenting a Private interface include, but are not limited to, the intention that the interface might be reclassified to one of the

public stability level classifications in the future or the fact that the interface is inordinately visible.

# MT-Level

Libraries are classified into categories that define their ability to support multiple threads. Manual pages containing functions that are of multiple or differing levels describe this in their NOTES or USAGE section.

### Safe

Safe is an attribute of code that can be called from a multithreaded application. The effect of calling into a Safe interface or a safe code segment is that the results are valid even when called by multiple threads. Often overlooked is the fact that the result of this Safe interface or safe code segment can have global consequences that affect all threads. For example, the action of opening or closing a file from one thread is visible by all the threads within a process. A multithreaded application has the responsibility for using these interfaces in a safe manner, which is different from whether or not the interface is Safe. For example, a multithreaded application that closes a file that is still in use by other threads within the application is not using the close(2) interface safely.

## Unsafe

An Unsafe library contains global and static data that is not protected. It is not safe to use unless the application arranges for only one thread at time to execute within the library. Unsafe libraries might contain functions that are Safe; however, most of the library's functions are unsafe to call. Some functions that are Unsafe have reentrant counterparts that are MT-Safe. Reentrant functions are designated by the \_r suffix appended to the function name.

# MT-Safe

An MT-Safe library is fully prepared for multithreaded access. It protects its global and static data with locks, and can provide a reasonable amount of concurrency. A library can be safe to use, but not MT-Safe. For example, surrounding an entire library with a monitor makes the library Safe, but it supports no concurrency so it is not considered MT-Safe. An MT-Safe library must permit a reasonable amount of concurrency. (This definition's purpose is to give precision to what is meant when a library is described as Safe. The definition of a Safe library does not specify if the library supports concurrency. The MT-Safe definition makes it clear that the library is Safe, and supports some concurrency. This clarifies the Safe definition, which can mean anything from being single threaded to being any degree of multithreaded.)

# Async-Signal-Safe

Async-Signal-Safe refers to particular library functions that can be safely called from a signal handler. A thread that is executing an Async-Signal-Safe function will not deadlock with itself if interrupted by a signal. Signals are only a problem for MT-Safe functions that acquire locks.

Async-Signal-Safe functions are also MT-Safe. Signals are disabled when locks are acquired in Async-Signal-Safe functions. These signals prevent a signal handler that might acquire the same lock from being called.

# MT-Safe with Exceptions

See the NOTES or USAGE sections of these pages for a description of the exceptions.

# attributes(5)

# Safe with Exceptions

See the NOTES or USAGE sections of these pages for a description of the exceptions.

## Fork-Safe

The fork(2) function replicates only the calling thread in the child process. The fork1(2) function exists for compatibility with the past and is synonymous with fork(). If a thread other than the one performing the fork holds a lock when fork() is called, the lock will still be held in the child process but there will be no lock owner since the owning thread was not replicated. A child calling a function that attempts to acquire the lock will deadlock itself.

When fork() is called, a Fork-Safe library arranges to have all of its internal locks held only by the thread performing the fork. This is usually accomplished with pthread\_atfork(3C), which is called when the library is initialized.

The forkall(2) function provides the capability for the rare case when a process needs to replicate all of its threads when performing a fork. No pthread\_atfork() actions are performed when forkall() is called. There are dangers associated with calling forkall(). If some threads in a process are performing I/O operations when another thread calls forkall(), they will continue performing the same I/O operations in both the parent and child processes, possibly causing data corruption. For this and other race-condition reasons, the use of forkall() is discouraged.

In all Solaris releases prior to Solaris 10, the behavior of fork() depended on whether or not the application was linked with -lpthread (POSIX threads, see standards(5)). If linked with -lpthread, fork() behaved like fork1(); otherwise it behaved like forkall(). To avoid any confusion concerning the behavior of fork(), applications can specifically call fork1() or forkall() as appropriate.

# Cancel-Safety

If a multithreaded application uses pthread cancel(3C) to cancel (that is, kill) a thread, it is possible that the target thread is killed while holding a resource, such as a lock or allocated memory. If the thread has not installed the appropriate cancellation cleanup handlers to release the resources appropriately (see pthread cancel(3C)), the application is "cancel-unsafe", that is, it is not safe with respect to cancellation. This unsafety could result in deadlocks due to locks not released by a thread that gets cancelled, or resource leaks; for example, memory not being freed on thread cancellation. All applications that use pthread cancel(3C) should ensure that they operate in a Cancel-Safe environment. Libraries that have cancellation points and which acquire resources such as locks or allocate memory dynamically, also contribute to the cancel-unsafety of applications that are linked with these libraries. This introduces another level of safety for libraries in a multithreaded program: Cancel-Safety. There are two sub-categories of Cancel-Safety: Deferred-Cancel-Safety, and Asynchronous-Cancel-Safety. An application is considered to be Deferred-Cancel-Safe when it is Cancel-Safe for threads whose cancellation type is PTHREAD CANCEL DEFERRED. An application is considered to be Asynchronous-Cancel-Safe when it is Cancel-Safe for threads whose cancellation type is PTHREAD CANCEL ASYNCHRONOUS.

attributes(5)

Deferred-Cancel-Safety is easier to achieve than Asynchronous-Cancel-Safety, since a thread with the deferred cancellation type can be cancelled only at well-defined cancellation points, whereas a thread with the asynchronous cancellation type can be cancelled anywhere. Since all threads are created by default to have the deferred cancellation type, it might never be necessary to worry about asynchronous cancel safety. Most applications and libraries are expected to always be Asynchronous-Cancel-Unsafe. An application which is Asynchronous-Cancel-Safe is also, by definition, Deferred-Cancel-Safe.

# audit binfile(5)

NAME

audit binfile – generation of Solaris audit logs

**SYNOPSIS** 

/usr/lib/security/audit\_binfile.so

# **DESCRIPTION**

The audit binfile plugin module for Solaris audit,

/usr/lib/security/audit\_binfile.so, writes binary audit data to files as configured in audit\_control(4); it is the default plugin for the Solaris audit daemon auditd(1M). Its output is described by audit.log(4).

The audit\_binfile plugin is loaded by auditd if audit\_control contains one or more lines defining audit directories by means of the dir: specification or if audit\_control has a plugin: specification of name=audit\_binfile.so.

# OBJECT ATTRIBUTES

The p\_dir and p\_minfree attributes are equivalent to the dir: and minfree: lines described in audit\_control. If both the dir: line and the p\_dir attribute are used, the plugin combines all directories into a single list with those specified by means of dir: at the front of the list. If both the minfree and the p\_minfree attributes are given, the p\_minfree value is used.

# **EXAMPLES**

The following directives cause audit\_binfile.so to be loaded, specify the directories for writing audit logs, and specify the percentage of required free space per directory.

```
flags: lo,ad,-fm
naflags: lo,ad
plugin: name=audit_binfile.so;\
p_minfree=20;\
p_dir=/etc/security/jedgar/eggplant,\
/etc/security/jedgar.aux/eggplant,\
/etc/security/global/eggplant
```

### NAME |

audit syslog – realtime conversion of Solaris audit data to syslog messages

# **SYNOPSIS**

/usr/lib/security/audit syslog.so

# **DESCRIPTION**

The audit syslog plugin module for Solaris audit,

/usr/lib/security/audit syslog.so, provides realtime conversion of Solaris audit data to syslog-formatted (text) data and sends it to a syslog daemon as configured in syslog.conf(4). The plugin's path is specified in the audit configuration file, audit control(4).

Messages to syslog are written if selected via the plugin option in audit control. Syslog messages are generated with the facility code of LOG AUDIT (audit in syslog.conf(4)) and severity of LOG NOTICE. Audit syslog messages contain data selected from the tokens described for the binary audit log. (See audit.log(4)). As with all syslog messages, each line in a syslog file consists of two parts, a syslog header and a message.

The syslog header contains the date and time the message was generated, the host name from which it was sent, auditd to indicate that it was generated by the audit daemon, an ID field used internally by syslogd, and audit.notice indicating the syslog facility and severity values. The syslog header ends with the characters "] ", that is, a closing square bracket and a space.

The message part starts with the event type from the header token. All subsequent data appears only if contained in the original audit record and there is room in the 1024-byte maximum length syslog line. In the following example, the backslash (\) indicates a continuation; actual syslog messages are contained on one line:

```
Oct 31 11:38:08 smothers auditd: [ID 917521 audit.notice] chdir(2) ok\
session 401 by joeuser as root:other from myultra obj /export/home
```

In the preceding example, chdir (2) is the event type. Following this field is additional data, described below. This data is omitted if it is not contained in the source audit record.

ok or failed

Comes from the return or exit token.

session <#>

<#> is the session ID from the subject token.

by <name>

<name> is the audit ID from the subject token.

as <name>:<group>

<name> is the effective user ID and <group> is the effective group ID from the subject token.

in <zone name>

The zone name. This field is generated only if the zonename audit policy is set.

from <terminal>

<terminal> is the text machine address from the subject token.

# audit\_syslog(5)

```
obj <path>
```

<path> is the path from the path token The path can be truncated from the left if necessary to fit it on the line. Truncation is indicated by leading ellipsis (...).

```
proc uid <owner>
```

<owner> is the effective user ID of the process owner.

```
proc auid <owner>
```

<owner> is the audit ID of the process owner.

# The following are example syslog messages:

```
Nov 4 8:27:07 smothers auditd: [ID 175219 audit.notice] \
system booted

Nov 4 9:28:17 smothers auditd: [ID 752191 audit.notice] \
login - rlogin ok session 401 by joeuser as joeuser:staff from myultra

Nov 4 10:29:27 smothers auditd: [ID 521917 audit.notice] \
access(2) ok session 255 by janeuser as janeuser:staff from 129.146.89.30 \
obj /etc/passwd
```

# OBJECT ATTRIBUTES

The p\_flag attribute, specified by means of the plugin directive (see audit\_control(4)), is used to further filter audit data being sent to the syslog daemon beyond the classes specified through the flags and naflags lines of audit\_control and through the user-specific lines of audit\_user(4). The parameter is a comma-separated list; each item represents an audit class (see audit\_class(4)) and is specified using the same syntax used in audit\_control for the flags and naflags lines. The default (no p\_flags listed) is that no audit records will be generated.

# **EXAMPLES**

**EXAMPLE 1** One Use of the plugin Line

In the specification shown below, the plugin line (in conjunction with flags and naflags) is used to allow class records for lo but allows class records for am for failures only. Omission of the fm class records results in no fm class records being output. The pc parameter has no effect because you cannot add classes to those defined by means of flags and naflags and by audit\_user(4). You can only remove them.

```
flags: lo,am,fm
naflags: lo
plugin: name=audit_syslog.so; p_flags=lo,-am
```

# **EXAMPLE 2** Use of all

In the specification shown below, with one exception, all allows all flags defined by means of flags and naflags (and audit\_user(4)). The exception the am metaclass, which is equivalent to ss, as, ua, which is modified to output all ua events but only failure events for ss and as.

```
flags: lo,am
naflags: lo
plugin: name=audit syslog.so; p flags=all,^+ss,^+as
```

**ATTRIBUTES** | See attributes(5) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT Level	MT-Safe
Interface Stability	:
message format	Unstable
message content	Unstable
config parameters	Evolving

# **SEE ALSO**

auditd(1M), audit class(4), audit control(4), syslog.conf(4), attributes(5)

# NOTES

Use of the plugin configuration line to include audit syslog. so requires that /etc/syslog.conf is configured to store syslog messages of facility audit and severity notice or above in a file intended for Solaris audit records. An example of such a line in syslog.conf is:

audit.notice /var/audit/audit.log

Messages from syslog are sent to remote syslog servers by means of UDP, which does not guarantee delivery or ensure the correct order of arrival of messages.

If the parameters specified for the plugin line result in no classes being preselected, an error is reported by means of a syslog alert with the LOG DAEMON facility code.

The time field in the syslog header is generated by syslog(3C) and only approximates the time given in the binary audit log. Normally the time field shows the same whole second or at most a few seconds' difference.

# cancellation(5)

# **NAME**

cancellation – overview of concepts related to POSIX thread cancellation

# **DESCRIPTION**

FUNCTION	ACTION
pthread_cancel	Cancels thread execution.
pthread_setcancelstate	Sets the cancellation <i>state</i> of a thread.
pthread_setcanceltype	Sets the cancellation type of a thread.
pthread_testcancel	Creates a cancellation point in the calling thread.
pthread_cleanup_push	Pushes a cleanup handler routine.
pthread_cleanup_pop	Pops a cleanup handler routine.

# Cancellation

Thread cancellation allows a thread to terminate the execution of any application thread in the process. Cancellation is useful when further operations of one or more threads are undesirable or unnecessary.

An example of a situation that could benefit from using cancellation is an asynchronously-generated cancel condition such as a user requesting to close or exit some running operation. Another example is the completion of a task undertaken by a number of threads, such as solving a maze. While many threads search for the solution, one of the threads might solve the puzzle while the others continue to operate. Since they are serving no purpose at that point, they should all be canceled.

# **Planning Steps**

Planning and programming for most cancellations follow this pattern:

- Identify which threads you want to cancel, and insert pthread\_cancel(3C) statements.
- 2. Identify system-defined cancellation points where a thread that might be canceled could have changed system or program state that should be restored. See the Cancellation Points for a list.
- 3. When a thread changes the system or program state just before a cancellation point, and should restore that state before the thread is canceled, place a cleanup handler before the cancellation point with pthread\_cleanup\_push(3C). Wherever a thread restores the changed state, pop the cleanup handler from the cleanup stack with pthread cleanup pop(3C).
- 4. Know whether the threads you are canceling call into cancel-unsafe libraries, and disable cancellation with pthread\_setcancelstate(3C) before the call into the library. See Cancellation State and Cancel-Safe.
- 5. To cancel a thread in a procedure that contains no cancellation points, insert your own cancellation points with pthread\_testcancel(3C). This function creates cancellation points by testing for pending cancellations and performing those cancellations if they are found. Push and pop cleanup handlers around the cancellation point, if necessary (see Step 3, above).

# Cancellation **Points**

The system defines certain points at which cancellation can occur (cancellation points), and you can create additional cancellation points in your application with pthread testcancel().

The following cancellation points are defined by the system (system-defined cancellation points): aio suspend(3RT), close(2), creat(2), getmsg(2), getpmsq(2), lockf(3C), mg receive(3RT), mg send(3RT), msgrcv(2), msgsnd(2), msync(3C), nanosleep(3RT), open(2), pause(2), poll(2), pread(2), pthread cond timedwait(3C), pthread cond wait(3C), pthread join(3C), pthread testcancel(3C), putmsq(2), putpmsq(2), pwrite(2), read(2), readv(2), select(3C), sem wait(3RT), sigpause(3C), sigwaitinfo(3RT), sigsuspend(2), sigtimedwait(3RT), sigwait(2), sleep(3C), sync(2), system(3C), tcdrain(3C), usleep(3C), wait(3C), waitid(2), wait3(3C), waitpid(3C), write(2), writev(2), and fcntl(2), when specifying F SETLKW as the command.

When cancellation is asynchronous, cancellation can occur at any time (before, during, or after the execution of the function defined as the cancellation point). When cancellation is deferred (the default case), cancellation occurs only within the scope of a function defined as a cancellation point (after the function is called and before the function returns). See Cancellation Type for more information about deferred and asynchronous cancellation.

Choosing where to place cancellation points and understanding how cancellation affects your program depend upon your understanding of both your application and of cancellation mechanics.

Typically, any call that might require a long wait should be a cancellation point. Operations need to check for pending cancellation requests when the operation is about to block indefinitely. This includes threads waiting in pthread cond wait() and pthread cond timedwait(), threads waiting for the termination of another thread in pthread join(), and threads blocked on sigwait().

A mutex is explicitly not a cancellation point and should be held for only the minimal essential time.

Most of the dangers in performing cancellations deal with properly restoring invariants and freeing shared resources. For example, a carelessly canceled thread might leave a mutex in a locked state, leading to a deadlock. Or it might leave a region of memory allocated with no way to identify it and therefore no way to free it.

# **Cleanup Handlers**

When a thread is canceled, it should release resources and clean up the state that is shared with other threads. So, whenever a thread that might be canceled changes the state of the system or of the program, be sure to push a cleanup handler with pthread cleanup push(3C) before the cancellation point.

When a thread is canceled, all the currently-stacked cleanup handlers are executed in last-in-first-out (LIFO) order. Each handler is run in the scope in which it was pushed. When the last cleanup handler returns, the thread-specific data destructor functions are called. Thread execution terminates when the last destructor function returns.

# cancellation(5)

When, in the normal course of the program, an uncanceled thread restores state that it had previously changed, be sure to pop the cleanup handler (that you had set up where the change took place) using pthread\_cleanup\_pop(3C). That way, if the thread is canceled later, only currently-changed state will be restored by the handlers that are left in the stack.

Be sure to pop the handler in the same scope in which it was pushed. Also, make sure that each push statement has a matching pop statement, or compiler errors will be generated.

# **Cancellation State**

Most programmers will use only the default cancellation state of PTHREAD\_CANCEL\_ENABLE, but can choose to change the state by using pthread\_setcancelstate(3C), which determines whether a thread is cancelable at all. With the default *state* of PTHREAD\_CANCEL\_ENABLE, cancellation is enabled and the thread is cancelable at points determined by its cancellation *type*. See Cancellation Type.

If the *state* is PTHREAD\_CANCEL\_DISABLE, cancellation is disabled, the thread is not cancelable at any point, and all cancellation requests to it are held pending.

You might want to disable cancellation before a call to a cancel-unsafe library, restoring the old cancel state when the call returns from the library. See Cancel-Safe for explanations of cancel safety.

# **Cancellation Type**

A thread's cancellation type is set with pthread\_setcanceltype(3C), and determines whether the thread can be canceled anywhere in its execution or only at cancellation points.

With the default *type* of PTHREAD\_CANCEL\_DEFERRED, the thread is cancelable only at cancellation points, and then only when cancellation is enabled.

If the *type* is PTHREAD\_CANCEL\_ASYNCHRONOUS, the thread is cancelable at any point in its execution (assuming, of course, that cancellation is enabled). Try to limit regions of asynchronous cancellation to sequences with no external dependencies that could result in dangling resources or unresolved state conditions. Using asynchronous cancellation is discouraged because of the danger involved in trying to guarantee correct cleanup handling at absolutely every point in the program.

Cancellation Type/State Table							
Туре	ate						
	Enabled (Default)	Disabled					
Deferred (Default)	Cancellation occurs when the target thread reaches a cancellation point and a cancel is pending. (Default)	All cancellation requests to the target thread are held pending.					

Cancellation Type/State Table						
Asynchronous	Receipt of a pthread_cancel() call causes immediate cancellation.	All cancellation requests to the target thread are held pending; as soon as cancellation is re-enabled, pending cancellations are executedimmediately.				

# Cancel-Safe

With the arrival of POSIX cancellation, the cancel-safe level has been added to the list of MT-Safety levels See Intro(3). An application or library is cancel-safe whenever it has arranged for cleanup handlers to restore system or program state wherever cancellation can occur. The application or library is specifically Deferred-cancel-safe when it is cancel-safe for threads whose cancellation type is PTHREAD CANCEL DEFERRED See Cancellation State. It is specifically Asynchronous-cancel-safe when it is cancel-safe for threads whose cancellation type is PTHREAD CANCEL ASYNCHRONOUS.

Obviously, it is easier to arrange for deferred cancel safety, as this requires system and program state protection only around cancellation points. In general, expect that most applications and libraries are *not* Asynchronous-cancel-safe.

# **POSIX Threads** Only

Note: The cancellation functions described in this reference page are available for POSIX threads, only (the Solaris threads interfaces do not provide cancellation functions).

# **EXAMPLES**

# **EXAMPLE 1** Cancellation example

The following short C++ example shows the pushing/popping of cancellation handlers, the disabling/enabling of cancellation, the use of pthread testcancel() , and so on. The free res () cancellation handler in this example is a dummy function that simply prints a message, but that would free resources in a real application. The function £2() is called from the main thread, and goes deep into its call stack by calling itself recursively.

Before £2() starts running, the newly created thread has probably posted a cancellation on the main thread since the main thread calls thr yield() right after creating thread2. Because cancellation was initially disabled in the main thread, through a call to pthread setcancelstate(), the call to f2() from main() continues and constructs X at each recursive call, even though the main thread has a pending cancellation.

When f2() is called for the fifty-first time (when "i == 50"), f2() enables cancellation by calling pthread setcancelstate(). It then establishes a cancellation point for itself by calling pthread testcancel(). (Because a cancellation is pending, a call to a cancellation point such as read(2) or write(2) would also cancel the caller here.)

# **EXAMPLE 1** Cancellation example (Continued)

After the main() thread is canceled at the fifty-first iteration, all the cleanup handlers that were pushed are called in sequence; this is indicated by the calls to free\_res() and the calls to the destructor for X. At each level, the C++ runtime calls the destructor for X and then the cancellation handler, free\_res(). The print messages from free res() and X's destructor show the sequence of calls.

At the end, the main thread is joined by thread2. Because the main thread was canceled, its return status from pthread\_join() is PTHREAD\_CANCELED. After the status is printed, thread2 returns, killing the process (since it is the last thread in the process).

```
#include <pthread.h>
#include <sched.h>
extern "C" void thr yield(void);
extern "C" void printf(...);
struct X {
        X(int i) \{x = i; printf("X(%d) constructed.\n", i);\}
        ~X() { printf("X(%d) destroyed.\n", x);}
};
void
free_res(void *i)
        printf("Freeing '%d'\n",i);
}
char* f2(int i)
        try {
        X dummy(i);
        pthread cleanup push(free res, (void *)i);
        if (i == 50) {
               pthread setcancelstate(PTHREAD CANCEL ENABLE, NULL);
            pthread_testcancel();
        f2(i+1);
        pthread cleanup pop(0);
        catch (int) {
        printf("Error: In handler.\n");
        return "f2";
}
void *
thread2(void *tid)
        void *sts:
        printf("I am new thread :%d\n", pthread_self());
```

#### **EXAMPLE 1** Cancellation example (Continued)

```
pthread_cancel((pthread_t)tid);
        pthread_join((pthread_t)tid, &sts);
        printf("main thread cancelled due to %d\n", sts);
        return (sts);
main()
        pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
        pthread create(NULL, NULL, thread2, (void *)pthread self());
        thr_yield();
        printf("Returned from %s\n",f2(0));
```

# charmap(5)

# **NAME**

charmap – character set description file

# **DESCRIPTION**

A character set description file or *charmap* defines characteristics for a coded character set. Other information about the coded character set may also be in the file. Coded character set character values are defined using symbolic character names followed by character encoding values.

The character set description file provides:

- The capability to describe character set attributes (such as collation order or character classes) independent of character set encoding, and using only the characters in the portable character set. This makes it possible to create generic localedef(1) source files for all codesets that share the portable character set.
- Standardized symbolic names for all characters in the portable character set, making it possible to refer to any such character regardless of encoding.

# Symbolic Names

Each symbolic name is included in the file and is mapped to a unique encoding value (except for those symbolic names that are shown with identical glyphs). If the control characters commonly associated with the symbolic names in the following table are supported by the implementation, the symbolic names and their corresponding encoding values are included in the file. Some of the encodings associated with the symbolic names in this table may be the same as characters in the portable character set table.

# **Declarations**

The following declarations can precede the character definitions. Each must consist of the symbol shown in the following list, starting in column 1, including the surrounding brackets, followed by one or more blank characters, followed by the value to be assigned to the symbol.

<code_set_name></code_set_name>	The name of the coded character set for which the character set description file is defined.
<mb_cur_max></mb_cur_max>	The maximum number of bytes in a multi-byte character. This defaults to 1.
<mb_cur_min></mb_cur_min>	An unsigned positive integer value that defines the minimum number of bytes in a character for the encoded character set.

<escape\_char> The escape character used to indicate that the

characters following will be interpreted in a special way, as defined later in this section. This defaults to backslash ('\'), which is the character glyph used in all the following text and examples, unless otherwise

noted.

<comment\_char> The character that when placed in column 1 of a

charmap line, is used to indicate that the line is to be ignored. The default character is the number sign (#).

#### **Format**

The character set mapping definitions will be all the lines immediately following an identifier line containing the string CHARMAP starting in column 1, and preceding a trailer line containing the string END CHARMAP starting in column 1. Empty lines and lines containing a *<comment\_char>* in the first column will be ignored. Each non-comment line of the character set mapping definition, that is, between the CHARMAP and END CHARMAP lines of the file), must be in either of two forms:

```
"%s %s %s\n", <symbolic-name>, <encoding>, <comments>
```

or

"%s...%s %s %s\n", <symbolic-name>, <symbolic-name>, <encoding>, <comments>

In the first format, the line in the character set mapping definition defines a single symbolic name and a corresponding encoding. A character following an escape character is interpreted as itself; for example, the sequence "<\\>>" represents the symbolic name "\>" enclosed between angle brackets.

In the second format, the line in the character set mapping definition defines a range of one or more symbolic names. In this form, the symbolic names must consist of zero or more non-numeric characters, followed by an integer formed by one or more decimal digits. The characters preceding the integer must be identical in the two symbolic names, and the integer formed by the digits in the second symbolic name must be equal to or greater than the integer formed by the digits in the first name. This is interpreted as a series of symbolic names formed from the common part and each of the integers between the first and the second integer, inclusive. As an example, <j0101>...<j0104> is interpreted as the symbolic names <j0101>, <j0102>, <j0103>, and <j0104>, in that order.

A character set mapping definition line must exist for all symbolic names and must define the coded character value that corresponds to the character glyph indicated in the table, or the coded character value that corresponds with the control character symbolic name. If the control characters commonly associated with the symbolic names are supported by the implementation, the symbolic name and the corresponding encoding value must be included in the file. Additional unique symbolic names may be included. A coded character value can be represented by more than one symbolic name.

# charmap(5)

The encoding part is expressed as one (for single-byte character values) or more concatenated decimal, octal or hexadecimal constants in the following formats:

"%cd%d", <escape\_char>, <decimal byte value>

"%cx%x", <escape\_char>, <hexadecimal byte value>

"%c%o", <escape\_char>, <octal byte value>

#### **Decimal Constants**

Decimal constants must be represented by two or three decimal digits, preceded by the escape character and the lower-case letter d; for example,  $\d05$ ,  $\d97$ , or  $\d143$ . Hexadecimal constants must be represented by two hexadecimal digits, preceded by the escape character and the lower-case letter x; for example,  $\d05$ ,  $\d05$ ,  $\d05$ , or  $\d05$ . Octal constants must be represented by two or three octal digits, preceded by the escape character; for example,  $\d05$ ,  $\d0$ 

# Ranges of Symbolic Names

In lines defining ranges of symbolic names, the encoded value is the value for the first symbolic name in the range (the symbolic name preceding the ellipsis). Subsequent symbolic names defined by the range will have encoding values in increasing order. Bytes are treated as unsigned octets and carry is propagated between the bytes as necessary to represent the range. However, because this causes a null byte in the second or subsequent bytes of a character, such a declaration should not be specified. For example, the line

<j0101>...<j0104> \d129\d254

#### is interpreted as:

<j0101></j0101>	\d129\d254
<j0102></j0102>	\d129\d255
<j0103></j0103>	\d130\d00
<i0104></i0104>	\d130\d01

The expanded declaration of the symbol <j0103> in the above example is an invalid specification, because it contains a null byte in the second byte of a character.

The comment is optional.

# Width Specification

The following declarations can follow the character set mapping definitions (after the "END CHARMAP" statement). Each consists of the keyword shown in the following list, starting in column 1, followed by the value(s) to be associated to the keyword, as defined below.

WIDTH

A non-negative integer value defining the column width for the printable character in the coded character set mapping definitions. Coded character set character values are defined using symbolic character names followed by column width values. Defining a character with more than one WIDTH produces undefined results. The END WIDTH keyword is used to terminate the WIDTH definitions. Specifying the width of a non-printable character in a WIDTH declaration produces undefined results.

WIDTH DEFAULT

A non-negative integer value defining the default column width for any printable character not listed by one of the WIDTH keywords. If no WIDTH\_DEFAULT keyword is included in the charmap, the default character width is 1.

# Example:

After the "END CHARMAP" statement, a syntax for a width definition would be:

```
WIDTH

<A> 1

<B> 1

<C>...<Z> 1

...

<fool>...<foon> 2

...

END WIDTH
```

In this example, the numerical code point values represented by the symbols <A> and <B> are assigned a width of 1. The code point values < C> to <Z> inclusive, that is, <C>, <D>, <E>, and so on, are also assigned a width of 1. Using <A>. . . <Z> would have required fewer lines, but the alternative was shown to demonstrate flexibility. The keyword WIDTH DEFAULT could have been added as appropriate.

```

### condition(5)

#### NAME

condition – concepts related to condition variables

#### **DESCRIPTION**

Occasionally, a thread running within a mutex needs to wait for an event, in which case it blocks or sleeps. When a thread is waiting for another thread to communicate its disposition, it uses a condition variable in conjunction with a mutex. Although a mutex is exclusive and the code it protects is sharable (at certain moments), condition variables enable the synchronization of differing events that share a mutex, but not necessarily data. Several condition variables may be used by threads to signal each other when a task is complete, which then allows the next waiting thread to take ownership of the mutex.

A condition variable enables threads to atomically block and test the condition under the protection of a mutual exclusion lock (mutex) until the condition is satisfied. If the condition is false, a thread blocks on a condition variable and atomically releases the mutex that is waiting for the condition to change. If another thread changes the condition, it may wake up waiting threads by signaling the associated condition variable. The waiting threads, upon awakening, reacquire the mutex and re-evaluate the condition.

# Initialize

Condition variables and mutexes should be global. Condition variables that are allocated in writable memory can synchronize threads among processes if they are shared by the cooperating processes (see mmap(2)) and are initialized for this purpose.

The scope of a condition variable is either intra-process or inter-process. This is dependent upon whether the argument is passed implicitly or explicitly to the initialization of that condition variable. A condition variable does not need to be explicitly initialized. A condition variable is initialized with all zeros, by default, and its scope is set to within the calling process. For inter-process synchronization, a condition variable must be initialized once, and only once, before use.

A condition variable must not be simultaneously initialized by multiple threads or re-initialized while in use by other threads.

Condition variables attributes may be set to the default or customized at initialization. POSIX threads even allow the default values to be customized. Establishing these attributes varies depending upon whether POSIX or Solaris threads are used. Similar to the distinctions between POSIX and Solaris thread creation, POSIX condition variables implement the default, intra-process, unless an attribute object is modified for inter-process prior to the initialization of the condition variable. Solaris condition variables also implement as the default, intra-process; however, they set this attribute according to the argument, *type*, passed to their initialization function.

### **Condition Wait**

The condition wait interface allows a thread to wait for a condition and atomically release the associated mutex that it needs to hold to check the condition. The thread waits for another thread to make the condition true and that thread's resulting call to signal and wakeup the waiting thread.

# Condition Signaling

A condition signal allows a thread to unblock the next thread waiting on the condition variable, whereas, a condition broadcast allows a thread to unblock all threads waiting on the condition variable.

Destroy

The condition destroy functions destroy any state, but not the space, associated with the condition variable.

# **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE	
MT-Level	MT-Safe	

#### **SEE ALSO**

 $\label{eq:fork-cond_signal} fork(2), mmap(2), setitimer(2), shmop(2), cond_broadcast(3C), cond_destroy(3C), cond_init(3C), cond_signal(3C), cond_timedwait(3C), cond_wait(3C), pthread_cond_broadcast(3C), pthread_cond_destroy(3C), pthread_cond_init(3C), pthread_cond_signal(3C), pthread_cond_timedwait(3C), pthread_cond_wait(3C), pthread_condattr_init(3C), signal(3C), attributes(5), mutex(5), standards(5)$ 

# **NOTES**

If more than one thread is blocked on a condition variable, the order in which threads are unblocked is determined by the scheduling policy.

USYNC\_THREAD does not support multiple mapplings to the same logical synch object. If you need to mmap () a synch object to different locations within the same address space, then the synch object should be initialized as a shared object USYNC\_PROCESS for Solaris, and PTHREAD PROCESS PRIVATE for POSIX.

# crypt\_bsdbf(5)

NAME | crypt\_bsdbf – password hashing module using Blowfish cryptographic algorithm

**SYNOPSIS** /usr/lib/security/\$ISA/crypt\_bsdbf.so

DESCRIPTION The crypt\_bsdbf module is a one-way password hashing module for use with crypt(3C) that uses the Blowfish cryptographic algorithm. The algorithm identifier for crypt.conf(4) and policy.conf(4) is 2a.

The maximum password length for crypt bsdbf is 255 characters.

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

NAME

crypt\_bsdmd5 – password hashing module using MD5 message hash algorithm

**SYNOPSIS** 

/usr/lib/security/\$ISA/crypt\_bsdmd5.so

**DESCRIPTION** 

The crypt bsdmd5 module is a one-way password hashing module for use with crypt(3C) that uses the MD5 message hash algorithm. The algorithm identifier for crypt.conf(4) and policy.conf(4) is 1. The output is compatible with md5crypt on BSD and Linux systems.

The maximum password length for crypt bsdmd5 is 255 characters.

# crypt\_sunmd5(5)

NAME

crypt sunmd5 – password hashing module using MD5 message hash algorithm

**SYNOPSIS** 

/usr/lib/security/\$ISA/crypt\_sunmd5.so

#### **DESCRIPTION**

The crypt\_sunmd5 module is a one-way password hashing module for use with crypt(3C) that uses the MD5 message hash algorithm. The algorithm identifier for crypt.conf(4) and policy.conf(4) is md5.

This module is designed to make it difficult to crack passwords that use brute force attacks based on high speed MD5 implementations that use code inlining, unrolled loops, and table lookup.

The maximum password length for crypt sunmd5 is 255 characters.

The following options can be passed to the module by means of crypt.conf(4):

rounds=<positive\_number>

Specifies the number of additional rounds of MD5 to use in generation of the salt; the default number of rounds is 4096. Negative values have no effect and are ignored, that is, the number of rounds cannot be lowered below 4096.

The number of additional rounds is stored in the salt string returned by crypt gensalt(3C). For example:

\$md5,rounds=1000\$nlxmTTpz\$

When crypt\_gensalt(3C) is being used to generate a new salt, if the number of additional rounds configured in crypt.conf(4) is greater than that in the old salt, the value from crypt.conf(4) is used instead. This allows for migration to stronger (but more time-consuming) salts on password change.

#### NAME

crypt\_unix - traditional UNIX crypt algorithm

# **DESCRIPTION**

The crypt unix algorithm is the traditional UNIX crypt algorithm. It is not considered sufficiently secure for current systems and is provided for backwards compatibility. The crypt sunmd5(5), crypt bsdmd5(5), or crypt bsdbf(5) algorithm should be used instead.

The algorithm identifier for policy.conf(4) is unix. There is no entry in crypt.conf(4) for this algorithm.

The crypt unix algorithm is internal to libc and provides the string encoding function used by crypt(3C) when the first character of the salt is not a "\$".

This algorithm is based on a one-way encryption algorithm with variations intended (among other things) to frustrate use of hardware implementations of a key search. Only the first eight characters of the key passed to crypt () are used with this algorithm; the rest are silently ignored. The salt is a two-character string chosen from the set [a-zA-Z0-9./]. This string is used to perturb the hashing algorithm in one of 4096 different ways.

The maximum password length for crypt unix is 8 characters.

#### **USAGE**

The return value of the crypt unix algorithm might not be portable among standard-conforming systems. See standards(5).

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

# dhcp(5)

#### NAME

dhcp – Dynamic Host Configuration Protocol

# **DESCRIPTION**

Dynamic Host Configuration Protocol (DHCP) enables host systems in a TCP/IP network to be configured automatically for the network as they boot. DHCP uses a client/server mechanism: servers store configuration information for clients, and provide that information upon a client's request. The information can include the client's IP address and information about network services available to the client.

This manual page provides a brief summary of the Solaris DHCP implementation.

### Solaris DHCP Client

The Solaris DHCP client is implemented as background daemon, dhcpagent(1M). This daemon is started automatically during bootup if there exists at least one dhcp.interface file in /etc. Only interfaces with a corresponding /etc/dhcp.interface file are automatically configured during boot. Network parameters needed for system configuration during bootup are extracted from the information recieved by the daemon through the use of the dhcpinfo(1) command. The daemon's default behavior can be altered by changing the tunables in the /etc/default/dhcpagent file. The daemon is controlled by the ifconfig(1M) utility. Check the status of the daemon using the netstat(1M) and ifconfig(1M) commands.

### Solaris DHCP Server

The Solaris DHCP server is implemented as a background daemon, in.dhcpd(1M). This daemon can deliver network configuration information to either BOOTP or DHCP clients. The Solaris DHCP service can be managed using the dhcpmgr(1M) GUI or the command line utilities dhcpconfig(1M), dhtadm(1M), and pntadm(1M).

# DHCP Configuration Tables

The Solaris DHCP server stores client configuration information in the following two types of tables:

dhcptab tables	Contain macros and op	ptions (also knowi	n as symbols),
----------------	-----------------------	--------------------	----------------

used to construct a package of configuration information to send to each DHCP client. There exists only one dhcptab for the DHCP service. The dhcptab(4) can be viewed and modified using the dhtadm(1M) command or dhcpmgr(1M) graphical utility. See dhcptab(4) for more information about the syntax of dhcptab records. See dhcp\_inittab(4) for more information about the DHCP options and symbols.

# DHCP network tables

DHCP network tables, which contain mappings of client IDs to IP addresses and parameters associated with those addresses. Network tables are named with the IP address of the network, and can be created, viewed, and modified using the pntadm command or dhcpmgr graphical utility. See dhcp\_network(4) for more information about network tables.

# dhcp\_modules(5)

**NAME** 

dhcp\_modules – data storage modules for the DHCP service

**DESCRIPTION** 

This man page describes the characteristics of data storage modules (public modules) for use by the Solaris Dynamic Host Configuration Protocol (DHCP) service.

Public modules are the part of the DHCP service architecture that encapsulate the details of storing DHCP service data in a data storage service. Examples of data storage services are NIS+, Oracle, and ufs file systems.

Public modules are dynamic objects which can be shipped separately from the Solaris DHCP service. Once installed, a public module is visible to the DHCP service, and can be selected for use by the service through the DHCP service management interfaces (dhcpmqr(1M), dhcpconfig(1M), dhtadm(1M), and pntadm(1M)).

Public modules may be provided by Sun Microsystems, Inc or by third parties.

The Solaris DHCP service management architecture provides a mechanism for plugging in public module-specific administration functionality into the dhcpmgr(1M) and dhcpconfig(1M) utilities. This functionality is in the form of a Java Bean, which is provided by the public module vendor. This Java Bean collects public module-specific configuration from the user (you) and provides it to the Solaris DHCP service.

The Solaris DHCP service bundles three modules with the service, which are described below. There are three dhcpsvc.conf(4) DHCP service configuration parameters pertaining to public modules: RESOURCE, PATH, and RESOURCE\_CONFIG. See dhcpsvc.conf(4) for more information about these parameters.

**SUNWfiles** 

This module stores its data in ASCII files. Although the format is ASCII, hand-editing is discouraged. It is useful for DHCP service environments that support several hundred to a couple thousand of clients and lease times are a few hours or more.

This module's data may be shared between DHCP servers through the use of NFS.

**SUNWbinfiles** 

This module stores its data in binary files. It is useful for DHCP service environments with many networks and many thousands of clients. This module provides an order of magnitude increase in performance and capacity over SUNWfiles.

This module's data cannot be shared between DHCP servers.

**SUNWnisplus** 

This module stores its data within a NIS+ domain. It is useful in environments where NIS+ is already deployed and facilitates sharing among multiple DHCP servers. This module suports several hundred to a few thousand clients with lease times of several hours or more.

The NIS+ service should be hosted on a machine with ample CPU power, memory, and disk space, as the load on NIS+ is significant when it is used to store DHCP data. Periodic checkpointing of the NIS+ service is necessary in order to roll the transaction logs and keep the NIS+ service operating at its highest efficiency. See nisping(1M) and crontab(1) for more information.

Solaris DHCP Service Developer's Guide

#### environ(5)

#### NAME |

environ – user environment

#### **DESCRIPTION**

When a process begins execution, one of the exec family of functions makes available an array of strings called the environment; see exec(2). By convention, these strings have the form *variable=value*, for example, PATH=/sbin:/usr/sbin. These environmental variables provide a way to make information about a program's environment available to programs.

A name may be placed in the environment by the export command and *name=value* arguments in sh(1), or by one of the exec functions. It is unwise to conflict with certain shell variables such as MAIL, PS1, PS2, and IFS that are frequently exported by .profile files; see profile(4).

The following environmental variables can be used by applications and are expected to be set in the target run-time environment.

#### HOME

The name of the user's login directory, set by login(1) from the password file; see passwd(4).

#### LANG

The string used to specify internationalization information that allows users to work with different national conventions. The setlocale(3C) function checks the LANG environment variable when it is called with "" as the locale argument. LANG is used as the default locale if the corresponding environment variable for a particular category is unset or null. If, however, LC\_ALL is set to a valid, non-empty value, its contents are used to override both the LANG and the other LC\_\* variables. For example, when invoked as setlocale(LC\_CTYPE, ""), setlocale() will query the LC\_CTYPE environment variable first to see if it is set and non-null. If LC\_CTYPE is not set or null, then setlocale() will check the LANG environment variable to see if it is set and non-null. If both LANG and LC\_CTYPE are unset or NULL, the default "C" locale will be used to set the LC\_CTYPE category.

Most commands will invoke setlocale (LC\_ALL, "") prior to any other processing. This allows the command to be used with different national conventions by setting the appropriate environment variables.

The following environment variables correspond to each category of setlocale(3C):

#### LC ALL

If set to a valid, non-empty string value, override the values of LANG and all the other LC\_\*variables.

# LC COLLATE

This category specifies the character collation sequence being used. The information corresponding to this category is stored in a database created by the localedef(1) command. This environment variable affects strcoll(3C) and strxfrm(3C).

#### LC CTYPE

This category specifies character classification, character conversion, and widths of multibyte characters. When LC\_CTYPE is set to a valid value, the calling utility can display and handle text and file names containing valid characters for that locale; Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide; and EUC characters of 1, 2, or 3 column widths. The default "C" locale corresponds to the 7-bit ASCII character set; only characters from ISO 8859-1 are valid. The information corresponding to this category is stored in a database created by the localedef() command. This environment variable is used by ctype(3C), mblen(3C), and many commands, such as cat(1), ed(1), ls(1), and vi(1).

### LC MESSAGES

This category specifies the language of the message database being used. For example, an application may have one message database with French messages, and another database with German messages. Message databases are created by the mkmsgs(1) command. This environment variable is used by exstr(1), gettxt(1), srchtxt(1), gettxt(3C), and gettext(3C).

#### LC MONETARY

This category specifies the monetary symbols and delimiters used for a particular locale. The information corresponding to this category is stored in a database created by the localedef(1) command. This environment variable is used by localeconv(3C).

# LC NUMERIC

This category specifies the decimal and thousands delimiters. The information corresponding to this category is stored in a database created by the localedef() command. The default C locale corresponds to "." as the decimal delimiter and no thousands delimiter. This environment variable is used by localeconv(3C), printf(3C), and strtod(3C).

#### LC TIME

This category specifies date and time formats. The information corresponding to this category is stored in a database specified in localedef(). The default C locale corresponds to U.S. date and time formats. This environment variable is used by many commands and functions; for example: at(1), calendar(1), date(1), strftime(3C), and getdate(3C).

# MSGVERB

Controls which standard format message components fmtmsg selects when messages are displayed to stderr; see fmtmsg(1) and fmtmsg(3C).

### NETPATH

A colon-separated list of network identifiers. A network identifier is a character string used by the Network Selection component of the system to provide application-specific default network search paths. A network identifier must consist of non-null characters and must have a length of at least 1. No maximum length is specified. Network identifiers are normally chosen by the system administrator. A network identifier is also the first field in any /etc/netconfig file entry.

NETPATH thus provides a link into the /etc/netconfig file and the information

#### environ(5)

about a network contained in that network's entry. /etc/netconfig is maintained by the system administrator. The library routines described in getnetpath(3NSL) access the NETPATH environment variable.

#### MI.SPATH

Contains a sequence of templates which catopen(3C) and gettext(3C) use when attempting to locate message catalogs. Each template consists of an optional prefix, one or more substitution fields, a filename and an optional suffix. For example:

```
NLSPATH="/system/nlslib/%N.cat"
```

defines that catopen() should look for all message catalogs in the directory /system/nlslib, where the catalog name should be constructed from the *name* parameter passed to catopen(), %N, with the suffix .cat.

Substitution fields consist of a % symbol, followed by a single-letter keyword. The following keywords are currently defined:

%N	The value of the <i>name</i>	parameter r	passed to	catopen().

%L The value of LANG or LC MESSAGES.

%l The language element from LANG or LC MESSAGES.

%t The territory element from LANG or LC MESSAGES.

%c The codeset element from LANG or LC MESSAGES.

%% A single % character.

An empty string is substituted if the specified value is not currently defined. The separators "\_" and "." are not included in %t and %c substitutions.

Templates defined in NLSPATH are separated by colons (:). A leading colon or two adjacent colons (::) is equivalent to specifying %N. For example:

```
NLSPATH=":%N.cat:/nlslib/%L/%N.cat"
```

indicates to catopen() that it should look for the requested message catalog in <code>name.name.cat</code> and <code>/nlslib/\$LANG/name.cat</code>. For <code>gettext(), %N</code> automatically maps to "messages".

If NLSPATH is unset or NULL, catopen() and gettext() call setlocale(3C), which checks LANG and the  $LC_*$  variables to locate the message catalogs.

NLSPATH will normally be set up on a system wide basis (in /etc/profile) and thus makes the location and naming conventions associated with message catalogs transparent to both programs and users.

# PATH

The sequence of directory prefixes that sh(1), time(1), nice(1), nohup(1), and other utilities apply in searching for a file known by an incomplete path name. The prefixes are separated by colons (:). login(1) sets PATH=/usr/bin. For more detail, see sh(1).

#### SEV LEVEL

Define severity levels and associate and print strings with them in standard format error messages; see addseverity(3C), fmtmsg(1), and fmtmsg(3C).

The kind of terminal for which output is to be prepared. This information is used by commands, such as vi(1), which may exploit special capabilities of that terminal.

TZ

Timezone information. The contents of this environment variable are used by the functions ctime(3C), localtime(3C), strftime(3C), and mktime(3C) to override the default timezone. The value of TZ has one of the two formats (spaces inserted for clarity):

```
:characters
or
std offset dst offset, rule
```

If TZ is of the first format (that is, if the first character is a colon (:)), or if TZ is not of the second format, then TZ designates a path to a timezone database file relative to /usr/share/lib/zoneinfo/, ignoring a leading colon if one exists.

Otherwise, TZ is of the second form, which when expanded is as follows:

```
stdoffset [dst [offset] [, start [/time], end [/time]]]
```

std and dst

Indicate no less than three, nor more than {TZNAME MAX}, bytes that are the designation for the standard (std) or the alternative (dst, such as Daylight Savings Time) timezone. Only std is required; if *dst* is missing, then the alternative time does not apply in this timezone. Each of these fields can occur in either of two formats, quoted or unquoted:

- In the quoted form, the first character is the less-than ('<') character and the last character is the greater-than ('>') character. All characters between these quoting characters are alphanumeric characters from the portable character set in the current locale, the plus-sign ('+') character, or the minus-sign ('-') character. The std and dst fields in this case do not include the quoting characters.
- In the unquoted form, all characters in these fields are alphabetic characters from the portable character set in the current locale.

# environ(5)

offset

start/time, end/time

The interpretation of these fields is unspecified if either field is less than three bytes (except for the case when *dst* is missing), more than {TZNAME\_MAX} bytes, or if they contain characters other than those specified.

Indicate the value one must add to the local time to arrive at Coordinated Universal Time. The offset has the form:

hh[:mm[:ss]]

The minutes (*mm*) and seconds (*ss*) are optional. The hour (*hh*) is required and can be a single digit. The *offset* following *std* is required. If no *offset* follows *dst*, daylight savings time is assumed to be one hour ahead of standard time. One or more digits can be used. The value is always interpreted as a decimal number. The hour must be between 0 and 24, and the minutes (and seconds), if present, must be between 0 and 59. Out of range values can cause unpredictable behavior. If preceded by a "–", the timezone is east of the Prime Meridian. Otherwise, it is west of the Prime Meridian (which can be indicated by an optional preceding "+" sign).

Indicate when to change to and back from daylight savings time, where *start/time* describes when the change from standard time to daylight savings time occurs, and *end/time* describes when the change back occurs. Each *time* field describes when, in current local time, the change is made.

The formats of *start* and *end* are one of the following:

Jn The Julian day n ( $1 \le n \le 365$ ). Leap days are not counted. That is, in all years, February 28 is day 59 and March 1 is day 60. It is impossible to refer to the occasional February 29.

*n* The zero-based Julian day  $(0 \le n \le 365)$ . Leap days are counted, and it is possible to refer to February 29.

Mm.n.d The  $d^{\text{th}}$  day,  $(0 \le d \le 6)$  of week n of month m of the year  $(1 \le n \le 5, 1 \le m \le 12)$ , where week 5 means "the last d-day in month m" which may occur in either the fourth or the fifth week). Week 1 is

# environ(5)

the first week in which the  $d^{th}$  day occurs. Day zero is Sunday.

Implementation specific defaults are used for *start* and end if these optional fields are not specified.

The *time* has the same format as *offset* except that no leading sign ("-" or "+" ) is allowed. If *time* is not specified, the default value is 02:00:00.

# eqnchar(5)

NAME |

eqnchar - special character definitions for eqn

**SYNOPSIS** 

```
eqn /usr/share/lib/pub/eqnchar filename | troff options neqn /usr/share/lib/pub/eqnchar filename | troff options
```

# **DESCRIPTION**

The eqnchar command contains nroff(1) and troff(1) character definitions for constructing characters that are not available on the Graphic Systems typesetter. These definitions are primarily intended for use with eqn(1) and neqn(1). It contains definitions for the following characters:

ciplus citimes	$\bigoplus_{\otimes}$	 langle	 	square circle	
wig	~	rangle	Ì	blot	
-wig	~	hbar	ħ	bullet	•
>wig	≳	ppd	<u> </u>	prop	$\infty$
<wig< td=""><td>≲ ≅</td><td>&lt;-&gt;</td><td><math>\leftrightarrow</math></td><td>empty</td><td>Ø</td></wig<>	≲ ≅	<->	$\leftrightarrow$	empty	Ø
=wig	≅	<=>	$\Leftrightarrow$	member	€
star	*	<	≮	nomem	∉
bigstar	*	>	<b>&gt;</b>	сир	$\cup$
=dot	Ė	ang	_	сар	$\cap$
orsign	Y	rang	L	incl	
andsign	X	3dot	:	subset	$\subseteq$
=del	$\overset{\Delta}{=}$	thf	<i>:</i> .	supset	$\supset$
oppA	$\rightarrow$	quarter	1/4	!subset	$\subseteq$
оррЕ	⊒I Å	3quarter	3/4	!supset	$\supseteq$
angstrom	Å	degree	o	,

#### **NAME**

extensions – localedef extensions description file

# **DESCRIPTION**

A localedef extensions description file or extensions file defines various extensions for the localedef(1) command.

The localedef extensions description file provides:

- EUC code set width information via the cswidth keyword: cswidth bc1 : sw1,bc2 : sw2,bc3 : sw3where bc1,bc2, and bc3 indicate the number of bytes (byte count) per character for EUC codesets 1, 2, and 3, respectively. sw1, sw2, and sw3 indicate screen width for EUC codesets 1, 2, and 3, respectively.
- Other extensions which will be documented in a future release.

NAME

filesystem – file system organization

**SYNOPSIS** 

,

/usr

#### DESCRIPTION

The file system tree is organized for administrative convenience. Distinct areas within the file system tree are provided for files that are private to one machine, files that can be shared by multiple machines of a common platform, files that can be shared by all machines, and home directories. This organization allows sharable files to be stored on one machine but accessed by many machines using a remote file access mechanism such as NFS. Grouping together similar files makes the file system tree easier to upgrade and manage.

The file system tree consists of a root file system and a collection of mountable file systems. The mount(2) program attaches mountable file systems to the file system tree at mount points (directory entries) in the root file system or other previously mounted file systems. Two file systems, / (the root) and /usr, must be mounted and /var must be accessible to have a functional system. The root file system is mounted automatically by the kernel at boot time; the /usr file system is mounted by the system start-up script, which is run as part of the booting process. /var can be mounted as its own file system or be part of /usr, as it is by default.

Certain locations, noted below, are approved installation locations for bundled Foundation Solaris software. In some cases, the approved locations for bundled software are also approved locations for add-on system software or for applications. The following descriptions make clear where the two locations differ. For example, /etc is the installation location for platform-dependent configuration files that are bundled with Solaris software. The analogous location for applications is /etc/opt/packagename.

In the following descriptions, *subsystem* is a category of application or system software, such as a window system (dt) or a language (java1.2)

The following descriptions make use of the terms platform, platform-dependent, platform-independent, and platform-specific. Platform refers to a machines Instruction Set Architecture or processor type, such as is returned by uname -i. Platform-dependent refers to a file that is installed on all platforms and whose contents vary depending on the platform. Like a platform-dependent file, a platform-independent file is installed on all platforms. However, the contents of the latter type remains the same on all platforms. An example of a platform-dependent file is compiled, executable program. An example of a platform-independent file is a standard configuration file, such as /etc/hosts. Unlike a platform-dependent or a platform-independent file, the platform-specific file is installed only on a subset of supported platforms. Most platform-specific files are gathered under /platform and /usr/platform.

In the following file or directory descriptions, GNOME stands for GNU Network Object Model Environment. The GNOME Desktop is shipped with the Solaris operating system.

```
Root File System
```

```
The root file system contains files that are unique to each machine. It contains the
following directories:
  Root of the overall file system name space.
  Primary location for special files. Typically, device files are built to match the kernel
  and hardware configuration of the machine.
/dev/cfg
  Symbolic links to physical ap_ids.
  Provides configuration and capability information about the processor type
/dev/cua
  Device files for uucp.
/dev/dsk
  Block disk devices.
/dev/fbs
  Frame buffer device files.
/dev/fd
  File descriptors.
/dev/md
  Logical volume management meta-disk devices.
/dev/printers
  USB printer device files.
/dev/pts
  Pseudo-terminal devices.
/dev/rdsk
  Raw disk devices.
/dev/rmt
  Raw tape devices.
/dev/sad
  Entry points for the STREAMS Administrative driver.
/dev/sound
  Audio device and audio device control files.
/dev/swap
  Default swap device.
/dev/term
  Terminal devices.
/devices
```

Physical device files.

```
Platform-dependent administrative and configuration files and databases that are
  not shared among systems. /etc may be viewed as the directory that defines the
  machine's identity. An approved installation location for bundled Solaris software.
  The analogous location for add-on system software or for applications is
  /etc/opt/packagename.
/etc/X11
  Xorg Xserver (X11) configuration files.
/etc/acct
  Accounting system configuration information.
/etc/apache
  Apache configuration files.
/etc/apoc
  Files for configuring Sun Java Desktop System Configuration Manager remote
/etc/bonobo-activation
  GNOME XML configuration file for identifying CORBA servers.
/etc/cron.d
  Configuration information for cron(1M).
/etc/dat
  Contains a list of interface adapters supported by uDAPL service providers.
/etc/default
  Defaults information for various programs.
/etc/devices
  Contains device-related data.
/etc/dfs
  Configuration information for shared file systems.
  Dynamic Host Configuration Protocol (DHCP) configuration files.
/etc/dmi
  Solstice Enterprise Agents configuration files.
/etc/dt
  Desktop configuration files.
/etc/flash
  Solaris Flash Archive configuration files.
  Fault manager configuration files. For more information, see fmd(1M).
/etc/fonts
  Font configuration information for the GNOME Desktop.
```

```
/etc/fs
  Binaries organized by file system types for operations required before /usr is
  mounted.
/etc/ftpd
  ftpd configuration files.
/etc/gconf
  GNOME Desktop user preference files.
/etc/gimp
  GNU Image Manipulation Program (GIMP) configuration files.
/etc/gnome
  GNOME Desktop configuration files.
/etc/gnome-vfs-2.0
  Files for customizing GNOME 2.0 desktop menus.
/etc/gnopernicus-1.0
  Configuration files for GNOME's Gnopernicus, an Assistive Technology (AT) screen
  reader.
/etc/gss
  Generic Security Service (GSS) Application Program Interface configuration files.
/etc/gtk
  GNOME configuration files.
/etc/gtk-2.0
  GNOME 2.0 Desktop configuration files.
  Sun Java System Message Queue security configuration files.
/etc/inet
  Configuration files for Internet services.
/etc/init.d
  Shell scripts for transitioning between run levels.
/etc/iplanet
  iPlanet configuration files.
/etc/krb5
  Kerberos configuration files.
/etc/lib
  Shared libraries needed during booting.
  Logical link control (11c2) driver configuration files.
/etc/lp
  Configuration information for the printer subsystem.
```

```
Solaris Live Upgrade configuration files.
/etc/lvm
  Solaris Logical Volume Manager configuration files.
/etc/mail
  Mail subsystem configuration.
/etc/nca
  Solaris Network Cache and Accelerator (NCA) configuration files.
  Configuration information for transport independent network services.
/etc/nfs
  NFS server logging configuration file.
/etc/opt
  Configuration information for optional packages.
/etc/pam.d
  This initially empty directory can be used to configure Kerberos for the GNOME
  Desktop Manager.
/etc/pango
  GNOME 2.0 Desktop locale files.
/etc/patch
  Configuration files for patch management.
/etc/ppp
  Solaris PPP configuration files.
/etc/rc0.d
  Scripts for entering or leaving run level 0. See init(1M).
  Scripts for entering or leaving run level 1. See init(1M).
/etc/rc2.d
  Scripts for entering or leaving run level 2. See init(1M).
/etc/rc3.d
  Scripts for entering or leaving run level 3. See init(1M).
/etc/rcS.d
  Scripts for bringing the system up in single user mode.
  Directory for reconfiguration manager (RCM) custom scripts.
/etc/rpcsec
  This directory might contain an NIS+ authentication configuration file.
/etc/saf
  Service Access Facility files.
```

```
/etc/sasl
  Simple Authentication and Security Layer (SASL) server configuration files.
/etc/security
  Basic Security Module (BSM) configuration files.
/etc/sfw
  Platform-dependent administrative, configuration files and databases for
  subsystems from /usr/sfw that are not shared among systems.
/etc/sfw/samba
  Samba configuration files.
/etc/skel
  Default profile scripts for new user accounts. See useradd(1M).
/etc/sma
  Systems Management Agent (SMA) configuration files.
/etc/smartcard
  Solaris Smart Card configuration files.
/etc/snmp
  Solstice Enterprise Agents configuration files.
/etc/sound
  Sound files for the GNOME desktop.
/etc/ssh
  Secure Shell configuration files. See ssh(1)
/etc/svc
  SMF service repository.
/etc/sysevent
  syseventd configuration files.
/etc/subsystem
  Platform-dependent subsystem configuration files that are not shared among
  systems. An approved installation location for bundled Solaris software. The
  analogous location for add-on system software or for applications is
  /etc/opt/packagename.
/etc/tm
  Trademark files; contents displayed at boot time.
/etc/usb
  USB configuration information.
/etc/uucp
  UUCP configuration information. See uucp(1C).
  Extensible Markup Language (XML) catalog.
/etc/zones
  Solaris Zones configuration files.
```

```
Default root of the shared file system tree.
  Default root of a subtree for user directories.
/kernel
  Subtree of platform-dependent loadable kernel modules required as part of the boot
  process. It includes the generic part of the core kernel that is platform-independent,
  /kernel/genunix. See kernel(1M) An approved installation location for
  bundled Solaris software and for add-on system software.
/kernel/drv
  32-bit x86 device drivers.
/kernel/drv/sparcv9
  64-bit SPARC device drivers.
/kernel/drv/amd64
  64-bit device drivers for 64-bit x86 platforms.
/kernel/genunix
  Platform-independent kernel.
/kernel/amd64/genunix
  64-bit, platform-independent kernel.
/kernel/subsystem/amd64
  64-bit x86 platform-dependent modules required for boot. An approved installation
  location for bundled Solaris software and for add-on system software.
/kernel/subsystem/sparcv9
  64-bit SPARC platform-dependent modules required for boot. An approved
  installation location for bundled Solaris software and for add-on system software.
  Default temporary mount point for file systems. This is an empty directory on
  which file systems can be temporarily mounted.
  Temporary mount point for file systems that are mounted by the automounter.
  Root of a subtree for add-on application packages.
/platform
  Subtree of platform-specific objects which need to reside on the root filesystem. It
  contains a series of directories, one per supported platform. The semantics of the
  series of directories is equivalent to / (root).
/platform/'uname -i'/kernel
  Platform-specific modules required for boot. These modules have semantics
  equivalent to /kernel. It includes the file unix, the core kernel. See kernel(1M).
  An approved installation location for bundled Solaris software and for add-on
  system software.
```

```
/platform/'uname -m'/kernel
  Hardware class-specific modules required for boot. An approved installation
  location for bundled Solaris software and for add-on system software.
/platform/'uname -i'/kernel/subsystem/amd64
  x86 64-bit, platform-dependent modules required for boot. This is an approved
  installation location for bundled Solaris software.
/platform/'uname -i'/kernel/subsystem/sparcv9
  SPARC 64-bit platform-specific modules required for boot. An approved installation
  location for bundled Solaris software.
/platform/'uname -i'/kernel/sparcv9/unix
  64-bit platform-dependent kernel.
/platform/'uname -i'/kernel/unix
  32-bit platform-dependent kernel on i86 and a symlink to sparcv9/unix on
  SPARC.
/platform/'uname -i'/lib
  Platform-specific shared objects required for boot. Semantics are equivalent to
  /lib. An approved installation location for bundled Solaris software and for
  add-on system software.
/platform/'uname -i'/sbin
  Platform-specific administrative utilities required for boot. Semantics are equivalent
  to /sbin. An approved installation location for bundled Solaris software and for
  add-on system software.
/proc
  Root of a subtree for the process file system.
  Essential executables used in the booting process and in manual system recovery.
  The full complement of utilities is available only after /usr is mounted. /sbin is
  an approved installation location for bundled Solaris software.
/system
  Mount point for the contract (CTFS) and object (OBJFS) file systems.
  Temporary files; cleared during the boot operation.
  Mount point for the /usr file system. See description of /usr file system, below.
/var
  Root of a subtree for varying files. Varying files are files that are unique to a
  machine but that can grow to an arbitrary (that is, variable) size. An example is a
  log file. An approved installation location for bundled Solaris software. The
```

/var/adm

System logging and accounting files.

/var/opt/packagename.

analogous location for add-on system software or for applications is

```
/var/apache
  Scripts, icons, logs, and cache pages for Apache web server.
/var/appserver
  Sun Java System Application Server administrative domain files.
/var/audit
  Basic Security Module (BSM) audit files.
/var/crash
  Default depository for kernel crash dumps.
/var/cron
  Log files for cron(1M).
/var/dmi
  Solstice Enterprise Agents (SEA) Desktop Management Interface (DMI) run-time
  components.
/var/dt
  dtlogin configuration files.
  Fault manager state files. For more information, see fmd(1M).
  Message queue broker instance configuration file.
  FTP server directory.
/var/inet
  IPv6 router state files.
/var/krb5
  Database and log files for Kerberos.
  Configuration files for runtime linker.
/var/ldap
  LDAP client configuration files.
/var/lib
  Login configuration files for GNOME Desktop Manager.
/var/log
  System log files.
  Line printer subsystem logging information.
/var/mail
  Directory where users' mail is kept.
/var/mysql
  Dynamic database directory for MySQL Database Management System.
```

```
/var/news
  Community service messages. This is not the same as USENET-style news.
/var/nfs
  NFS server log files.
/var/nis
  NIS+ databases.
/var/ntp
  Network Time Protocol (NTP) server state directory.
/var/opt
  Root of a subtree for varying files associated with optional software packages. An
  approved installation location for add-on system software and applications.
/var/patchsrv
  Patch management log files.
/var/preserve
  Backup files for vi(1) and ex(1).
  Temporary files which are not needed across reboots. Only root may modify the
  contents of this directory.
/var/sadm
  Databases maintained by the software package management utilities.
/var/sadm/system/logs
  Status log files produced by software management functions and/or applications.
  For example, log files produced for product installation. An approved installation
  location for bundled Solaris software and for add-on system software and
  applications.
/var/saf
  Service access facility logging and accounting files.
/var/samba
  Log and lock files for Samba.
/var/sma snmp
  Systems Management Agent (SMA) security and MIB component information.
/var/snmp
  SNMP status and configuration information.
/var/spool
  Contains directories for files used in printer spooling, mail delivery, cron(1M),
  at(1), and so forth.
/var/spool/clientmqueue
  sendmail(1M) client files.
/var/spool/cron
  cron(1M) and at(1) spooling files.
```

```
/var/spool/locks
  Spooling lock files.
/var/spool/lp
  Line printer spool files. See 1p(1).
/var/spool/mqueue
  Mail queued for delivery.
/var/spool/pkg
  Spooled packages.
/var/spool/print
  LP print service client-side request staging area.
/var/spool/samba
  Samba print queue.
/var/spool/uucp
  Queued uucp(1C) jobs.
/var/spool/uucppublic
  Files deposited by uucp(1C).
/var/statmon
  Network status monitor files.
/var/svc
  SMF log files.
/var/tmp
  Files that vary in size or presence during normal system operations. This directory
  is not cleared during the boot operation. An approved installation location for
  bundled Solaris software and for add-on system software and applications.
/var/uucp
  uucp(1C) log and status files.
/var/yp
  Databases needed for backwards compatibility with NIS and ypbind(1M);
  unnecessary after full transition to NIS+.
```

# /usr File System

Because it is desirable to keep the root file system small and not volatile, on disk-based systems larger file systems are often mounted on /home, /opt, /usr, and /var.

The file system mounted on /usr contains platform-dependent and platform-independent sharable files. The subtree rooted at /usr/share contains platform-independent sharable files; the rest of the /usr tree contains platform-dependent files. By mounting a common remote file system, a group of machines with a common platform may share a single /usr file system. A single /usr/share file system can be shared by machines of any platform. A machine acting as a file server can share many different /usr file systems to support several different architectures and operating system releases. Clients usually mount /usr read-only so that they do not accidentally change any shared files.

The /usr file system contains the following subdirectories:

/usr/4lib

a.out libraries for the Binary Compatibility Package.

/usr/5bin

Symbolic link to the /usr/bin directory.

/usr/SUNWale

Configuration files for Asian Lanuguage Environment (ALE).

Symbolic link to the /usr/openwin directory.

Xorg Xserver (X11) executables and documentation.

Symbolic link to the /var/adm directory.

Apache executables, loadable modules, and documentation.

/usr/appserver

Sun Java System Application Server software.

/usr/aset

Directory for Automated Security Enhancement Tools (ASET) programs and files.

/usr/bin

Platform-dependent, user-invoked executables. These are commands users expect to be run as part of their normal \$PATH. For executables that are different on a 64-bit system than on a 32-bit system, a wrapper that selects the appropriate executable is placed here. See isaexec(3C). An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin.

/usr/bin/amd64

x86 64-bit, platform-dependent, user-invoked executables. This directory should not be part of a user's \$PATH. A wrapper in /usr/bin should invoke the executable in this directory. See isaexec(3C). An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin/amd64.

/usr/bin/sparcv9

SPARC platform-dependent, user-invoked executables. This directory should not be part of a user's \$PATH. A wrapper in /usr/bin should invoke the executable in this directory. See isaexec(3C). An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin/sparcv9.

/usr/bin/amd64

x86 platform-dependent, user-invoked executables. This directory should not be part of a user's \$PATH. A wrapper in /usr/bin should invoke the executable in

this directory. See isaexec(3C). An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin/amd64.

/usr/bin/subsystem

Platform-dependent user-invoked executables that are associated with *subsystem*. These are commands users expect to be run as part of their normal \$PATH. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin.

/usr/subsystem/bin

Platform-dependent user-invoked executables that are associated with *subsystem*. These are commands users expect to be run as part of their normal \$PATH. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin.

/usr/subsystem/bin/amd64

x86 64-bit, platform-dependent, user-invoked executables. This directory should not be part of a user's \$PATH. A wrapper in /usr/bin should invoke the executable in this directory. See isaexec(3C). An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin/amd64.

/usr/subsystem/bin/sparcv9

SPARC 64-bit, platform-dependent, user-invoked executables. This directory should not be part of a user's \$PATH. A wrapper in /usr/bin should invoke the executable in this directory. See isaexec(3C). An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/bin/sparcv9.

/usr/ccs

C compilation system.

/usr/ccs/bin

C compilation commands and system utilities.

/usr/ccs/lib

Symbolic link to /usr/lib.

/usr/demo

Demo programs and data.

/usr/dict

Symbolic link to the /usr/share/lib/dict directory, which contains the dictionary file used by the UNIX spell program.

/usr/dt

root of a subtree for CDE software.

/usr/dt/bin

Primary location for CDE system utilities.

/usr/dt/include

Header files for CDE software.

```
/usr/dt/lib
  Libraries for CDE software.
/usr/dt/share/man
  On-line reference manual pages for CDE software.
/usr/games
  An empty directory, a remnant of the SunOS 4.0/4.1 software.
/usr/qnome
  GNOME Desktop applications.
/usr/include
  Include headers (for C programs).
/usr/iplanet
  Directory server executables, loadable modules, and documentation.
/usr/j2se
  Java 2 SDK executables, loadable modules, and documentation.
/usr/java*
  Directories containing Java programs and libraries.
/usr/jdk*
  Java Platform virtual machine and core class libraries.
/usr/kernel
  Subtree of platform-dependent loadable kernel modules, not needed in the root
  filesystem. An approved installation location for bundled Solaris software.
/usr/kvm
  A mount point, retained for backward compatibility, that formerly contained
  platform-specific binaries and libraries.
/usr/lib
  Platform-dependent libraries, various databases, commands and daemons not
  invoked directly by a human user. An approved installation location for bundled
  Solaris software. The analogous location for add-on system software or for
  applications is /opt/packagename/lib.
/usr/lib/32
  Symbolic link to /usr/lib.
/usr/lib/64
  Symbolic link to the most portable 64-bit Solaris interfaces, on both SPARC and x86
  platforms.
/usr/lib/acct
  Accounting scripts and binaries. See acct(1M).
/usr/lib/adb
  adb accounting scripts.
```

```
/usr/lib/amd64
  Platform-dependent libraries, various databases, commands and daemons not
  invoked directly by a human user on 64-bit x86. An approved installation location
  for bundled Solaris software. The analogous location for add-on system software or
  for applications is /opt/packagename/lib/amd64.
/usr/lib/autofs
  Contains the automountd executable.
/usr/lib/cfqadm
  Contains cfgadm hardware-specific driver plugins.
/usr/lib/class
  Scheduling-class-specific directories containing executables for priocnt1(1) and
  dispadmin(1M).
/usr/lib/crypto
  Contains the kernel-level cryptographic framework daemon (kcfd).
/usr/lib/devfsadm
  Contains devfsadm, the daemon version of devfsadm.
/usr/lib/dict
  Database files for spell(1).
/usr/lib/dns
  Contains DNS resolver libraries.
/usr/lib/dtrace
  Contains dtrace D source files.
/usr/lib/flash
  Contains Solaris flash archive deployment scripts.
  Contains fmd, the fault manager daemon and the fault manager library.
/usr/lib/font
  troff(1) font description files.
/usr/lib/fs
  File system type dependent modules; generally not intended to be invoked directly
  by the user.
/usr/lib/qss
  Secure services-related libraries.
/usr/lib/iconv
  Conversion tables for iconv(1).
/usr/lib/inet
  Contains many network-related daemons and libraries.
/usr/lib/ipf
  Contains IPFILTER.LICENCE and ipftest.
```

```
/usr/lib/ipgosconf
  IPQoS configuration utility.
/usr/lib/krb5
  Contains the Kerberos database propagation program and libraries.
/usr/lib/ld
  Contains the map files for the 1d link editor.
/usr/lib/ldap
  Contains LDAP client configuration utilities.
/usr/lib/libp
  Profiled libraries.
/usr/lib/llc2
  Contains logical link control (11c2) driver configuration files.
/usr/lib/locale
  Localization databases.
/usr/lib/lp
  Line printer subsystem databases and back-end executables.
/usr/lib/lu
  Live Upgrade utilities.
/usr/lib/netsvc
  Internet network services.
/usr/lib/nfs
  Auxiliary NFS-related programs and daemons.
/usr/lib/nis
  Contains NIS+ administrative commands.
/usr/lib/pics
  Position Independent Code (PIC) archives needed to rebuild the run-time linker.
/usr/lib/picl
  Platform Information and Control Library.
/usr/lib/pool
  Contains the automated resource pools partitioning daemon (poold) and
  associated libraries.
/usr/lib/power
  Power management daemon, powerd.
/usr/lib/print
  Contains 1p conversion scripts and the in.1pd daemon.
/usr/lib/rcap
  Resource cap enforcement daemon, rcapd.
```

# filesystem(5)

```
/usr/lib/rcm
  Contains the Reconfiguration and Coordination Manager daemon (rcm daemon)
  and RCM scripts.
/usr/lib/refer
  Auxiliary programs for refer(1).
/usr/lib/rmmount
  Removable media mounter shared objects.
/usr/lib/sa
  Scripts and commands for the system activity report package. See sar(1).
/usr/lib/saf
  Auxiliary programs and daemons related to the service access facility.
/usr/lib/sasl
  Simple Authentication and Security Layer (SASL) plug-in modules.
/usr/lib/secure
  Default trusted libraries.
/usr/lib/security
  Solaris security plug-in modules.
/usr/lib/smartcard
  IFD handler libraries.
/usr/lib/smedia
  Removable media device server daemon, rpc.smserverd.
/usr/lib/sparcv9
  SPARC 64-bit, platform-dependent libraries, various databases, commands and
  daemons not invoked directly by a human user. An approved installation location
  for bundled Solaris software. The analogous location for add-on system software or
  for applications is /opt/packagename/lib/sparcv9.
/usr/lib/spell
  Auxiliary programs and databases for spell(1). This directory is only present
  when the Binary Compatibility Package is installed.
/usr/lib/ssh
  Contains the Secure Shell daemon (sshd) and supporting programs.
/usr/lib/subsystem
  Platform-dependent libraries, various databases, commands and daemons that are
  associated with subsystem and that are not invoked directly by a human user. An
  approved installation location for bundled Solaris software. The analogous location
  for add-on system software or for applications is /opt/packagename/lib.
```

#### /usr/lib/subsystem/amd64

x86 64-bit, platform-dependent libraries, various databases, commands and daemons that are associated with subsystem and that are not invoked directly by a human user. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/lib/amd64.

## /usr/lib/subsystem/sparcv9

SPARC 64-bit, platform-dependent libraries, various databases, commands and daemons that are associated with subsystem and that are not invoked directly by a human user. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/lib/sparcv9.

## /usr/subsystem/lib

Platform-dependent libraries, various databases, commands and daemons not invoked directly by a human user. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/lib.

## /usr/subsystem/lib/amd64

x86 64-bit, platform-dependent libraries, various databases, commands and daemons that are associated with *subsystem* and that are not invoked directly by a human user. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/lib/amd64.

## /usr/subsystem/lib/sparcv9

SPARC 64-bit, platform-dependent libraries, various databases, commands and daemons that are associated with subsystem and that are not invoked directly by a human user. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/lib/sparcv9.

#### /usr/lib/sysevent

Contains the system event notification daemon (syseventd) and the syseventd loadable module (SLM) repository.

#### /usr/lib/uucp

Auxiliary programs and daemons for uucp(1C).

#### /usr/lib/vold

Auxiliary vold programs and shared libraries.

# /usr/lib/webconsole

Sun Java web console programs and scripts.

# /usr/lib/zones

Zone administration daemon (zoneamd).

## /usr/local

Not part of the SVR4-based Solaris distribution. The /usr directory is exclusively for software bundled with the Solaris operating system. If needed for storing

## filesystem(5)

Symbolic link to the /var/mail directory. /usr/man Symbolic link to the /usr/share/man directory. /usr/net/servers Entry points for foreign name service requests relayed using the network listener. See listen(1M). /usr/news Symbolic link to the /var/news directory. /usr/oasys Commands and files related to the Form and Menu Language Interpreter (FMLI) execution environment. See face(1). /usr/old Programs that are being phased out. /usr/openwin Installation or mount point for the OpenWindows software. /usr/perl5 Perl 5 programs and documentation /usr/platform Subtree of platform-specific objects which does not need to reside on the root filesystem. It contains a series of directories, one per supported platform. The semantics of the series of directories is equivalent to /platform, except for subdirectories which do not provide utility under one or the other (for example, /platform/include is not needed). /usr/platform/'uname -i'/include Symbolic link to / . . / 'uname -i'/include.Platform-specific system (sys, vm) header files with semantics equivalent to /usr/include. An approved installation location for bundled Solaris software and for add-on system software. /usr/platform/'uname -i'/lib Platform-specific shared objects with semantics equivalent to /usr/lib. An approved installation location for bundled Solaris software and for add-on system software. /usr/platform/'uname -i'/lib/subsystem/amd64 x86 64-bit, platform-specific daemon and shared objects. An approved installation location for bundled Solaris software and for add-on system software. /usr/platform/'uname -i'/sbin Platform-specific system administration utilities with semantics equivalent to /usr/sbin. An approved installation location for bundled Solaris software and for add-on system software.

machine-local add-on software, create the directory /opt/local and make /usr/local a symbolic link to /opt/local. The /opt directory or filesystem is

for storing add-on software to the system.

/usr/preserve

Symbolic link to the /var/preserve directory.

/usr/proc

Directory for the proc tools.

/usr/pub

Symbolic link to /share/lib/pub, which contains files for online man page and character processing.

/usr/sadm

System administration files and directories.

/usr/sadm/bin

Binaries for the Form and Menu Language Interpreter (FMLI) scripts. See fmli(1).

/usr/sadm/install

Executables and scripts for package management.

/usr/sbin

Platform-dependent executables for system administration, expected to be run only by system administrators. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/sbin.

/usr/sbin/install.d

Custom Jumpstart scripts and executables.

/usr/sbin/sparc7 and sparc9

32-bit and 64-bit versions of commands.

/usr/sbin/amd64

64-bit x86versions of commands.

/usr/sbin/subsystem

Platform-dependent executables for system administration, expected to be run only by system administrators, and associated with subsystem. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/sbin.

/usr/subsystem/sbin

Platform-dependent executables for system administration, expected to be run only by system administrators, and associated with subsystem. An approved installation location for bundled Solaris software. The analogous location for add-on system software or for applications is /opt/packagename/sbin.

/usr/sfw

GNU and open source executables, libraries, and documentation.

Platform-independent sharable files. An approved installation location for bundled Solaris software.

/usr/share/aclocal

Open source m4 files.

# filesystem(5)

```
/usr/share/admserv5.1
  iPlanet Console and Administration Server documentation.
/usr/share/applications
  Open source desktop applications files.
/usr/share/audio
  Sample audio files.
/usr/share/ds5
  iPlanet Server documentation.
/usr/share/glib-2.0
  Makefile for glib.
/usr/share/gnome
  GNOME Desktop application registry files.
/usr/share/gtk-2.0
  GNOME 2.0 Desktop demo files.
/usr/share/qtk-doc
  GNOME 2.0 Desktop help files.
/usr/share/icons
  Sun Java Desktop icons.
/usr/share/idl
  Open source Interface Definition Language (IDL) files.
/usr/share/intltool
  XML translation tools.
/usr/share/ipfilter
  Open source IP Filter sample files.
/usr/share/javadoc
  Help files for Message Queue broker and Smart Card applications.
/usr/share/lib
  Platform-independent sharable databases. An approved installation location for
  bundled Solaris software.
/usr/share/lib/dict
  Contains word list for spell(1).
/usr/share/lib/keytables
  Keyboard layout description tables.
/usr/share/lib/mailx
  Help files for mailx(1).
/usr/share/lib/nterm
  nroff(1) terminal tables.
/usr/share/lib/pub
  Character set data files.
```

```
/usr/share/lib/tabset
  Tab setting escape sequences.
/usr/share/lib/terminfo
  Terminal description files for terminfo(4).
/usr/share/lib/tmac
  Macro packages and related files for text processing tools, for example, nroff(1)
  and troff(1).
/usr/share/lib/zoneinfo
  Time zone information.
/usr/share/man
  Platform-independent sharable manual pages. An approved installation location for
  bundled Solaris software. The analogous location for add-on system software or for
  applications is /opt/packagename/man.
/usr/share/omf
  GNOME Scrollkeeper database files.
/usr/share/pixmaps
  Sun Java graphics.
/usr/share/scrollkeeper
  GNOME Scrollkeeper templates and xslt files.
/usr/share/sgml
  Open source SGML files.
/usr/share/sounds
  Sound files.
/usr/share/src
  Source code for kernel, utilities, and libraries.
/usr/share/themes
  GNOME 2.0 Desktop themes.
/usr/share/webconsole
  Sun Web Console status files.
/usr/share/xml
  GNOME Scrollkeeper DTD files.
/usr/snadm
  Files related to system and network administration.
/usr/spool
  Symbolic link to the /var/spool directory.
/usr/src
  Symbolic link to the /usr/share/src directory.
/usr/tmp
  Symbolic link to the /var/tmp directory.
```

# filesystem(5)

/usr/ucbinclude
Berkeley compatibility package binaries.

/usr/ucbinclude
Berkeley compatibility package headers.

/usr/ucblib
Berkeley compatibility package libraries.

/usr/vmsys
Commands and files related to the Framed Access Command Environment (FACE) programs. See face(1).

/usr/xpg4
Directory for POSIX-compliant utilities.

/usr/xpg6
Directory for newer versions of POSIX-compliant utilities.

#### NAME

fnmatch – file name pattern matching

## **DESCRIPTION**

The pattern matching notation described below is used to specify patterns for matching strings in the shell. Historically, pattern matching notation is related to, but slightly different from, the regular expression notation. For this reason, the description of the rules for this pattern matching notation is based on the description of regular expression notation described on the regex(5) manual page.

# Patterns Matching a Single Character

The following *patterns matching a single character* match a single character: *ordinary characters, special pattern characters* and *pattern bracket expressions*. The pattern bracket expression will also match a single collating element.

An ordinary character is a pattern that matches itself. It can be any character in the supported character set except for NUL, those special shell characters that require quoting, and the following three special pattern characters. Matching is based on the bit pattern used for encoding the character, not on the graphic representation of the character. If any character (ordinary, shell special, or pattern special) is quoted, that pattern will match the character itself. The shell special characters always require quoting.

When unquoted and outside a bracket expression, the following three characters will have special meaning in the specification of patterns:

- ? A question-mark is a pattern that will match any character.
- \* An asterisk is a pattern that will match multiple characters, as described in Patterns Matching Multiple Characters, below.
- [ The open bracket will introduce a pattern bracket expression.

The description of basic regular expression bracket expressions on the  $\mathtt{regex}(5)$  manual page also applies to the pattern bracket expression, except that the exclamation-mark character (!) replaces the circumflex character (^) in its role in a non-matching list in the regular expression notation. A bracket expression starting with an unquoted circumflex character produces unspecified results.

The restriction on a circumflex in a bracket expression is to allow implementations that support pattern matching using the circumflex as the negation character in addition to the exclamation-mark. A portable application must use something like  $\lceil ^! \rceil$  to match either character.

When pattern matching is used where shell quote removal is not performed (such as in the argument to the find -name primary when find is being called using one of the exec functions, or in the *pattern* argument to the fnmatch(3C) function, special characters can be escaped to remove their special meaning by preceding them with a backslash character. This escaping backslash will be discarded. The sequence \\ represents one literal backslash. All of the requirements and effects of quoting on ordinary, shell special and special pattern characters will apply to escaping in this context.

## fnmatch(5)

Both quoting and escaping are described here because pattern matching must work in three separate circumstances:

• Calling directly upon the shell, such as in pathname expansion or in a case statement. All of the following will match the string or file abc:

abc	"abc"	a"b"c	a\bc	a[b]c
a ["b"] c The following	a[\b]c	a["\b"]c	a?c	a*c
"a?c"		a\*c	a\[b]	C

- Calling a utility or function without going through a shell, as described for find(1) and the function fnmatch(3C)
- Calling utilities such as find, cpio, tar or pax through the shell command line. In this case, shell quote removal is performed before the utility sees the argument. For example, in:

find /bin -name e\c[\h]o -print after quote removal, the backslashes are presented to find and it treats them as escape characters. Both precede ordinary characters, so the c and h represent themselves and echo would be found on many historical systems (that have it in /bin). To find a file name that contained shell special characters or pattern characters, both quoting and escaping are required, such as:

```
pax -r . . . "*a\ (\?"to extract a filename ending with a (?.
```

Conforming applications are required to quote or escape the shell special characters (sometimes called metacharacters). If used without this protection, syntax errors can result or implementation extensions can be triggered. For example, the KornShell supports a series of extensions based on parentheses in patterns; see ksh(1)

## Patterns Matching Multiple Characters

The following rules are used to construct *patterns matching multiple characters* from *patterns matching a single character*:

- The asterisk (\*) is a pattern that will match any string, including the null string.
- The concatenation of *patterns matching a single character* is a valid pattern that will match the concatenation of the single characters or collating elements matched by each of the concatenated patterns.
- The concatenation of one or more *patterns matching a single character* with one or more asterisks is a valid pattern. In such patterns, each asterisk will match a string of zero or more characters, matching the greatest possible number of characters that still allows the remainder of the pattern to match the string.

Since each asterisk matches zero or more occurrences, the patterns a\*b and a\*\*b have identical functionality.

## Examples:

a[bc]	matches the strings ab and ac.
a*d	matches the strings ad, abd and abcd, but not the string abc.
a*d*	matches the strings ad, abcd, abcdef, aaaad and adddd.
*a*d	matches the strings ad, abcd, efabcd, aaaad and adddd.

## Patterns Used for Filename **Expansion**

The rules described so far in Patterns Matching Multiple Characters and Patterns Matching a Single Character are qualified by the following rules that apply when pattern matching notation is used for filename expansion.

- 1. The slash character in a pathname must be explicitly matched by using one or more slashes in the pattern; it cannot be matched by the asterisk or question-mark special characters or by a bracket expression. Slashes in the pattern are identified before bracket expressions; thus, a slash cannot be included in a pattern bracket expression used for filename expansion. For example, the pattern a [b/c] d will not match such pathnames as abd or a/d. It will only match a pathname of literally a [b/c]d.
- 2. If a filename begins with a period (.), the period must be explicitly matched by using a period as the first character of the pattern or immediately following a slash character. The leading period will not be matched by:
  - the asterisk or question-mark special characters
  - a bracket expression containing a non-matching list, such as:

[!a] a range expression, such as:

[%-0] or a character class expression, such as:

[[:punct:]] It is unspecified whether an explicit period in a bracket expression matching list, such as:

[.abc] can match a leading period in a filename.

3. Specified patterns are matched against existing filenames and pathnames, as appropriate. Each component that contains a pattern character requires read permission in the directory containing that component. Any component, except the last, that does not contain a pattern character requires search permission. For example, given the pattern:

/foo/bar/x\*/bamsearch permission is needed for directories / and foo, search and read permissions are needed for directory bar, and search permission is needed for each x\* directory. If the pattern matches any existing filenames or pathnames, the pattern will be replaced with those filenames and pathnames, sorted according to the collating sequence in effect in the current locale. If the

fnmatch(5)

pattern contains an invalid bracket expression or does not match any existing  $file names \ or \ pathnames, \ the \ pattern \ string \ is \ left \ unchanged.$ 

SEE ALSO find(1), ksh(1), fnmatch(3C), regex(5)

#### NAME

formats – file format notation

# **DESCRIPTION**

Utility descriptions use a syntax to describe the data organization within files—stdin, stdout, stderr, input files, and output files—when that organization is not otherwise obvious. The syntax is similar to that used by the printf(3C) function. When used for stdin or input file descriptions, this syntax describes the format that could have been used to write the text to be read, not a format that could be used by the scanf(3C) function to read the input file.

#### **Format**

The description of an individual record is as follows:

```
"<format>", [<arg1>, <arg2>, . . ., <argn>]
```

The format is a character string that contains three types of objects defined below:

*characters* Characters that are not *escape sequences* or *conversion specifications*, as described below, are copied to the

output.

escape sequences Represent non-graphic characters.

conversion specifications Specifies the output format of each argument. (See

below.)

The following characters have the following special meaning in the format string:

" (An empty character position.) One or more blank

characters.

\ Exactly one space character.

The notation for spaces allows some flexibility for application output. Note that an empty character position in format represents one or more blank characters on the output (not *white space*, which can include newline characters). Therefore, another utility that reads that output as its input must be prepared to parse the data using scanf(3C), awk(1), and so forth. The character is used when exactly one space character is output.

## **Escape Sequences**

The following table lists escape sequences and associated actions on display devices capable of the action.

Sequence	Character	Terminal Action
\\	backslash	None.
\a	alert	Attempts to alert the user through audible or visible notification.
\b	backspace	Moves the printing position to one column before the current position, unless the current position is the start of a line.

# formats(5)

Sequence	Character	Terminal Action
\f	form-feed	Moves the printing position to the initial printing position of the next logical page.
\n	newline	Moves the printing position to the start of the next line.
\r	carriage-return	Moves the printing position to the start of the current line.
\t	tab	Moves the printing position to the next tab position on the current line. If there are no more tab positions left on the line, the behavior is undefined.
\v	vertical-tab	Moves the printing position to the start of the next vertical tab position. If there are no more vertical tab positions left on the page, the behavior is undefined.

# **Conversion Specifications**

Each conversion specification is introduced by the percent-sign character (%). After the character %, the following appear in sequence:

flags	Zero or more <i>flags</i> , in any order, that modify the meaning of the conversion specification.
field width	An optional string of decimal digits to specify a minimum <i>field width</i> . For an output field, if the converted value has fewer bytes than the field width, it is padded on the left (or right, if the left-adjustment flag (–), described below, has been given to the field width).
precision	Gives the minimum number of digits to appear for the d, o, i, u, x or X conversions (the field is padded with leading zeros), the number of digits to appear after the radix character for the e and f conversions, the maximum number of significant digits for the g conversion; or the maximum number of bytes to be written from a string in s conversion. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero.
conversion characters	A conversion character (see below) that indicates the type of conversion to be applied.

# flags

The *flags* and their meanings are:

- The result of the conversion is left-justified within the field.
- + The result of a signed conversion always begins with a sign (+ or –).

<space>

If the first character of a signed conversion is not a sign, a space character is prefixed to the result. This means that if the space character and + flags both appear, the space character flag is ignored.

#

The value is to be converted to an alternative form. For c, d, i, u, and s conversions, the behaviour is undefined. For o conversion, it increases the precision to force the first digit of the result to be a zero. For x or X conversion, a non-zero result has 0x or 0X prefixed to it, respectively. For e, E, f, g, and G conversions, the result always contains a radix character, even if no digits follow the radix character. For g and G conversions, trailing zeros are not removed from the result as they usually are.

0

For d, i, o, u, x, X, e, E, f, g, and G conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the 0 and – flags both appear, the 0 flag is ignored. For d, i, o, u, x and X conversions, if a precision is specified, the 0 flag is ignored. For other conversions, the behaviour is undefined.

# **Conversion Characters**

Each conversion character results in fetching zero or more arguments. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are ignored.

The conversion characters and their meanings are:

d,i,o,u,x,X

The integer argument is written as signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X). The d and i specifiers convert to signed decimal in the style [-] *dddd*. The x conversion uses the numbers and letters 0123456789abcdef and the X conversion uses the numbers and letters 0123456789ABCDEF. The *precision* component of the argument specifies the minimum number of digits to appear. If the value being converted can be represented in fewer digits than the specified minimum, it is expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of 0 is no characters. If both the field width and precision are omitted, the implementation may precede, follow or precede and follow numeric arguments of types d, i and u with blank characters; arguments of type o (octal) may be preceded with leading zeros.

The treatment of integers and spaces is different from the printf(3C) function in that they can be surrounded with blank characters. This was done so that, given a format such as:

"%d\n", <foo>

the implementation could use a printf() call such as:

## formats(5)

printf("%6d\n", foo); and still conform. This notation is thus somewhat like scanf () in addition to printf(). The floating point number argument is written in decimal notation in the style [-] *ddd.ddd*, where the number of digits after the radix character (shown here as a decimal point) is equal to the precision specification. The LC NUMERIC locale category determines the radix character to use in this format. If the precision is omitted from the argument, six digits are written after the radix character; if the precision is explicitly 0, no radix character appears. e,EThe floating point number argument is written in the style [-] d.ddde±dd (the symbol ± indicates either a plus or minus sign), where there is one digit before the radix character (shown here as a decimal point) and the number of digits after it is equal to the precision. The LC NUMERIC locale category determines the radix character to use in this format. When the precision is missing, six digits are written after the radix character; if the precision is 0, no radix character appears. The E conversion character produces a number with E instead of e introducing the exponent. The exponent always contains at least two digits. However, if the value to be written requires an exponent greater than two digits, additional exponent digits are written as necessary. The floating point number argument is written in style f or e (or in g,G style E in the case of a G conversion character), with the precision specifying the number of significant digits. The style used depends on the value converted: style g is used only if the exponent resulting from the conversion is less than –4 or greater than or equal to the precision. Trailing zeros are removed from the result. A radix character appears only if it is followed by a digit. The integer argument is converted to an unsigned char and the С resulting byte is written. The argument is taken to be a string and bytes from the string are Swritten until the end of the string or the number of bytes indicated by the *precision* specification of the argument is reached. If the precision is omitted from the argument, it is taken to be infinite, so all bytes up to the end of the string are written. % Write a % character; no argument is converted.

In no case does a non-existent or insufficient *field width* cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. The term *field width* should not be confused with the term *precision* used in the description of %s.

One difference from the C function printf() is that the l and h conversion characters are not used. There is no differentiation between decimal values for type int, type long, or type short. The specifications %d or %i should be interpreted as an arbitrary length sequence of digits. Also, no distinction is made between single precision and double precision numbers (float or double in C). These are simply referred to as floating point numbers.

Many of the output descriptions use the term line, such as:

"%s", <input line>

Since the definition of line includes the trailing newline character already, there is no need to include a \n in the format; a double newline character would otherwise result.

# **EXAMPLES**

**EXAMPLE 1** To represent the output of a program that prints a date and time in the form Sunday, July 3, 10:02, where <weekday> and <month> are strings:

 $"\$s,/\$s/\$d,/\$d:\$.2d\n",<\!\!\mathit{weekday},<\!\!\mathit{month}>,<\!\!\mathit{day}>,<\!\!\mathit{hour}>,<\!\!\mathit{min}>$ 

**EXAMPLE 2** To show pi written to 5 decimal places:

"pi/\=/\%.5f\n",  $< value \ of \ pi >$ 

**EXAMPLE 3** To show an input file format consisting of five colon-separated fields:

"%s:%s:%s:%s:%s\n", <arg1>, <arg2>, <arg3>, <arg4>, <arg5>

## **SEE ALSO**

awk(1), printf(1), printf(3C), scanf(3C)

## fsattr(5)

#### NAME |

fsattr – extended file attributes

## **DESCRIPTION**

Attributes are logically supported as files within the file system. The file system is therefore augmented with an orthogonal name space of file attributes. Any file (including attribute files) can have an arbitrarily deep attribute tree associated with it. Attribute values are accessed by file descriptors obtained through a special attribute interface. This logical view of "attributes as files" allows the leveraging of existing file system interface functionality to support the construction, deletion, and manipulation of attributes.

The special files "." and ".." retain their accustomed semantics within the attribute hierarchy. The "." attribute file refers to the current directory and the ".." attribute file refers to the parent directory. The unnamed directory at the head of each attribute tree is considered the "child" of the file it is associated with and the ".." file refers to the associated file. For any non-directory file with attributes, the ".." entry in the unnamed directory refers to a file that is not a directory.

Conceptually, the attribute model is fully general. Extended attributes can be any type of file (doors, links, directories, and so forth) and can even have their own attributes (fully recursive). As a result, the attributes associated with a file could be an arbitrarily deep directory hierarchy where each attribute could have an equally complex attribute tree associated with it. Not all implementations are able to, or want to, support the full model. Implementation are therefore permitted to reject operations that are not supported. For example, the implementation for the UFS file system allows only regular files as attributes (for example, no sub-directories) and rejects attempts to place attributes on attributes.

The following list details the operations that are rejected in the current implementation:

link Any attempt to create links between attribute and

non-attribute space is rejected to prevent

security-related or otherwise sensitive attributes from being exposed, and therefore manipulable, as regular

files.

rename Any attempt to rename between attribute and

non-attribute space is rejected to prevent an already

linked file from being renamed and thereby circumventing the link restriction above.

mkdir, symlink, mknod Any attempt to create a "non-regular" file in attribute

space is rejected to reduce the functionality, and

therefore exposure and risk, of the initial

implementation.

The entire available name space has been allocated to "general use" to bring the implementation in line with the NFSv4 draft standard [NFSv4]. That standard defines "named attributes" (equivalent to Solaris Extended Attributes) with no naming restrictions. All Sun applications making use of opaque extended attributes will use the prefix "SUNW".

## Shell-level API

The command interface for extended attributes is the set of applications provided by Solaris for the manipulation of attributes from the command line. This interface consists of a set of existing utilities that have been extended to be "attribute-aware", plus the runat utility designed to "expose" the extended attribute space so that extended attributes can be manipulated as regular files.

The -@ option enable utilities to manipulate extended attributes. As a rule, this option enables the utility to enter into attribute space when the utility is performing a recursive traversal of file system space. This is a fully recursive concept. If the underlying file system supports recursive attributes and directory structures, the -@ option opens these spaces to the file tree-walking algorithms.

The following utilities accommodate extended attributes (see the individual manual pages for details):

ср	By default, cp ignores attributes and copies only file data. This is intended to maintain the semantics implied by cp currently, where attributes (such as owner and mode) are not copied unless the -p option is specified. With the -@ (or -p) option, cp attempts to copy all attributes along with the file data.
cpio	The -@ option informs cpio to archive attributes, but by default cpio ignores extended attributes. See Extended Archive Formats below for a description of the new archive records.
du	File sizes computed include the space allocated for any extended attributes present.
find	By default, find ignores attributes. The -xattr expression provides support for searches involving attribute space. It returns true if extended attributes are present on the current file.
fsck	The fsck utility manages extended attribute data on the disk. A file system with extended attributes can be mounted on versions of Solaris that are not attribute-aware (versions prior to Solaris 9), but the attributes will not be accessible and fsck will strip them from the files and place them in lost+found. Once the attributes have been stripped the file system is completely stable on Solaris versions that are not attribute-aware, but would now be

considered corrupted on attribute-aware versions of Solaris. The attribute-aware fsck utility should be run to stabilize the file system before using it in an attribute-aware environment.

# fsattr(5)

fsdb	This fsdb utility is able to find the inode for the "hidden" extended attribute directory.
ls	The ls -@ command displays an "@" following the mode information when extended attributes are present. More precisely, the output line for a given file contains an "@" character following the mode characters if the pathconf(2) variable XATTR_EXISTS is set to true. See the pathconf () section below. The -@ option uses the same general output format as the -l option.
mv	When a file is moved, all attributes are carried along with the file rename. When a file is moved across a file system boundary, the copy command invoked is similar to the cp -p variant described above and extended attributes are "moved". If the extended file attributes cannot be replicated, the move operation fails and the source file is not removed.
pax	The -@ option informs pax to archive attributes, but by default pax ignores extended attributes. The pax(1) utility is a generic replacement for both tar(1) and cpio(1) and is able to produce either output format in its archive. See Extended Archive Formats below for a description of the new archive records.
tar	In the default case, tar does not attempt to place attributes in the archive. If the -@ option is specified, however, tar traverses into the attribute space of all files being placed in the archive and attempts to add the attributes to the archive. A new record type has been introduced for extended attribute entries in tar archive files (the same is true for pax and cpio archives) similar to the way ACLs records were defined. See Extended Archive Formats below for a description of the new archive records.

There is a class of utilities (chmod, chown, chgrp) that one might expect to be modified in a manner similar to those listed above. For example, one might expect that performing chmod on a file would not only affect the file itself but would also affect at least the extended attribute directory if not any existing extended attribute files. This is not the case. The model chosen for extended attributes implies that the attribute directory and the attributes themselves are all file objects in their own right, and can therefore have independent file status attributes associated with them (a given implementation cannot support this, for example, for intrinsic attributes). The relationship is left undefined and a fine-grained control mechanism (runat(1)) is provided to allow manipulation of extended attribute status attributes as necessary.

The runat utility has the following syntax:

runat filename [command]

The runat utility executes the supplied command in the context of the "attribute space" associated with the indicated file. If no command argument is supplied, a shell is invoked. See runat(1) for details.

# Application-level API

The primary interface required to access extended attributes at the programmatic level is the openat(2) function. Once a file descriptor has been obtained for an attribute file by an openat() call, all normal file system semantics apply. There is no attempt to place special semantics on read(2), write(2), ftruncate(3C), or other functions when applied to attribute file descriptors relative to "normal" file descriptors.

The set of existing attributes can be browsed by calling openat () with "." as the file name and the O\_XATTR flag set, resulting in a file descriptor for the attribute directory. The list of attributes is obtained by calls to getdents(2) on the returned file descriptor. If the target file did not previously have any attributes associated with it, an empty top-level attribute directory is created for the file and subsequent getdents() calls will return only "." and "..". While the owner of the parent file owns the extended attribute directory, it is not charged against its quota if the directory is empty. Attribute files themselves, however, are charged against the user quota as any other regular file.

Additional system calls have been provided as convenience functions. These include the fchownat(2), fstatat(2), futimesat(2), renameat(2), unlinkat(2). These new functions, along with openat(), provide a mechanism to access files relative to an arbitrary point in the file system, rather than only the current working directory. This mechanism is particularly useful in situations when a file descriptor is available with no path. The openat() function, in particular, can be used in many contexts where chdir() or fchdir() is currently required. See chdir(2).

## Open a file relative to a file descriptor

```
int openat (int fd, const char *path, int oflag [, mode t mode])
```

The openat(2) function behaves exactly as open(2) except when given a relative path. Where open() resolves a relative path from the current working directory, openat() resolves the path based on the vnode indicated by the supplied file descriptor. When oflag is O\_XATTR, openat() interprets the path argument as an extended attribute reference. The following code fragment uses openat() to examine the attributes of some already opened file:

```
dfd = openat(fd, ".", O_RDONLY|O_XATTR);
(void)getdents(dfd, buf, nbytes);
```

If openat () is passed the special value AT\_FDCWD as its first (fd) argument, its behavior is identical to open() and the relative path arguments are interpreted relative to the current working directory. If the O\_XATTR flag is provided to openat() or to open(), the supplied path is interpreted as a reference to an extended attribute on the current working directory.

## Unlink a file relative to a directory file descriptor

```
int unlinkat (int dirfd, const char *pathflag, int flagflag)
```

The unlinkat(2) function deletes an entry from a directory. The *path* argument indicates the name of the entry to remove. If *path* an absolute path, the *dirfd* argument is ignored. If it is a relative path, it is interpreted relative to the directory indicated by the *dirfd* argument. If *dirfd* does not refer to a valid directory, the function returns ENOTDIR. If the special value AT\_FDCWD is specified for *dirfd*, a relative path argument is resolved relative to the current working directory. If the *flag* argument is 0, all other semantics of this function are equivalent to unlink(2). If *flag* is set to AT\_REMOVEDIR, all other semantics of this function are equivalent to rmdir(2).

## Rename a file relative to directories

```
int renameat (int fromfd, const char *old, int tofd, const char *new)
```

The renameat(2) function renames an entry in a directory, possibly moving the entry into a different directory. The *old* argument indicates the name of the entry to rename. If this argument is a relative path, it is interpreted relative to the directory indicated by the *fd* argument. If it is an absolute path, the *fromfd* argument is ignored. The *new* argument indicates the new name for the entry. If this argument is a relative path, it is interpreted relative to the directory indicated by the *tofd* argument. If it is an absolute path, the *tofd* argument is ignored.

In the relative path cases, if the directory file descriptor arguments do not refer to a valid directory, the function returns ENOTDIR. All other semantics of this function are equivalent to rename(2).

If a special value AT\_FDCWD is specified for either the *fromfd* or *tofd* arguments, their associated path arguments (*old* and *new*) are interpreted relative to the current working directory if they are not specified as absolute paths. Any attempt to use renameat () to move a file that is not an extended attribute into an extended attribute directory (so that it becomes an extended attribute) will fail. The same is true for an attempt to move a file that is an extended attribute into a directory that is not an extended attribute directory.

## Obtain information about a file

```
int fstatat (int fd, const char *path, struct stat* buf, int flag)
```

The fstatat(2) function obtains information about a file. If the path argument is relative, it is resolved relative to the fd argument file descriptor, otherwise the fd argument is ignored. If the fd argument is a special value  $AT_FDCWD$  the path is resolved relative to the current working directory. If the path argument is a null pointer, the function returns information about the file referenced by the fd argument. In all other relative path cases, if the fd argument does not refer to a valid directory, the function returns ENOTDIR. If the flag argument is set to  $AT_SYMLINK_NOFOLLOW$ , the function will not automatically traverse a symbolic link at the position of the path. The fstatat() function is a multi-purpose function that can be used in place of stat(), lstat(), or fstat(). See stat(2).

The function call stat(path, buf) is identical to  $fstatat(AT_FDCWD, path, buf, 0)$ .

The function call lstat (path, buf) is identical to fstatat (AT FDCWD, path, buf, AT SYMLINK NOFOLLOW)

The function call fstat (fildes, buf) is identical to fstatat (fildes, NULL, buf, 0).

## Set owner and group ID

```
int fchownat (int fd, const char *path, uid t owner, gid t group, int flag)
```

The fchownat(2) function sets the owner ID and group ID for a file. If the path argument is relative, it is resolved relative to the fd argument file descriptor, otherwise the fd argument is ignored. If the fd argument is a special value AT FDCWD the path is resolved relative to the current working directory. If the path argument is a null pointer, the function sets the owner and group ID of the file referenced by the fd argument. In all other relative path cases, if the fd argument does not refer to a valid directory, the function returns ENOTDIR. If the flag argument is set to AT SYMLINK NOFOLLOW, the function will not automatically traverse a symbolic link at the position of the path. The fchownat () function is a multi-purpose function that can be used in place of chown(), lchown(), or fchown(). See chown(2).

The function call chown (path, owner, group) is equivalent to fchownat (AT FDCWD, path, owner, group, 0).

The function call 1chown (path, owner, group) is equivalent to fchownat (AT FDCWD, path, owner, group, AT SYMLINK NOFOLLOW).

## Set file access and modification times

```
int futimesat (int fd, const char *path, const struct timeval times[2])
```

The futimesat(2) function sets the access and modification times for a file. If the path argument is relative, it is resolved relative to the fd argument file descriptor; otherwise the fd argument is ignored. If the fd argument is the special value AT FDCWD, the path is resolved relative to the current working directory. If the path argument is a null pointer, the function sets the access and modification times of the file referenced by the fd argument. In all other relative path cases, if the fd argument does not refer to a valid directory, the function returns ENOTDIR. The futimesat () function can be used in place of utimes(2).

The function call utimes (path, times) is equivalent to futimesat (AT FDCWD, path, times).

## New pathconf() functionality

```
long int pathconf(const char *path, int name)
```

Two variables have been added to pathconf(2) to provide enhanced support for extended attribute manipulation. The XATTR ENABLED variable allows an application to determine if attribute support is currently enabled for the file in question. The XATTR EXISTS variable allows an application to determine whether there are any extended attributes associated with the supplied path.

## Open/Create an attribute file

```
int attropen (const char *path, const char *attrpath, int oflag [, mode_t mode])
```

The attropen(3C) function returns a file descriptor for the named attribute, attrpath, of the file indicated by path. The oflag and mode arguments are identical to the open(2) arguments and are applied to the open operation on the attribute file (for example, using the O\_CREAT flag creates a new attribute). Once opened, all normal file system operations can be used on the attribute file descriptor. The attropen() function is a convenience function and is equivalent to the following sequence of operations:

```
fd = open (path, O_RDONLY);
attrfd = openat(fd, attrpath, oflag|O_XATTR, mode);
close(fd);
```

The set of existing attributes can be browsed by calling attropen() with "." as the attribute name. The list of attributes is obtained by calling getdents(2) (or fdopendir(3C) followed by readdir(3C), see below) on the returned file descriptor.

# Convert an open file descriptor for a directory into a directory descriptor

```
DIR * fdopendir (const int fd)
```

The fdopendir(3C) function promotes a file descriptor for a directory to a directory pointer suitable for use with the readdir(3C) function. The originating file descriptor should not be used again following the call to fdopendir(). The directory pointer should be closed with a call to closedir(3C). If the provided file descriptor does not reference a directory, the function returns ENOTDIR. This function is useful in circumstances where the only available handle on a directory is a file descriptor. See attropen(3C) and openat(2).

# Using the API

The following examples demonstrate how the API might be used to perform basic operations on extended attributes:

#### **EXAMPLE 1** List extended attributes on a file.

```
attrdirfd = attropen("test", ".", O_RDONLY);
dirp = fdopendir(attrdirfd);
while (dp = readdir(dirp)) {
    ...
```

# **EXAMPLE 2** Open an extended attribute.

```
attrfd = attropen("test", dp->d_name, O_RDONLY);
or
attrfd = openat(attrdirfd, dp->d_name, O_RDONLY);
```

#### **EXAMPLE 3** Read from an extended attribute.

```
while (read(attrfd, buf, 512) > 0) {
```

## **EXAMPLE 4** Create an extended attribute.

```
newfd = attropen("test", "attr", O CREAT O RDWR);
or
newfd = openat(attrdirfd, "attr", O_CREAT|O_RDWR);
```

## **EXAMPLE 5** Write to an extended attribute.

```
count = write(newfd, buf, length);
```

## **EXAMPLE 6** Delete an extended attribute.

```
error = unlinkat(attrdirfd, "attr");
```

Applications intending to access the interfaces defined here as well as the POSIX and X/Open specification-conforming interfaces should define the macro ATFILE SOURCE to be 1 and set whichever feature test macros are appropriate to obtain the desired environment. See standards(5).

## **Extended Archive Formats**

As noted above in the description of command utilities modified to provide support for extended attributes, the archive formats for tar(1) and cpio(1) have been extended to provide support for archiving extended attributes. This section describes the specifics of the archive format extensions.

#### Extended tar format

The tar archive is made up of a series of 512 byte blocks. Each archived file is represented by a header block and zero or more data blocks containing the file contents. The header block is structured as shown in the following table.

Field Name	Length (in Octets)	Description
Name	100	File name string
Mode	8	12 file mode bits
Uid	8	User ID of file owner
Gid	8	Group ID of file owner
Size	12	Size of file
Mtime	12	File modification time

# fsattr(5)

Field Name	Length (in Octets)	Description
Chksum	8	File contents checksum
Typeflag	1	File type flag
Linkname	100	Link target name if file linked
Magic	6	"ustar"
Version	2	"00"
Uname	32	User name of file owner
Gname	32	Group name of file owner
Devmajor	8	Major device ID if special file
Devminor	8	Minor device ID if special file
Prefix	155	Path prefix string for file

The extended attribute project extends the above header format by defining a new header type (for the Typeflag field). The type 'E' is defined to be used for all extended attribute files. Attribute files are stored in the tar archive as a sequence of two <header , data> pairs. The first file contains the data necessary to locate and name the extended attribute in the file system. The second file contains the actual attribute file data. Both files use an 'E' type header. The prefix and name fields in extended attribute headers are ignored, though they should be set to meaningful values for the benefit of archivers that do not process these headers. Solaris archivers set the prefix field to "/dev/null" to prevent archivers that do not understand the type 'E' header from trying to restore extended attribute files in inappropriate places.

## Extended cpio format

The cpio archive format is octet-oriented rather than block-oriented. Each file entry in the archive includes a header that describes the file, followed by the file name, followed by the contents of the file. These data are arranged as described in the following table.

Field Name	Length (in Octets)	Description
c_magic	6	70707
c_dev	6	First half of unique file ID
c_ino	6	Second half of unique file ID
c_mode	6	File mode bits
c_uid	6	User ID of file owner
c_gid	6	Group ID of file owner

Field Name	Length (in Octets)	Description
c_nlink	6	Number of links referencing file
c_rdev	6	Information for special files
c_mtime	11	Modification time of file
c_namesize	6	Length of file pathname
c_filesize	11	Length of file content
c_name	c_namesize	File pathname
c_filedata	c_filesize	File content

The basic archive file structure is not changed for extended attributes. The file type bits stored in the <code>c\_mode</code> field for an attribute file are set to <code>0xB000</code>. As with the <code>tar</code> archive format, extended attributes are stored in <code>cpio</code> archives as two consecutive file entries. The first file describes the location/name for the extended attribute. The second file contains the actual attribute file content. The <code>c\_name</code> field in extended attribute headers is ignored, though it should be set to a meaningful value for the benefit of archivers that do not process these headers. Solaris archivers start the pathname with "<code>/dev/null/"</code> to prevent archivers that do not understand the type 'E' header from trying to restore extended attribute files in inappropriate places.

#### Attribute identification data format

Both the tar and cpio archive formats can contain the special files described above, always paired with the extended attribute data record, for identifying the precise location of the extended attribute. These special data files are necessary because there is no simple naming mechanism for extended attribute files. Extended attributes are not visible in the file system name space. The extended attribute name space must be "tunneled into" using the openat () function. The attribute identification data must support not only the flat naming structure for extended attributes, but also the possibility of future extensions allowing for attribute directory hierarchies and recursive attributes. The data file is therefore composed of a sequence of records. It begins with a fixed length header describing the content. The following table describes the format of this data file.

Field Name	Length (in Octets)	Description
h_version	7	Name file version
h_size	10	Length of data file
h_component_len	10	Total length of all path segments
h_link_comp_len	10	Total length of all link segments

# fsattr(5)

Field Name	Length (in Octets)	Description
path	h_component_len	Complex path
link_path	h_link_comp_len	Complex link path

As demonstrated above, the header is followed by a record describing the "path" to the attribute file. This path is composed of two or more path segments separated by a null character. Each segment describes a path rooted at the hidden extended attribute directory of the leaf file of the previous segment, making it possible to name attributes on attributes. The first segment is always the path to the parent file that roots the entire sequence in the normal name space. The following table describes the format of each segment.

Field Name	Length (in Octets)	Description
h_namesz	7	Length of segment path
h_typeflag	1	Actual file type of attribute file
h_names	h_namesz	Parent path + segment path

If the attribute file is linked to another file, the path record is followed by a second record describing the location of the referencing file. The structure of this record is identical to the record described above.

#### NAME

gss\_auth\_rules - overview of GSS authorization

# **DESCRIPTION**

The establishment of the veracity of a user's credentials requires both authentication (Is this an authentic user?) and authorization (Is this authentic user, in fact, authorized?).

When a user makes use of Generic Security Services (GSS) versions of the ftp or ssh clients to connect to a server, the user is not necessarily authorized, even if his claimed GSS identity is authenticated, Authentication merely establishes that the user is who he says he is to the GSS mechanism's authentication system. Authorization is then required: it determines whether the GSS identity is permitted to access the specified Solaris user account.

The GSS authorization rules are as follows:

- If the mechanism of the connection has a set of authorization rules, then use those rules. For example, if the mechanism is Kerberos, then use the krb5\_auth\_rules(5), so that authorization is consistent between raw Kerberos applications and GSS/Kerberos applications.
- If the mechanism of the connection does not have a set of authorization rules, then authorization is successful if the remote user's gssname matches the local user's gssname exactly, as compared by gss\_compare\_name(3GSS).

## **FILES**

/etc/passwd

System account file. This information may also be in a directory service. See passwd(4).

## **ATTRIBUTES**

See attributes(5) for a description of the following attributes:

iconv\_1250(5)

**NAME** 

iconv\_1250 - code set conversion tables for MS 1250 (Windows Latin 2)

**DESCRIPTION** 

The following code set conversions are supported:

Code Set Conversions Supported					
Code Symbol Target Code Symbol Target Output					
MS 1250	win2	ISO 8859-2	iso2	ISO Latin 2	
MS 1250	win2	MS 852	dos2	MS-DOS Latin 2	
MS 1250	win2	Mazovia	maz	Mazovia	
MS 1250	win2	DHN	dhn	Dom Handlowy Nauki	

**CONVERSIONS** 

The conversions are performed according to the following tables. All values in the tables are given in octal.

**MS 1250 to ISO** 8859-2 For the conversion of MS 1250 to ISO 8859-2, all characters not in the following table are mapped unchanged.

Conversions Performed				
MS 1250	ISO 8859-2	MS 1250	ISO 8859-2

NAME

iconv\_1251 - code set conversion tables for MS 1251 (Windows Cyrillic)

**DESCRIPTION** 

The following code set conversions are supported:

Code Set Conversions Supported						
Code	Symbol	Target Code	Symbol	Target Output		
MS 1251	win5	ISO 8859-5	iso5	ISO 8859-5 Cyrillic		
MS 1251	win5	KOI8-R	koi8	KOI8-R		
MS 1251	win5	PC Cyrillic	alt	Alternative PC Cyrillic		
MS 1251	win5	Mac Cyrillic	mac	Macintosh Cyrillic		

**CONVERSIONS** 

The conversions are performed according to the following tables. All values in the tables are given in octal.

MS 1251 to ISO 8859-5

For the conversion of MS 1251 to ISO 8859-5, all characters not in the following table are mapped unchanged.

Conversions Performed					
MS 1251	ISO 8859-5	MS 1251	ISO 8859-5		
24	4	310	270

**NAME** 

iconv\_646 - code set conversion tables for ISO 646

**DESCRIPTION** 

The following code set conversions are supported:

	Code Set Conversions Supported				
Code	Symbol	Target Code	Symbol	Target Output	
ISO 646	646	ISO 8859-1	8859	US ASCII	
ISO 646de	646de	ISO 8859-1	8859	German	
ISO 646da	646da	ISO 8859-1	8859	Danish	
ISO 646en	646en	ISO 8859-1	8859	English ASCII	
ISO 646es	646es	ISO 8859-1	8859	Spanish	
ISO 646fr	646fr	ISO 8859-1	8859	French	
ISO 646it	646it	ISO 8859-1	8859	Italian	
ISO 646sv	646sv	ISO 8859-1	8859	Swedish	

#### **CONVERSIONS**

The conversions are performed according to the following tables. All values in the tables are given in octal.

ISO 646 (US ASCII) to ISO 8859-1 For the conversion of ISO 646 to ISO 8859-1, all characters in ISO 646 can be mapped unchanged to ISO 8859-1

ISO 646de (GERMAN) to ISO 8859-1

For the conversion of ISO 646de to ISO 8859-1, all characters not in the following table are mapped unchanged.

Conversions Performed			
ISO 646de ISO 8859-1 ISO 646de		ISO 646de	ISO 8859-1
100	247	173	344
133	304	174	366
134	326	175	374
135	334	176	337

ISO 646da (DANISH) to ISO 8859-1 For the conversion of ISO 646da to ISO 8859-1, all characters not in the following table are mapped unchanged.

Conversions Performed			
ISO 646da	ISO 8859-1	ISO 646da	ISO 8859-1
133	306	173	346
134	330	174	370
135	305	175	345

#### ISO 646en (ENGLISH ASCII) to ISO 8859-1

For the conversion of ISO 646en to ISO 8859-1, all characters not in the following table are mapped unchanged.

	Conversions Performed			
ISO 646en ISO 8859-1		ISO 8859-1		
	043	243		

#### ISO 646es (SPANISH) to ISO 8859-1

For the conversion of ISO 646es to ISO 8859-1, all characters not in the following table are mapped unchanged.

Conversions Performed			
ISO 646es ISO 8859-1 ISO 646es ISO 8859-1			
100	247	173	260
133	241	174	361
134	321	175	347
135	277		

#### ISO 646fr (FRENCH) to ISO 8859-1

For the conversion of ISO 646fr to ISO 8859-1, all characters not in the following table are mapped unchanged.

Conversions Performed			
ISO 646fr	ISO 8859-1	ISO 646fr	ISO 8859-1
043	243	173	351
100	340	174	371
133	260	175	350
134	347	176	250
135	247		

ISO 646it (ITALIAN) to ISO 8859-1 For the conversion of ISO 646it to ISO 8859-1, all characters not in the following table are mapped unchanged.

## iconv\_646(5)

	Conversions Performed			
ISO 646it ISO 8859-1 ISO 64		ISO 646it	ISO 8859-1	
043	243	140	371	
100	247	173	340	
133	260	174	362	
134	347	175	350	
135	351	176	354	

#### ISO 646sv (SWEDISH) to ISO 8859-1

For the conversion of ISO 646sv to ISO 8859-1, all characters not in the following table are mapped unchanged.

Conversions Performed					
ISO 646sv ISO 8859-1 ISO 646sv ISO 8859-1					
100	311	140	351		
133	304	173	344		
134	326	174	366		
135	305	175	345		
136	334	176	374

**NAME** 

iconv\_852 – code set conversion tables for MS 852 (MS-DOS Latin 2)

#### **DESCRIPTION**

The following code set conversions are supported:

Code Set Conversions Supported					
Code	Symbol	Target Code	Symbol	Target Output	
MS 852	dos2	ISO 8859-2	iso2	ISO Latin 2	
MS 852	dos2	MS 1250	win2	Windows Latin 2	
MS 852	dos2	Mazovia	maz	Mazovia	
MS 852	dos2	DHN	dhn	Dom Handlowy Nauki	

#### **CONVERSIONS**

The conversions are performed according to the following tables. All values in the tables are given in octal.

## MS 852 to ISO 8859-2

For the conversion of MS 852 to ISO 8859-2, all characters not in the following table are mapped unchanged.

Conversions Performed				
MS 852	ISO 8859-2	MS 852	ISO 8859-2	
24-177	40	271-274	40	
200	307	275	257

#### **NAME**

iconv\_8859-1 - code set conversion tables for ISO 8859-1 (Latin 1)

#### **DESCRIPTION**

The following code set conversions are supported:

Code Set Conversions Supported				
Code	Symbol	Target Code	Symbol	Target Output
ISO 8859-1	8859	ISO 646	646	7 bit ASCII
ISO 8859-1	8859	ISO 646de	646de	German
ISO 8859-1	8859	ISO 646da	646da	Danish
ISO 8859-1	8859	ISO 646en	646en	English ASCII
ISO 8859-1	8859	ISO 646es	646es	Spanish
ISO 8859-1	8859	ISO 646fr	646fr	French
ISO 8859-1	8859	ISO 646it	646it	Italian
ISO 8859-1	8859	ISO 646sv	646sv	Swedish

#### **CONVERSIONS**

The conversions are performed according to the following tables. All values in the tables are given in octal.

## ISO 8859-1 to ISO 646 (7-bit ASCII)

For the conversion of ISO 8859-1 to ISO 646, all characters not in the following table are mapped unchanged.

```
Converted to Underscore ^{\prime}_{\phantom{1}} (137)
200 201 202 203 204 205 206 207

**NAME** 

| iconv\_pc\_cyr - code set conversion tables for Alternative PC Cyrillic

#### **DESCRIPTION**

The following code set conversions are supported:

Code Set Conversions Supported				
Code	Symbol	Target Code	Symbol	Target Output
PC Cyrillic	alt	ISO 8859-5	iso5	ISO 8859-5 Cyrillic
PC Cyrillic	alt	KOI8-R	koi8	KOI8-R
PC Cyrillic	alt	MS 1251	win5	Windows Cyrillic
PC Cyrillic	alt	Mac Cyrillic	mac	Macintosh Cyrillic

#### **CONVERSIONS**

The conversions are performed according to the following tables. All values in the tables are given in octal.

#### PC Cyrillic to ISO 8859-5

For the conversion of PC Cyrillic to ISO 8859-5, all characters not in the following table are mapped unchanged.

Conversions Performed				
PC Cyrillic	ISO 8859-5	PC Cyrillic	ISO 8859-5	
24	4	231	311	
200	260	232	312	
201	261	233	313	
202	262	234	314	
203	263	235	315

#### **EXAMPLES**

#### **EXAMPLE 1** The library module filename

In the conversion library, /usr/lib/iconv (see iconv(3C)), the library module filename is composed of two symbolic elements separated by the percent sign (%). The first symbol specifies the code set that is being converted; the second symbol specifies the *target code*, that is, the code set to which the first one is being converted.

**EXAMPLE 1** The library module filename (Continued)

In the conversion table above, the first symbol is termed the "FROM Filename Element". The second symbol, representing the target code set, is the "TO Filename Element".

For example, the library module filename to convert from the *Korean EUC* code set to the *Korean UTF-8* code set is

ko\_KR-euc%ko\_KR-UTF-8

FILES /usr/lib/iconv/\*.so

conversion modules

### **NOTES**

ISO 8859 character sets using Latin alphabetic characters are distinguished as follows:

ISO 8859-1 (Latin 1)

For most West European languages, including:

Albanian	Finnish	Italian
Catalan	French	Norwegian
Danish	German	Portuguese
Dutch	Galician	Spanish
English	Irish	Swedish
Faeroese	Icelandic	

# ISO 8859-2 (Latin 2)

For most Latin-written Slavic and Central European languages:

Czech	Polish	Slovak
German	Rumanian	Slovene
***	C .:	

Hungarian Croatian

ISO 8859-3 (Latin 3)

Popularly used for Esperanto, Galician, Maltese, and Turkish.

ISO 8859-4 (Latin 4)

Introduces letters for Estonian, Latvian, and Lithuanian. It is an incomplete predecessor of ISO 8859-10 (Latin 6).

ISO 8859-9 (Latin 5)

Replaces the rarely needed Icelandic letters in ISO 8859-1 (Latin 1) with the Turkish ones.

ISO 8859-10 (Latin 6)

Adds the last Inuit (Greenlandic) and Sami (Lappish) letters that were not included in ISO 8859-4 (Latin 4) to complete coverage of the Nordic area.

### ieee802.3(5)

### NAME |

ieee802.3, cap\_autoneg, cap\_1000fdx, cap\_1000hdx, cap\_100fdx, cap\_100hdx, cap\_10fdx, cap\_10hdx, cap\_rem\_fault, cap\_pause, cap\_asmpause, adv\_cap\_autoneg, adv\_cap\_1000fdx, adv\_cap\_1000hdx, adv\_cap\_100fdx, adv\_cap\_100hdx, adv\_cap\_10fdx, adv\_cap\_asmpause, adv\_rem\_fault, lp\_cap\_autoneg, lp\_cap\_1000fdx, lp\_cap\_1000hdx, lp\_cap\_100fdx, lp\_cap\_100fdx, lp\_cap\_100hdx, lp\_cap\_10fdx, lp\_cap\_10hdx, lp\_cap\_asmpause, lp\_rem\_fault, xcvr\_addr, xcvr\_id, xcvr\_inuse, link\_up, link\_duplex, link\_pause, link\_asmpause – Ethernet mii kstat and ndd parameters

### **DESCRIPTION**

This page describes the kernel statistics and the ndd(1M) configuration parameters used to monitor and configure the Ethernet physical layer.

The cap\_\* parameters exist in the kernel statistics for an Ethernet device. The parameters describe the maximum capability of a device. When the value of a statistic is 1, the device has the capability described. When the value is 0, the device does not have the capability.

The exceptions to this rule are the cap\_asmpause and cap\_pause parameters which are explained later in the page.

cap_autoneg	Capable of auto-negotiation
cap_1000fdx	Capable of 1000 full duplex operation
cap_1000hdx	Capable of 1000 half duplex operation
cap_100fdx	Capable of 100 full duplex operation
cap_100hdx	Capable of 100 half duplex operation
cap_10fdx	Capable of 10 full duplex operation
cap_10hdx	Capable of 10 half duplex operation
cap_rem_fault	Capable of reporting locally detected faults to link partner

The adv\_cap\_\* parameters exist in the kernel statistics and represent a mirror image of the ndd adv\_\*\_cap parameter list for an Ethernet device. The ndd adv\_\*\_cap tuning parameters allow fine grain control of the Ethernet device physical layer. The parameters are also a subset of the cap\_\* statistics. If the cap\_\* value is 0, the corresponding adv\_cap\_\* must also be 0. The exceptions to this rule are the adv cap asmpause and adv cap pause parameters.

When auto-negotiation is enabled, the adv\_\*\_cap statistics show which capabilities are advertised to the link partner. When auto-negotiation is disabled in *forced mode*, the statistics precisely show how a link should function and that it must be matched on the link partner to achieve a valid link up.

Statistics with values other than 0 and 1 are also described in the following.

adv_cap_autoneg	Advertise auto-negotiation capability
adv cap 1000fdx	Advertise 1000 full duplex capability

adv_cap_1000hdx	Advertise	e 1000 half duplex capability
adv_cap_100fdx	Advertise	e 100 full duplex capability
adv_cap_100hdx	Advertise	e 100 half duplex capability
adv_cap_10fdx	Advertise	e 10 full duplex capability
adv_cap_10hdxv	Advertise	e 10 half duplex capability
adv_rem_fault	Fault valu	ne reported by the local system to the peer
	0	Link is good
	1	Off line
	2	Link failure
	3	Auto-negotiation failure

The lp\_cap\_\* parameters exist as kernel statistics for an Ethernet device. The statistics are the advertised capabilities provided by the link partner on completion of auto-negotiation. If the capabilities match the capabilities provided in the local advertisement, the link can proceed to a link up state. If no match is found, the link remains down. In two other instances, lp\_cap\_\* values might all be zero: when a cable is not present, when forced mode is enabled.

lp_cap_autoneg	Link partı	ner advertises auto-negotiation capability
lp_cap_1000fdx	Link partı	ner advertises 1000 full duplex capability
lp_cap_1000hdx	Link partı	ner advertises 1000 half duplex capability
lp_cap_100fdx	Link partı	ner advertises 100 full duplex capability
lp_cap_100hdx	Link partı	ner advertises 100 half duplex capability
lp_cap_10fdx	Link partı	ner advertises 10 full duplex capability
lp_cap_10hdx	Link partı	ner advertises 10 half duplex capability
lp_rem_fault	Fault valu	e the remote system reports
	0	Link is good
	1	Off line
	2	Link failure
	3	Auto-negotiation failure

The xcvr\_\* kernel statistics provide information about the physical layer device that is in use.

xcvr_addr	MII address in the 0 to 31 range of the physical layer device in use for a given Ethernet device
xcvr_id	MII transceiver manufacturer and device ID

# ieee802.3(5)

xcvr inuse	MII trans	ceiver tv	pe, based on the following list:
_	0 other	J .	Undefined
	1 none		MII present, but nothing connected
	2 10Mb/s	5	10Mb/s Manchester encoding
	3 100Base	eT4	100 Mb/s 8B/6T
	4 100Base	eX	100 Mb/s 4B/5B
	5 100Base	eT2	100 Mb/s PAM5X5
	6 1000Bas	seX	1000 Mb/s 8B/10B
	7 1000Bas	seT	1000 Mb/s 4D-PAM5
	cases, low	ver speed	define maximum capability. In many ls can occur. The cap_* statistics oestablish the range of capability.
The link_* kernel statistics	show the li	nk state a	at the local end of the connection.
link_up	1	Link is	ир
	0	Link is	down
link_duplex	2	Full du	plex link
	1	Half du	plex link
	0	Unknov	vn
The cap_asmpause, cap_parameters do not follow the parameters.			mpause, and adv_cap_pause * and adv_cap_* kstats or
cap_pause			is statistic depends on the value asmpause.
	if cap_as	smpause	= 1, pause one direction
	1	Send p	ause frames when there is receive tion.
	0	Pause receive	transmission when a pause frame is d.
	if cap_as	smpause	= 0, pause in either direction

Send pause frames when there is receive congestion, and pause transmission when a

pause frame is received.

Pause capability is not available in either 0 direction.

cap asmpause Asymmetric pause capability

The adv cap pause and adv cap asmpause statistics are limited by the available settings for cap pause and cap asmpause. For a device that is fully capable of pausing both Rx (receive) and Tx (transmit) operations, the settings available are defined in the truth table that follows the adv\_cap\_pause and adv\_cap\_asmpause parameter descriptions below.

1		
adv_cap_pause		ing of this statistic depends on the value by adv_cap_asmpause.
	if adv_ca	p_asmpause = 1
	1	Send pause frames when there is receive congestion.
	0	Pause transmission when a pause frame is received.
	if adv_ca	p_asmpause = 0
	1	Send pause frames when there is receive congestion, and pause transmission when a pause frame is received.
	0	Pause capability is not available in either direction.

The cap asmpause and cap pause statistics show the capability of a device and also limit the legal setting for adv\_cap\_asmpause and adv\_cap\_pause. The following truth table describes the available adv cap asmpause and adv cap pause settings limited by cap asmpause and cap pause statistics. The abbreviations below are used in the table.

Asymmetric pause capability

CA	cap_asmpause
CP	cap_pause
AA	adv_cap_asmpause
AP	adv_cap_pause

adv\_cap\_asmpause

CP	CA	AP	$\mathbf{A}\mathbf{A}$	Description
0	0	0	0	No pause in use
0	0	x	x	Device not pause capable, cannot set

# ieee802.3(5)

0	1	0	0	Asymmetric Rx pause capable, but not advertised
0	1	0	1	Asymmetric Rx pause capable and advertised
0	1	1	0	Asymmetric Rx pause capable, making it impossible advertise symmetric pause
0	1	1	1	Asymmetric Rx pause capable, making it impossible advertise asymmetric Tx pause
1	0	0	0	Symmetric pause capable, but not advertised
1	0	0	1	Symmetric pause capable, advertising asymmetric Rx pause only
1	0	1	0	Symmetric pause capable, advertising symmetric Rx and Tx pause capability
1	0	1	1	Symmetric pause capable, advertising asymmetric Tx pause only
1	1	0	0	Asymmetric Tx pause capable, but not advertised
1	1	0	1	Asymmetric Tx pause capable, making it impossible to advertise Asymmetric Rx pause
1	1	1	0	Asymmetric Tx pause capable, making it impossible advertise symmetric pause
1	1	1	1	Asymmetric Tx pause capable and advertised

In the cases above, an error is posted when a device driver cannot advertise. A new setting is ignored and values revert to the previous setting.

The lp\_cap\_pause and the lp\_cap\_asmpause provide the advertised capabilities of the link partners.

The meaning of this statistic depends on the value provided by lp\_cap\_asmpause.

if lp\_cap\_asmpause = 1

Send pause frames when there is receive congestion.

Pause transmission when a pause frame is received.

if lp\_cap\_asmpause = 0

Send pause frames when there is receive congestion, and pause transmission when a pause frame is received.

Pause capability is not available in either direction.

lp\_cap\_asmpause Asymmetric pause capability

When adv\_\*pause\_cap and lp\_\*pause\_cap are compared on completion of auto-negotiation, the chosen flow control mechanism for the link depends on what is most meaningful.

link\_asmpause 1 indicates flow control in one direction.

0 indicates flow control in both directions when

link\_pause is set to one.

link pause if link asmpause = 0

1 Flow control in both Rx and Tx directions is

available.

0 No flow control available on the link.

if link\_asmpause = 1

The local station will honor received pause frames by temporarily suspending transmit

of further frames.

0 In the event of receive congestion, the local

station will transmit a pause frame to the

peer.

lp\_cap\_asmpause Asymmetric pause capability

The following truth table illustrates the meaningful flow control combinations related to local and link partner configurations. The abbreviations below are used in the table.

AA	adv_cap_asmpause
AP	adv_cap_pause
LAC	lp_cap_asmpause
LPC	lp_cap_pause
LA	link_asmpause
LP	link_pause

AA	AP	LAC	LPC	LA	LP	Description
1	0	1	1	1	0	Local station will Tx a pause when Rx is congested.
0	1	0	1	0	1	Flow control in both Rx and Tx directions.

# ieee802.3(5)

x	1	1	0	1	1	Local station will honor received Pause frames by temporarily suspending Transmit.
x	х	х	х	0	0	All other combinations: Flow control not avilable on the link

When forced mode is enabled, the current setting of adv\_cap\_asmpause and adv\_cap\_pause are used for the link. The link\_asmpause and link\_pause become equal to the current adv\_cap\_asmpause and adv\_cap\_pause settings. The above table also applies in forced mode, but the link partner configuration must be checked to verify that flow control is operating on the link.

### **SEE ALSO**

ndd(1M), driver.conf(4), bge(7D), ce(7D), dlpi(7P), eri(7D), ge(7D), gld(7D), hme(7D), qfe(7D)

# **NOTES**

When adv\_cap\_autoneg is set to 0, the highest priority speed and duplex is used for forced mode.

The highest priority is the highest speed at full duplex. The lowest priority is the lowest speed at half duplex.

MII transceivers can exist internally to a system or can be connected to an external MII connector. Typically, an internal transceiver has an xcvr\_addr of 1, while an external connection has an xcvr\_addr of 0.

### **NAME**

ipfilter – IP packet filtering software

# **DESCRIPTION**

IP Filter is software that provides packet filtering capabilities. On a properly setup system, it can be used to build a firewall.

The IP Filter feature requires that the file /etc/ipf/pfil.ap be modified to include the names of the network interface(s) to be filtered.

A system with filtering on the hme and qfe interfaces would have entries in /etc/ipf/pfil.ap such as those shown below.

```
# IP Filter pfil autopush setup
# See autopush(1M) manpage for more information.
# Format of the entries in this file is:
#major minor lastminor modules
              0
                     pfil
#le
       - 1
          0
#qe
       -1
                     pfil
                     pfil
      -1
hme
       -1
             0
                      pfil
qfe
```

See System Administration Guide: IP Services for more information.

# **NOTES**

To view license terms, attribution, and copyright for IP Filter, the default path is /usr/lib/ipf/IPFILTER.LICENCE. If the Solaris operating system has been installed anywhere other than the default, modify the given path to access the file at the installed location.

### isalist(5)

### NAME |

isalist – the native instruction sets known to Solaris software

# **DESCRIPTION**

The possible instruction set names returned by isalist(1) and the SI ISALIST command of sysinfo(2) are listed here.

The list is ordered within an instruction set family in the sense that later names are generally faster then earlier names; note that this is in the reverse order than listed by isalist(1) and sysinfo(2). In the following list of values, numbered entries generally represent increasing performance; lettered entries are either mutually exclusive or cannot be ordered.

### SPARC Platforms

Where appropriate, correspondence with a given value of the -xarch option of Sun's C 4.0 compiler is indicated. Other compilers may have similar options.

### 1a. sparc

Indicates the SPARC V8 instruction set, as defined in The SPARC Architecture Manual, Version 8, Prentice-Hall, Inc., 1992. Some instructions (such as integer multiply and divide, FSMULD, and all floating point operations on quad operands) may be emulated by the kernel on certain systems.

Same as sparc. This corresponds to code produced with the -xarch=v7 option of Sun's C 4.0 compiler.

# 2. sparcv8-fsmuld

Like sparc, except that integer multiply and divide must be executed in hardware. This corresponds to code produced with the -xarch=v8a option of Sun's C 4.0 compiler.

### 3. sparcv8

Like sparcv8-fsmuld, except that FSMULD must also be executed in hardware. This corresponds to code produced with the -xarch=v8 option of Sun's C 4.0 compiler.

# 4. sparcv8plus

Indicates the SPARC V8 instruction set plus those instructions in the SPARC V9 instruction set, as defined in The SPARC Architecture Manual, Version 9, Prentice-Hall, 1994, that can be used according to The V8+ Technical Specification. This corresponds to code produced with the -xarch=v8plus option of Sun's C 4.0 compiler.

### 5a. sparcv8plus+vis

Like sparcy8plus, with the addition of those UltraSPARC I Visualization Instructions that can be used according to The V8+ Technical Specification. This corresponds to code produced with the -xarch=v8plusa option of Sun's C 4.0 compiler.

# 5b. sparcv8plus+fmuladd

Like sparcv8plus, with the addition of the Hal SPARC64 floating multiply-add and multiply-subtract instructions.

### 6. sparcv9

Indicates the SPARC V9 instruction set, as defined in The SPARC Architecture Manual, Version 9, Prentice-Hall, 1994.

7a. sparcv9+vis

Like sparcy9, with the addition of the UltraSPARC I Visualization Instructions.

7b. sparcv9+fmuladd

Like sparcv9, with the addition of the Hal SPARC64 floating multiply-add and multiply-subtract instructions.

### x86 Platforms

The Intel 80386 instruction set, as described in The i386 Microprocessor Programmer's Reference Manual.

2. i486

The Intel 80486 instruction set, as described in The i486 Microprocessor Programmer's Reference Manual. (This is effectively i386, plus the CMPXCHG, BSWAP, and XADD instructions.)

3. pentium

The Intel Pentium instruction set, as described in The Pentium Processor User's Manual. (This is effectively i486, plus the CPU\_ID instruction, and any features that the CPU\_ID instruction indicates are present.)

Like pentium, with the MMX instructions guaranteed present.

5. pentium pro

The Intel PentiumPro instruction set, as described in The PentiumPro Family Developer's Manual. (This is effectively pentium, with the CMOVcc, FCMOVcc, FCOMI, and RDPMC instructions guaranteed present.)

6. pentium pro+mmx

Like pentium\_pro, with the MMX instructions guaranteed present.

7. amd64

The AMD Opteron instruction set, as described in the AMD64 Architecture Programmer's Manual.

isalist(1), sysinfo(2)

krb5 auth rules(5)

NAME

krb5\_auth\_rules - Overview of Kerberos V5 authorization

### **DESCRIPTION**

When a user uses kerberized versions of the ftp, rdist, rcp, rlogin, rsh, or telnet clients to connect to a server, even if the user's claimed Kerberos V5 identity is authenticated, the user is not necessarily authorized. Authentication merely proves that the user is "who he says he is" to the Kerberos V5 authentication system. Authorization also needs to be done, since it determines if that Kerberos identity is permitted to access the Solaris user account that the client wants to access.

Each user may have a private authorization list in a file ~/.k5login in his login directory (on the server). Each line in this file should contain a Kerberos principal name of the form *principal/instance@realm*. If the server finds a ~/.k5login file, then access is granted to the account if and only if the originating user is authenticated to one of the principals named in the ~/.k5login file.

If there is no ~/.k5login file, the originating user will then be checked against the gsscred table (see gsscred(1M)). If the originating user's Kerberos V5 identity is in the gsscred table, and if the UNIX user id in the gsscred table corresponds to the user account the client is trying access, then the originating user is granted access to the account on the server. If the UNIX user id does not match, then the originating user is denied access.

For example, suppose the originating user has a principal name of jdb@ENG.ACME.COM and the target account is jdb-user. If jdb@ENG.ACME.COM appears in the gsscred table with uid 23154 and if jdb-user appears in the user account database (see passwd(4)) with uid 23154, then access to account jdb-user is granted. Of course, normally, the target account name in this example would be jdb and not jdb-user.

Finally, if there is no ~/.k5login file and if the originating user's Kerberos V5 identity is not in the gsscred table, then the user will be granted access to the account if and only if all of the following are true:

- The user part of the authenticated principal name is the same as the target account name specified by the client.
- The realm part of the client and server are the same.
- The target account name exists on the server.

For example, if the originating user has a principal name of jdb@ENG.ACME.COM and if the server is in realm SALES.ACME.COM, then even if jdb is a valid account name on the server, the client would be denied access. This is because the realms SALES.ACME.COM and ENG.ACME.COM differ.

**FILES** 

~/.k5login Per user-account authorization file.

/etc/passwd System account file. This information may also be in a directory

service. See passwd(4).

# krb5envvar(5)

### NAME |

krb5envvar – Kerberos environment variables

### DESCRIPTION

The Kerberos mechanism provides a number of environment variables to configure different behavior in order to meet applications' needs. Environment variables used within the Kerberos mechanism are:

### KRB5 KTNAME

Used by the mechanism to specify the location of the key table file. The variable can be set to the following value:

```
[ [<kt type>: ] <file name>]
```

where <*kt type*> can be FILE or WRFILE. FILE is for read operations; WRFILE is for write operations. <*file name*> is the location of the keytab file.

If KRB5 KTNAME is not defined, the default value is:

```
FILE:/etc/krb5/krb5.keytab
```

The keytab file is used to store credentials persistently and is used commonly for service daemons.

Specifying the FILE type assumes that the subsequent operations on the associated file are readable by the invoking process. Care must be taken to ensure that the file is readable only by the set of principals that need to retrieve their unencrypted keys.

The WRFILE type is used by the kadmin(1M) command. Specifying this type allows the administrator to designate an alternate keytab file to write to without using extra command line arguments for file location.

### KRB5CCNAME

Used by the mechanism to specify the location of the credential cache. The variable can be set to the following value:

```
[ [<cc type>: ] <file name>]
```

where <*cc type*> can be FILE or MEMORY. <*file name*> is the location of the principal's credential cache.

If KRB5CCNAME is not defined, the default value is:

```
FILE:/tmp/krb5cc <uid>
```

where *<uid>* is the user id of the process that created the cache file.

The credential cache file is used to store tickets that have been granted to the principal.

Specifying the FILE types assumes that subsequent operations on the associated file are readable and writable by the invoking process. Care must be taken to ensure that the file is accessible only by the set of principals that need to access their credentials. If the credential file is in a directory to which other users have write access, you will need to set that directory's sticky bit (see chmod(1)).

The MEMORY credential cache type is used only in special cases, such as when making a temporary cache for the life of the invoking process.

### KRB5RCNAME

Used by the mechanism to specify the type and location of the replay cache. The variable can be set to the following value:

```
[ [<rc type>: ] <file name>]
```

where <rc type> can be either FILE or MEMORY. <file name> is relevant only when specifying the replay cache file type.

If not defined, the default value is:

```
FILE:/var/krb5/rcache/root/rc <service>
```

...if the process is owned by root, or:

```
FILE:/var/krb5/rcache/rc <service>
```

...if the process is owned by a user other than root. <service> is the service process name associated with the replay cache file.

The replay cache is used by Kerberos to detect the replay of authentication data. This prevents people who capture authentication messages on the network from authenticating to the server by resending these messages.

When specifying the FILE replay cache type, care must be taken to prevent the replay cache file from being deleted by another user. Make sure that every directory in the replay cache path is either writable only by the owner of the replay cache or that the sticky bit ("t") is set on every directory in the replay cache path to which others have write permission.

When specifying the MEMORY replay cache type you need to weigh the trade-off of performance against the slight security risk created by using a non-persistent cache. The risk occurs during system reboots when the following condition obtains:

The duration from the last write to the replay cache before reboot to the point when the Kerberized server applications are running is less than the Kerberos clockskew (see krb5.conf(4)).

Under this condition, the server applications can accept a replay of Kerberos authentication data (up to the difference between the time of the last write and the clockskew). Typically, this is a small window of time. If the server applications take longer than the clockskew to start accepting connections there is no replay risk.

The risk described above is the same when using FILE replay cache types when the replay cache resides on swap file systems, such as /tmp and /var/run.

The performance improvement in MEMORY replay cache types over FILE types is derived from the absence of disk I/O. This is true even if the FILE replay cache is on a memory-backed file system, such as swap (/tmp and /var/run).

**NAME** 

largefile – large file status of utilities

# **DESCRIPTION**

A *large file* is a regular file whose size is greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes). A *small file* is a regular file whose size is less than 2 Gbyte.

# Large file aware utilities

A utility is called *large file aware* if it can process large files in the same manner as it does small files. A utility that is large file aware is able to handle large files as input and generate as output large files that are being processed. The exception is where additional files are used as system configuration files or support files that can augment the processing. For example, the file utility supports the -m option for an alternative "magic" file and the -f option for a support file that can contain a list of file names. It is unspecified whether a utility that is large file aware will accept configuration or support files that are large files. If a large file aware utility does not accept configuration or support files that are large files, it will cause no data loss or corruption upon encountering such files and will return an appropriate error.

The following /usr/bin utilities are large file aware:

adb	awk	bdiff	cat	chgrp
chmod	chown	cksum	cmp	compress
ср	csh	csplit	cut	dd
dircmp	du	egrep	fgrep	file
find	ftp	getconf	grep	gzip
head	join	jsh	ksh	ln
ls	mdb	mkdir	mkfifo	more
mv	nawk	page	paste	pathchck
ba	rcp	remsh	rksh	rm
rmdir	rsh	sed	sh	sort
split	sum	tail	tar	tee
test	touch	tr	uncompress	uudecode
uuencode	wc	zcat		

The following /usr/xpg4/bin utilities are large file aware:

awk	ср	chgrp	chown	du
egrep	fgrep	file	grep	ln
ls	more	mv	rm	sed

largefile(5)

sh sort tail tr

The following /usr/xpg6/bin utilities are large file aware:

getconf ls tr

The following /usr/sbin utilities are large file aware:

install mkfile mknod mvdir swap

See the USAGE section of the swap(1M) manual page for limitations of swap on block devices greater than 2 Gbyte on a 32–bit operating system.

The following /usr/ucb utilities are large file aware:

chown from ln ls sed

sum touch

The /usr/bin/cpio and /usr/bin/pax utilities are large file aware, but cannot archive a file whose size exceeds 8 Gbyte – 1 byte.

The /usr/bin/truss utilities has been modified to read a dump file and display information relevant to large files, such as offsets.

cachefs file systems The following /usr/bin utilities are large file aware for cachefs file systems:

cachefspack cachefsstat

The following /usr/sbin utilities are large file aware for cachefs file systems:

cachefslog cachefswssize cfsadmin fsck

mount umount

**nfs file systems** The following utilities are large file aware for nfs file systems:

/usr/lib/autofs/automountd /usr/sbin/mount

/usr/lib/nfs/rquotad

**ufs file systems** | The following /usr/bin utility is large file aware for ufs file systems:

df

The following /usr/lib/nfs utility is large file aware for ufs file systems: rquotad

The following /usr/xpg4/bin utility is large file aware for ufs file systems:

The following /usr/sbin utilities are large file aware for ufs file systems:

clri	dcopy	edquota	ff	fsck
fsdb	fsirand	fstyp	labelit	lockfs
mkfs	mount	ncheck	newfs	quot
quota	quotacheck	quotaoff	quotaon	repquota
tunefs	ufsdump	ufsrestore	umount	

# Large file safe utilities

A utility is called *large file safe* if it causes no data loss or corruption when it encounters a large file. A utility that is large file safe is unable to process properly a large file, but returns an appropriate error.

The following /usr/bin utilities are large file safe:

audioconvert	audioplay	audiorecord	comm	diff
diff3	diffmk	ed	lp	mail
mailcompat	mailstats	mailx	pack	pcat
red	rmail	sdiff	unpack	vi
view				

The following /usr/xpg4/bin utilities are large file safe:

ed vi view

The following /usr/xpg6/bin utility is large file safe:

ed

# largefile(5)

The following /usr/sbin utilities are large file safe:

lpforms lpfilter

The following /usr/ucb utilities are large file safe:

Mail lpr

The following /usr/lib utility is large file safe:

sendmail

### NAME

| lf64 – transitional interfaces for 64-bit file offsets

# **DESCRIPTION**

The data types, interfaces, and macros described on this page provide explicit access to 64-bit file offsets. They are accessible through the transitional compilation environment described on the lfcompile64(5) manual page. The function prototype and semantics of a transitional interface are equivalent to those of the standard version of the call, except that relevant data types are 64-bit entities.

# **Data Types**

The following tables list the standard data or struct types in the left-hand column and their corresponding explicit 64-bit file offset types in the right-hand column, grouped by header. The absence of an entry in the left-hand column indicates that there is no existing explicit 32-bit type that corresponds to the 64-bit type listed in the right—hand column. Note that in a 64-bit application, the standard definition is equivalent to the 64-bit file offset definition.

# **System Interfaces**

The following tables display the standard API and the corresponding transitional interfaces for 64-bit file offsets. The interfaces are grouped by header. The interface name and the affected data types are displayed in courier font.

# <aio.h>

```
int aio_cancel(...,
                                              int aio_cancel64(...,

### **NAME**

lfcompile – large file compilation environment for 32-bit applications

### DESCRIPTION

All 64-bit applications can manipulate large files by default. The methods described on this page allow 32-bit applications to manipulate large files.

In the large file compilation environment, source interfaces are bound to appropriate 64-bit functions, structures, and types. Compiling in this environment allows 32-bit applications to access files whose size is greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

Each interface named xxx() that needs to access 64-bit entities to access large files maps to a xxx64() call in the resulting binary. All relevant data types are defined to be of correct size (for example, off thas a typedef definition for a 64-bit entity).

An application compiled in this environment is able to use the xxx () source interfaces to access both large and small files, rather than having to explicitly utilize the transitional xxx64 () interface calls to access large files. See the lfcompile64(5) manual page for information regarding the transitional compilation environment.

Applications can be compiled in the large file compilation environment by using the following methods:

 Use the getconf(1) utility with one or more of the arguments listed in the table below. This method is recommended for portable applications.

argument	purpose
LFS_CFLAGS	obtain compilation flags necessary to enable the large file compilation environment
LFS_LDFLAGS	obtain link editor options
LFS_LIBS	obtain link library names
LFS_LINTFLAGS	obtain lint options

■ Set the compile-time flag \_FILE\_OFFSET\_BITS to 64 before including any headers. Applications may combine objects produced in the large file compilation environment with objects produced in the transitional compilation environment, but must be careful with respect to interoperability between those objects. Applications should not declare global variables of types whose sizes change between compilation environments.

### Access to Additional Large File Interfaces

The fseek() and ftell() functions do not map to functions named fseek64() and ftell64(); rather, the large file additions fseeko() and ftello(), have functionality identical to fseek() and ftell() and do map to the 64-bit functions fseeko64() and ftello64(). Applications wishing to access large files should use fseeko() and ftello() in place of fseek() and ftell(). See the fseek(3C) and ftell(3C) manual pages for information about fseeko() and ftello().

Applications wishing to access fseeko() and ftello() as well as the POSIX and X/Open specification-conforming interfaces should define the macro \_LARGEFILE\_SOURCE to be 1 and set whichever feature test macros are appropriate to obtain the desired environment (see standards(5)).

### **EXAMPLES**

In the following examples, the large file compilation environment is accessed by invoking the getconf utility with one of the arguments listed in the table above. The additional large file interfaces are accessed by specifying -D LARGEFILE SOURCE.

The examples that use the form of command substitution specifying the command within parentheses preceded by a dollar sign can be executed only in a POSIX-conforming shell such as the Korn Shell (see ksh(1)). In a shell that is not POSIX-conforming, such as the Bourne Shell (see sh(1)) and the C Shell (see csh(1)), the getconf calls must be enclosed within grave accent marks, as shown in the second example.

**EXAMPLE 1** An example of compiling a program with a "large" off\_t, and that uses fseeko(), ftello(), and yacc(1)

**EXAMPLE 2** An example of compiling a program with a "large" off\_t that does not use fseeko() and ftello() and has no application specific libraries:

```
% c89 -D_FILE_OFFSET_BITS=64
  `getconf LFS_CFLAGS` a.c
  `getconf LFS_LDFLAGS` \
  `getconf LFS_LIBS` \
```

**EXAMPLE 3** An example of compiling a program with a "default" off\_t and that uses fseeko() and ftello():

```
$ c89 -D LARGEFILE SOURCE a.c
```

# **SEE ALSO**

```
csh(1), getconf(1), ksh(1), lint(1B), sh(1), fseek(3C), ftell(3C), lf64(5), lfcompile64(5), standards(5)
```

### **NOTES**

Certain system-specific or non-portable interfaces are not usable in the large file compilation environment. Known cases are:

- Kernel data structures read from /dev/kmem.
- Interfaces in the kernel virtual memory library, -1kvm.
- Interfaces in the ELF access library, -lelf.
- Interfaces to /proc defined in <procfs.h>.
- The ustat(2) system call.

Programs that use these interfaces should not be compiled in the large file compilation environment. As a partial safeguard against making this mistake, including either of the libelf.h> or <sys/procfs.h> header files will induce a compilation error when the large file compilation environment is enabled.

# lfcompile(5)

In general, caution should be exercised when using any separately-compiled library whose interfaces include data items of type off t or the other redefined types either directly or indirectly, such as with 'struct stat'. (The redefined types are off t, rlim t, ino t, blkcnt t, fsblkcnt t, and fsfilcnt t.) For the large file compilation environment to work correctly with such a library, the library interfaces must include the appropriate xxx64 () binary entry points and must have them mapped to the corresponding primary functions when FILE OFFSET BITS is set to

Care should be exercised using any of the printf() or scanf() routines on variables of the types mentioned above. In the large file compilation environment, these variables should be printed or scanned using long long formats.

# **BUGS**

The lint(1B) utility will generate spurious error messages when \_FILE\_OFFSET\_BITS is set to 64. This is because the binary libc lint library, /usr/lib/llib-lc.ln, is compiled only for the standard interfaces, not with FILE OFFSET BITS set to 64. This deficiency hampers static error-checking for programs compiled in the large file compilation environment.

Symbolic formats analogous to those found in <sys/int fmtio.h> do not exist for printing or scanning variables of the types that are redefined in the large file compilation environment.

### NAME

lfcompile64 – transitional compilation environment

# **DESCRIPTION**

All 64-bit applications can manipulate large files by default. The transitional interfaces described on this page can be used by 32-bit and 64-bit applications to manipulate large files.

In the transitional compilation environment, explicit 64-bit functions, structures, and types are added to the API. Compiling in this environment allows both 32-bit and 64-bit applications to access files whose size is greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

The transitional compilation environment exports all the explicit 64-bit functions (xxx64()) and types in addition to all the regular functions (xxx()) and types. Both xxx() and xxx64() functions are available to the program source. A 32-bit application must use the xxx64() functions in order to access large files. See the 1f64(5) manual page for a complete listing of the 64-bit transitional interfaces.

The transitional compilation environment differs from the large file compilation environment, wherein the underlying interfaces are bound to 64-bit functions, structures, and types. An application compiled in the large file compilation environment is able to use the xxx() source interfaces to access both large and small files, rather than having to explicitly utilize the transitional xxx64() interface calls to access large files. See the <code>lfcompile(5)</code> manual page for more information regarding the large file compilation environment.

Applications may combine objects produced in the large file compilation environment with objects produced in the transitional compilation environment, but must be careful with respect to interoperability between those objects. Applications should not declare global variables of types whose sizes change between compilation environments.

For applications that do not wish to conform to the POSIX or X/Open specifications, the 64-bit transitional interfaces are available by default. No compile-time flags need to be set.

### Access to Additional Large File Interfaces

Applications that wish to access the transitional interfaces as well as the POSIX or X/Open specification-conforming interfaces should use the following compilation methods and set whichever feature test macros are appropriate to obtain the desired environment (see standards(5)).

- Set the compile-time flag \_LARGEFILE64\_SOURCE to 1 before including any headers.
- Use the getconf(1) command with one or more of the following arguments:

argument	purpose
LFS64_CFLAGS	obtain compilation flags necessary to enable the transitional compilation environment

# lfcompile64(5)

argument	purpose
LFS64_LDFLAGS	obtain link editor options
LFS64_LIBS	obtain link library names
LFS64_LINTFLAGS	obtain lint options

### **EXAMPLES**

In the following examples, the transitional compilation environment is accessed by invoking the getconf utility with one of the arguments listed in the table above. The additional large file interfaces are accessed either by specifying

 $-\mbox{D\_LARGEFILE64\_SOURCE}$  or by invoking the getconf utility with the arguments listed above.

The example that uses the form of command substitution specifying the command within parentheses preceded by a dollar sign can be executed only in a POSIX-conforming shell such as the Korn Shell (see ksh(1)). In a shell that is not POSIX-conforming, such as the Bourne Shell (see sh(1)) and the C Shell (see csh(1)), the command must be enclosed within grave accent marks.

**EXAMPLE 1** An example of compiling a program using transitional interfaces such as lsek64() and fopen64():

**EXAMPLE 2** An example of running lint on a program using transitional interfaces:

### NAME

live\_upgrade – overview of Live Upgrade feature

# **DESCRIPTION**

The Live Upgrade feature of the Solaris operating environment enables you to maintain multiple operating system images on a single system. An image—called a boot environment, or BE—represents a set of operating system and application software packages. The BEs might contain different operating system and/or application versions.

On a system with the Solaris Live Upgrade software, your currently booted OS environment is referred to as your active, or current BE. You have one active, or current BE; all others are inactive. You can perform any number of modifications to inactive BEs on the same system, then boot from one of those BEs. If there is a failure or some undesired behavior in the newly booted BE, Live Upgrade software makes it easy for you to fall back to the previously running BE.

Live Upgrade software includes a full suite of commands, listed below and described in individual man pages, which implement all of the Live Upgrade features and functions. The software also includes a Forms and Menu Language Interpreter-based user interface named lu(1M). (See fmli(1) for a description of the Forms and Menu Language Interpreter.) The FMLI interface implements a subset of Live Upgrade functions. Unlike the command-line interfaces, output from the FMLI interface is not internationalizable.

The following are some of the tasks you can perform with Live Upgrade software:

- You can make one or more copies of the currently running system.
- You can upgrade to a new OS version on a second boot environment, then boot from that environment. If you choose, you can then fall back to your original boot environment or boot from yet another environment.
- You can install application or OS packages to a boot environment, then boot from that environment.
- You can install OS patches to a boot environment, then boot from that environment.
- From a flash archive, you can install an OS to a boot environment, then boot from that environment. See flar(1M) for information on administering flash archives.
- You can split and rejoin file systems in a new BE. For example, you can separate /usr, /var, and /opt from /, putting them on their own partitions. Conversely, you could join these file systems on a single partition under /.
- You can mount any or all of the filesystems of a BE that is not active, compare the files in any pair of BEs, delete or rename a BE, and perform other administrative tasks.

The Live Upgrade software supports upgrade from any valid Solaris installation medium, including a CD-ROM, an NFS or UFS directory, or a flash archive. (See flash\_archive(4) for a description of the flash archive feature.)

# live\_upgrade(5)

In simplest terms, a BE, for Live Upgrade, consists of the disk slice containing a root file system and the file system/device (usually disk) slice entries specified in vfstab(4). This set of slices is not limited to a single disk. This means that you can have multiple BEs on a single device, or have a BE spread across slices on multiple devices.

The minimal requirement for a Live Upgrade BE is the same as for any Solaris boot environment: you must have root (/) and usr filesystems (which might both reside on /). All filesystems except for /, /usr, /var, and /opt can be shared among multiple BEs, if you choose.

Each BE must have a unique copy of the file systems that contain the OS—/, /usr, /var, and /opt. For Live Upgrade purposes, these are referred to as non–shareable (sometimes referred to as *critical*) file systems. With other file systems, such as /export or /home, you have the option of copying the files to a new BE or, the default, sharing them among BEs. These are referred to as shareable file systems. A BE is made up of a unique copy of one or more non–shareable file systems and zero or more copies of shareable file systems.

Live Upgrade commands support an option (-X) that enables XML output. Characteristics of the XML are specified in a DTD shipped with the product. XML output enables programmatic parsing of portions of the command output.

Live Upgrade supports the notion of a BE description, an optional attribute of a BE. A BE description can be of any length and format. It might be a text string or a binary file. See ludesc(1M) for details.

Below is an example set of steps that you might follow in the use of Live Upgrade software. These steps specify the use of commands rather than lu(1M), the FMLI interface. Many Live Upgrade functions are accessible through lu. Except where lu does not support a function, the choice between lu and Live Upgrade commands is a matter of your requirements and preferences. The following example is by no means exhaustive of the possibilities of the use of the Live Upgrade software.

- 1. You create a new BE, using lucreate(1M). The first time you create a BE on a given system, you must designate the current Solaris operating environment as a BE (give it a name). You then specify a name and a set of device (disk) slices you want to use for the new BE. The lucreate command copies the contents of the current Solaris operating environment (now a BE) to the new BE.
  - After you have created additional BEs, you can use a BE other than the current BE as the source for a new BE. Also, you can create an empty BE onto which you can later install a flash archive.
- 2. Using luupgrade(1M), you upgrade the OS version on your new BE (or on yet another BE you created with lucreate). The luupgrade enables you to upgrade an OS (from any valid Solaris installation medium, including a flash archive), add or remove packages (OS or application), and add or remove patches.
- 3. You use luactivate(1M) to make the new BE bootable. The next time you reboot your system, you will come up in the new BE.

- 4. Using lucompare(1M), you compare the system files on two different BEs. This utility gives you a comprehensive list of the files that have differences.
- 5. Using lumount(1M), you mount the filesystems of a BE that is not active, enabling you to make changes. When you are finished with the changes, use luumount(1M) to unmount the BE's file systems.
- 6. Upon booting a new BE, you discover a failure or some other undesirable behavior. Using the procedure specified in luactivate, you can fall back to the previous BE.
- 7. Using ludelete then lucreate, you reassign file systems on the now-deleted BE to different disk slices. You separate /opt and /var from / on the new BE. Also, you specify that swap be spread over slices on multiple disks.

The following is a summary of Live Upgrade commands. All commands require root privileges.

lu

FMLI-based interface for creating and administering BEs.

luactivate

Designate a BE as the BE to boot from upon the next reboot of the system.

lucancel

Cancel a previously scheduled operation.

lucompare

Compare the contents of two BEs.

lucreate

Create a BE.

lucurr

Display the name of the current BE.

ludelete

Delete a BE.

ludesc

Add or change BE descriptions.

lufslist

List the file systems on a specified BE.

lumake

Re-create a BE based on the active BE.

lumount, luumount

Mount, unmount file systems of a specified BE.

lurename

Rename a BE.

#### live\_upgrade(5)

lustatus

For all BEs on a system, report on whether a BE is active, active upon the next reboot, in the midst of a copy operation, and whether a copy operation is scheduled for it.

luupgrade

Upgrade an OS and install application software on a BE. Such software includes flash archives, complete OS installations, OS and application packages, and OS patches.

**FILES**

**NOTES** 

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be installed for a given OS version. Before installing or running Live Upgrade, you are required to install the limited set of patch revisions. Make sure you have the most recently updated patch list by consulting http://sunsolve.sun.com. Search for the infodoc 72099 on the SunSolve web site.

It is possible for an operating system upgrade to remove installed patches. Prior to such an upgrade, use analyze\_patches, as described in luupgrade(1M), to determine which, if any, patches will be removed.

Live Upgrade supports the release it is distributed on and up to three marketing releases back. For example, if you obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

NAME | locale – subset of a user's environment that depends on language and cultural conventions

#### **DESCRIPTION**

A locale is the definition of the subset of a user's environment that depends on language and cultural conventions. It is made up from one or more categories. Each category is identified by its name and controls specific aspects of the behavior of components of the system. Category names correspond to the following environment variable names:

LC CTYPE Character classification and case conversion.

Collation order. LC COLLATE

Date and time formats. LC TIME LC NUMERIC Numeric formatting. Monetary formatting. LC MONETARY

LC MESSAGES Formats of informative and diagnostic messages and

interactive responses.

The standard utilities base their behavior on the current locale, as defined in the ENVIRONMENT VARIABLES section for each utility. The behavior of some of the C-language functions will also be modified based on the current locale, as defined by the last call to setlocale(3C).

Locales other than those supplied by the implementation can be created by the application via the localedef(1) utility. The value that is used to specify a locale when using environment variables will be the string specified as the *name* operand to localedef when the locale was created. The strings "C" and "POSIX" are reserved as identifiers for the POSIX locale.

Applications can select the desired locale by invoking the setlocale() function with the appropriate value. If the function is invoked with an empty string, such as:

```
setlocale(LC ALL, "");
```

the value of the corresponding environment variable is used. If the environment variable is unset or is set to the empty string, the setlocale() function sets the appropriate environment.

#### Locale Definition

Locales can be described with the file format accepted by the localedef utility.

The locale definition file must contain one or more locale category source definitions, and must not contain more than one definition for the same locale category.

A category source definition consists of a category header, a category body and a category trailer. A category header consists of the character string naming of the category, beginning with the characters LC . The category trailer consists of the string END, followed by one or more blank characters and the string used in the corresponding category header.

The category body consists of one or more lines of text. Each line contains an identifier, optionally followed by one or more operands. Identifiers are either keywords, identifying a particular locale element, or collating elements. Each keyword within a locale must have a unique name (that is, two categories cannot have a commonly-named keyword). No keyword can start with the characters LC\_. Identifiers must be separated from the operands by one or more blank characters.

Operands must be characters, collating elements, or strings of characters. Strings must be enclosed in double-quotes ("). Literal double-quotes within strings must be preceded by the *<escape character>*, as described below. When a keyword is followed by more than one operand, the operands must be separated by semicolons (;). Blank characters are allowed both before and after a semicolon.

The first category header in the file can be preceded by a line modifying the comment character. It has the following format, starting in column 1:

```
"comment char %c\n", <comment character>
```

The comment character defaults to the number sign (#). Blank lines and lines containing the *<comment character>* in the first position are ignored.

The first category header in the file can be preceded by a line modifying the escape character to be used in the file. It has the following format, starting in column 1:

```
"escape_char %c\n", <escape character>
```

The escape character defaults to backslash.

A line can be continued by placing an escape character as the last character on the line; this continuation character will be discarded from the input. Although the implementation need not accept any one portion of a continued line with a length exceeding {LINE\_MAX} bytes, it places no limits on the accumulated length of the continued line. Comment lines cannot be continued on a subsequent line using an escaped newline character.

Individual characters, characters in strings, and collating elements must be represented using symbolic names, as defined below. In addition, characters can be represented using the characters themselves or as octal, hexadecimal or decimal constants. When non-symbolic notation is used, the resultant locale definitions will in many cases not be portable between systems. The left angle bracket (<) is a reserved symbol, denoting the start of a symbolic name; when used to represent itself it must be preceded by the escape character. The following rules apply to character representation:

A character can be represented via a symbolic name, enclosed within angle brackets < and >. The symbolic name, including the angle brackets, must exactly match a symbolic name defined in the charmap file specified via the localedef -f option, and will be replaced by a character value determined from the value associated with the symbolic name in the charmap file. The use of a symbolic name not found in the charmap file constitutes an error, unless the category is LC\_CTYPE

or LC\_COLLATE, in which case it constitutes a warning condition (see localedef(1) for a description of action resulting from errors and warnings). The specification of a symbolic name in a collating-element or collating-symbol section that duplicates a symbolic name in the charmap file (if present) is an error. Use of the escape character or a right angle bracket within a symbolic name is invalid unless the character is preceded by the escape character.

#### Example:

```
<C>;<c-cedilla> "<M><a><y>"
```

2. A character can be represented by the character itself, in which case the value of the character is implementation-dependent. Within a string, the double-quote character, the escape character and the right angle bracket character must be escaped (preceded by the escape character) to be interpreted as the character itself. Outside strings, the characters

```
, ; < > escape_char
```

must be escaped to be interpreted as the character itself.

#### Example:

```
c "May"
```

3. A character can be represented as an octal constant. An octal constant is specified as the escape character followed by two or more octal digits. Each constant represents a byte value. Multi-byte values can be represented by concatenated constants specified in byte order with the last constant specifying the least significant byte of the character.

# Example:

```
\143;\347;\143\150 "\115\141\171"
```

4. A character can be represented as a hexadecimal constant. A hexadecimal constant is specified as the escape character followed by an x followed by two or more hexadecimal digits. Each constant represents a byte value. Multi-byte values can be represented by concatenated constants specified in byte order with the last constant specifying the least significant byte of the character.

#### Example:

```
x63; xe7; x63 x68  "x4d x61 x79"
```

5. A character can be represented as a decimal constant. A decimal constant is specified as the escape character followed by a d followed by two or more decimal digits. Each constant represents a byte value. Multi-byte values can be represented by concatenated constants specified in byte order with the last constant specifying the least significant byte of the character.

#### Example:

```
\d99;\d231;\d99\d104 "\d77\d97\d121"
```

Only characters existing in the character set for which the locale definition is created can be specified, whether using symbolic names, the characters themselves, or octal, decimal or hexadecimal constants. If a charmap file is present, only characters defined in the charmap can be specified using octal, decimal or hexadecimal constants. Symbolic names not present in the charmap file can be specified and will be ignored, as specified under item 1 above.

# LC\_CTYPE

The LC CTYPE category defines character classification, case conversion and other character attributes. In addition, a series of characters can be represented by three adjacent periods representing an ellipsis symbol (...). The ellipsis specification is interpreted as meaning that all values between the values preceding and following it represent valid characters. The ellipsis specification is valid only within a single encoded character set, that is, within a group of characters of the same size. An ellipsis is interpreted as including in the list all characters with an encoded value higher than the encoded value of the character preceding the ellipsis and lower than the encoded value of the character following the ellipsis.

#### Example:

\x30;...;\x39;

includes in the character class all characters with encoded values between the endpoints.

The following keywords are recognized. In the descriptions, the term "automatically included" means that it is not an error either to include or omit any of the referenced characters.

The character classes digit, xdigit, lower, upper, and space have a set of automatically included characters. These only need to be specified if the character values (that is, encoding) differ from the implementation default values.

upper Define characters to be classified as upper-case letters.

> In the POSIX locale, the 26 upper-case letters are included:

ABCDEFGHIJKLMNOPQRSTUVWXYZ

In a locale definition file, no character specified for the keywords cntrl, digit, punct, or space can be specified. The upper-case letters A to Z are automatically included in this class.

Define characters to be classified as lower-case letters. In the POSIX locale, the 26 lower-case letters are

included:

abcdefghijklmnopqrstuvwxyz

lower

In a locale definition file, no character specified for the keywords cntrl, digit, punct, or space can be specified. The lower-case letters a to z of the portable character set are automatically included in this class.

Define characters to be classified as letters.

In the POSIX locale, all characters in the classes upper and lower are included.

In a locale definition file, no character specified for the keywords cntrl, digit, punct, or space can be specified. Characters classified as either upper or lower are automatically included in this class.

Define the characters to be classified as numeric digits.

In the POSIX locale, only

0 1 2 3 4 5 6 7 8 9

are included.

In a locale definition file, only the digits 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9 can be specified, and in contiguous ascending sequence by numerical value. The digits 0 to 9 of the portable character set are automatically included in this class.

The definition of character class digit requires that only ten characters; the ones defining digits can be specified; alternative digits (for example, Hindi or Kanji) cannot be specified here.

Define characters to be classified as letters and numeric digits. Only the characters specified for the alpha and digit keywords are specified. Characters specified for the keywords alpha and digit are automatically included in this class.

Define characters to be classified as white-space characters.

In the POSIX locale, at a minimum, the characters SPACE, FORMFEED, NEWLINE, CARRIAGE RETURN, TAB, and VERTICAL TAB are included.

digit

alpha

alnum

space

	In a locale definition file, no character specified for the keywords upper, lower, alpha, digit, graph, or xdigit can be specified. The characters SPACE, FORMFEED, NEWLINE, CARRIAGE RETURN, TAB, and VERTICAL TAB of the portable character set, and any characters included in the class blank are automatically included in this class.
cntrl	Define characters to be classified as control characters.
	In the POSIX locale, no characters in classes alpha or print are included.
	In a locale definition file, no character specified for the keywords upper, lower, alpha, digit, punct, graph, print, or xdigit can be specified.
punct	Define characters to be classified as punctuation characters.
	In the POSIX locale, neither the space character nor any characters in classes alpha, digit, or cntrl are included.
	In a locale definition file, no character specified for the keywords upper, lower, alpha, digit, cntrl, xdigit or as the space character can be specified.
graph	Define characters to be classified as printable characters, not including the space character.
	In the POSIX locale, all characters in classes alpha, digit, and punct are included; no characters in class cntrl are included.
	In a locale definition file, characters specified for the keywords upper, lower, alpha, digit, xdigit, and punct are automatically included in this class. No character specified for the keyword cntrl can be specified.
print	Define characters to be classified as printable characters, including the space character.
	In the POSIX locale, all characters in class graph are included; no characters in class cntrl are included.

In a locale definition file, characters specified for the keywords upper, lower, alpha, digit, xdigit, punct, and the space character are automatically included in this class. No character specified for the keyword cntrl can be specified.

Define the characters to be classified as hexadecimal digits.

In the POSIX locale, only:

0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f

are included.

In a locale definition file, only the characters defined for the class digit can be specified, in contiguous ascending sequence by numerical value, followed by one or more sets of six characters representing the hexadecimal digits 10 to 15 inclusive, with each set in ascending order (for example A, B, C, D, E, F, a, b, c, d, e, f). The digits 0 to 9, the upper-case letters A to F and the lower-case letters a to f of the portable character set are automatically included in this class.

The definition of character class xdigit requires that the characters included in character class digit be included here also.

Define characters to be classified as blank characters.

In the POSIX locale, only the space and tab characters are included.

In a locale definition file, the characters space and tab are automatically included in this class.

Define one or more locale-specific character class names as strings separated by semi-colons. Each named character class can then be defined subsequently in the LC\_CTYPE definition. A character class name consists of at least one and at most {CHARCLASS\_NAME\_MAX} bytes of alphanumeric characters from the portable filename character set. The first character of a character class name cannot be a digit. The name cannot match any of the LC\_CTYPE keywords defined in this document.

Define characters to be classified as belonging to the named locale-specific character class. In the POSIX locale, the locale-specific named character classes need

xdigit

blank

charclass

charclass-name

not exist. If a class name is defined by a charclass keyword, but no characters are subsequently assigned to it, this is not an error; it represents a class without any characters belonging to it. The charclass-name can be used as the *property* argument to the wctype(3C) function, in regular expression and shell pattern-matching bracket expressions, and by the tr(1) command.

Define the mapping of lower-case letters to upper-case letters.

In the POSIX locale, at a minimum, the 26 lower-case characters:

abcdefghijklmnopqrstuvwxyz

are mapped to the corresponding 26 upper-case characters:

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

In a locale definition file, the operand consists of character pairs, separated by semicolons. The characters in each character pair are separated by a comma and the pair enclosed by parentheses. The first character in each pair is the lower-case letter, the second the corresponding upper-case letter. Only characters specified for the keywords lower and upper can be specified. The lower-case letters a to z, and their corresponding upper-case letters A to Z, of the portable character set are automatically included in this mapping, but only when the toupper keyword is omitted from the locale definition.

Define the mapping of upper-case letters to lower-case letters.

In the POSIX locale, at a minimum, the 26 upper-case characters:

ABCDEFGHIJKLMNOPQRSTUVWXYZ

are mapped to the corresponding 26 lower-case characters:

abcdefghijklmnopqrstuvwxyz

toupper

tolower

In a locale definition file, the operand consists of character pairs, separated by semicolons. The characters in each character pair are separated by a comma and the pair enclosed by parentheses. The first character in each pair is the upper-case letter, the second the corresponding lower-case letter. Only characters specified for the keywords lower and upper can be specified. If the tolower keyword is omitted from the locale definition, the mapping will be the reverse mapping of the one specified for toupper.

#### LC\_COLLATE

The LC\_COLLATE category provides a collation sequence definition for numerous utilities (such as sort(1), uniq(1), and so forth), regular expression matching (see regex(5)), and the strcoll(3C), strxfrm(3C), wcscoll(3C), and wcsxfrm(3C) functions.

A collation sequence definition defines the relative order between collating elements (characters and multi-character collating elements) in the locale. This order is expressed in terms of collation values, that is, by assigning each element one or more collation values (also known as collation weights). The following capabilities are provided:

- 1. Multi-character collating elements. Specification of multi-character collating elements (that is, sequences of two or more characters to be collated as an entity).
- User-defined ordering of collating elements. Each collating element is assigned a collation value defining its order in the character (or basic) collation sequence. This ordering is used by regular expressions and pattern matching and, unless collation weights are explicitly specified, also as the collation weight to be used in sorting.
- 3. Multiple weights and equivalence classes. Collating elements can be assigned one or more (up to the limit {COLL\_WEIGHTS\_MAX}) collating weights for use in sorting. The first weight is hereafter referred to as the primary weight.
- 4. One-to-Many mapping. A single character is mapped into a string of collating elements.
- 5. Equivalence class definition. Two or more collating elements have the same collation value (primary weight).
- 6. Ordering by weights. When two strings are compared to determine their relative order, the two strings are first broken up into a series of collating elements. The elements in each successive pair of elements are then compared according to the relative primary weights for the elements. If equal, and more than one weight has been assigned, the pairs of collating elements are recompared according to the relative subsequent weights, until either a pair of collating elements compare unequal or the weights are exhausted.

The following keywords are recognized in a collation sequence definition. They are described in detail in the following sections.

copy Specify the name of an existing locale which is used as

the definition of this category. If this keyword is

specified, no other keyword is specified.

collating-element Define a collating-element symbol representing a

multi-character collating element. This keyword is

optional.

collating-symbol Define a collating symbol for use in collation order

statements. This keyword is optional.

order start Define collation rules. This statement is followed by

one or more collation order statements, assigning character collation values and collation weights to

collating elements.

order\_end Specify the end of the collation-order statements.

# collating-element keyword

In addition to the collating elements in the character set, the collating-element keyword is used to define multi-character collating elements. The syntax is:

"collating-element %s from \"%s\"\n", <collating-symbol>, <string>

The <code><collating-symbol></code> operand is a symbolic name, enclosed between angle brackets (<code><</code> and <code>></code>), and must not duplicate any symbolic name in the current charmap file (if any), or any other symbolic name defined in this collation definition. The string operand is a string of two or more characters that collates as an entity. A <code><collating-element></code> defined via this keyword is only recognized with the <code>LC\_COLLATE</code> category.

#### Example:

```
collating-element <ch> from "<c><h>"
collating-element <e-acute> from "<acute><e>"
collating-element <11> from "11"
```

# collating-symbol keyword

This keyword will be used to define symbols for use in collation sequence statements; that is, between the order start and the order end keywords. The syntax is:

"collating-symbol %s\n", < collating-symbol>

The *<collating-symbol>* is a symbolic name, enclosed between angle brackets (*<* and *>*), and must not duplicate any symbolic name in the current charmap file (if any), or any other symbolic name defined in this collation definition.

A collating-symbol defined via this keyword is only recognized with the LC COLLATE category.

#### Example:

```
collating-symbol <UPPER_CASE>
collating-symbol <HIGH>
```

The collating-symbol keyword defines a symbolic name that can be associated with a relative position in the character order sequence. While such a symbolic name does not represent any collating element, it can be used as a weight.

order\_start keyword

The order\_start keyword must precede collation order entries and also defines the number of weights for this collation sequence definition and other collation rules.

The syntax of the order start keyword is:

```
"order_start %s;%s;...;%s\n",<sort-rules>,<sort-rules>
```

The operands to the order\_start keyword are optional. If present, the operands define rules to be applied when strings are compared. The number of operands define how many weights each element is assigned. If no operands are present, one forward operand is assumed. If present, the first operand defines rules to be applied when comparing strings using the first (primary) weight; the second when comparing strings using the second weight, and so on. Operands are separated by semicolons (;). Each operand consists of one or more collation directives, separated by commas (,). If the number of operands exceeds the {COLL\_WEIGHTS\_MAX} limit, the utility will issue a warning message. The following directives will be supported:

forward Specifies that comparison operations for the weight

level proceed from start of string towards the end of

string.

backward Specifies that comparison operations for the weight

level proceed from end of string towards the beginning

of string.

position Specifies that comparison operations for the weight

level will consider the relative position of elements in

the strings not subject to IGNORE. The string

containing an element not subject to IGNORE after the fewest collating elements subject to IGNORE from the start of the compare will collate first. If both strings contain a character not subject to IGNORE in the same relative position, the collating values assigned to the elements will determine the ordering. In case of equality, subsequent characters not subject to IGNORE

are considered in the same manner.

The directives forward and backward are mutually exclusive.

Example:

order\_start forward; backward

If no operands are specified, a single forward operand is assumed.

#### **Collation Order**

The order\_start keyword is followed by collating identifier entries. The syntax for the collating element entries is:

"%s %s;%s;...;%s\n"<collating-identifier>,<weight>,<weight>,...

Each *collating-identifier* consists of either a character described in Locale Definition above, a *<collating-element>*, a *<collating-symbol>*, an ellipsis, or the special symbol UNDEFINED. The order in which collating elements are specified determines the character order sequence, such that each collating element compares less than the elements following it. The NUL character compares lower than any other character.

A <*collating-element>* is used to specify multi-character collating elements, and indicates that the character sequence specified via the <*collating-element>* is to be collated as a unit and in the relative order specified by its place.

A <*collating-symbol*> is used to define a position in the relative order for use in weights. No weights are specified with a <*collating-symbol*>.

The ellipsis symbol specifies that a sequence of characters will collate according to their encoded character values. It is interpreted as indicating that all characters with a coded character set value higher than the value of the character in the preceding line, and lower than the coded character set value for the character in the following line, in the current coded character set, will be placed in the character collation order between the previous and the following character in ascending order according to their coded character set values. An initial ellipsis is interpreted as if the preceding line specified the NUL character, and a trailing ellipsis as if the following line specified the highest coded character set value in the current coded character set. An ellipsis is treated as invalid if the preceding or following lines do not specify characters in the current coded character set. The use of the ellipsis symbol ties the definition to a specific coded character set and may preclude the definition from being portable beween implementations.

The symbol UNDEFINED is interpreted as including all coded character set values not specified explicitly or via the ellipsis symbol. Such characters are inserted in the character collation order at the point indicated by the symbol, and in ascending order according to their coded character set values. If no UNDEFINED symbol is specified, and the current coded character set contains characters not specified in this section, the utility will issue a warning message and place such characters at the end of the character collation order.

The optional operands for each collation-element are used to define the primary, secondary, or subsequent weights for the collating element. The first operand specifies the relative primary weight, the second the relative secondary weight, and so on. Two or more collation-elements can be assigned the same weight; they belong to the same

equivalence class if they have the same primary weight. Collation behaves as if, for each weight level, elements subject to IGNORE are removed, unless the position collation directive is specified for the corresponding level with the order\_start keyword. Then each successive pair of elements is compared according to the relative weights for the elements. If the two strings compare equal, the process is repeated for the next weight level, up to the limit {COLL WEIGHTS MAX}.

Weights are expressed as characters described in Locale Definition above, <collating-symbol>s, <collating-element>s, an ellipsis, or the special symbol IGNORE. A single character, a <collating-symbol> or a <collating-element> represent the relative position in the character collating sequence of the character or symbol, rather than the character or characters themselves. Thus, rather than assigning absolute values to weights, a particular weight is expressed using the relative order value assigned to a collating element based on its order in the character collation sequence.

One-to-many mapping is indicated by specifying two or more concatenated characters or symbolic names. For example, if the character <eszet> is given the string "<s><s>" as a weight, comparisons are performed as if all occurrences of the character <eszet> are replaced by <s><s> (assuming that <s> has the collating weight <s>). If it is necessary to define <eszet> and <s><s> as an equivalence class, then a collating element must be defined for the string ss.

All characters specified via an ellipsis will by default be assigned unique weights, equal to the relative order of characters. Characters specified via an explicit or implicit UNDEFINED special symbol will by default be assigned the same primary weight (that is, belong to the same equivalence class). An ellipsis symbol as a weight is interpreted to mean that each character in the sequence has unique weights, equal to the relative order of their character in the character collation sequence. The use of the ellipsis as a weight is treated as an error if the collating element is neither an ellipsis nor the special symbol UNDEFINED.

The special keyword IGNORE as a weight indicates that when strings are compared using the weights at the level where IGNORE is specified, the collating element is ignored; that is, as if the string did not contain the collating element. In regular expressions and pattern matching, all characters that are subject to IGNORE in their primary weight form an equivalence class.

An empty operand is interpreted as the collating element itself.

For example, the order statement:

```
<a> <a>;<a>
is equal to:
```

<a>>

An ellipsis can be used as an operand if the collating element was an ellipsis, and is interpreted as the value of each character defined by the ellipsis.

The collation order as defined in this section defines the interpretation of bracket expressions in regular expressions.

#### Example:

```
forward; backward
order_start
UNDEFINED
                                       IGNORE; IGNORE
<LOW>
                                       <LOW>;<space>
<space>
                                       <LOW>; . . .
                                       <a>;<a>
<a>>
<a-acute>
                                       <a>;<a-acute>
<a-grave>
                                       <a>;<a-grave>
<A>
                                       <a>;<A>
<A-acute>
                                       <a>;<A-acute>
<A-grave>
                                       <a>;<A-grave>
                                       <ch>; <ch>
<ch>
<Ch>>
                                       <ch>; <Ch>
<S>
                                       <S>;<S>
<eszet>
                                       "<s><s>"; "<eszet><eszet>"
order end
```

This example is interpreted as follows:

- 1. The UNDEFINED means that all characters not specified in this definition (explicitly or via the ellipsis) are ignored for collation purposes; for regular expression purposes they are ordered first.
- 2. All characters between <space> and <a> have the same primary equivalence class and individual secondary weights based on their ordinal encoded values.
- 3. All characters based on the upper– or lower–case character a belong to the same primary equivalence class.
- 4. The multi-character collating element <ch> is represented by the collating symbol <ch> and belongs to the same primary equivalence class as the multi-character collating element <Ch>.

order\_end keyword

The collating order entries must be terminated with an order\_end keyword.

#### LC\_MONETARY

The LC\_MONETARY category defines the rules and symbols that are used to format monetary numeric information. This information is available through the localeconv(3C) function

The following items are defined in this category of the locale. The item names are the keywords recognized by the localedef(1) utility when defining a locale. They are also similar to the member names of the localederonv structure defined in <locale. h>. The localedorv function returns {CHAR\_MAX} for unspecified integer items and the empty string ("") for unspecified or size zero string items.

In a locale definition file the operands are strings. For some keywords, the strings can contain only integers. Keywords that are not provided, string values set to the empty string (""), or integer keywords set to -1, are used to indicate that the value is not available in the locale.

int_curr_symbol	The international currency symbol. The operand is a
	four-character string, with the first three characters
	containing the alphabetic international currency
	symbol in accordance with those specified in the ISO
	4217 standard. The fourth character is the character
	used to separate the international currency symbol
	from the monetary quantity.

currency_symbol	The string used as the local	currency symbol.

monetary formatted quantities.

mon\_thousands\_sep

The operand is a string containing the symbol that is

used as a separator for groups of digits to the left of the

used as a separator for groups of digits to the left of the decimal delimiter in formatted monetary quantities.

mon\_grouping Define the size of each group of digits in formatted monetary quantities. The operand is a sequence of

integers separated by semicolons. Each integer specifies the number of digits in each group, with the initial integer defining the size of the group immediately preceding the decimal delimiter, and the following integers defining the preceding groups. If the last integer is not -1, then the size of the previous group (if any) will be repeatedly used for the remainder of the digits. If the last integer is -1, then no further grouping

will be performed.

The following is an example of the interpretation of the mon grouping keyword. Assuming that the value to be formatted is 123456789 and the mon\_thousands\_sep is ', then the following table shows the result. The third column shows the equivalent string in the ISO C standard that would be used by the localeconv function to accommodate this grouping.

mon_grouping	Formatted Value	ISO C String
3;-1 3 3;2;-1 3;2	123456'789 123'456'789 1234'56'789 12'34'56'789	"\3\177" "\3" "\3\2\177" "\3\2\177"
-1	1234567898	"\177"

In these examples, the octal value of {CHAR MAX} is

positive\_sign A string used to indicate a non-negative-valued formatted monetary quantity.

A string used to indicate a negative-valued formatted negative\_sign monetary quantity.

int frac digits An integer representing the number of fractional digits (those to the right of the decimal delimiter) to be written in a formatted monetary quantity using int curr symbol.

> An integer representing the number of fractional digits (those to the right of the decimal delimiter) to be written in a formatted monetary quantity using currency symbol.

In an application conforming to the SUSv3 standard, an integer set to 1 if the currency symbol precedes the value for a monetary quantity with a non-negative value, and set to 0 if the symbol succeeds the value.

In an application *not* conforming to the SUSv3 standard, an integer set to 1 if the currency\_symbol or int currency symbol precedes the value for a monetary quantity with a non-negative value, and set to 0 if the symbol succeeds the value.

In an application conforming to the SUSv3 standard, an integer set to 0 if no space separates the

currency symbol from the value for a monetary

frac digits

p\_cs\_precedes

p\_sep\_by\_space

quantity with a non-negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.

In an application *not* conforming to the SUSv3 standard, an integer set to 0 if no space separates the currency\_symbol or int\_curr\_symbol from the value for a monetary quantity with a non-negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.

n cs precedes

In an application conforming to the SUSv3 standard, an integer set to 1 if the currency\_symbol precedes the value for a monetary quantity with a negative value, and set to 0 if the symbol succeeds the value.

In an application *not* conforming to the SUSv3 standard, an integer set to 1 if the currency\_symbol or int\_currency\_symbol precedes the value for a monetary quantity with a negative value, and set to 0 if the symbol succeeds the value.

n\_sep\_by\_space

In an application conforming to the SUSv3 standard, an integer set to 0 if no space separates the currency\_symbol from the value for a monetary quantity with a negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.

In an application *not* conforming to the SUSv3 standard, an integer set to 0 if no space separates the currency\_symbol or int\_curr\_symbol from the value for a monetary quantity with a negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.

p sign posn

An integer set to a value indicating the positioning of the positive\_sign for a monetary quantity with a non-negative value. The following integer values are recognized for both p\_sign\_posn and n\_sign\_posn:

In an application conforming to the SUSv3 standard:

Parentheses enclose the quantity and the currency\_symbol.

	1	The sign string precedes the quantity and the currency_symbol.
	2	The sign string succeeds the quantity and the currency_symbol.
	3	The sign string precedes the currency_symbol.
	4	The sign string succeeds the currency_symbol.
	In an app	olication <i>not</i> conforming to the SUSv3
	0	Parentheses enclose the quantity and the currency_symbol or int_curr_symbol.
	1	The sign string precedes the quantity and the currency_symbol or int_curr_symbol.
	2	The sign string succeeds the quantity and the currency_symbol or int_curr_symbol.
	3	The sign string precedes the currency_symbol or int_curr_symbol.
	4	The sign string succeeds the currency_symbol or int_curr_symbol.
n_sign_posn	the nega	er set to a value indicating the positioning of tive_sign for a negative formatted quantity.
int_p_cs_precedes	the value	er set to 1 if the int_curr_symbol precedes for a monetary quantity with a non-negative d set to 0 if the symbol succeeds the value.
int_n_cs_precedes	the value	er set to 1 if the int_curr_symbol precedes for a monetary quantity with a negative d set to 0 if the symbol succeeds the value.
<pre>int_p_sep_by_space</pre>	int_cur quantity separates	er set to 0 if no space separates the er_symbol from the value for a monetary with a non-negative value, set to 1 if a space the symbol from the value, and set to 2 if a parates the symbol and the sign string, if

<pre>int_n_sep_by_space</pre>	int_curr quantity v separates	r set to 0 if no space separates the r_symbol from the value for a monetary with a negative value, set to 1 if a space the symbol from the value, and set to 2 if a parates the symbol and the sign string, if
int_p_sign_posn	the posit formatted integer va	r set to a value indicating the positioning of rive_sign for a positive monetary quantity with the international format. The following lues are recognized for int_p_sign_posn n_sign_posn:
	0	Parentheses enclose the quantity and the int_curr_symbol.
	1	The sign string precedes the quantity and the int_curr_symbol.
	2	The sign string precedes the quantity and the int_curr_symbol.
	3	The sign string precedes the int_curr_symbol.
	4	The sign string succeeds the int_curr_symbol.
int_n_sign_posn	the negat	r set to a value indicating the positioning of ive_sign for a negative monetary quantity with the international format.

The following table shows the result of various combinations:

		ŗ	_sep_by_spa	ace
		2	1	0
p_cs_precedes=1	p_sign_posn=0	(\$1.25)	(\$1.25)	(\$1.25)
	p_sign_posn=1	+\$1.25	+\$1.25	+\$1.25
	p_sign_posn=2	\$1.25+	\$1.25+	\$1.25+
	p_sign_posn=3	+\$1.25	+\$1.25	+\$1.25
	p_sign_posn=4	\$+1.25	\$+1.25	\$+1.25
p_cs_precedes=0	p_sign_posn=0	(1.25 \$)	(1.25 \$)	(1.25\$)
	p_sign_posn=1	+1.25 \$	+1.25 \$	+1.25\$
	p_sign_posn=2	1.25\$ +	1.25 \$+	1.25\$+

The monetary formatting definitions for the POSIX locale follow. The code listing depicts the localedef(1) input, the table representing the same information with the addition of localeconv(3C) and nl\_langinfo(3C) formats. All values are unspecified in the POSIX locale.

```
LC MONETARY
# This is the POSIX locale definition for
# the LC MONETARY category.
int curr symbol
currency symbol
mon decimal point
mon_thousands_sep
mon_grouping
positive_sign
                    -1
negative sign
                   -1
int frac digits
frac_digits
                    - 1
p cs precedes
                    -1
p_sep_by_space
                   - 1
n cs precedes
                   -1
                   -1
n_sep_by_space
p sign posn
                   -1
n sign posn
int_p_cs_precedes -1
int p sep by space -1
                   -1
int_n_cs_precedes
int n sep by space
                   -1
int_p_sign_posn
                   -1
                    -1
int_n_sign_posn
END LC MONETARY
```

The entry n/a indicates that the value is not available in the POSIX locale.

### LC\_NUMERIC

The LC\_NUMERIC category defines the rules and symbols that will be used to format non-monetary numeric information. This information is available through the localeconv(3C) function.

The following items are defined in this category of the locale. The item names are the keywords recognized by the localedef utility when defining a locale. They are also similar to the member names of the *lconv* structure defined in <locale.h>. The localeconv() function returns {CHAR\_MAX} for unspecified integer items and the empty string ("") for unspecified or size zero string items.

In a locale definition file the operands are strings. For some keywords, the strings only can contain integers. Keywords that are not provided, string values set to the empty string (""), or integer keywords set to -1, will be used to indicate that the value is not available in the locale. The following keywords are recognized:

de	cim	a I	$n \cap$	int
uc.	$\sim$ $\pm$ 1110	ит	$\rho \circ$	TII

The operand is a string containing the symbol that is used as the decimal delimiter (radix character) in numeric, non-monetary formatted quantities. This keyword cannot be omitted and cannot be set to the empty string. In contexts where standards limit the decimal\_point to a single byte, the result of specifying a multi-byte operand is unspecified.

thousands sep

The operand is a string containing the symbol that is used as a separator for groups of digits to the left of the decimal delimiter in numeric, non-monetary formatted monetary quantities. In contexts where standards limit the thousands\_sep to a single byte, the result of specifying a multi-byte operand is unspecified.

grouping

Define the size of each group of digits in formatted non-monetary quantities. The operand is a sequence of integers separated by semicolons. Each integer specifies the number of digits in each group, with the initial integer defining the size of the group immediately preceding the decimal delimiter, and the following integers defining the preceding groups. If the last integer is not -1, then the size of the previous group (if any) will be repeatedly used for the remainder of the digits. If the last integer is -1, then no further grouping will be performed. The non-monetary numeric formatting definitions for the POSIX locale follow. The code listing depicts the localedef input, the table representing the same information with the addition of localecony values, and nl\_langinfo constants.

```
LC_NUMERIC
# This is the POSIX locale definition for
# the LC_NUMERIC category.
#
decimal_point "<period>"
thousands_sep ""
grouping -1
#
END LC_NUMERIC
```

	POSIX locale	langinfo	localeconv()	localedef	
Item	Value	Constant	Value	Value	
decimal_point	"."	RADIXCHAR	"."	•	
thousands_sep	n/a	THOUSEP	п.п	п п	
grouping	n/a	-	н н	-1	

The entry n/a indicates that the value is not available in the POSIX locale.

#### LC\_TIME

The LC\_TIME category defines the interpretation of the field descriptors supported by date(1) and affects the behavior of the strftime(3C), wcsftime(3C), strptime(3C), and nl\_langinfo(3C) functions. Because the interfaces for C-language access and locale definition differ significantly, they are described separately. For locale definition, the following mandatory keywords are recognized:

	c-language access and locale definition differ significantly, they are described separately. For locale definition, the following mandatory keywords are recognized:		
	abday	Define the abbreviated weekday names, corresponding to the %a field descriptor (conversion specification in the strftime(), wcsftime(), and strptime() functions). The operand consists of seven semicolon-separated strings, each surrounded by double-quotes. The first string is the abbreviated name of the day corresponding to Sunday, the second the abbreviated name of the day corresponding to Monday, and so on.	
	day	Define the full weekday names, corresponding to the %A field descriptor. The operand consists of seven semicolon-separated strings, each surrounded by double-quotes. The first string is the full name of the day corresponding to Sunday, the second the full name of the day corresponding to Monday, and so on.	
	abmon	Define the abbreviated month names, corresponding to the %b field descriptor. The operand consists of twelve semicolon-separated strings, each surrounded by double-quotes. The first string is the abbreviated name of the first month of the year (January), the second the abbreviated name of the second month, and so on.	
	mon	Define the full month names, corresponding to the %B field descriptor. The operand consists of twelve semicolon-separated strings, each surrounded by double-quotes. The first string is the full name of the first month of the year (January), the second the full name of the second month, and so on.	
	d_t_fmt	Define the appropriate date and time representation, corresponding to the $c$ field descriptor. The operand consists of a string, and can contain any combination of characters and field descriptors. In addition, the string can contain the escape sequences $\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \$	
	date_fmt	Define the appropriate date and time representation, corresponding to the %C field descriptor. The operand consists of a string, and can contain any combination of characters and field descriptors. In addition, the string can contain the escape sequences $\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \$	
J			

d\_fmt Define the appropriate date representation, corresponding to the

%x field descriptor. The operand consists of a string, and can contain any combination of characters and field descriptors. In addition, the string can contain the escape sequences \\, \a, \b,

f, n, r, t, v.

t\_fmt Define the appropriate time representation, corresponding to the

%X field descriptor. The operand consists of a string, and can contain any combination of characters and field descriptors. In addition, the string can contain the escape sequences \\, \a, \b,

f, n, r, t, v.

am\_pm Define the appropriate representation of the ante meridiem and post

meridiem strings, corresponding to the \*p field descriptor. The operand consists of two strings, separated by a semicolon, each surrounded by double-quotes. The first string represents the ante meridiem designation, the last string the post meridiem designation.

t\_fmt\_ampm Define the appropriate time representation in the 12-hour clock format with ampm corresponding to the %r field descriptor. The

format with am\_pm, corresponding to the r field descriptor. The operand consists of a string and can contain any combination of characters and field descriptors. If the string is empty, the 12-hour

format is not supported in the locale.

era Define how years are counted and displayed for each era in a locale. The operand consists of semicolon-separated strings. Each

string is an era description segment with the format:

direction:offset:start\_date:end\_date:era\_name:era\_format

according to the definitions below. There can be as many era description segments as are necessary to describe the different

eras.

The start of an era might not be the earliest point For example, the Christian era B.C. starts on the day before January 1, A.D. 1, and

increases with earlier time.

direction Either a + or a – character. The + character

indicates that years closer to the *start\_date* have lower numbers than those closer to the *end\_date*. The – character indicates that years closer to the *start\_date* have higher numbers

than those closer to the *end\_date*.

offset The number of the year closest to the start\_date

in the era, corresponding to the %Eg and %Ey

field descriptors.

iocaic(3)			
		start_date	A date in the form <code>yyyy/mm/dd</code> , where <code>yyyy</code> , <code>mm</code> , and <code>dd</code> are the year, month and day numbers respectively of the start of the era. Years prior to A.D. 1 are represented as negative numbers.
		end_date	The ending date of the era, in the same format as the <i>start_date</i> , or one of the two special values –* or +*. The value –* indicates that the ending date is the beginning of time. The value +* indicates that the ending date is the end of time.
		era_name	A string representing the name of the era, corresponding to the %EC field descriptor.
		era_format	A string for formatting the year in the era, corresponding to the %EG and %EY field descriptors.
	era_d_fmt		of the date in alternative era notation, the %Ex field descriptor.
	era_t_fmt		appropriate alternative time format, the %EX field descriptor.
	era_d_t_fmt		appropriate alternative date and time format, the %Ec field descriptor.
	alt_digits	descriptor modifie strings, each surro alternative symbol symbol correspond symbol strings car	symbols for digits, corresponding to the %0 field er. The operand consists of semicolon-separated unded by double-quotes. The first string is the l corresponding with zero, the second string the ding with one, and so on. Up to 100 alternative is be specified. The %0 modifier indicates that the ing to the value specified via the field descriptor and of the value.
LC_TIME C-language Access	_		essed. These correspond to constants defined in the tothe nl_langinfo(3C) function.
	ABDAY_x	The abbreviated w number from 1 to	veekday names (for example Sun), where $x$ is a 7.
	DAY_x	The full weekday in number from 1 to	names (for example Sunday), where $x$ is a 7.
	ABMON_x	The abbreviated m number from 1 to	nonth names (for example Jan), where $x$ is a 12.
	MON_x	The full month natifrom 1 to 12.	mes (for example January), where $x$ is a number
	•		

D\_T\_FMT The appropriate date and time representation.

D\_FMT The appropriate date representation.
T\_FMT The appropriate time representation.
AM\_STR The appropriate ante-meridiem affix.
PM\_STR The appropriate post-meridiem affix.

T FMT AMPM The appropriate time representation in the 12-hour clock format

with AM STR and PM STR.

ERA The era description segments, which describe how years are

counted and displayed for each era in a locale. Each era

description segment has the format:

direction: offset: start\_date: end\_date: era\_name: era\_format

according to the definitions below. There will be as many era description segments as are necessary to describe the different eras. Era description segments are separated by semicolons.

The start of an era might not be the earliest point For example, the Christian era B.C. starts on the day before January 1, A.D. 1, and increases with earlier time.

direction Either a + or a – character. The + character

indicates that years closer to the *start\_date* have lower numbers than those closer to the *end\_date*. The – character indicates that years closer to the *start\_date* have higher numbers

than those closer to the end\_date.

offset The number of the year closest to the

start\_date in the era.

start\_date A date in the form yyyy/mm/dd, where yyyy,

*mm*, and dd are the year, month and day numbers respectively of the start of the era. Years prior to AD 1 are represented as negative

numbers.

end\_date The ending date of the era, in the same format

as the *start\_date*, or one of the two special values, -\* or +\*. The value -\* indicates that the ending date is the beginning of time. The value +\* indicates that the ending date is the

end of time.

era\_name The era, corresponding to the %EC conversion

specification.

	era_format	The format of the year in the era, corresponding to the %EY and %EY conversion specifications.	
ERA_D_FMT	The era date forma	at.	
ERA_T_FMT	The locale's appropriate alternative time format, corresponding to the %EX field descriptor.		
ERA_D_T_FMT	The locale's appropriate alternative date and time format, corresponding to the %Ec field descriptor.		
ALT_DIGITS	The alternative symbols for digits, corresponding to the %0 conversion specification modifier. The value consists of semicolon-separated symbols. The first is the alternative symbol corresponding to zero, the second is the symbol corresponding to one, and so on. Up to 100 alternative symbols may be specified. The following table displays the correspondence between the items described above and the conversion specifiers used by date(1) and the strftime(3C), wcsftime(3C), and strptime(3C) functions.		

localedef	langinfo	Conversion
Keyword	Constant	Specifier
abday	ABDAY_x	%a
day	DAY_x	%A
abmon	ABMON_x	%b
mon	MON	%B
d_t_fmt	D_T_FMT	%C
date_fmt	DATE_FMT	%C
d_fmt	D_FMT	%x
t_fmt	T_FMT	%X
am_pm	AM_STR	%p
am_pm	PM_STR	%p
t_fmt_ampm	T_FMT_AMPM	%r
era	ERA	%EC, %Eg,
		%EG, %Ey, %EY
era_d_fmt	ERA_D_FMT	%Ex
era_t_fmt	ERA_T_FMT	%EX

localedef	langinfo	Conversion
Keyword	Constant	Specifier
era_d_t_fmt	ERA_D_T_FMT	%Ec
alt_digits	ALT_DIGITS	%O

#### LC\_TIME General Information

Although certain of the field descriptors in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these fields may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The LC TIME descriptions of abday, day, mon, and abmon imply a Gregorian style calendar (7-day weeks, 12-month years, leap years, and so forth). Formatting time strings for other types of calendars is outside the scope of this document set.

As specified under date in Locale Definition and strftime(3C), the field descriptors corresponding to the optional keywords consist of a modifier followed by a traditional field descriptor (for instance %Ex). If the optional keywords are not supported by the implementation or are unspecified for the current locale, these field descriptors are treated as the traditional field descriptor. For instance, assume the following keywords:

```
"0th"; "1st"; "2nd"; "3rd"; "4th"; "5th"; \
alt digits
 "6th"; "7th"; "8th"; "9th"; "10th"
d fmt
        "The %Od day of %B in %Y"
```

On 7/4/1776, the %x field descriptor would result in "The 4th day of July in 1776" while 7/14/1789 would come out as "The 14 day of July in 1789" The above example is for illustrative purposes only. The %0 modifier is primarily intended to provide for Kanji or Hindi digits in date formats.

#### LC\_MESSAGES

The LC MESSAGES category defines the format and values for affirmative and negative responses.

The following keywords are recognized as part of the locale definition file. The nl langinfo(3C) function accepts upper-case versions of the first four keywords.

yesexpr	The operand consists of an extended regular expression (see regex(5)) that describes the acceptable affirmative response to a question expecting an affirmative or negative response.
noexpr	The operand consists of an extended regular expression that describes the acceptable negative response to a question expecting an affirmative or negative response.
yesstr	The operand consists of a fixed string (not a regular expression) that can be used by an application for composition of a message that lists an acceptable affirmative response, such as in a prompt.

nostr

The operand consists of a fixed string that can be used by an application for composition of a message that lists an acceptable negative response. The format and values for affirmative and negative responses of the POSIX locale follow; the code listing depicting the localedef input, the table representing the same information with the addition of nl langinfo() constants.

localedef Keyword	langinfo Constant	POSIX Locale Value
yesexpr	YESEXPR	"^[yY]"
noexpr	NOEXPR	"^[nN]"
yesstr	YESSTR	"yes"
nostr	NOSTR	"no"

NAME | man – macros to format Reference Manual pages

**SYNOPSIS** 

nroff -man filename...

troff -man filename...

#### **DESCRIPTION**

These macros are used to lay out the reference pages in this manual. Note: if *filename* contains format input for a preprocessor, the commands shown above must be piped through the appropriate preprocessor. This is handled automatically by the man(1) command. See the "Conventions" section.

Any text argument t may be zero to six words. Quotes may be used to include SPACE characters in a "word". If text is empty, the special treatment is applied to the next input line with text to be printed. In this way . I may be used to italicize a whole line, or . SB may be used to make small bold letters.

A prevailing indent distance is remembered between successive indented paragraphs, and is reset to default value upon reaching a non-indented paragraph. Default units for indents i are ens.

Type font and size are reset to default values before each paragraph, and after processing font and size setting macros.

These strings are predefined by -man:

\\*R '®', '(Reg)' in nroff.

\\*S Change to default type size.

#### Requests

\* n.t.l. = next text line; p.i. = prevailing indent

Request	Cause	If no	Explanation
	Break	Argument	
.в <i>t</i>	no	<i>t</i> =n.t.l.*	Text is in bold font.
.BI $t$	no	t=n.t.l.	Join words, alternating bold and italic.
.BR $t$	no	t=n.t.l.	Join words, alternating bold and roman.
.DT	no	.5i 1i	Restore default tabs.
.HP $i$	yes	<i>i</i> =p.i.*	Begin paragraph with hanging indent. Set prevailing indent to $i$ .
.I $t$	no	t=n.t.l.	Text is italic.
.IB $t$	no	t=n.t.l.	Join words, alternating italic and bold.
. IP $x$ $i$	yes	<i>x</i> =""	Same as . $TP$ with tag $x$ .
.IR $t$	no	t=n.t.l.	Join words, alternating italic and roman.

# man(5)

Request	Cause	If no	Explanation
	Break	Argument	
.IX t	no	-	Index macro, for SunSoft internal use.
.LP	yes	-	Begin left-aligned paragraph. Set prevailing indent to .5i.
.P	yes	-	Same as .LP.
.PD $d$	no	$d$ =.4 $\mathrm{v}$	Set vertical distance between paragraphs.
.PP	yes	-	Same as .LP.
.RE	yes	-	End of relative indent. Restores prevailing indent.
.RB t	no	<i>t</i> =n.t.l.	Join words, alternating roman and bold.
.RI t	no	<i>t</i> =n.t.l.	Join words, alternating roman and italic.
.RS i	yes	<i>i</i> =p.i.	Start relative indent, increase indent by <i>i</i> . Sets prevailing indent to .5i for nested indents.
.SB t	no	-	Reduce size of text by 1 point, make text bold.
.SH t	yes	-	Section Heading.
.SM t	no	<i>t</i> =n.t.l.	Reduce size of text by 1 point.
.ss t	yes	<i>t</i> =n.t.l.	Section Subheading.
. TH $n s d f m$	yes	-	Begin reference page $n$ , of of section $s$ ; $d$ is the date of the most recent change. If present, $f$ is the left page footer; $m$ is the main page (center) header. Sets prevailing indent and tabs to .5i.
.TP i	yes	<i>i</i> =p.i.	Begin indented paragraph, with the tag given on the next text line. Set prevailing indent to $i$ .
.TX t p	no	-	Resolve the title abbreviation $t$ ; join to punctuation mark (or text) $p$ .

#### Conventions

When formatting a manual page, man examines the first line to determine whether it requires special processing. For example a first line consisting of:

'\" t

indicates that the manual page must be run through the tbl(1) preprocessor.

A typical manual page for a command or function is laid out as follows:

.TH *title* [1-9] The name of the command or function, which serves as

the title of the manual page. This is followed by the

number of the section in which it appears.

.SH NAME The name, or list of names, by which the command is

called, followed by a dash and then a one-line summary of the action performed. All in roman font, this section contains no troff(1) commands or escapes, and no macro requests. It is used to generate the windex database, which is used by the whatis(1)

command.

.SH SYNOPSIS

#### Commands:

The syntax of the command and its arguments, as typed on the command line. When in boldface, a word must be typed exactly as printed. When in italics, a word can be replaced with an argument that you supply. References to bold or italicized items are not capitalized in other sections, even when they begin a sentence.

Syntactic symbols appear in roman face:

[] An argument, when surrounded by brackets is optional.

Arguments separated by a vertical bar are exclusive. You can supply only one item from such a list.

. . . Arguments followed by an ellipsis can be repeated. When an ellipsis follows a bracketed set, the expression within the brackets can be repeated.

#### **Functions:**

If required, the data declaration, or #include directive, is shown first, followed by the function declaration. Otherwise, the function declaration is shown.

.SH DESCRIPTION

A narrative overview of the command or function's external behavior. This includes how it interacts with files or data, and how it handles the standard input, standard output and standard error. Internals and implementation details are normally omitted. This section attempts to provide a succinct overview in answer to the question, "what does it do?"

Literal text from the synopsis appears in constant width, as do literal filenames and references to items that appear elsewhere in the reference manuals.

Arguments are italicized.

If a command interprets either subcommands or an input grammar, its command interface or input grammar is normally described in a USAGE section,

which follows the OPTIONS section. The

DESCRIPTION section only describes the behavior of the command itself, not that of subcommands.

.SH OPTIONS The list of options along with a description of how each

affects the command's operation.

SH RETURN VALUES A list of the values the library routine will return to the

calling program and the conditions that cause these

values to be returned.

.SH EXIT STATUS A list of the values the utility will return to the calling

program or shell, and the conditions that cause these

values to be returned.

.SH FILES A list of files associated with the command or function.

.SH SEE ALSO A comma-separated list of related manual pages,

followed by references to other published materials.

.SH DIAGNOSTICS A list of diagnostic messages and an explanation of

each.

.SH BUGS A description of limitations, known defects, and

possible problems associated with the command or

function.

**NAME** | mansun – macros to format Reference Manual pages

**SYNOPSIS** 

nroff -mansun filename...

troff -mansun filename...

#### **DESCRIPTION**

These macros are used to lay out the reference pages in this manual. Note: if filename contains format input for a preprocessor, the commands shown above must be piped through the appropriate preprocessor. This is handled automatically by man(1). See the "Conventions" section.

Any text argument t may be zero to six words. Quotes may be used to include SPACE characters in a "word". If text is empty, the special treatment is applied to the next input line with text to be printed. In this way . I may be used to italicize a whole line, or . SB may be used to make small bold letters.

A prevailing indent distance is remembered between successive indented paragraphs, and is reset to default value upon reaching a non-indented paragraph. Default units for indents *i* are ens.

Type font and size are reset to default values before each paragraph, and after processing font and size setting macros.

These strings are predefined by -mansun:

\\*R '®', '(Reg)' in nroff.

\\*S Change to default type size.

#### Requests

\* n.t.l. = next text line; p.i. = prevailing indent

Request	Cause	If no	Explanation
	Break	Argument	
.в <i>t</i>	no	<i>t</i> =n.t.l.*	Text is in bold font.
.BI $t$	no	t=n.t.l.	Join words, alternating bold and italic.
.BR $t$	no	<i>t</i> =n.t.l.	Join words, alternating bold and Roman.
.DT	no	.5i 1i	Restore default tabs.
.HP $i$	yes	<i>i</i> =p.i.*	Begin paragraph with hanging indent. Set prevailing indent to $i$ .
.I $t$	no	t=n.t.l.	Text is italic.
.IB t	no	t=n.t.l.	Join words, alternating italic and bold.
. IP $x$ $i$	yes	<i>x</i> =""	Same as $. TP $ with tag $x.$
.IR t	no	t=n.t.l.	Join words, alternating italic and Roman.

# mansun(5)

Request	Cause	If no	Explanation
	Break	Argument	
.IX $t$	no	-	Index macro, for SunSoft internal use.
.LP	yes	-	Begin left-aligned paragraph. Set prevailing indent to .5i.
.P	yes	-	Same as .LP.
.PD $d$	no	d=.4 $v$	Set vertical distance between paragraphs.
.PP	yes	-	Same as .LP.
.RE	yes	-	End of relative indent. Restores prevailing indent.
.RB t	no	t=n.t.l.	Join words, alternating Roman and bold.
.RI t	no	t=n.t.l.	Join words, alternating Roman and italic.
.RS i	yes	<i>i</i> =p.i.	Start relative indent, increase indent by <i>i</i> . Sets prevailing indent to .5i for nested indents.
.SB t	no	-	Reduce size of text by 1 point, make text bold.
.SH $t$	yes	-	Section Heading.
.SM $t$	no	t=n.t.l.	Reduce size of text by 1 point.
.ss t	yes	t=n.t.l.	Section Subheading.
. TH $n s d f m$	yes	-	Begin reference page $n$ , of of section $s$ ; $d$ is the date of the most recent change. If present, $f$ is the left page footer; $m$ is the main page (center) header. Sets prevailing indent and tabs to .5i.
.TP $i$	yes	<i>i</i> =p.i.	Begin indented paragraph, with the tag given on the next text line. Set prevailing indent to $i$ .
.TX $t$ $p$	no	-	Resolve the title abbreviation <i>t</i> ; join to punctuation mark (or text) <i>p</i> .

#### Conventions

When formatting a manual page, mansun examines the first line to determine whether it requires special processing. For example a first line consisting of:

'\" t

indicates that the manual page must be run through the tbl(1) preprocessor.

A typical manual page for a command or function is laid out as follows:

.TH title [1-8] The name of the command or function, which serves as

the title of the manual page. This is followed by the

number of the section in which it appears.

.SH NAME The name, or list of names, by which the command is

called, followed by a dash and then a one-line summary of the action performed. All in Roman font, this section contains no troff(1) commands or escapes, and no macro requests. It is used to generate the windex database, which is used by the whatis(1)

command.

.SH SYNOPSIS

#### Commands:

The syntax of the command and its arguments, as typed on the command line. When in boldface, a word must be typed exactly as printed. When in italics, a word can be replaced with an argument that you supply. References to bold or italicized items are not capitalized in other sections, even when they begin a sentence.

Syntactic symbols appear in Roman face:

[ ] An argument, when surrounded by brackets is optional.

Arguments separated by a vertical bar are exclusive. You can supply only one

item from such a list.

. . . Arguments followed by an ellipsis can be repeated. When an ellipsis follows a bracketed set, the expression within the brackets can be repeated.

#### **Functions:**

If required, the data declaration, or #include directive, is shown first, followed by the function declaration. Otherwise, the function declaration is shown.

.SH DESCRIPTION

A narrative overview of the command or function's external behavior. This includes how it interacts with files or data, and how it handles the standard input, standard output and standard error. Internals and implementation details are normally omitted. This section attempts to provide a succinct overview in answer to the question, "what does it do?"

#### mansun(5)

Literal text from the synopsis appears in constant width, as do literal filenames and references to items that appear elsewhere in the reference manuals.

Dale Dougherty and Tim O'Reilly, Unix Text Processing

**NAME** | me – macros for formatting papers

### **SYNOPSIS**

nroff -me [options] filename...

troff -me [options] filename...

#### **DESCRIPTION**

This package of nroff and troff macro definitions provides a canned formatting facility for technical papers in various formats. When producing 2-column output on a terminal, filter the output through col(1).

The macro requests are defined below. Many nroff and troff requests are unsafe in conjunction with this package, however, these requests may be used with impunity after the first .pp:

.bp	begin new page
.br	break output line here
.sp n	insert $n$ spacing lines
.ls n	(line spacing) <i>n</i> =1 single, <i>n</i> =2 double space
.na	no alignment of right margin
.ce n	center next $n$ lines
.ul <i>n</i>	underline next <i>n</i> lines
.sz +n	add $n$ to point size

Output of the eqn(1), neqn(1), refer(1), and tbl(1) preprocessors for equations and tables is acceptable as input.

### **REQUESTS**

In the following list, "initialization" refers to the first .pp, .lp, .ip, .np, .sh, or . uh macro. This list is incomplete.

Request	Initial	Cause	Explanation
	Value	Break	
.(c	-	yes	Begin centered block.
.(d	-	no	Begin delayed text.
.(f	-	no	Begin footnote.
.(1	-	yes	Begin list.
.(q	-	yes	Begin major quote.
. (xx	-	no	Begin indexed item in index $x$ .
.(z	-	no	Begin floating keep.
.)c	-	yes	End centered block.

### me(5)

Request	Initial	Cause	Explanation
	Value	Break	
.)d	-	yes	End delayed text.
.)f	-	yes	End footnote.
.)1	-	yes	End list.
.)q	-	yes	End major quote.
.)x	-	yes	End index item.
.)z	-	yes	End floating keep.
.++ m H	-	no	Define paper section.
			m defines the part of the paper,
			and can be $\mathbb C$ (chapter), $\mathbb A$ (appendix), $\mathbb P$ (preliminary, for instance,
			abstract, table of contents, etc.),
			B (bibliography), RC (chapters
			renumbered from page one each
			chapter), or RA (appendix renumbered
			from page one).
.+c T	-	yes	Begin chapter (or appendix, etc.,
			as set by $.++$ ). $T$ is
			the chapter title.
.1c	1	yes	One column format on a new page.
.2c	1	yes	Two column format.
.EN	-	yes	Space after equation produced by eqn
			or neqn.
.EQ x y	-	yes	Precede equation; break out and
			add space. Equation number is y.
			The optional argument $x$ may be $I$
			to indent equation (default),
			L to left-adjust the equation, or
			<i>C</i> to center the equation.
.GE	-	yes	End gremlin picture.

ı	Request	Initial	Cause	Explanation
		Value	Break	
	.GS	-	yes	Begin <i>gremlin</i> picture.
	.PE	-	yes	End pic picture.
	.PS	-	yes	Begin pic picture.
	.TE	-	yes	End table.
	.TH	-	yes	End heading section of table.
	.TS x	-	yes	Begin table; if $x$ is $H$ table
				has repeated heading.
	.ac $AN$	-	no	Set up for ACM style output.
				A is the Author's name(s), $N$ is the
				total number of pages. Must be given
				before the first initialization.
	.b x	no	no	Print <i>x</i> in boldface; if no argument
				switch to boldface.
	.ba +n	0	yes	Augments the base indent by $n$ .
				This indent is used to set the indent
				on regular text (like paragraphs).
	.bc	no	yes	Begin new column.
	.bi x	no	no	Print <i>x</i> in bold italics
				(nofill only).
	.bu	-	yes	Begin bulleted paragraph.
	. bx x	no	no	Print $x$ in a box (nofill only).
	.ef $'x'y'z$	,,,,,	no	Set even footer to $x$ $y$ $z$ .
	.eh $'x'y'z$	,,,,,	no	Set even header to $x$ $y$ $z$ .
	.fo' $x'y'z$	,,,,,	no	Set footer to $x$ $y$ $z$ .
	.hx	-	no	Suppress headers and footers on
				next page.
	. he $'x'y'z$	,,,,,	no	Set header to $x$ $y$ $z$ .
	.hl	-	yes	Draw a horizontal line.

### me(5)

Request	Initial	Cause	Explanation
	Value	Break	
.i x	no	no	Italicize <i>x</i> ; if <i>x</i> missing, italic
			text follows.
.ip x y	no	yes	Start indented paragraph, with
			hanging tag x. Indentation is
			y ens (default 5).
.lp	yes	yes	Start left-blocked paragraph.
.lo	-	no	Read in a file of local macros
			of the form $.*x$ . Must be
			given before initialization.
.np	1	yes	Start numbered paragraph.
.of $'x'y'z$	,,,,,	no	Set odd footer to x y z.
.oh $'x'y'z$	,,,,,	no	Set odd header to x y z.
.pd	-	yes	Print delayed text.
.pp	no	yes	Begin paragraph. First line indented.
.r	yes	no	Roman text follows.
.re	-	no	Reset tabs to default values.
.sc	no	no	Read in a file of special characters
			and diacritical marks. Must be
			given before initialization.
$. \sinh n x$	-	yes	Section head follows, font
			automatically bold. $n$ is level
			of section, <i>x</i> is title of section.
.sk	no	no	Leave the next page blank.
			Only one page is remembered ahead.
$. \operatorname{sm} x$	-	no	Set <i>x</i> in a smaller pointsize.
.sz+n	10p	no	Augment the point size by $n$ points.
.th	no	no	Produce the paper in thesis format.
			Must be given before initialization.

Request	Initial	Cause	Explanation
	Value	Break	
.tp	no	yes	Begin title page.
.u <i>x</i>	-	no	Underline argument (even in troff).
			(Nofill only).
.uh	-	yes	Like .sh but unnumbered.
.xp x	-	no	Print index $x$ .
/ /1-	/1 - 1 - /	/ .

#### mech\_spnego(5)

NAME

mech\_spnego - Simple and Protected GSS-API Negotiation Mechanism

**SYNOPSIS** 

/usr/lib/gss/mech\_spnego.so.1

#### **DESCRIPTION**

The SPNEGO security mechanism for GSS-API allows GSS-API applications to negotiate the actual security mechanism to be used in the GSS-API session. mech\_spnego.so.1 is a shared object module that is dynamically opened by applications that specify the SPNEGO Object Identifier (OID) in calls to the GSS-API functions (see libgss(3LIB)).

SPNEGO is described by IETF RFC 2478 and is intended to be used in environments where multiple GSS-API mechanisms are available to the client or server and neither side knows what mechanisms are supported by the other.

When SPNEGO is used, it selects the list of mechanisms to advertise by reading the GSS mechanism configuration file, /etc/gss/mech (see mech(4)), and by listing all active mechanisms except for itself.

#### **OPTIONS**

SPNEGO may be configured to function in two ways. The first way is to interoperate with Microsoft SSPI clients and servers that use the Microsoft "Negotiate" method, which is also based on SPNEGO. The Microsoft "Negotiate" mechanism does not strictly follow the IETF RFC. Therefore, use special handling in order to enable full interoperability. In order to interoperate, place option "[msinterop]" at the end of the SPNEGO line in /etc/gss/mech.

This is an example (from /etc/gss/mech):

```
spnego 1.3.6.1.5.5.2 mech_spnego.so [ msinterop ]
```

Without the "[msinterop]" option, mech\_spnego will follow the strict IETF RFC 2478 specification and will not be able to negotiate with Microsoft applications that try to use the SSPI "Negotiate" mechanism.

#### **INTERFACES**

mech\_spnego.so.1 has no public interfaces. It is only activated and used through the GSS-API interface provided by libgss.so.1 (see libgss(3LIB)).

### **FILES**

```
/usr/lib/gss/mech_spnego.so.1 shared object file

Solaris Security for Developers Guide

NAME |

mm – text formatting (memorandum) macros

**SYNOPSIS** 

nroff -mm [options] filename...

troff -mm [options] filename...

#### **DESCRIPTION**

This package of nroff(1) and troff(1) macro definitions provides a formatting facility for various styles of articles, theses, and books. When producing 2-column output on a terminal or lineprinter, or when reverse line motions are needed, filter the output through col(1). All external -mm macros are defined below.

Note: this -mm macro package is an extended version written at Berkeley and is a superset of the standard -mm macro packages as supplied by Bell Labs. Some of the Bell Labs macros have been removed; for instance, it is assumed that the user has little interest in producing headers stating that the memo was generated at Whippany Labs.

Many nroff and troff requests are unsafe in conjunction with this package. However, the first four requests below may be used with impunity after initialization, and the last two may be used even before initialization:

.bp begin new page

.br break output line

. spn insert n spacing lines

.cen center next n lines

.1sn line spacing: n=1 single, n=2 double space

.na no alignment of right margin

Font and point size changes with \f and \s are also allowed; for example, \fIword\fR will italicize word. Output of the tbl(1), eqn(1) and refer(1) preprocessors for equations, tables, and references is acceptable as input.

#### **REOUESTS**

Here is a table of macros.

Macro Name	Initial Value	Break? Reset?	Explanation
.1C	on	у,у	one column format on a new page
.20[1]	_	y,y	two column format <i>l</i> =line length
.AE	_	у	end abstract
.AL[t][i][s]	t=1;i=.Li;s=0	у	Start automatic list type $t=[1,A,a,I,i]$ 1=arabic numbers; A=uppercase letters a=lowercase letters; I=uppercase Roman numerals; i=lowercase Roman numerals indentation $i$ ; separation $s$

Macro Name	Initial Value	Break? Reset?	Explanation
. AS m [ n ]	<i>n</i> =0	у	begin abstract
. AU	_	у	author's name
. AV x	_	y	signature and date line of verifier <i>x</i>
.B x	-	n	embolden <i>x</i> ; if no <i>x</i> , switch to boldface
.BE	_	у	end block text
.BI <i>x y</i>	_	n	embolden x and underline y
.BL	_	y	bullet list
. BR <i>x y</i>	-	n	embolden <i>x</i> and use Roman font for <i>y</i>
.BS	_	n	start block text
. CN	_	у	same as .DE (nroff)
.CS	_	y	cover sheet
. CW	_	n	same as .DS I (nroff)
.DE	_	у	end display
.DF[p][f][rp]	p=L;f=N	у	start floating display; position $p=[L,C,CB]$ L=left; I=indent; C=center; CB=center block fill $f=[N,Y]$ ; right position $rp$ (fill only)
.DL[i][s]	_	у	start dash list
.DS[p][f][rp]	p=L;f=N	у	begin static display (see .DF for argument descriptions)
. EC x [ n ]	n=1	y	equation title; equation $x$ ; number $n$
. EF x	-	n	even footer appears at the bottom of even-numbered pages; $x="l'c'r"$ $l$ =left; $c$ =center; $r$ =right
. ЕН х	-	n	even header appears at the top of even-numbered pages; $x="l'c'r"$ $l$ =left; $c$ =center; $r$ =right
. EN	-	у	end displayed equation produced by eqn
. EQ	-	у	break out equation produced by eqn
. EX x [ n ]	n=1	у	exhibit title; exhibit <i>x</i>

Macro Name	Initial Value	Break? Reset?	Explanation
			number n
.FD[f][r]	f=10;r=1	n	set footnote style format $f=[0-11]$ ; renumber $r=[0,1]$
. FE	_	у	end footnote
. FG x [ n ]	n=1	у	figure title; figure x; number n
.FS	_	n	start footnote
.H l [ t ]	-	у	produce numbered heading level $l=[1-7]$ ; title $t$
. HU $t$	-	у	produce unnumbered heading; title t
. I x	_	n	underline x
. IB <i>x y</i>	_	n	underline x and embolden y
.IR x y	-	n	underline <i>x</i> and use Roman font on <i>y</i>
. LE [ s ]	s=0	у	end list; separation s
.LI[m][p]	_	у	start new list item; mark m
			prefix <i>p</i> (mark only)
.ML m[i][s]	s=0	у	start marked list; mark $m$ indentation $i$ ; separation $s$ =[0,1]
. MT <i>x</i>		у	memo title; title x
. ND x		n	no date in page footer; <i>x</i> is date on cover
. NE	_	у	end block text
.NS	_	у	start block text
.OF x	-	n	odd footer appears at the bottom of odd-numbered pages; $x="l'c'r"$ $l=left; c=center; r=right$
. OF x	-	n	odd header appears at the top of odd-numbered pages; $x="l'c'r"$ $l=$ left; $c=$ center; $r=$ right
.OP	_	у	skip to the top of an odd-number page
.P[t]	t=0	у,у	begin paragraph; <i>t</i> =[0,1] 0=justified; 1=indented

Macro Name	Initial Value	Break? Reset?	Explanation
. PF x	-	n	page footer appears at the bottom of every page; $x="l'c'r"$ $l=$ left; $c=$ center; $r=$ right
. РН х	-	n	page header appears at the top of every page; $x="l'c'r"$ $l=$ left; $c=$ center; $r=$ right
.R	on	n	return to Roman font
. RB <i>x y</i>	_	n	use Roman on $x$ and embolden $y$
.RI x y	_	n	use Roman on x and underline y
.RP x	-	у,у	released paper format ? <i>x</i> =no stops title on first
.RS	5n	у,у	right shift: start level of relative indentation
.S m n	-	n	set character point size & vertical space character point size <i>m</i> ; vertical space <i>n</i>
.SA x	x=1	n	justification; <i>x</i> =[0,1]
.SK x	_	у	skip <i>x</i> pages
.SM	_	n	smaller; decrease point size by 2
.SP[x]	_	у	leave x blank lines
. TB x [ n ]	n=1	у	table title; table <i>x</i> ; number <i>n</i>
.TC	-	у	print table of contents (put at end of input file)
.TE	_	у	end of table processed by tbl
.TH	_	у	end multi-page header of table
.TL	-	n	title in boldface and two points larger
. TM	_	n	UC Berkeley thesis mode
.TP i	у	у	<i>i</i> =p.i. Begin indented paragraph, with the tag given on the next text line. Set prevailing indent to <i>i</i> .
.TS x	-	у,у	begin table; if <i>x</i> =H table has multi-page header
.TY	_	у	display centered title CONTENTS

Macro Name	Initial Value	Break? Reset?	Explanation
.VL i[m][s]	<i>m</i> =0; <i>s</i> =0	-	start variable-item list; indentation $i$ mark-indentation $m$ ; separation $s$

#### **REGISTERS**

Formatting distances can be controlled in -mm by means of built-in number registers. For example, this sets the line length to 6.5 inches:

.nr LL 6.5i

Here is a table of number registers and their default values:

Name	Register Controls	Takes Effect	Default
Cl	contents level	table of contents	2
De	display eject	display	0
Df	display floating	display	5
Ds	display spacing	display	1v
Hb	heading break	heading	2
НС	heading centering	heading	0
Hi	heading indent	heading	1
Hi	heading spacing	heading	1
Hu	heading unnumbered	heading	2
Li	list indentation	list	6 (nroff) 5 (troff)
Ls	list spacing	list	6
Pi	paragraph indent	paragraph	5
Pt	paragraph type	paragraph	1
Si	static indent	display	5(nroff) 3(troff)

When resetting these values, make sure to specify the appropriate units. Setting the line length to 7, for example, will result in output with one character per line. Setting Pi to 0 suppresses paragraph indentation

Here is a list of string registers available in -mm; they may be used anywhere in the text:

Name	String's Function	
\*Q	<pre>quote(" in nroff, '' in troff)</pre>	
/*U	unquote("in nroff, ''in troff)	
\*-	dash ( in nroff, — in troff)	
\* (MO	month (month of the year)	
\* (DY	day (current date)	
\**	automatically numbered footnote	
\* <i>'</i>	acute accent (before letter)	
/*'	grave accent (before letter)	
\*^	circumflex (before letter)	
\*,	cedilla (before letter)	
\*:	umlaut (before letter)	
\*~	tilde (before letter)	
\ (BU	bullet item	
\(DT	date (month day, yr)	
\ (EM	em dash	
\(Lf	LIST OF FIGURES title	
\(Lt	LIST OF TABLES title	
\(Lx	LIST OF EXHIBITS title	
\(Le	LIST OF EQUATIONS title	
\(Rp	REFERENCES title	
\(Tm	trademark character (TM)	

When using the extended accent mark definitions available with .AM, these strings should come after, rather than before, the letter to be accented.

### **BUGS**

Floating keeps and regular keeps are diverted to the same space, so they cannot be mixed together with predictable results.

**NAME** | ms – text formatting macros

**SYNOPSIS** 

nroff -ms [options] filename...

troff -ms [options] filename...

#### **DESCRIPTION**

This package of nroff(1) and troff(1) macro definitions provides a formatting facility for various styles of articles, theses, and books. When producing 2-column output on a terminal or lineprinter, or when reverse line motions are needed, filter the output through col(1). All external -ms macros are defined below.

Note: this -ms macro package is an extended version written at Berkeley and is a superset of the standard -ms macro packages as supplied by Bell Labs. Some of the Bell Labs macros have been removed; for instance, it is assumed that the user has little interest in producing headers stating that the memo was generated at Whippany Labs.

Many nroff and troff requests are unsafe in conjunction with this package. However, the first four requests below may be used with impunity after initialization, and the last two may be used even before initialization:

- .bp begin new page
- .br break output line
- insert n spacing lines .spn
- center next n lines .ce n
- .1snline spacing: n=1 single, n=2 double space
- no alignment of right margin .na

Font and point size changes with \f and \s are also allowed; for example,  $fIword\fR$  will italicize word. Output of the tbl(1), eqn(1) and refer(1) preprocessors for equations, tables, and references is acceptable as input.

#### **REQUESTS**

Macro Name	Initial Value	Break? Reset?	Explanation
. AB <i>x</i>	_	у	begin abstract; if <i>x</i> =no do not label abstract
.AE	_	y	end abstract
.AI	_	у	author's institution
.AM	_	n	better accent mark definitions
.AU	_	у	author's name
.B x	_	n	embolden <i>x</i> ; if no <i>x</i> , switch to boldface
.B1	_	у	begin text to be enclosed in a box
.B2	_	y	end boxed text and print it

### ms(5)

Macro Name	Initial Value	Break? Reset?	Explanation
.BT	date	n	bottom title, printed at foot of page

Macro Name	Initial Value	Break? Reset?	Explanation
. NH <i>x y</i>	_	у,у	numbered header; $x$ =level, $x$ =0 resets, $x$ =S sets to $y$
.NL	10p	n	set point size back to normal
.OF x	_	n	odd page footer x (3 part as for .tl)
. ОН х	_	n	odd page header x (3 part as for .tl)
.P1	if TM	n	print header on first page
.PP	_	у,у	paragraph with first line indented
.PT	- % -	n	page title, printed at head of page
. PX <i>x</i>	_	у	print index (table of contents); <i>x</i> =no suppresses title
.QP	_	у,у	quote paragraph (indented and shorter)
.R	on	n	return to Roman font
.RE	5n	у,у	retreat: end level of relative indentation
.RP x	_	n	released paper format; x=no stops title on first page
.RS	5n	у,у	right shift: start level of relative indentation
.SH	_	у,у	section header, in boldface
.SM	_	n	smaller; decrease point size by 2
.TA	8n,5n	n	set TAB characters to 8n 16n (nroff) or 5n 10n (troff)
.TC x	_	у	print table of contents at end; <i>x</i> =no suppresses title
.TE	_	у	end of table processed by tbl
.TH	_	у	end multi-page header of table
.TL	_	у	title in boldface and two points larger
.TM	off	n	UC Berkeley thesis mode
.TS x	_	у,у	begin table; if <i>x</i> =H table has multi-page header
.UL x	_	n	underline x, even in troff
.UX x	_	n	UNIX; trademark message first time; x appended
. XA <i>x y</i>	-	у	another index entry; <i>x</i> =page or no for none; y=indent
.XE	_	у	end index entry (or series of . IX entries)
.XP		у,у	paragraph with first line indented, others indented
.XS x y	_	у	begin index entry; <i>x</i> =page or no for none; <i>y</i> =indent

Macro Name	Initial Value	Break? Reset?	Explanation
.1C	on	у,у	one column format, on a new page
.2C	_	у,у	begin two column format
.] -	_	n	beginning of refer reference
.[0	-	n	end of unclassifiable type of reference
.[ N	-	n	N= 1:journal-article, 2:book, 3:book-article, 4:report

#### **REGISTERS**

Formatting distances can be controlled in -ms by means of built-in number registers. For example, this sets the line length to 6.5 inches:

.nr LL 6.5i

Here is a table of number registers and their default values:

Name	Register Controls	Takes Effect	Default
PS	point size	paragraph	10
VS	vertical spacing	paragraph	12
LL	line length	paragraph	6i
LT	title length	next page	same as LL
FL	footnote length	next .FS	5.5i
PD	paragraph distance	paragraph	1v (if n), .3v (if t)
DD	display distance	displays	1v (if n), .5v (if t)
PI	paragraph indent	paragraph	5n
QI	quote indent	next .QP	5n
FI	footnote indent	next .FS	2n
PO	page offset	next page	0 (if n), ≈1i (if t)
HM	header margin	next page	1i
FM	footer margin	next page	1i
FF	footnote format	next .FS	0 (1, 2, 3 available)

When resetting these values, make sure to specify the appropriate units. Setting the line length to 7, for example, will result in output with one character per line. Setting  ${\tt FF}$  to 1 suppresses footnote superscripting; setting it to 2 also suppresses indentation of the first line; and setting it to 3 produces an . IP-like footnote paragraph.

Here is a list of string registers available in -ms; they may be used anywhere in the text:

Name	String's Function
\*Q	quote (" in nroff, " in troff)
\*U	unquote(" in nroff, " in troff)
\*-	dash ( in nroff, -in troff)
\*(MO	month (month of the year)
/* (DY	day (current date)
\**	automatically numbered footnote
\*'	acute accent (before letter)
\*'	grave accent (before letter)
\*^	circumflex (before letter)
\*,	cedilla (before letter)
\*:	umlaut (before letter)
\*~	tilde (before letter)

When using the extended accent mark definitions available with  $\,$  . AM, these strings should come after, rather than before, the letter to be accented.

**SEE ALSO** 

col(1), eqn(1), nroff(1), refer(1), tbl(1), troff(1)

**BUGS** 

Floating keeps and regular keeps are diverted to the same space, so they cannot be mixed together with predictable results.

#### mutex(5)

#### NAME

mutex – concepts relating to mutual exclusion locks

#### **DESCRIPTION**

Mutual exclusion locks (mutexes) prevent multiple threads from simultaneously executing critical sections of code which access shared data (that is, mutexes are used to serialize the execution of threads). All mutexes must be global. A successful call to acquire a mutex will cause another thread that is also trying to lock the same mutex to block until the owner thread unlocks the mutex.

Mutexes can synchronize threads within the same process or in other processes. Mutexes can be used to synchronize threads between processes if the mutexes are allocated in writable memory and shared among the cooperating processes (see mmap(2)), and have been initialized for this task.

The following table lists mutex functions and the actions they perform.

FUNCTION	ACTION
mutex_init	Initialize a mutex.
mutex_destroy	Destroy a mutex.
mutex_lock	Lock a mutex.
mutex_trylock	Attempt to lock a mutex.
mutex_unlock	Unlock a mutex.
pthread_mutex_init	Initialize a mutex.
pthread_mutex_destroy	Destroy a mutex.
pthread_mutex_lock	Lock a mutex.
pthread_mutex_trylock	Attempt to lock a mutex.
pthread_mutex_unlock	Unlock a mutex.

#### Initialization

Mutexes are either intra-process or inter-process, depending upon the argument passed implicitly or explicitly to the initialization of that mutex. A statically allocated mutex does not need to be explicitly initialized; by default, a statically allocated mutex is initialized with all zeros and its scope is set to be within the calling process.

For inter-process synchronization, a mutex needs to be allocated in memory shared between these processes. Since the memory for such a mutex must be allocated dynamically, the mutex needs to be explicitly initialized with the appropriate attribute that indicates inter-process use.

# Locking and Unlocking

A critical section of code is enclosed by a call to lock the mutex and the call to unlock the mutex to protect it from simultaneous access by multiple threads. Only one thread at a time may possess mutually exclusive access to the critical section of code that is enclosed by the mutex-locking call and the mutex-unlocking call, whether the mutex's scope is intra-process or inter-process. A thread calling to lock the mutex either gets exclusive access to the code starting from the successful locking until its call to unlock the mutex, or it waits until the mutex is unlocked by the thread that locked it.

Mutexes have ownership, unlike semaphores. Only the thread that locked a mutex, (that is, the owner of the mutex), should unlock it.

If a thread waiting for a mutex receives a signal, upon return from the signal handler, the thread resumes waiting for the mutex as if there was no interrupt.

#### Caveats

Mutexes are almost like data – they can be embedded in data structures, files, dynamic or static memory, and so forth. Hence, they are easy to introduce into a program. However, too many mutexes can degrade performance and scalability of the application. Because too few mutexes can hinder the concurrency of the application, they should be introduced with care. Also, incorrect usage (such as recursive calls, or violation of locking order, and so forth) can lead to deadlocks, or worse, data inconsistencies.

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE	
MT-Level	MT-Safe	

#### **SEE ALSO**

$$\label{eq:mmap} \begin{split} & \texttt{mmap}(2), \texttt{shmop}(2), \texttt{mutex\_destroy}(3C), \texttt{mutex\_init}(3C), \texttt{mutex\_lock}(3C), \\ & \texttt{mutex\_trylock}(3C), \texttt{mutex\_unlock}(3C), \texttt{pthread\_create}(3C), \\ & \texttt{pthread\_mutex\_destroy}(3C), \texttt{pthread\_mutex\_init}(3C), \\ & \texttt{pthread\_mutex\_lock}(3C), \texttt{pthread\_mutex\_trylock}(3C), \\ & \texttt{pthread\_mutex\_unlock}(3C), \texttt{pthread\_mutexattr\_init}(3C), \texttt{attributes}(5), \\ & \texttt{standards}(5) \end{split}$$

#### **NOTES**

In the current implementation of threads, pthread\_mutex\_lock(), pthread\_mutex\_unlock(), mutex\_lock() mutex\_unlock(), pthread\_mutex\_trylock(), and mutex\_trylock() do not validate the mutex type. Therefore, an uninitialized mutex or a mutex with an invalid type does not return EINVAL. Interfaces for mutexes with an invalid type have unspecified behavior.

By default, if multiple threads are waiting for a mutex, the order of acquisition is undefined.

USYNC\_THREAD does not support multiple mappings to the same logical synch object. If you need to mmap () a synch object to different locations within the same address space, then the synch object should be initialized as a shared object USYNC\_PROCESS for Solaris, and PTHREAD\_PROCESS\_PRIVATE for POSIX.

#### nfssec(5)

#### NAME |

nfssec – overview of NFS security modes

#### **DESCRIPTION**

The mount\_nfs(1M) and share\_nfs(1M) commands each provide a way to specify the security mode to be used on an NFS file system through the sec=mode option. mode can be either sys, dh, krb5, krb5i, krb5p, or none. These security modes may also be added to the automount maps. Note that mount\_nfs(1M) and automount(1M) do not support sec=none at this time.

The sec=mode option on the share\_nfs(1M) command line establishes the security mode of NFS servers. If the NFS connection uses the NFS Version 3 protocol, the NFS clients must query the server for the appropriate mode to use. If the NFS connection uses the NFS Version 2 protocol, then the NFS client uses the default security mode, which is currently sys. NFS clients may force the use of a specific security mode by specifying the sec=mode option on the command line. However, if the file system on the server is not shared with that security mode, the client may be denied access.

If the NFS client wants to authenticate the NFS server using a particular (stronger) security mode, the client wants to specify the security mode to be used, even if the connection uses the NFS Version 3 protocol. This guarantees that an attacker masquerading as the server does not compromise the client.

The NFS security modes are described below. Of these, the krb5, krb5i, krb5p modes use the Kerberos V5 protocol for authenticating and protecting the shared filesystems. Before these can be used, the system must be configured to be part of a Kerberos realm. See SEAM(5).

sys	Use AUTH_SYS authentication. The user's UNIX user-id and group-ids are passed in the clear on the network, unauthenticated by the NFS server. This is the simplest security method and requires no additional administration. It is the default used by Solaris NFS Version 2 clients and Solaris NFS servers.
dh	Use a Diffie-Hellman public key system (AUTH_DES, which is referred to as AUTH_DH in the forthcoming Internet RFC).
krb5	Use Kerberos V5 protocol to authenticate users before granting access to the shared filesystem.
krb5i	Use Kerberos V5 authentication with integrity checking (checksums) to verify that the data has not been tampered with.
krb5p	User Kerberos V5 authentication, integrity checksums, and privacy protection (encryption) on the shared filesystem. This provides the most secure filesystem sharing, as all traffic is encrypted. It should be noted that performance might suffer on some systems when using krb5p, depending on the computational intensity of the encryption algorithm and the amount of data being transferred.

Use null authentication (AUTH NONE). NFS clients using AUTH NONE have

no identity and are mapped to the anonymous user nobody by NFS servers. A client using a security mode other than the one with which a Solaris NFS server shares the file system has its security mode mapped to

none

AUTH NONE. In this case, if the file system is shared with sec=none, users from the client are mapped to the anonymous user. The NFS security mode none is supported by share nfs(1M), but not by mount nfs(1M) or automount(1M).

**FILES**

**NOTES** 

/etc/nfssec.conf lists the NFS security services. Do not edit this file. It is not intended to be user-configurable.

openssl(5)

**NAME** 

openssl - OpenSSL cryptographic & Secure Sockets Layer toolkit

**DESCRIPTION** 

OpenSSL is a crypography toolkit that implements the Secure Sockets Layer (SSLv2/v3) and Transport Layer Security (TLS v1) network protocols.

The following features are omitted from the binaries for issues including but not limited to patents, trademark, and US export restrictions: MDC2, RC3, RC5, IDEA, ECC, Dynamic Engine Loading, CSWIFT Engine, nCipher Engine, Atalla Engine, NURON Engine, UBSEC Engine, AEP Engine, Sureware Engine, and 4758\_CCA Engine.

A new PKCS#11 engine has been included with ENGINE name "pkcs11".

The PKCS#11 engine is configured to use the Solaris Cryptographic Framework. See cryptoadm(1M) for configuration information.

Due to requirements of the PKCS#11 standard regarding fork(2) behavior, some applications that use the OpenSSL EVP interfaces and fork() with active crypto contexts might experience unexpected behavior.

To build an OpenSSL application, use the following cc command line options:

```
cc [ flag... ] file... -I/usr/sfw/include -lcrypto -lssl \
   -L/usr/sfw/lib -R/usr/sfw/lib [ library... ]
```

Extensive additional documentation for OpenSSL modules is available in the /usr/sfw/share/man directory. This documentation can be viewed with man(1) by including /usr/sfw/share/man in the MANPATH environment variable. Running catman(1M) on the OpenSSL manual pages is not supported.

To view the license terms, attribution, and copyright for OpenSSL, see /var/sadm/pkg/SUNWopensslr/install/copyright.

**ATTRIBUTES**

#### NAME

pam\_authtok\_check – authentication and password management module

### **SYNOPSIS**

pam\_authtok\_check.so.1

#### DESCRIPTION

pam\_authtok\_check provides functionality to the Password Management stack. The implementation of pam\_sm\_chauthtok() performs a number of checks on the construction of the newly entered password. pam\_sm\_chauthtok() is invoked twice by the PAM framework, once with flags set to PAM\_PRELIM\_CHECK, and once with flags set to PAM\_UPDATE\_AUTHTOK. This module only performs its checks during the first invocation. This module expects the current authentication token in the PAM\_OLDAUTHTOK item, the new (to be checked) password in the PAM\_AUTHTOK item, and the login name in the PAM\_USER item. The checks performed by this module are:

length The password length should not be less that the minimum

specified in /etc/default/passwd.

circular shift The password should not be a circular shift of the login name. This

check may be disabled in /etc/default/passwd.

complexity The password should contain at least the minimum number of

characters described by the parameters MINALPHA, MINNONALPHA, MINDIGIT, and MINSPECIAL. Note that MINNONALPHA describes the same character classes as MINDIGIT and MINSPECIAL combined; therefore the user cannot specify both MINNONALPHA and MINSPECIAL (or MINDIGIT). The user must choose which of the two options to use. Furthermore, the WHITESPACE parameter determines whether whitespace characters are allowed. If

unspecified MINALPHA is 2, MINNONALPHA is 1 and WHITESPACE

is yes

variation The old and new passwords must differ by at least the MINDIFF

value specified in /etc/default/passwd. If unspecified, the default is 3. For accounts in name services which support password history checking, if prior history is defined, the new

password must not match the prior passwords.

dictionary check The password must not be based on a dictionary word. The list of

words to be used for the site's dictionary can be specified with DICTIONLIST. It should contain a comma-separated list of filenames, one word per line. The database that is created from these files is stored in the directory named by DICTIONDBDIR (defaults to /var/passwd). See mkpwdict(1M) for information on pre-generating the database. If neither DICTIONLIST nor DICTIONDBDIR is specified, no dictionary check is made.

upper/lower case The password must contain at least the minimum of upper- and

lower-case letters specified by the MINUPPER and MINLOWER values in /etc/default/passwd. If unspecified, the defaults are

nues in / ecc/ defautc/ passwa. In unspecifica, the

0.

### pam\_authtok\_check(5)

maximum repeats The password must not contain more consecutively repeating

characters than specified by the MAXREPEATS value in

/etc/default/passwd. If unspecified, no repeat character check

is made.

The following option may be passed to the module:

debug syslog(3C) debugging information at the LOG DEBUG level

**RETURN VALUES** 

If the password in PAM\_AUTHTOK passes all tests, PAM\_SUCCESS is returned. If any of the tests fail, PAM\_AUTHTOK\_ERR is returned.

**FILES** 

/etc/default/passwd

See passwd(1) for a description of the contents.

**ATTRIBUTES** 

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT Level	MT-Safe with exceptions

SEE ALSO

passwd(1), pam(3PAM), mkpwdict(1M), pam\_chauthtok(3PAM), syslog(3C),
libpam(3LIB), pam.conf(4), passwd(4), shadow(4), attributes(5),
pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5),
pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5),
pam\_unix\_session(5)

**NOTES** 

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

The pam\_unix(5) module is no longer supported. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

NAME

pam\_authtok\_get – authentication and password management module

**SYNOPSIS** 

pam\_authtok\_get.so.1

DESCRIPTION

The pam\_authtok\_get service module provides password prompting funtionality to the PAM stack. It implements pam\_sm\_authenticate() and pam\_sm\_chauthtok(), providing functionality to both the Authentication Stack and the Password Management Stack.

#### Authentication Service

The implementation of pam\_sm\_authenticate(3PAM) prompts the user name if not set and then tries to get the authentication token from the pam handle. If the token is not set, it then prompts the user for a password and stores it in the PAM item PAM\_AUTHTOK. This module is meant to be the first module on an authentication stack where users are to authenticate using a keyboard.

#### Password Management Service

Due to the nature of the PAM Password Management stack traversal mechanism, the pam\_sm\_chauthtok(3PAM) function is called twice. Once with the PAM PRELIM CHECK flag, and one with the PAM UPDATE AUTHTOK flag.

In the first (PRELIM) invocation, the implementation of pam\_sm\_chauthtok(3PAM) moves the contents of the PAM\_AUTHTOK (current authentication token) to PAM\_OLDAUTHTOK, and subsequentially prompts the user for a new password. This new password is stored in PAM\_AUTHTOK.

If a previous module has set PAM\_OLDAUTHTOK prior to the invocation of pam\_authtok\_get, this module turns into a NO-OP and immediately returns PAM\_SUCCESS.

In the second (UPDATE) invocation, the user is prompted to Re-enter his password. The pam\_sm\_chauthtok implementation verifies this reentered password with the password stored in PAM\_AUTHTOK. If the passwords match, the module returns PAM\_SUCCESS.

The following option can be passed to the module:

debug syslog(3C) debugging information at the LOG DEBUG level

**ERRORS** 

The authentication service returns the following error codes:

PAM SUCCESS Successfully obtains authentication token

PAM\_SYSTEM\_ERR Fails to retrieve username, username is NULL or empty

The password management service returns the following error codes:

PAM SUCCESS Successfully obtains authentication token

PAM\_AUTHTOK\_ERR Authentication token manipulation error

### pam\_authtok\_get(5)

#### **ATTRIBUTES**

pam\_unix\_account(5), pam\_unix\_auth(5), pam\_unix\_session(5)

#### **NOTES**

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

The pam\_unix(5) module is no longer supported. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

#### NAME

pam\_authtok\_store – password management module

#### **SYNOPSIS**

pam\_authtok\_store.so.1

#### **DESCRIPTION**

 ${\tt pam\_authtok\_store}\ provides\ functionality\ to\ the\ PAM\ password\ management\ stack.\ It\ provides\ one\ function: \\ {\tt pam\_sm\_chauthtok()}.$ 

When invoked with flags set to PAM\_UPDATE\_AUTHTOK, this module updates the authentication token for the user specified by PAM\_USER.

The authentication token PAM\_OLDAUTHTOK can be used to authenticate the user against repositories that need updating (NIS, LDAP). After successful updates, the new authentication token stored in PAM\_AUTHTOK is the user's valid password.

This module honors the PAM\_REPOSITORY item, which, if set, specifies which repository is to be updated. If PAM\_REPOSITORY is unset, it follows the nsswitch.conf(4).

The following option can be passed to the module:

debug syslog(3C) debugging information at the LOG DEBUG level

server\_policy If the account authority for the user, as specified by PAM\_USER, is a

server, do not encrypt the authentication token before updating.

#### **ERRORS**

PAM SUCCESS Successfully obtains authentication token

PAM SYSTEM ERR Fails to get username, service name, old password or

new password, user name null or empty, or password

null.

#### **ATTRIBUTES**

See  ${\tt attributes}(5)$  for descriptions of the following attributes:

type, the se	_REPOSITORY <i>item_type</i> is set and a service module does not recognize the ervice module does not process any information, and returns PAM_IGNORE_REPOSITORY <i>item_type</i> is not set, a service module performs its default

#### NAME

pam\_deny - PAM module to deny operations

#### **SYNOPSIS**

```
pam_deny.so.1
```

#### **DESCRIPTION**

The pam\_deny module implements all the PAM service module functions and returns the module type default failure return code for all calls.

The following options are interpreted:

debug syslog(3C) debugging information at LOG AUTH and

LOG DEBUG levels

#### **ERRORS**

The authentication service returns the following error codes:

```
PAM_ACCT_EXPIRED If pam_sm_acct_mgmt is called.

PAM_AUTH_ERR If pam_sm_authenticate is called.

PAM_AUTHOK_ERR If pam_sm_chauthtok is called.

PAM_CRED_ERR If pam_sm_setcred is called.

PAM_SESSION_ERR If pam_sm_open_session or
```

pam sm close session are called.

#### **EXAMPLES**

#### **EXAMPLE 1** Disabling a specified service

The following example shows how to disable the service ssh-none authentication type:

```
sshd-none auth pam_deny.so.1
sshd-none account pam_deny.so.1
sshd-none session pam_deny.so.1
sshd-none password pam_deny.so.1
```

#### **EXAMPLE 2** Disabling all sevices

The following example shows how to disable all services that are not explicitly defined:

other	auth pam_deny.so.1
other	account pam_deny.so.1
other	session pam_deny.so.1
other	password pam deny.so.1

#### **ATTRIBUTES**

pam\_unix\_session(5), privileges(5)

#### **NOTES**

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

This module is intended to be used to either deny access to specific services names, or to all service names not specified (by specifying pam\_deny.so.1 as the default, "other", service stack).

NAME

pam\_dhkeys - authentication Diffie-Hellman keys management module

**SYNOPSIS** 

pam dhkeys.so.1

**DESCRIPTION** 

The pam\_dhkeys.so.1 service module provides functionality to two PAM services: Secure RPC authentication and Secure RPC authentication token management.

Secure RPC authentication differs from regular unix authentication because NIS+ and other ONC RPCs use Secure RPC as the underlying security mechanism.

The following options may be passed to the module:

debug syslog(3C) debugging information at LOG DEBUG level

nowarn Turn off warning messages

#### Authentication Services

If the user has Diffie-Hellman keys, pam\_sm\_authenticate() establishes secret keys for the user specified by the PAM\_USER (equivalent to running keylogin(1)), using the authentication token found in the PAM\_AUTHTOK item. Not being able to establish the secret keys results in an authentication error if the NIS+ repository is used to authenticate the user and the NIS+ table permissions require secure RPC credentials to access the password field. If pam\_sm\_setcred() is called with PAM\_ESTABLISH\_CRED and the user's secure RPC credentials need to be established, these credentials are set. This is equivalent to running keylogin(1).

If the credentials could not be set and PAM\_SILENT is not specified, a diagnostic message is displayed. If pam\_setcred() is called with PAM\_DELETE\_CRED, the user's secure RPC credentials are unset. This is equivalent to running keylogout(1).

 ${\tt PAM\_REINITIALIZE\_CRED}$  and  ${\tt PAM\_REFRESH\_CRED}$  are not supported and return  ${\tt PAM\_IGNORE}.$ 

#### Authentication Token Management

The pam\_sm\_chauthtok() implementation checks whether the old login password decrypts the users secret keys. If it doesn't this module prompts the user for an old Secure RPC password and stores it in a pam data item called SUNW\_OLDRPCPASS. This data item can be used by the store module to effectively update the users secret keys.

#### **ERRORS**

The authentication service returns the following error codes:

PAM\_SUCCESS Credentials set successfully.

PAM\_IGNORE Credentials not needed to access the password

repository.

PAM USER UNKNOWN PAM USER is not set, or the user is unknown.

PAM\_AUTH\_ERR No secret keys were set. PAM\_AUTHTOK is not set, no

credentials are present or there is a wrong password.

PAM BUF ERR Module ran out of memory.

### pam\_dhkeys(5)

PAM\_SYSTEM\_ERR The NIS<sup>-</sup>+ subsystem failed .

The authentication token management returns the following error codes:

PAM SUCCESS Old rpc password is set in SUNW OLDRPCPASS

PAM USER UNKNOWN User in PAM USER is unknown.

PAM\_AUTHTOK\_ERR User did not provide a password that decrypts the

secret keys.

PAM\_BUF\_ERR Module ran out of memory.

#### **ATTRIBUTES**

The pam\_unix(5) module is no longer supported. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

#### NAME

pam\_dial\_auth – authentication management PAM module for dialups

## **SYNOPSIS**

pam dial auth.so.1

#### **DESCRIPTION**

The pam\_dial\_auth module implements pam\_sm\_authenticate(3PAM) which authenticates the user according to the dialups(4) and d\_passwd(4) files configuration.

Authentication service modules must implement both pam\_sm\_authenticate() and pam\_sm\_setcred().pam\_sm\_setcred() in this module always returns PAM IGNORE.

The value of the PAM\_TTY item is checked against entries in dialups(4). If there is a match, the user's shell is compared against entries in d\_passwd(4). If there is a matching entry, the user is prompted for a password which is validated against the entry found.

The following option may be passed in to this service module:

debug syslog(3C) debugging information at LOG DEBUG level.

## **ERRORS**

If dialups(4) is not present, PAM\_IGNORE is returned. Upon successful completion of pam\_sm\_authenticate(), PAM\_SUCCESS is returned. The following error codes are returned upon error:

PAM AUTH ERR Authentication failure.

PAM\_SERVICE\_ERR Error in the calling service, PAM\_TTY is not set.

PAM SYSTEM ERR System error (d passwd(4) is not present).

PAM USER UNKNOWN No account is present for *user*.

## pam\_krb5(5)

NAME |

pam\_krb5 – authentication, account, session, and password management PAM modules for Kerberos V5

**SYNOPSIS** 

/usr/lib/security/pam krb5.so.1

**DESCRIPTION** 

The Kerberos V5 service module for PAM provides functionality for all four PAM modules: authentication, account management, session management, and password management. The service module is a shared object that can be dynamically loaded to provide the necessary functionality upon demand. Its path is specified in the PAM configuration file.

## Kerberos Authentication Module

The Kerberos V5 authentication component provides functions to verify the identity of a user, pam\_sm\_authenticate(), and to manage the Kerberos credentials cache, pam\_sm\_stcred().

pam\_sm\_authenticate() authenticates a user principal through the Kerberos authentication service. If the authentication request is successful, the authentication service sends a ticket-granting ticket (TGT) back to the service module, which then verifies that the TGT came from a valid Key Distribution Center (KDC) by attempting to get a service ticket for the local host service. For this to succeed, the local host's keytab file (/etc/krb5/krb5.keytab) must contain the entry for the local host service. For example, in the file host/hostname.com@REALM, hostname.com is the fully qualified local hostname and REALM is the default realm of the local host as defined in /etc/krb5/krb5.conf. If the host entry is not found in the keytab file, the authentication fails. Administrators may optionally disable this "strict" verification by setting the "verify\_ap\_req\_nofail = false" in /etc/krb5/krb5.conf. See krb5.conf(4) for more details on this option. This allows TGT verification to succeed in the absence of a keytab host principal entry.

pam sm authenticate(3PAM) may be passed the following flag:

PAM DISALLOW NULL AUTHTOK

This flag is ignored. The Kerberos authentication mechanism will not allow an empty password string by default.

pam\_sm\_setcred() creates and modifies the user's credential cache. This function initializes the user's credential cache, if it does not already exist, and stores the initial credentials for later use by Kerberized network applications. The following flags may be set in the flags field. They are best described by their effect on the user's credential cache.

PAM ESTABLISH CRED

Stores the initial credentials in the user's credential cache so that the user may access Kerberos network services. If the credential cache exists, then this function is functionally equivalent to using the PAM\_REFRESH\_CRED flag. That is, the user's credentials are refreshed. If the credential cache does not exist, then it is created, and new credentials are stored in it.

PAM DELETE CRED

This flag has no effect on the credential cache and always returns PAM\_SUCCESS. The credential cache is not deleted because there is no accurate method to

determine if the credentials are needed by another process. The credential cache may be deleted with the kdestroy(1) command.

## PAM REINITIALIZE CRED

Deletes the user's existing credential cache, if it exists, and creates a new credential cache. The new credentials are stored in the new cache and the user's ticket lifetime and renewable life time values are reset.

## PAM REFRESH CRED

Extends lifetime of user's credentials. Does not wipe out the credentials cache, but instead just extends the lifetime of the user's TGT. Notice that this function fails if the user's renewable ticket lifetime has expired.

The following options can be passed to the Kerberos V5 authentication module:

debug Provides syslog(3C) debugging information at LOG DEBUG level.

nowarn Turns off warning messages.

## Kerberos V5 Account Management Module

The Kerberos account management component provides a function to perform account management, pam\_sm\_acct\_mgmt(). This function checks to see if the pam\_krb5 authentication module has noted that the user's password has not expired. The following options may be passed in to the Kerberos V5 account management module:

debug Provides syslog(3C) debugging information at LOG DEBUG level

nowarn Turns off warning messages. Also, does not query KDC for

impending password expiration information used to warn the

user.

#### Kerberos V5 Session Management Module

The Kerberos V5 session management component provides functions to initiate pam\_sm\_open\_session() and terminate pam\_sm\_close\_session() Kerberos sessions. For Kerberos V5, both pam\_sm\_open\_session and pam sm close session() are null functions, returning PAM IGNORE.

## Kerberos V5 Password Management Module

The Kerberos V5 password management component provides a function to change passwords, pam\_sm\_chauthtok(), in the Key Distribution Center (KDC) database. The following flags may be passed to pam\_sm\_chauthtok(3PAM):

# PAM\_CHANGE\_EXPIRED\_AUTHTOK

The password service should only update the user's Kerberos password if it is expired. Otherwise, this function returns PAM\_IGNORE. The default behaviour is to always change the user's Kerberos password.

## PAM PRELIM CHECK

This is a null function that always returns PAM\_SUCCESS.

# ${\tt PAM\_UPDATE\_AUTHTOK}$

This flag is necessary to change the user's Kerberos password. If this flag is not set, pam\_krb5 returns PAM\_SYSTEM\_ERR.

The following option can be passed to the Kerberos V5 password module:

```
debug
                             Provides syslog(3C) debugging information at LOG DEBUG level.
ERRORS
           The following error codes are returned for pam sm authenticate():
           PAM AUTH ERR
              Authentication failure
           PAM BUF ERR
              Memory buffer error.
           PAM IGNORE
              The user is "root" and the root key exists in the default keytab.
           PAM SUCCESS
              Successfully obtained Kerberos credentials.

  Error in module. At least one input parameter is missing.
PAM SYSTEM ERR
  System error.
PAM USER UNKNOWN
  An unknown Kerberos principal was requested.
PAM SUCCESS
  Successfully changed the user's Kerberos password.
```

## **EXAMPLES**

## **EXAMPLE 1** Authenticate Users Through Kerberos as First Choice

The following is an excerpt of a sample pam. conf configuration file that authenticates users through the Kerberos authentication service and authenticates through the Unix login only if the Kerberos authentication fails. This arrangement is helpful when a majority of the users are networked by means of Kerberos and when there are only a few non-Kerberos type user accounts, such as root. The service illustrated below is for dtlogin.

```
dtlogin auth requisite pam_smartcard.so.1
dtlogin auth requisite pam_authtok_get.so.1
dtlogin auth required pam_dhkeys.so.1
dtlogin auth required pam_unix_cred.so.1
dtlogin auth sufficient pam_krb5.so.1
dtlogin auth required pam_unix_auth.so.1
```

**EXAMPLE 1** Authenticate Users Through Kerberos as First Choice (Continued)

Note that these changes should not be made to the existing krlogin, krsh, and ktelnet service entries. Those services require Kerberos authentication, so using a seemingly sufficient control flag would not provide the necessary functionality for privacy and integrity. There should be no need to change those entries.

The following entries check for password expiration when dealing with Kerberos and Unix password aging policies:

```
other account requisite pam_roles.so.1
other account required pam_unix_account.so.1
other account required pam_krb5.so.1
```

The following entries would change the Kerberos password of the user and continue to change the Unix login password only if the Kerberos password change had failed:

```
other password required pam_dhkeys.so.1
other password requisite pam_authtok_get.so.1
other password requisite pam_authtok_check.so.1
other password sufficient pam_krb5.so.1
other password required pam_authtok_store.so.1
```

When changing Kerberos based user's password, use kpasswd(1). When changing a non-Kerberos user's password, it is recommended that the repository is specified (-r) with the passwd(1) command.

## **EXAMPLE 2** Authenticate Users Through Kerberos Only

The following example allows authentication only to users that have Kerberos-based accounts.

```
dtlogin auth requisite pam_smartcard.so.1
dtlogin auth requisite pam_authtok_get.so.1
dtlogin auth required pam_dhkeys.so.1
dtlogin auth required pam_unix_cred.so.1
dtlogin auth binding pam_krb5.so.1
dtlogin auth required pam unix auth.so.1
```

Typically, you would have another service specified in the pam.conf file that would allow local users, such as database, web server, system administrator accounts, to log in to the host machine. For example, the "login" service name could be used for these users. Note that these users should not belong to any roles.

The rest of the module types look similar to that shown in the previous example:

```
other account requisite pam_roles.so.1
other account required pam_unix_account.so.1
other account required pam_krb5.so.1
```

With binding specified in the following, it is important that non-Kerberos users specify the repository in which they reside using the -r option with the passwd(1) command. This configuration is also based on the assumptions that:

#### **EXAMPLE 2** Authenticate Users Through Kerberos Only (Continued)

- Kerberos users maintain only their Kerberos passwords;
- changing their Unix password is not necessary, given that they are authenticated only through their Kerberos passwords when logging in.

```
other password required pam_dhkeys.so.1
other password requisite pam_authtok_get.so.1
other password requisite pam_authtok_check.so.1
other password binding pam_krb5.so.1
other password required pam_authtok_store.so.1
```

## **EXAMPLE 3** Authenticate Through Kerberos Optionally

This configuration is helpful when the majority of users are non-Kerberos users and would like to authenticate through Kerberos if they happened to exist in the Kerberos database. The effect of this is similar to users voluntarily executing kinit(1) after they have successfully logged in:

```
dtlogin auth requisite pam_smartcard.so.1
dtlogin auth requisite pam_authtok_get.so.1
dtlogin auth required pam_dhkeys.so.1
dtlogin auth required pam_unix_cred.so.1
dtlogin auth required pam_unix_auth.so.1
dtlogin auth optional pam krb5.so.1
```

## The rest of the configuration is as follows:

```
account requisite
                              pam roles.so.1
other account required
                              pam unix account.so.1
other account required
                             pam krb5.so.1
other password required
                             pam dhkeys.so.1
other password requisite
                              pam authtok get.so.1
other password requisite
                              pam authtok check.so.1
other password required
                              pam authtok store.so.1
other password optional
                              pam krb5.so.1
```

Non-Kerberos users should specify their respective repositories by using the -r option when changing their password with the passwd(1) command.

## **ATTRIBUTES**

# NOTES

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

On successful acquisition of initial credentials (ticket-granting ticket),  $ktkt\_warnd(1M)$  will be notified, to alert the user when the initial credentials are about to expire.

#### NAME |

 $pam\_krb5\_migrate-authentication\ PAM\ module\ for\ the\ KerberosV5\ auto-migration\ of\ users\ feature$ 

## **SYNOPSIS**

/usr/lib/security/pam krb5 migrate.so.1

#### DESCRIPTION

The KerberosV5 auto-migrate service module for PAM provides functionality for the PAM authentication component. The service module helps in the automatic migration of PAM\_USER to the client's local Kerberos realm, using PAM\_AUTHTOK (the PAM authentication token associated with PAM\_USER) as the new Kerberos principal's password.

### Kerberos V5 Auto-migrate Authentication Module

The KerberosV5 auto-migrate authentication component provides the pam\_sm\_authenticate(3PAM) function to migrate a user who does not have a corresponding krb5 principal account to the default Kerberos realm of the client.

pam\_sm\_authenticate(3PAM) uses a host-based client service principal, present in the local keytab (/etc/krb5/krb5.keytab) to authenticate to kadmind(1M) (defaults to the host/nodename.fqdn service principal), for the principal creation operation. Also, for successful creation of the krb5 user principal account, the host-based client service principal being used needs to be assigned the appropriate privilege on the master KDC's kadm5.acl(4) file.kadmind(1M) checks for the appropriate privilege and validates the user password using PAM by calling pam\_authenticate(3PAM) and pam\_acct\_mgmt(3PAM) for the k5migrate service.

If migration of the user to the KerberosV5 infrastructure is successful, the module will inform users about it by means of a PAM\_TEXT\_INFO message, unless instructed otherwise by the presence of the quiet option.

The authentication component always returns PAM\_IGNORE and is meant to be stacked in pam.conf with a requirement that it be listed below pam\_authtok\_get(5) in the authentication stack. Also, if pam\_krb5\_migrate is used in the authentication stack of a particular service, it is mandatory that pam\_krb5(5) be listed in the PAM account stack of that service for proper operation (see EXAMPLES).

#### **OPTIONS**

The following options can be passed to the KerberosV5 auto-migrate authentication module:

debug

Provides syslog(3C) debugging information at LOG DEBUG level.

client service=<service name>

Name of the service used to authenticate to kadmind(1M) defaults to host. This means that the module uses host/<nodename.fqdn> as its client service principal name, KerberosV5 user principal creation operation or <service>/<nodename.fqdn> if this option is provided.

quiet

Do not explain KerberosV5 migration to the user.

## pam\_krb5\_migrate(5)

This has the same effect as passing the PAM\_SILENT flag to pam\_sm\_authenticate(3PAM) and is useful where applications cannot handle PAM TEXT INFO messages.

If not set, the authentication component will issue a PAM\_TEXT\_INFO message after creation of the Kerberos V5 principal, indicating that it has done so.

```
expire pw
```

Causes the creation of KerberosV5 user principals with password expiration set to now (current time).

#### **EXAMPLES**

#### **EXAMPLE 1** Sample Entries from pam.conf

The following entries from pam.conf(4) demonstrate the use of the pam krb5 migrate.so.1 module:

```
login auth requisite pam_authtok_get.so.1
login auth required pam_dhkeys.so.1
login auth required pam_unix_cred.so.1
login auth sufficient pam_krb5.so.1
login auth requisite pam_unix_auth.so.1
login auth optional pam_krb5_migrate.so.1 expire_pw
login auth required pam_dial_auth.so.1

other account requisite pam_roles.so.1
other account required pam_krb5.so.1
other account required pam_unix_account.so.1
```

The pam\_krb5\_migrate module can generally be present on the authorization stack of any service where the application calls pam\_sm\_authenticate(3PAM) and an authentication token (in the preceding example, the authentication token would be the user's Unix password) is available for use as a Kerberos V5 password.

## **EXAMPLE 2** Sample Entries from kadm5.acl

The following entries from kadm5.acl(4) permit or deny privileges to the host client service principal:

```
host/*@ACME.COM U root
host/*@ACME.COM ui *
```

The preceding entries permit the pam\_krb5\_migrate add privilege to the host client service principal of any machine in the ACME. COM KerberosV5 realm, but denies the add privilege to all host service principals for addition of the root user account.

## **EXAMPLE 3** Sample Entries in pam. conf of the Master KDC

The entries below enable kadmind(1M) on the master KDC to use the k5migrate PAM service in order to validate Unix user passwords for accounts that require migration to the Kerberos realm.

```
k5migrate auth required pam_unix_auth.so.1
k5migrate account required pam_unix_account.so.1
```

pam\_ldap(5)

NAME

pam\_ldap - authentication and account management PAM module for LDAP

**SYNOPSIS** 

/usr/lib/security/pam ldap.so.1

**DESCRIPTION** 

The pam\_ldap module implements pam\_sm\_authenticate() and pam\_sm\_acct\_mgmt(), the functions that provide functionality for the PAM authentication and account management stacks. The pam\_ldap module ties the authentication and account management functionality to the functionality of the supporting LDAP server. For authentication, pam\_ldap can authenticate the user directly to any LDAP directory server by using any supported authentication mechanism, such as DIGEST-MD5. However, the account management component of pam\_ldap will work only with the Sun Java System Directory Server. The server's user account management must be properly configured before it can be used by pam\_ldap. Refer to the Sun Java System Directory Server Administration Guide for information on how to configure user account management, including password and account lockout policy.

pam\_ldap must be used in conjunction with the modules that support the UNIX authentication, password, and account management, which are pam\_authtok\_get(5), pam\_passwd\_auth(5), pam\_unix\_account(5), and pam\_unix\_auth(5). pam\_ldap is designed to be stacked directly below these modules. If other modules are designed to be stacked in this manner, the modules can be stacked below the pam\_ldap module. The EXAMPLES section shows how the UNIX modules are stacked with pam\_ldap. When stacked together, the UNIX modules are used to control local accounts, such as root. pam\_ldap is used to control network accounts, that is, LDAP users. For the stacks to work, pam\_unix\_auth, pam\_unix\_account, and pam\_passwd\_auth must be configured with the binding control flag and the server\_policy option. This configuration allows local account override of a network account.

## LDAP Authentication Module

The LDAP authentication module verifies the identity of a user. The pam\_sm\_authenticate(3PAM) function uses the password entered by the user to attempt to authenticate to the LDAP server. If successful, the user is authenticated. See NOTES for information on password prompting.

The authentication method used is either defined in the client profile, or the authentication method is configured by using the ldapclient(1M) command. To determine the authentication method to use, this module first attempts to use the authentication method that is defined, for service pam\_ldap, for example, serviceAuthenticationMethod:pam\_ldap:sasl/DIGEST-MD5. If no authentication method is defined, pam\_ldap uses the default authentication method. If neither are set, the authentication fails. This module skips the configured authentication method if the authentication method is set to none.

The following options may be passed to the LDAP service module:

debug

syslog(3C) debugging information at LOG DEBUG level.

nowarn

Turn off warning messages.

These options are case sensitive, and the options must be used exactly as presented here.

## LDAP Account Management Module

The LDAP account management module validates the user's account. The pam\_sm\_acct\_mgmt(3PAM) function authenticates to the LDAP server to verify that the user's password has not expired, or that the user's account has not been locked. The following options may be passed to the LDAP service module:

debuc

syslog(3C) debugging information at LOG DEBUG level.

nowarn

Turn off warning messages.

These options are case sensitive, and the options must be used exactly as presented here.

## LDAP Password Management Module

LDAP password management is no longer supported by pam\_ldap. Use pam\_authtok\_store(5) instead of pam\_ldap for password change. pam\_authtok\_store(5) handles both the local and LDAP accounts and updates the passwords in all the repositories configured by nsswitch.conf(4).

#### **ERRORS**

The authentication service returns the following error codes:

PAM SUCCESS Authentication successful

PAM MAXTRIES Maximum number of authentication attempts exceeded

PAM AUTH ERR Authentication failure

PAM\_USER\_UNKNOWN No account present for user

PAM BUF ERR Memory buffer error

PAM SYSTEM ERR System error

PAM IGNORE User's account inactivated

The account management service returns the following error codes:

PAM\_SUCCESS User allowed access to account

PAM NEW AUTHTOK REQD New authentication token required

PAM ACCT EXPIRED User account has expired

PAM\_PERM\_DENIED User denied access to account at this time

PAM USER UNKNOWN No account present for user

PAM BUF ERROR Memory buffer error

PAM\_SYSTEM\_ERR System error

#### EXAMPLES

**EXAMPLE 1** Using pam ldap With Authentication

The following is a configuration for the login service when using pam ldap. The service name login can be substituted for any other authentication service such as dtlogin or su. Lines that begin with the # symbol are comments and are ignored.

```
# Authentication management for login service is stacked.
# If pam_unix_auth succeeds, pam_ldap is not invoked.
# The control flag "binding" provides a local overriding
# remote (LDAP) control. The "server_policy" option is used
# to tell pam unix auth.so.1 to ignore the LDAP users.
login auth requisite pam_authtok_get.so.1 login auth required pam_dhkeys.so.1 login auth binding pam_unix_auth.so.1 so
login auth binding pam_unix_auth.so.1 server_policy
login auth required pam_ldap.so.1
```

## **EXAMPLE 2** Using pam\_ldap With Account Management

The following is a configuration for account management when using pam ldap. Lines that begin with the # symbol are comments and are ignored.

```
# Account management for all services is stacked
# If pam_unix_account succeeds, pam_ldap is not invoked.
# The control flag "binding" provides a local overriding
# remote (LDAP) control. The "server_policy" option is used
# to tell pam_unix_account.so.1 to ignore the LDAP users.

    other
    account
    requisite
    pam_roles.so.1

    other
    account
    required
    pam_projects.so.1

    other
    account
    binding
    pam_unix_account.so.1 server_policy

    other
    account
    required
    pam_ldap.so.1
```

**EXAMPLE 3** Using pam authtok store With Password Management For Both Local and LDAP Accounts

The following is a configuration for password management when using pam authtok store. Lines that begin with the # symbol are comments and are ignored.

```
# Password management (authentication)
# The control flag "binding" provides a local overriding
# remote (LDAP) control. The server policy option is used
# to tell pam passwd auth.so.1 to ignore the LDAP users.
passwd auth binding pam passwd auth.so.1 server policy
passwd auth required pam_ldap.so.1
# Password management (updates)
\# This updates passwords stored both in the local /etc
# files and in the LDAP directory. The "server policy"
# option is used to tell pam_authtok_store to
# follow the LDAP server's policy when updating
# passwords stored in the LDAP directory
```

**EXAMPLE 3** Using pam\_authtok\_store With Password Management For Both Local and LDAP Accounts (Continued)

```
other password required pam_dhkeys.so.1
other password requisite pam_authtok_get.so.1
other password requisite pam_authtok_check.so.1
other password required pam authtok store.so.1 server policy
```

#### FILES

/var/ldap/ldap\_client\_file

/var/ldap/ldap\_client\_cred The LDAP configuration files of the client.

Do not manually modify these files, as these files may not be human readable. Use ldapclient(1M) to update these files.

/etc/pam.conf PAM configuration file.

## **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
Stability Level	Evolving

#### SEE ALSO

ldap(1), idsconfig(1M), ldap\_cachemgr(1M), ldapclient(1M), libpam(3LIB),
pam(3PAM), pam\_sm\_authenticate(3PAM), pam\_sm\_chauthtok(3PAM),
pam\_sm\_close\_session(3PAM), pam\_sm\_open\_session(3PAM),
pam\_sm\_setcred(3PAM), syslog(3C), pam.conf(4), attributes(5),
pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5),
pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5)

#### **NOTES**

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

The previously supported use\_first\_pass and try\_first\_pass options are obsolete in this version, are no longer needed, can safely be removed from pam.conf(4), and are silently ignored. They might be removed in a future release. Password prompting must be provided for by stacking pam\_authtok\_get(5) before pam\_ldap in the auth and password module stacks and pam\_passwd\_auth(5) in the passwd service auth stack (as described in the EXAMPLES section). The previously supported password update function is replaced in this release by the previously recommended use of pam\_authtok\_store with the server\_policy option (as described in the EXAMPLES section).

The functions: pam\_sm\_setcred(3PAM), pam\_sm\_chauthtok(3PAM), pam\_sm\_open\_session(3PAM), and pam\_sm\_close\_session(3PAM) do nothing and return PAM\_IGNORE in pam\_ldap.

## pam\_passwd\_auth(5)

**NAME** 

pam\_passwd\_auth - authentication module for password

**SYNOPSIS** 

pam\_passwd\_auth.so.1

#### **DESCRIPTION**

pam\_passwd\_auth provides authentication functionality to the password service as implemented by passwd(1). It differs from the standard PAM authentication modules in its prompting behavior.

The name of the user whose password attributes are to be updated must be present in the PAM\_USER item. This can be accomplished due to a previous call to pam\_start(3PAM), or explicitly set by pam\_set\_item(3PAM). Based on the current user-id and the repository that is to by updated, the module determines whether a password is necessary for a successful update of the password repository, and if so, which password is required.

The following option can be passed to the module:

debug syslog(3C) debugging information at the LOG DEBUG

level

nowarn Turn off warning messages

PAM\_USER, is a server, do not apply the Unix policy from the passwd entry in the name service switch.

**ERRORS** 

The following error codes are returned:

PAM\_BUF\_ERR Memory buffer error

PAM\_IGNORE Ignore module, not participating in result
PAM\_SUCCESS Successfully obtains authentication token

PAM SYSTEM ERR System error

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT Level	MT-Safe with exceptions

## SEE ALSO

pam\_set\_item(3PAM), syslog(3C), libpam(3LIB), pam.conf(4), attributes(5),
pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5),
pam\_dhkeys(5), pam\_unix\_account(5), pam\_unix\_auth(5),
pam\_unix\_session(5)

# NOTES

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

pam\_passwd\_auth(5)

This module relies on the value of the current real UID, this module is only safe for MT-applications that don't change UIDs during the call to pam\_authenticate(3PAM).

The pam\_unix(5) module is no longer supported. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

pam\_projects(5)

NAME | pam\_projects – account management PAM module for projects

SYNOPSIS | /usr/lib/security/pam\_projects.so.1

**DESCRIPTION** | This man page has been superceded by pam\_unix\_cred(5).

**ATTRIBUTES** | See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Obsolete
MT-Level	MT-Safe with exceptions

**SEE ALSO** attributes(5), pam\_unix\_cred(5)

NOTES The pam\_projects(5) functionality has been replaced by pam\_unix\_cred(5), and is subject to being removed from future releases.

NAME

pam\_rhosts\_auth - authentication management PAM module using ruserok()

**SYNOPSIS** 

/usr/lib/security/pam\_rhosts\_auth.so.1

#### **DESCRIPTION**

The rhosts PAM module, /usr/lib/security/pam\_rhosts\_auth.so.1, authenticates a user via the rlogin authentication protocol. Only pam\_sm\_authenticate() is implemented within this module. pam\_sm\_authenticate() uses the ruserok(3SOCKET) library function to authenticate the rlogin or rsh user. pam sm setcred() is a null function.

/usr/lib/security/pam\_rhosts\_auth.so.1 is designed to be stacked on top of the /usr/lib/security/pam\_unix.so.1 module for both the rlogin and rsh services. This module is normally configured as *sufficient* so that subsequent authentication is performed only on failure of pam\_sm\_authenticate(). The following option may be passed in to this service module:

debug

syslog(3C) debugging information at LOG\_DEBUG level.

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT Level	MT-Safe with exceptions

#### **SEE ALSO**

pam(3PAM), pam\_authenticate(3PAM), ruserok(3SOCKET), syslog(3C), libpam(3LIB), pam.conf(4), attributes(5)

#### **NOTES**

The interfaces in libpam() are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

## pam\_roles(5)

#### NAME |

pam\_roles - Solaris Roles account management module

## **SYNOPSIS**

pam roles.so.1

#### **DESCRIPTION**

The pam\_roles module implements pam\_sm\_acct\_mgmt(3PAM). It provides functionality to verify that a user is authorized to assume a role. It also prevents direct logins to a role. The user\_attr(4) database is used to determine which users can assume which roles.

The PAM items PAM\_USER and PAM\_RUSER are used to determine the outcome of this module. PAM\_USER represents the new identity being verified. PAM\_RUSER, if set, represents the user asserting a new identity. If PAM\_RUSER is not set, the real user ID of the calling service implies that the user is asserting a new identity. Notice that root can never have roles.

This module is generally stacked above the pam unix account(5) module.

The following options are interpreted:

debug Provides syslog(3C) debugging information at the LOG DEBUG

level.

## **ERRORS**

The following values are returned:

PAM\_IGNORE If the type of the new user identity (PAM\_USER) is

"normal". Or, if the type of the new user identity is "role" and the user asserting the new identity (PAM\_RUSER) has the new identity name in its list or

roles.

PAM USER UNKNOWN No account is present for user.

PAM PERM DENIED If the type of the new user identity (PAM USER) is

"role" and the user asserting the new identity

(PAM\_RUSER) does not have the new identity name in

its list of roles.

## **EXAMPLES**

**EXAMPLE 1** Using the pam\_roles.so.1 module

Here are sample entries from pam.conf(4) demonstrating the use of the pam roles.so.1 module:

```
cron account required pam_unix_account.so.1
#
other account requisite pam_roles.so.1
other account required pam_unix_account.so.1
#
```

The cron service does not invoke pam\_roles.so.1. Delayed jobs are independent of role assumption. All other services verify that roles cannot directly login. The "su" service (covered by the "other" service entry) verifies that if the new user is a role, the calling user is authorized for that role.

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT Level	MT-Safe with exceptions

## **SEE ALSO**

roles(1), su(1M), libpam(3LIB), pam(3PAM), pam\_acct\_mgmt(3PAM), pam setcred(3PAM), pam set item(3PAM), pam sm acct mgmt(3PAM), syslog(3C), pam.conf(4), user\_attr(4), attributes(5), pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam unix auth(5), pam unix session(5)

## **NOTES**

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

This module should never be stacked alone. It never returns PAM SUCCESS, as it never makes a positive decision.

# pam\_sample(5)

NAME

pam\_sample – a sample PAM module

**SYNOPSIS** 

/usr/lib/security/pam\_sample.so.1

DESCRIPTION

The SAMPLE service module for PAM is divided into four components: authentication, account management, password management, and session management. The sample module is a shared object that is dynamically loaded to provide the necessary functionality.

SAMPLE Authentication Component The SAMPLE authentication module, typically

/usr/lib/security/pam\_sample.so.1, provides functions to test the PAM framework functionality using the pam\_sm\_authenticate(3PAM) call. The SAMPLE module implementation of the pam\_sm\_authenticate(3PAM) function compares the user entered password with the password set in the pam.conf(4) file, or the string "test" if a default test password has not been set. The following options may be passed in to the SAMPLE Authentication module:

debug Syslog debugging information at the LOG DEBUG level.

passwd=newone Sets the password to be "newone."

first\_pass\_good The first password is always good when used with the

use\_first\_pass or try\_first\_pass option.

first\_pass\_bad The first password is always bad when used with the

use\_first\_pass or try\_first\_pass option.

always\_fail Always returns PAM\_AUTH\_ERR.
always\_succeed Always returns PAM\_SUCCESS.

always\_ignore Always returns PAM\_IGNORE.

Use the user's initial password (entered when the user is authenticated to the first authentication module in the stack) to authenticate with the SAMPLE module. If the passwords do not match, or if this is the first authentication module in the stack, quit and do not prompt the user for a password. It is recommended that this option only be used if the SAMPLE

authentication module is designated as optional in the

pam.conf configuration file.

try first pass Use the user's initial password (entered when the user

is authenticated to the first authentication module in the stack) to authenticate with the SAMPLE module. If the passwords do not match, or if this is the first authentication module in the stack, prompt the user for

a password. The SAMPLE module

pam\_sm\_setcred(3PAM) function always returns

PAM SUCCESS.

use first pass

## SAMPLE Account Management Component

The SAMPLE Account Management Component, typically pam\_sample.so.1, implements a simple access control scheme that limits machine access to a list of authorized users. The list of authorized users is supplied as option arguments to the entry for the SAMPLE account management PAM module in the pam.conf file. Note that the module always permits access to the root super user.

The option field syntax to limit access is shown below: allow= name[,name] allow= name [allow=name]

The example pam.conf show below permits only larry to login directly. rlogin is allowed only for don and larry. Once a user is logged in, the user can use su if the user are sam or eric.

login	account	require	pam_sample.so.1	allow=larry
dtlogin	account	require	pam_sample.so.1	allow=larry
rlogin	account	require	pam_sample.so.1	allow=don allow=larry
su	account	require	pam_sample.so.1	allow=sam,eric

The debug and nowarn options are also supported.

SAMPLE Password Management SAMPLEMENTAL Management Component

The SAMPLE Password Management Component function (  ${\tt pam\_sm\_chauthtok(3PAM)), always \ returns \ PAM\_SUCCESS.}$ 

The SAMPLE Session Management Component functions (
pam\_sm\_open\_session(3PAM), pam\_sm\_close\_session(3PAM)) always return
PAM SUCCESS.

## **ATTRIBUTES**

See attributes(5) for description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE	
MT Level	MT-Safe with exceptions	

## **SEE ALSO**

pam(3PAM), pam\_sm\_authenticate(3PAM), pam\_sm\_chauthtok(3PAM), pam\_sm\_close\_session(3PAM), pam\_sm\_open\_session(3PAM), pam\_sm\_stcred(3PAM), libpam(3LIB), pam.conf(4), attributes(5)

## **NOTES**

The interfaces in libpam() are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

## pam\_smartcard(5)

## NAME

pam\_smartcard - PAM authentication module for Smart Card

## **SYNOPSIS**

/usr/lib/security/pam\_smartcard.so

#### **DESCRIPTION**

The Smart Card service module for PAM,

/usr/lib/security/pam smartcard.so, provides functionality to obtain a user's information (such as user name and password) for a smart card. The pam smartcard. so module is a shared object that can be dynamically loaded to provide the necessary functionality upon demand. Its path is specified in the PAM configuration file pam. conf. See pam. conf(4).

## Smart Card Authentication Module

The Smart Card authentication component provides the pam sm authenticate(3PAM) function to verify the identity of a smart card user.

The pam sm authenticate () function collects as user input the PIN number. It passes this data back to its underlying layer, OCF, to perform PIN verification. If verification is successful, the module returns PAM SUCCESS, and passes the username and password from the smart card to PAM modules stacked below.pam smartcard.

The following options can be passed to the Smart Card service module:

debug syslog(3C) debugging information at LOG DEBUG level.

Turn off warning messages. nowarn

verbose Turn on verbose authentication failure reporting to the user.

## Smart Card Module Configuration

The PAM smart card module (pam smartcard) can be configured in the PAM configuration file (/etc/pam.conf). For example, the following configuration on on the desktop (Common Desktop Environment) forces a user to use a smart card for logging in.

The following are typical values set by 'smartcard -c enable', if the command is applied to the default configuration.

dtlogin dtlogin dtlogin	auth requisite auth required auth required	<pre>pam_smartcard.so.1 pam_authtok_get.so.1 pam_dhkeys.so.1</pre>
dtsession dtsession dtsession	auth requisite auth required auth required	<pre>pam_smartcard.so.1 pam_authtok_get.so.1 pam_dhkeys.so.1</pre>

## SEE ALSO

smartcard(1M), libpam(3LIB), pam(3PAM), pam authenticate(3PAM), pam start(3PAM), pam.conf(4), pam authtok check(5), pam authtok get(5), pam authtok store(5), pam dhkeys(5), pam passwd auth(5), pam unix account(5), pam unix auth(5), pam unix session(5)

## NOTES

The pam unix(5) module is no longer supported. Similar functionality is provided by pam authtok check(5), pam authtok get(5), pam authtok store(5), pam dhkeys(5), pam passwd auth(5), pam unix account(5), pam unix auth(5), and pam unix session(5).

#### NAME

pam\_unix\_account – PAM account management module for UNIX

## **SYNOPSIS**

pam\_unix\_account.so.1

#### **DESCRIPTION**

pam\_unix\_account module implements pam\_sm\_acct\_mgmt(), which provides functionality to the PAM account management stack. The module provides functions to validate that the user's account is not locked or expired and that the user's password does not need to be changed. The module retrieves account information from the configured databases in nsswitch.conf(4).

The following options can be passed to the module:

debug syslog(3C) debugging information at the LOG DEBUG level

nowarn Turn off warning messages

server policy If the account authority for the user, as specified by PAM USER, is a

server, do not apply the Unix policy from the passwd entry in the

name service switch.

## **ERRORS**

The following values are returned:

PAM\_UNIX\_ACCOUNT User account has expired

PAM AUTHTOK EXPIRED Password expired and no longer usable

PAM BUF ERR Memory buffer error

PAM IGNORE Ignore module, not participating in result

PAM NEW AUTHTOK REQD Obtain new authentication token from the user

PAM\_PERM\_DENIED The account is locked or has been inactive for too long

PAM\_SERVICE\_ERR Error in underlying service module

PAM SUCCESS The account is valid for use at this time

PAM USER UNKNOWN No account is present for the user

## **ATTRIBUTES**

#### **NOTES**

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

# pam\_unix\_account(5)

NAME

pam\_unix\_auth - PAM authentication module for UNIX

**SYNOPSIS** 

pam unix auth.so.1

#### **DESCRIPTION**

The pam\_unix\_auth module implements pam\_sm\_authenticate(), which provides functionality to the PAM authentication stack. It provides functions to verify that the password contained in the PAM item PAM\_AUTHTOK is the correct password for the user specified in the item PAM\_USER. If PAM\_REPOSITORY is specified, then user's passwd is fetched from that repository. Otherwise, the default nsswitch.conf(4) repository is searched for that user. For accounts in the name services which support automatic account locking, the account may be configured to be automatically locked (see user\_attr(4) and policy.conf(4)) after multiple failed login attempts. If the number of successive failures equals or exceeds RETRIES, the account is locked and PAM\_MAXTRIES is returned. Currently, only the "files" repository (see passwd(4) and shadow(4)) supports automatic account locking. A successful authentication by this module clears the failed login counter and reports the number of failed attempts since the last successful authentication.

Authentication service modules must implement both pam\_sm\_authenticate() and pam\_sm\_setcred(). To allow replacability of the authentication portion of UNIX authentication, pam\_sm\_setcred() in this module always returns PAM\_IGNORE. This module should be stacked with pam\_unix\_cred(5) to ensure a successful return from pam\_setcred(3PAM).

The following options can be passed to the module:

nowarn Turn off warning messages.

 ${\tt server\_policy} \quad \text{If the account authority for the user, as specified by $\tt PAM\_USER$, is a}$ 

server, do not apply the Unix policy from the passwd entry in the

name service switch.

nolock Regardless of the automatic account locking setting for the

account, do not lock the account, increment or clear the failed login count. The nolock option allows for exempting account

locking on a per service basis.

## **ERRORS**

The following error codes are returned from pam sm authenticate():

PAM\_AUTH\_ERR

Authentication failure.

PAM BUF ERR

Memory buffer error.

PAM IGNORE

Ignores module, not participating in result.

PAM MAXTRIES

Maximum number of retries exceeded.

PAM\_PERM\_DENIED

Permission denied.

## pam\_unix\_auth(5)

PAM SUCCESS

Successfully obtains authentication token.

PAM\_SYSTEM\_ERR

System error.

PAM USER UNKNOWN

No account present for user.

The following error codes are returned from pam sm setcred():

PAM IGNORE

Ignores this module regardless of the control flag.

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

## **SEE ALSO**

$$\label{eq:login} \begin{split} &\log \operatorname{in}(1), \operatorname{passwd}(1), \operatorname{useradd}(1M), \operatorname{usermod}(1M), \operatorname{roleadd}(1M), \operatorname{rolemod}(1M), \\ &\operatorname{libpam}(3\operatorname{LIB}), \operatorname{pam}(3\operatorname{PAM}), \operatorname{pam}\_\operatorname{authenticate}(3\operatorname{PAM}), \operatorname{pam}\_\operatorname{setcred}(3\operatorname{PAM}), \\ &\operatorname{syslog}(3\operatorname{C}), \operatorname{pam}.\operatorname{conf}(4), \operatorname{passwd}(4), \operatorname{policy}.\operatorname{conf}(4), \operatorname{nsswitch}.\operatorname{conf}(4), \\ &\operatorname{shadow}(4), \operatorname{user}\_\operatorname{attr}(4), \operatorname{attributes}(5), \operatorname{pam}\_\operatorname{authtok}\_\operatorname{check}(5), \\ &\operatorname{pam}\_\operatorname{authtok}\_\operatorname{get}(5), \operatorname{pam}\_\operatorname{authtok}\_\operatorname{store}(5), \operatorname{pam}\_\operatorname{dhkeys}(5), \\ &\operatorname{pam}\_\operatorname{passwd}\_\operatorname{auth}(5), \operatorname{pam}\_\operatorname{unix}\_\operatorname{account}(5), \operatorname{pam}\_\operatorname{unix}\_\operatorname{session}(5) \end{split}$$

## NOTES

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

The pam\_unix(5) module is no longer supported. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5),pam\_setcred(3PAM), pam\_unix\_account(5), pam\_unix\_cred(5), pam\_unix\_session(5).

If the PAM\_REPOSITORY *item\_type* is set and a service module does not recognize the type, the service module does not process any information, and returns PAM\_IGNORE. If the PAM\_REPOSITORY *item\_type* is not set, a service module performs its default action.

NAME

pam\_unix\_cred - PAM user credential authentication module for UNIX

**SYNOPSIS** 

pam\_unix\_cred.so.1

#### **DESCRIPTION**

The pam\_unix\_cred module implements pam\_sm\_setcred(3PAM). It provides functions that establish user credential information. It is a module separate from the pam\_unix\_auth(5) module to allow replacement of the authentication functionality independently from the credential functionality.

The pam\_unix\_cred module must always be stacked along with whatever authentication module is used to ensure correct credential setting.

Authentication service modules must implement both pam\_sm\_authenticate() and pam sm setcred().

pam\_sm\_authenticate() in this module always returns PAM\_IGNORE.

pam\_sm\_setcred() initializes the user's project, privilege sets and initializes or updates the user's audit context if it hasn't already been initialized. The following flags may be set in the flags field:

PAM\_ESTABLISH\_CRED
PAM\_REFRESH\_CRED
PAM\_REINITIALIZE CRED

Initializes the user's project to the project specified in PAM\_RESOURCE, or if PAM\_RESOURCE is not specified, to the user's default project. Establishes the user's

privilege sets.

If the audit context is not already initialized and auditing is configured, these flags cause the context to be initialized to that of the user specified in PAM\_USER and host specified in PAM\_RHOST. If PAM\_RHOST is not specified, the local host is used. Additionally, if the audit context is already initialized, the PAM\_REINITIALIZE\_CRED flag merges the current audit context with that of the user specified in PAM\_USER. PAM\_REINITIALIZE\_CRED is useful when

a user is assuming a new identity, as with su(1M).

PAM\_DELETE\_CRED

This flag has no effect and always returns PAM SUCCESS.

The following options are interpreted:

debug Provides syslog(3C) debugging information at the LOG\_DEBUG

level.

nowarn Disables any warning messages.

#### **ERRORS**

Upon successful completion of pam\_sm\_setcred(), PAM\_SUCCESS is returned. The following error codes are returned upon error:

# pam\_unix\_cred(5)

PAM CRED UNAVAIL Underlying authentication service cannot retrieve user

credentials

PAM\_CRED\_EXPIRED User credentials have expired

PAM USER UNKNOWN User is unknown to the authentication service

PAM\_CRED\_ERR Failure in setting user credentials

PAM\_BUF\_ERR Memory buffer error

PAM SYSTEM ERR System error

The following values are returned from pam sm authenticate():

PAM\_IGNORE Ignores this module regardless of the control flag

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT Level	MT-Safe with exceptions

#### **SEE ALSO**

su(1M), settaskid(2), libpam(3LIB), getprojent(3PROJECT), pam(3PAM), pam\_set\_item(3PAM), pam\_sm\_authenticate(3PAM), syslog(3C), setproject(3PROJECT),pam.conf(4), nsswitch.conf(4), project(4), attributes(5), pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_auth(5), pam\_unix\_account(5), pam\_unix\_session(5), privileges(5)

## **NOTES**

The interfaces in libpam(3LIB) are MT-Safe only if each thread within the multi-threaded application uses its own PAM handle.

If this module is replaced, the audit context and credential may not be correctly configured.

#### NAME

pam\_unix\_session – session management PAM module for UNIX

## **SYNOPSIS**

pam\_unix\_session.so.1

#### **DESCRIPTION**

The pam\_unix\_session module implements pam\_sm\_open\_session(3PAM) and pam\_sm\_close\_session(3PAM).

pam\_sm\_open\_session() updates the /var/adm/lastlog file with the information contained in the PAM\_USER, PAM\_TTY, and PAM\_RHOSTS items. pam\_unix\_account(5) uses this account to determine the previous time the user logged in.

pam\_sm\_close\_session() is a null function.

The following options can be passed to the module:

debug syslog(3C) debugging information at the LOG DEBUG level

#### **ERRORS**

Upon successful completion, PAM\_SUCCESS is returned. The following error codes are returned upon error:

PAM SESSION ERR Cannot make or remove the entry for the specified

session (PAM\_TTY is not present).

PAM USER UNKNOWN No account is present for *user*.

The pam\_unix(5) module is no longer supported. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

## pkcs11\_kernel(5)

## NAME |

pkcs11\_kernel – PKCS#11 interface to Kernel Cryptographic Framework

## **SYNOPSIS**

/usr/lib/security/pkcs11\_kernel.so /usr/lib/security/64/pkcs11\_kernel.so

## **DESCRIPTION**

The pkcs11\_kernel.so object implements the RSA PKCS#11 v2.11 specification by using a private interface to communicate with the Kernel Cryptographic Framework.

Each unique hardware provider is represented by a PKCS#11 slot. In a system with no hardware Kernel Cryptographic Framework providers, this PKCS#11 library presents no slots.

The PKCS#11 mechanisms provided by this library is determined by the available hardware providers.

Application developers should link to libpkcs11.so rather than link directly to pkcs11 kernel.so. See libpkcs11(3LIB).

All of the Standard PKCS#11 functions listed on libpkcs11(3LIB) are implemented except for the following:

- C\_DecryptDigestUpdate
- C DecryptVerifyUpdate
- C DigestEncryptUpdate
- C GetOperationState
- C InitToken
- C\_InitPIN
- C SetOperationState
- C\_SignEncryptUpdate
- C WaitForSlotEvent

A call to these functions returns CKR FUNCTION NOT SUPPORTED.

Buffers cannot be greater than 2 megabytes. For example, C\_Encrypt() can be called with a 2 megabyte buffer of plaintext and a 2 megabyte buffer for the ciphertext.

The maximum number of object handles that can be returned by a call to C\_FindObjects() is 512.

The maximum amount of kernel memory that can be used for crypto operations is limited by the project.max-crypto-memory resource control. Allocations in the kernel for buffers and session-related structures are charged against this resource control.

## **RETURN VALUES**

The return values of each of the implemented functions are defined and listed in the RSA PKCS#11 v2.11 specification. See

http://www.rsasecurity.com/rsalabs/pkcs/pkcs-11.

## **ATTRIBUTES**

See attributes(5) for a description of the following attributes:

# pkcs11\_kernel(5)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard: PKCS#11 v2.11
MT-Level	MT-Safe with exceptions. See section 6.5.2 of RSA PKCS#11 v2.11

## **SEE ALSO**

RSA PKCS#11 v2.11 http://www.rsasecurity.com

## **NOTES**

Applications that have an open session to a PKCS#11 slot make the corresponding hardware provider driver not unloadable. An administrator must close the applications that have an PKCS#11 session open to the hardware provider to make the driver unloadable.

## pkcs11\_softtoken(5)

#### NAME |

pkcs11\_softtoken – Software RSA PKCS#11 softtoken

## SYNOPSIS

```
/usr/lib/security/pkcs11 softtoken.so
/usr/lib/security/64/pkcs11 softtoken.so
/usr/lib/security/pkcs11_softtoken_extra.so
/usr/lib/security/64/pkcs11_softtoken_extra.so
```

#### DESCRIPTION

The pkcs11 softtoken.so object implements the RSA PKCS#11 v2.11 specification in software. Persistent storage for "token" objects is provided by this PKCS#11 implementation.

The pkcs11 softtoken.so object contains only implementations of symmetric key algorithms of up to 128-bit keylength. pkcs11 softtoken extra.so, if available, might contain longer key lengths.

Application developers should link to libpkcs11.so rather than link directly to pkcs11 softtoken.so. See libpkcs11(3LIB).

The following cryptographic algorithms are implemented: DES, 3DES, AES, Blowfish, RC4, MD5, SHA1, RSA, DSA, and DH.

All of the Standard PKCS#11 functions listed on libpkcs11(3LIB) are implemented except for the following:

```
C GetObjectSize
C InitPIN
C InitToken
C WaitForSlotEvent
```

A call to these functions returns CKR FUNCTION NOT SUPPORTED.

The following RSA PKCS#11 v2.11 mechanisms are supported:

```
CKM RSA PKCS KEY PAIR GEN
CKM RSA PKCS
CKM_RSA_X_509
CKM_DSA_KEY_PAIR_GEN
CKM DSA
CKM DSA SHA1
CKM DH PKCS KEY PAIR GEN
CKM DH PKCS DERIVE
CKM DES KEY GEN
CKM DES ECB
CKM DES CBC
CKM DES CBC PAD
CKM DES3 KEY GEN
CKM DES3 ECB
CKM_DES3_CBC
CKM DES3 CBC PAD
CKM_AES_KEY_GEN
CKM AES ECB
```

```
CKM AES CBC
CKM_AES_CBC_PAD
CKM BF KEY GEN
CKM_BF_ECB
CKM_BF_CBC
CKM_RC4_KEY_GEN
CKM RC4
CKM MD5 RSA PKCS
CKM_SHA1_RSA_PKCS
CKM SHA 1
CKM_MD5
CKM MD5 1 HMAC
CKM MD5 1 HMAC GENERAL
CKM_SHA_1_HMAC
CKM SHA 1 HMAC GENERAL
CKM MD5 KEY DERIVATION
CKM_SHA1_KEY_DERIVATION
CKM_SSL3_PRE_MASTER_KEY_GEN
CKM SSL3 MASTER KEY DERIVE
CKM_SSL3_KEY_AND_MAC_DERIVE
CKM SSL3 MASTER KEY DERIVE DH
CKM_TLS_PRE_MASTER_KEY_GEN
CKM TLS MASTER KEY DERIVE
CKM TLS KEY AND MAC DERIVE
CKM TLS MASTER KEY DERIVE DH
```

Each of the following types of key objects has certain token-specific attributes that will be set to true by default as a result of object creation, key/key pair generation, and key derivation.

Public key object CKA ENCRYPT, CKA VERIFY, CKA VERIFY RECOVER

Private key object CKA DECRYPT, CKA SIGN, CKA SIGN RECOVER,

CKA EXTRACTABLE

Secret key object CKA ENCRYPT, CKA DECRYPT, CKA SIGN,

CKA VERIFY, CKA EXTRACTABLE

The following certificate objects are supported:

CKC\_X\_509 For CKC\_X\_509 certificate objects, the following

attributes are supported: CKA SUBJECT, CKA VALUE,

CKA LABEL, CKA ID, CKA ISSUER,

CKA\_SERIAL\_NUMBER, and CKA\_CERTIFICATE\_TYPE.

CKC X 509 ATTR CERT For CKC X 509 ATTR CERT certificate objects, the

following attributes are supported: CKA\_OWNER, CKA\_VALUE, CKA\_LABEL, CKA\_SERIAL\_NUMBER,

CKA\_AC\_ISSUER, CKA\_ATTR\_TYPES, and CKA CERTIFICATE TYPE.

The search operation of objects matching the template is performed at C\_FindObjectsInit. The matched objects are cached for sublequent C FindObjects operations.

The pkcsll\_softtoken.so object provides a filesystem-based persistent token object store for storing token objects. The default location of the token object store is the user's \$HOME directory. The user can override the default location by using the \${SOFTTOKEN DIR} environment variable.

If the token object store has never been initialized, the C\_Login() function might return CKR\_OK but the user will not be able to create, generate, derive or find any private token object and will receive CKR\_PIN\_EXPIRED.

The user must use the pktool(1) setpin command with the default passphrase "changeme" as the old passphrase to change the passphrase of the object store. This action is needed to initialize and set the passphrase to a newly created token object store.

After logging into object store with the new passphrase that was set by the pktool setpin command, the user can create and store the private token object in this newly created object store. Until the token object store is initialized by setpin, the C\_Login() function is allowed, but all attempts by the user to create, generate, derive or find any private token object will fail with a CKR\_PIN\_EXPIRED error.

The PIN provided for C\_Login() and C\_SetPIN() functions can be any string of characters with lengths between 1 and 256 and no embedded nulls.

## **RETURN VALUES**

The return values for each of the implemented functions are defined and listed in the RSA PKCS#11 v2.11 specification. See http://www.rsasecurity.com

## **FILES**

\${HOME}/.sunw/pkcs11\_softtoken user's default token object store

\${SOFTTOKEN\_DIR}/pkcs11\_softtoken alternate token object store

## **ATTRIBUTES**

# privileges(5)

#### **NAME**

privileges – process privilege model

#### DESCRIPTION

Solaris software implements a set of privileges that provide fine-grained control over the actions of processes. The possession of a certain privilege allows a process to perform a specific set of restricted operations.

The change to a primarily privilege-based security model in the Solaris operating system gives developers an opportunity to restrict processes to those privileged operations actually needed instead of all (super-user) or no privileges (non-zero uids). Additionally, a set of previously unrestricted operations now requires a privilege; these privileges are dubbed the "basic" privileges and are by default given to all processes.

Taken together, all defined privileges with the exception of the "basic" privileges compose the set of privileges that are traditionally associated with the root user. The "basic" privileges are "privileges" unprivileged processes were accustomed to having.

The defined privileges are:

```
PRIV CONTRACT EVENT
```

Allows a process to request reliable delivery of events to an event endpoint. Allows a process to include events in the critical event set term of a template which could be generated in volume by the user.

```
PRIV CONTRACT OBSERVER
```

Allows a process to observe contract events generated by contracts created and owned by users other than the process's effective user ID. Allows a process to open contract event endpoints belonging to contracts created and owned by users other than the process's effective user ID.

```
PRIV_CPC_CPU
```

Allow a process to access per-CPU hardware performance counters.

```
PRIV DTRACE PROC
```

Allow DTrace process-level tracing. Allow process-level tracing probes to be placed and enabled in processes to which the user has permissions.

```
PRIV DTRACE USER
```

Allow DTrace user-level tracing. Allow use of the syscall and profile DTrace providers to examine processes to which the user has permissions.

```
PRIV DTRACE KERNEL
```

Allow DTrace kernel-level tracing.

```
PRIV_FILE_CHOWN
```

Allow a process to change a file's owner user ID. Allow a process to change a file's group ID to one other than the process's effective group ID or one of the process's supplemental group IDs.

```
PRIV_FILE_CHOWN_SELF
```

Allow a process to give away its files. A process with this privilege will run as if { POSIX CHOWN RESTRICTED} is not in effect.

# PRIV FILE DAC EXECUTE

Allow a process to execute an executable file whose permission bits or ACL would otherwise disallow the process execute permission.

#### PRIV FILE DAC READ

Allow a process to read a file or directory whose permission bits or ACL would otherwise disallow the process read permission.

#### PRIV FILE DAC SEARCH

Allow a process to search a directory whose permission bits or ACL would not otherwise allow the process search permission.

#### PRIV FILE DAC WRITE

Allow a process to write a file or directory whose permission bits or ACL do not allow the process write permission. All privileges are required to write files owned by UID 0 in the absence of an effective UID of 0.

# PRIV FILE LINK ANY

Allow a process to create hardlinks to files owned by a UID different from the process's effective UID.

#### PRIV FILE OWNER

Allow a process that is not the owner of a file to modify that file's access and modification times. Allow a process that is not the owner of a directory to modify that directory's access and modification times. Allow a process that is not the owner of a file or directory to remove or rename a file or directory whose parent directory has the "save text image after execution" (sticky) bit set. Allow a process that is not the owner of a file to mount a namefs upon that file. Allow a process that is not the owner of a file or directory to modify that file's or directory's permission bits or ACL.

# PRIV FILE SETID

Allow a process to change the ownership of a file or write to a file without the set-user-ID and set-group-ID bits being cleared. Allow a process to set the set-group-ID bit on a file or directory whose group is not the process' effective group or one of the process' supplemental groups. Allow a process to set the set-user-ID bit on a file with different ownership in the presence of PRIV FILE OWNER. Additional restrictions apply when creating or modifying a setuid 0 file.

# PRIV IPC DAC READ

Allow a process to read a System V IPC Message Queue, Semaphore Set, or Shared Memory Segment whose permission bits would not otherwise allow the process read permission.

# PRIV IPC DAC WRITE

Allow a process to write a System V IPC Message Queue, Semaphore Set, or Shared Memory Segment whose permission bits would not otherwise allow the process write permission.

# privileges(5)

PRIV IPC OWNER

Allow a process that is not the owner of a System V IPC Message Queue, Semaphore Set, or Shared Memory Segment to remove, change ownership of, or change permission bits of the Message Queue, Semaphore Set, or Shared Memory Segment.

PRIV NET ICMPACCESS

Allow a process to send and receive ICMP packets.

PRIV NET PRIVADDR

Allow a process to bind to a privileged port number. The privilege port numbers are 1-1023 (the traditional UNIX privileged ports) as well as those ports marked as "udp/tcp\_extra\_priv\_ports" with the exception of the ports reserved for use by NFS.

PRIV NET RAWACCESS

Allow a process to have direct access to the network layer.

PRIV PROC CHROOT

Allow a process to change its root directory.

PRIV PROC CLOCK HIGHRES

Allow a process to use high resolution timers.

PRIV PROC AUDIT

Allow a process to generate audit records. Allow a process to get its own audit pre-selection information.

PRIV PROC EXEC

Allow a process to call execve(2).

PRIV PROC FORK

Allow a process to call fork(2), fork1(2), or vfork(2).

PRIV PROC INFO

Allow a process to examine the status of processes other than those to which it can send signals. Processes that cannot be examined cannot be seen in /proc and appear not to exist.

PRIV PROC LOCK MEMORY

Allow a process to lock pages in physical memory.

PRIV PROC OWNER

Allow a process to send signals to other processes and inspect and modify the process state in other processes, regardless of ownership. When modifying another process, additional restrictions apply: the effective privilege set of the attaching process must be a superset of the target process's effective, permitted, and inheritable sets; the limit set must be a superset of the target's limit set; if the target process has any UID set to 0 all privilege must be asserted unless the effective UID is 0. Allow a process to bind arbitrary processes to CPUs.

PRIV PROC PRIOCNTL

Allow a process to elevate its priority above its current level. Allow a process to change its scheduling class to any scheduling class, including the RT class.

#### PRIV PROC SESSION

Allow a process to send signals or trace processes outside its session.

#### PRIV PROC SETID

Allow a process to set its UIDs at will, assuming UID 0 requires all privileges to be asserted.

#### PRIV PROC TASKID

Allow a process to assign a new task ID to the calling process.

#### PRIV PROC ZONE

Allow a process to trace or send signals to processes in other zones. See zones(5).

# PRIV SYS ACCT

Allow a process to enable and disable and manage accounting through acct(2).

#### PRIV SYS ADMIN

Allow a process to perform system administration tasks such as setting node and domain name and specifying coreadm(1M) and nscd(1M) settings

#### PRIV SYS AUDIT

Allow a process to start the (kernel) audit daemon. Allow a process to view and set audit state (audit user ID, audit terminal ID, audit sessions ID, audit pre-selection mask). Allow a process to turn off and on auditing. Allow a process to configure the audit parameters (cache and queue sizes, event to class mappings, and policy options).

# PRIV SYS CONFIG

Allow a process to perform various system configuration tasks. Allow filesystem-specific administrative procedures, such as filesystem configuration ioctls, quota calls, creation and deletion of snapshots, and manipulating the PCFS bootsector.

# PRIV SYS DEVICES

Allow a process to create device special files. Allow a process to successfully call a kernel module that calls the kernel drv\_priv(9F) function to check for allowed access. Allow a process to open the real console device directly. Allow a process to open devices that have been exclusively opened.

#### PRIV SYS IPC CONFIG

Allow a process to increase the size of a System V IPC Message Queue buffer.

# PRIV SYS LINKDIR

Allow a process to unlink and link directories.

# PRIV SYS MOUNT

Allow a process to mount and unmount filesystems that would otherwise be restricted (that is, most filesystems except namefs). Allow a process to add and remove swap devices.

# PRIV SYS NET CONFIG

Allow a process to configure a system's network interfaces and routes. Allow a process to configure network parameters using ndd. Allow a process access to otherwise restricted information using ndd.

# privileges(5)

#### PRIV SYS NFS

Allow a process to provide NFS service: start NFS kernel threads, perform NFS locking operations, bind to NFS reserved ports: ports 2049 (nfs) and port 4045 (lockd).

# PRIV SYS RES CONFIG

Allow a process to create and delete processor sets, assign CPUs to processor sets and override the PSET\_NOESCAPE property. Allow a process to change the operational status of CPUs in the system using p\_online(2). Allow a process to configure filesystem quotas. Allow a process to configure resource pools and bind processes to pools.

#### PRIV SYS RESOURCE

Allow a process to exceed the resource limits imposed on it by setrlimit(2) and setrctl(2).

#### PRIV SYS SUSER COMPAT

Allow a process to successfully call a third party loadable module that calls the kernel <code>suser()</code> function to check for allowed access. This privilege exists only for third party loadable module compatibility and is not used by Solaris proper.

# PRIV SYS TIME

Allow a process to manipulate system time using any of the appropriate system calls: stime(2), adjtime(2), and ntp adjtime(2).

Of the privileges listed above, the privileges PRIV\_FILE\_LINK\_ANY, PRIV\_PROC\_INFO, PRIV\_PROC\_SESSION, PRIV\_PROC\_FORK and PRIV\_PROC\_EXEC are considered "basic" privileges. These are privileges that used to be always available to unprivileged processes. By default, processes still have the basic privileges.

The privileges PRIV\_PROC\_SETID and PRIV\_PROC\_AUDIT must be present in the Limit set (see below) of a process in order for set-uid root execs to be successful, that is, get an effective UID of 0 and additional privileges.

The privilege implementation in Solaris extends the process credential with four privilege sets:

#### I, the inheritable set

The privileges inherited on exec.

# P, the permitted set

The maximum set of privileges for the process.

# E, the effective set

The privileges currently in effect.

# L, the limit set

The upper bound of the privileges a process and its offspring can obtain. Changes to L take effect on the next exec.

The sets I, P and E are typically identical to the basic set of privileges for unprivileged processes. The limit set is typically the full set of privileges.

Additionally, each process has a Privilege Awareness State (PAS) which can take the value PA (Privilege Aware) and NPA (Not-PA). PAS is a transitional mechanism which allows a choice between full compatibility with the old super-user model and completely ignoring the effective UID.

In order to facilitate the discussion, we introduce the notion of "observed effective set" (oE) and "observed permitted set" (oP) and the implementation sets iE and iP.

When a process is Privilege Aware, oE and oP are invariant under UID changes; when a process is not privilege aware, oE and oP are observed as follows:

```
oE = euid == 0 ? L : iE
oP = (euid == 0 || ruid == 0 || suid == 0) ? L : iP
```

That is, when a non-privilege-aware process has an effective UID of 0, it can exercise the privileges contained in its limit set, the upper bound of its privileges. If a non-privilege-aware process has any of the uids 0, it will appear to be able to potentially exercise all privileges in L.

A process can attempt to become NPA using setpflags(2); the kernel will always attempt this on exec(2).

Only privileges in the process's (observed) effective privilege set allow the process to perform restricted operations. A process may use any of the privilege manipulation functions to add or remove privileges from the privilege sets. Privileges can be removed always; only privileges found in the permitted set can be added to the effective and inheritable set. The limit set cannot grow. The inheritable set can be larger than the permitted set.

When a process performs an exec(2), the kernel will first try to relinquish privilege awareness and then the following privilege set modifications take place:

```
E' = P' = I' = L \& I
L is unchanged
```

If a process has not manipulated its privileges, then the privilege sets effectively remain the same, as E, P and I are already identical.

To run a non-privilege-aware application in a backward-compatible manner, a privilege-aware application should start the non-privilege-aware application with I=basic.

For most privileges, absence of the privilege simply results in a failure. In some instances, the absense of a privilege can cause system calls to behave differently. In other instances, the removal of a privilege can force a set-uid application to seriously malfunction. Privileges of this type are considered "unsafe". When a process is lacking any of the unsafe privileges from its limit set, the system will not honor the set-uid bit of set-uid root applications. The following unsafe privileges have been identified: proc setid, sys resource and proc audit.

# privileges(5)

#### Privilege Escalation

In certain circumstances, a single privilege could lead to a process gaining one or more additional privileges that were not explicitly granted to that process. To prevent such an escalation of privileges, the security policy will require explicit permission for those additional privileges.

Common examples of escalation are those mechanisms that allow modification of system resources through "raw" interfaces; for example, changing kernel data structures through /dev/kmem or changing files through /dev/dsk/\*. Escalation also occurs when a process controls processes with more privileges than the controlling process. A special case of this is manipulating or creating objects owned by UID 0 or trying to obtain UID 0 using setuid(2). The special treatment of UID 0 is needed because the UID 0 owns all system configuration files and ordinary file protection mechanisms allow processes with UID 0 to modify the system configuration. With appropriate file modifications, a given process running with an effective UID of 0 can gain all privileges.

In situations where a process might obtain UID 0, the security policy requires additional privileges, up to the full set of privileges. Such restrictions could be relaxed or removed at such time as additional mechanisms for protection of system files became available. There are no such mechanisms in the current Solaris release.

The use of UID 0 processes should be limited as much as possible. They should be replaced with programs running under a different UID but with exactly the privileges they need.

Daemons that never need to exec subprocesses should remove the PRIV\_PROC\_EXEC privilege from their permitted and limit sets.

# Privilege Debugging

When a system call fails with a permission error, it is not always immediately obvious what caused the problem. To debug such a problem, you can use a tool called *privilege debugging*. When privilege debugging is enabled for a process, the kernel reports missing privileges on the controlling terminal of the process. (Enable debugging for a process with the -D option of ppriv(1).) Additionally, the administrator can enable system-wide privilege debugging by setting the system(4) variable priv\_debug using:

```
set priv debug = 1
```

On a running system, you can use mdb(1) to change this variable.

# prof(5)

**NAME** | prof – profile within a function

#### SYNOPSIS

```
#define MARK
#include <prof.h>
void MARK(name);
```

#### **DESCRIPTION**

MARK introduces a mark called *name* that is treated the same as a function entry point. Execution of the mark adds to a counter for that mark, and program-counter time spent is accounted to the immediately preceding mark or to the function if there are no preceding marks within the active function.

name may be any combination of letters, numbers, or underscores. Each name in a single compilation must be unique, but may be the same as any ordinary program symbol.

For marks to be effective, the symbol MARK must be defined before the header prof.h is included, either by a preprocessor directive as in the synopsis, or by a command line argument:

```
cc -p -DMARK work.c
```

If MARK is not defined, the MARK (name) statements may be left in the source files containing them and are ignored. prof -q must be used to get information on all labels.

# **EXAMPLES**

In this example, marks can be used to determine how much time is spent in each loop. Unless this example is compiled with MARK defined on the command line, the marks are ignored.

```
#include <prof.h>
work()
        int i, j;
        MARK(loop1);
        for (i = 0; i < 2000; i++) {
       MARK(loop2);
        for (j = 0; j < 2000; j++) {
```

#### NAME

| rbac - role-based access control

# **DESCRIPTION**

The addition of role-based access control (RBAC) to the Solaris operating environment gives developers the opportunity to deliver fine-grained security in new and modified applications. RBAC is an alternative to the all-or-nothing security model of traditional superuser-based systems. With RBAC, an administrator can assign privileged functions to specific user accounts (or special accounts called roles).

There are two ways to give applications privileges:

- 1. Administrators can assign special attributes such as setUID to application binaries (executable files).
- 2. Administrators can assign special attributes such as setUID to applications using execution profiles.

Special attribute assignment along with the theory behind RBAC is discussed in detail in "Role Based Access Control" chapter of the *System Administration Guide: Security Services*. This chapter describes what authorizations are and how to code for them.

#### Authorizations

An authorization is a unique string that represents a user's right to perform some operation or class of operations. Authorization definitions are stored in a database called auth\_atr(4). For programming authorization checks, only the authorization name is significant.

Some typical values in an auth attr database are shown below.

```
solaris.jobs.:::Cron and At Jobs::help=JobHeader.html
solaris.jobs.grant:::Delegate Cron & At Administration::help=JobsGrant.html
solaris.jobs.admin:::Manage All Jobs::help=AuthJobsAdmin.html
solaris.jobs.user:::Cron & At User::help=JobsUser.html
```

Authorization name strings ending with the grant suffix are special authorizations that give a user the ability to delegate authorizations with the same prefix and functional area to other users.

# Creating Authorization Checks

To check authorizations, use the chkauthattr(3SECDB) library function, which verifies whether or not a user has a given authorization. The synopsis is:

```
int chkauthattr(const char *authname, const char *username);
```

The chkauthattr() function checks the policy.conf(4), user\_attr(4), and prof\_attr(4) databases in order for a match to the given authorization.

If you are modifying existing code that tests for root UID, you should find the test in the code and replace it with the chkauthattr() function. A typical root UID check is shown in the first code segment below. An authorization check replacing it is shown in the second code segment; it uses the solaris.jobs.admin authorization and a variable called real\_login representing the user.

**EXAMPLE 1** Standard root check

```
ruid = getuid();
```

# **EXAMPLE 1** Standard root check (Continued)

#### **EXAMPLE 2** Authorization check

For new applications, find an appropriate location for the test and use chkauthattr() as shown above. Typically the authorization check makes an access decision based on the identity of the calling user to determine if a privileged action (for example, a system call) should be taken on behalf of that user.

Applications that perform a test to restrict who can perform their security-relevant functionality are generally setuid to root. Programs that were written prior to RBAC and that are only available to the root user may not have such checks. In most cases, the kernel requires an effective user ID of root to override policy enforcement. Therefore, authorization checking is most useful in programs that are setuid to root.

For instance, if you want to write a program that allows authorized users to set the system date, the command must be run with an effective user ID of root. Typically, this means that the file modes for the file would be <code>-rwsr-xr-x</code> with root ownership.

Use caution, though, when making programs setuid to root. For example, the effective UID should be set to the real UID as early as possible in the program's initialization function. The effective UID can then be set back to root after the authorization check is performed and before the system call is made. On return from the system call, the effective UID should be set back to the real UID again to adhere to the principle of least privilege.

Another consideration is that LD\_LIBRARY path is ignored for setuid programs (see SECURITY section in ld.so.l(1)) and that shell scripts must be modified to work properly when the effective and real UIDs are different. For example, the -p flag in Bourne shell is required to avoid resetting the effective UID back to the real UID.

Using an effective UID of root instead of the real UID requires extra care when writing shell scripts. For example, many shell scripts check to see if the user is root before executing their functionality. With RBAC, these shell scripts may be running with the effective UID of root and with a real UID of a user or role. Thus, the shell script should check euid instead of uid. For example,

Authorizations can be explicitly checked in shell scripts by checking the output of the auths(1) utility. For example,

```
for auth in 'auths | tr , " "' NOTFOUND
do
    [ "$auth" = "solaris.date" ] && break  # authorization found
done

if [ "$auth" != "solaris.date" ]
then
    echo >&2 "$PROG: ERROR: you are not authorized to set the date"
    exit 1
fi
```

System Administration Guide: Security Services

#### NAME

regex – internationalized basic and extended regular expression matching

# **DESCRIPTION**

Regular Expressions (REs) provide a mechanism to select specific strings from a set of character strings. The Internationalized Regular Expressions described below differ from the Simple Regular Expressions described on the regexp(5) manual page in the following ways:

- both Basic and Extended Regular Expressions are supported
- the Internationalization features—character class, equivalence class, and multi-character collation—are supported.

The Basic Regular Expression (BRE) notation and construction rules described in the BASIC REGULAR EXPRESSIONS section apply to most utilities supporting regular expressions. Some utilities, instead, support the Extended Regular Expressions (ERE) described in the EXTENDED REGULAR EXPRESSIONS section; any exceptions for both cases are noted in the descriptions of the specific utilities using regular expressions. Both BREs and EREs are supported by the Regular Expression Matching interfaces regcomp(3C) and regexec(3C).

# BASIC REGULAR EXPRESSIONS BREs Matching a Single Character

A BRE ordinary character, a special character preceded by a backslash, or a period matches a single character. A bracket expression matches a single character or a single collating element. See RE Bracket Expression, below.

#### BRE Ordinary Characters

An ordinary character is a BRE that matches itself: any character in the supported character set, except for the BRE special characters listed in BRE Special Characters, below.

The interpretation of an ordinary character preceded by a backslash (\) is undefined, except for:

- 1. the characters ), (, {, and }
- 2. the digits 1 to 9 inclusive (see BREs Matching Multiple Characters, below)
- 3. a character inside a bracket expression.

# BRE Special Characters

A BRE *special character* has special properties in certain contexts. Outside those contexts, or when preceded by a backslash, such a character will be a BRE that matches the special character itself. The BRE special characters and the contexts in which they have their special meaning are:

- . [ \ The period, left-bracket, and backslash are special except when used in a bracket expression (see RE Bracket Expression, below). An expression containing a [ that is not preceded by a backslash and is not part of a bracket expression produces undefined results.
- \* The asterisk is special except when used:
  - in a bracket expression
  - as the first character of an entire BRE (after an initial ^, if any)
  - as the first character of a subexpression (after an initial ^, if any); see BREs Matching Multiple Characters, below.

- ^ The circumflex is special when used:
  - as an anchor (see BRE Expression Anchoring, below).
  - as the first character of a bracket expression (see RE Bracket Expression, below).
- \$ The dollar sign is special when used as an anchor.

#### Periods in BREs

A period ( . ), when used outside a bracket expression, is a BRE that matches any character in the supported character set except NUL.

# RE Bracket Expression

A bracket expression (an expression enclosed in square brackets, []) is an RE that matches a single collating element contained in the non-empty set of collating elements represented by the bracket expression.

The following rules and definitions apply to bracket expressions:

1. A *bracket expression* is either a matching list expression or a non-matching list expression. It consists of one or more expressions: collating elements, collating symbols, equivalence classes, character classes, or range expressions (see rule 7 below). Portable applications must not use range expressions, even though all implementations support them. The right-bracket (]) loses its special meaning and represents itself in a bracket expression if it occurs first in the list (after an initial circumflex (^), if any). Otherwise, it terminates the bracket expression, unless it appears in a collating symbol (such as [.].]) or is the ending right-bracket for a collating symbol, equivalence class, or character class. The special characters:

(period, asterisk, left-bracket and backslash, respectively) lose their special meaning within a bracket expression. The character sequences:

.1 =1 1

(left-bracket followed by a period, equals-sign, or colon) are special inside a bracket expression and are used to delimit collating symbols, equivalence class expressions, and character class expressions. These symbols must be followed by a valid expression and the matching terminating sequence .], =] or :], as described in the following items.

- 2. A *matching list* expression specifies a list that matches any one of the expressions represented in the list. The first character in the list must not be the circumflex. For example, [abc] is an RE that matches any of the characters a, b or c.
- 3. A non-matching list expression begins with a circumflex (^), and specifies a list that matches any character or collating element except for the expressions represented in the list after the leading circumflex. For example, [^abc] is an RE that matches any character or collating element except the characters a, b, or c. The circumflex will have this special meaning only when it occurs first in the list, immediately following the left-bracket.

- 4. A collating symbol is a collating element enclosed within bracket-period ([..]) delimiters. Multi-character collating elements must be represented as collating symbols when it is necessary to distinguish them from a list of the individual characters that make up the multi-character collating element. For example, if the string ch is a collating element in the current collation sequence with the associated collating symbol <ch>, the expression [[.ch.]] will be treated as an RE matching the character sequence ch, while [ch] will be treated as an RE matching c or h. Collating symbols will be recognized only inside bracket expressions. This implies that the RE [[.ch.]]\*c matches the first to fifth character in the string chechel. If the string is not a collating element in the current collating sequence definition, or if the collating element has no characters associated with it, the symbol will be treated as an invalid expression.
- 5. An *equivalence class expression* represents the set of collating elements belonging to an equivalence class. Only primary equivalence classes will be recognised. The class is expressed by enclosing any one of the collating elements in the equivalence class within bracket-equal ([==]) delimiters. For example, if a, and belong to the same equivalence class, then [[=a=]b], [[==]b] and [[==]b] will each be equivalent to [ab]. If the collating element does not belong to an equivalence class, the equivalence class expression will be treated as a *collating symbol*.
- 6. A character class expression represents the set of characters belonging to a character class, as defined in the LC\_CTYPE category in the current locale. All character classes specified in the current locale will be recognized. A character class expression is expressed as a character class name enclosed within bracket-colon ([::]) delimiters.

The following character class expressions are supported in all locales:

[:alnum:]	[:cntrl:]	[:lower:]	[:space:]
[:alpha:]	[:digit:]	[:print:]	[:upper:]
[:blank:]	[:graph:]	[:punct:]	[:xdigit:]

In addition, character class expressions of the form:

[:name:]

are recognized in those locales where the *name* keyword has been given a charclass definition in the LC CTYPE category.

7. A *range expression* represents the set of collating elements that fall between two elements in the current collation sequence, inclusively. It is expressed as the starting point and the ending point separated by a hyphen (–).

Range expressions must not be used in portable applications because their behavior is dependent on the collating sequence. Ranges will be treated according to the current collating sequence, and include such characters that fall within the range based on that collating sequence, regardless of character values. This, however, means that the interpretation will differ depending on collating sequence. If, for instance, one collating sequence defines as a variant of a, while another

defines it as a letter following z, then the expression [–z] is valid in the first language and invalid in the second.

In the following, all examples assume the collation sequence specified for the POSIX locale, unless another collation sequence is specifically defined.

The starting range point and the ending range point must be a collating element or collating symbol. An equivalence class expression used as a starting or ending point of a range expression produces unspecified results. An equivalence class can be used portably within a bracket expression, but only outside the range. For example, the unspecified expression [[=e=]-f] should be given as [[=e=]e-f]. The ending range point must collate equal to or higher than the starting range point; otherwise, the expression will be treated as invalid. The order used is the order in which the collating elements are specified in the current collation definition. One-to-many mappings (see locale(5)) will not be performed. For example, assuming that the character eszet is placed in the collation sequence after r and s, but before t, and that it maps to the sequence ss for collation purposes, then the expression [r-s] matches only r and s, but the expression [s-t] matches s, beta, or t.

The interpretation of range expressions where the ending range point is also the starting range point of a subsequent range expression (for instance [a-m-o]) is undefined.

The hyphen character will be treated as itself if it occurs first (after an initial  $^$ , if any) or last in the list, or as an ending range point in a range expression. As examples, the expressions [-ac] and [ac-] are equivalent and match any of the characters a, c, or -; [ $^-ac$ ] and [ $^ac$ -] are equivalent and match any characters except a, c, or -; the expression [ $^-ac$ ] matches any of the characters between  $^+ac$  and  $^-ac$  inclusive; the expression [ $^-ac$ ] matches any of the characters between  $^-ac$  and  $^-ac$  inclusive; and the expression [ $^-ac$ ] is invalid, because the letter  $^-ac$  follows the symbol  $^-ac$  in the POSIX locale. To use  $^-ac$  hyphen as the starting range point, it must either come first in the bracket expression or be specified as  $^-ac$  collating symbol, for example: [][ $^-ac$ ] which matches either  $^-ac$  right bracket or any character or collating element that collates between hyphen and  $^-ac$ 0, inclusive.

If a bracket expression must specify both – and ], the ] must be placed first (after the  $^{\wedge}$ , if any) and the – last within the bracket expression.

Note: Latin-1 characters such as `or `are not printable in some locales, for example, the ja locale.

# BREs Matching Multiple Characters

The following rules can be used to construct BREs matching multiple characters from BREs matching a single character:

- 1. The concatenation of BREs matches the concatenation of the strings matched by each component of the BRE.
- 2. A *subexpression* can be defined within a BRE by enclosing it between the character pairs \( ( and \) . Such a subexpression matches whatever it would have matched without the \( ( and \)), except that anchoring within subexpressions is optional behavior; see BRE Expression Anchoring, below. Subexpressions can be arbitrarily nested.

3. The *back-reference* expression \n matches the same (possibly empty) string of characters as was matched by a subexpression enclosed between \( and \) preceding the \n. The character n must be a digit from 1 to 9 inclusive, nth subexpression (the one that begins with the nth \( and ends with the corresponding paired \)). The expression is invalid if less than n subexpressions precede the \n. For example, the expression \\( (.\*\)\1\$ matches a line consisting of two adjacent appearances of the same string, and the expression \( (a\)\*\1 fails to match a. The limit of nine back-references to subexpressions in the RE is based on the use of a single digit identifier. This does not imply that only nine subexpressions are allowed in REs. The following is a valid BRE with ten subexpressions:

- 4. When a BRE matching a single character, a subexpression or a back-reference is followed by the special character asterisk (\*), together with that asterisk it matches what zero or more consecutive occurrences of the BRE would match. For example, [ab] \* and [ab] [ab] are equivalent when matching the string ab.
- 5. When a BRE matching a single character, a subexpression, or a back-reference is followed by an *interval expression* of the format \{m\}, \{m,\} or \{m,n\}, together with that interval expression it matches what repeated consecutive occurrences of the BRE would match. The values of *m* and *n* will be decimal integers in the range 0 ≤ m ≤ n ≤ RE\_DUP\_MAX}, where m specifies the exact or minimum number of occurrences and n specifies the maximum number of occurrences. The expression \{m\} matches exactly m occurrences of the preceding BRE, \{m,\} matches at least m occurrences and \{m,n\} matches any number of occurrences between m and n, inclusive.

For example, in the string ababacccccd, the BRE  $\$  is matched by characters seven to nine, the BRE  $\$  is not matched at all and the BRE  $\$  is matched by characters ten to thirteen.

The behavior of multiple adjacent duplication symbols ( \* and intervals) produces undefined results.

#### **BRE Precedence**

The order of precedence is as shown in the following table:

BRE Precedence (from high to low)		
collation-related bracket symbols	[= =] [: :] []	
escaped characters	\ <special character=""></special>	
bracket expression	[]	
subexpressions/back-references	\(\)\n	
single-character-BRE duplication	* \{m,n\}	
concatenation		

anchoring	^ \$

# BRE Expression Anchoring

A BRE can be limited to matching strings that begin or end a line; this is called *anchoring*. The circumflex and dollar sign special characters will be considered BRE anchors in the following contexts:

- 1. A circumflex ( ^ ) is an anchor when used as the first character of an entire BRE. The implementation may treat circumflex as an anchor when used as the first character of a subexpression. The circumflex will anchor the expression to the beginning of a string; only sequences starting at the first character of a string will be matched by the BRE. For example, the BRE ^ab matches ab in the string abcdef, but fails to match in the string cdefab. A portable BRE must escape a leading circumflex in a subexpression to match a literal circumflex.
- 2. A dollar sign (\$) is an anchor when used as the last character of an entire BRE. The implementation may treat a dollar sign as an anchor when used as the last character of a subexpression. The dollar sign will anchor the expression to the end of the string being matched; the dollar sign can be said to match the end-of-string following the last character.
- 3. A BRE anchored by both ^ and \$ matches only an entire string. For example, the BRE ^abcdef\$ matches strings consisting only of abcdef.
- 4. ^ and \$ are not special in subexpressions.

Note: The Solaris implementation does not support anchoring in BRE subexpressions.

# EXTENDED REGULAR EXPRESSIONS

The rules specififed for BREs apply to Extended Regular Expressions (EREs) with the following exceptions:

- The characters | , +, and ? have special meaning, as defined below.
- The { and } characters, when used as the duplication operator, are not preceded by backslashes. The constructs \ { and \ } simply match the characters { and }, respectively.
- The back reference operator is not supported.
- Anchoring (^\$) is supported in subexpressions.

# EREs Matching a Single Character

An ERE ordinary character, a special character preceded by a backslash, or a period matches a single character. A bracket expression matches a single character or a single collating element. An *ERE matching a single character* enclosed in parentheses matches the same as the ERE without parentheses would have matched.

# **ERE Ordinary Characters**

An *ordinary character* is an ERE that matches itself. An ordinary character is any character in the supported character set, except for the ERE special characters listed in ERE Special Characters below. The interpretation of an ordinary character preceded by a backslash (\) is undefined.

# ERE Special Characters

An *ERE special character* has special properties in certain contexts. Outside those contexts, or when preceded by a backslash, such a character is an ERE that matches the special character itself. The extended regular expression special characters and the contexts in which they have their special meaning are:

. [ \ ( The period, left-bracket, backslash, and left-parenthesis are special except when used in a bracket expression (see RE Bracket Expression, above). Outside a bracket expression, a left-parenthesis immediately followed by a right-parenthesis produces undefined results. The right-parenthesis is special when matched with a preceding left-parenthesis, both outside a bracket expression. \* + ? { The asterisk, plus-sign, question-mark, and left-brace are special except when used in a bracket expression (see RE Bracket Expression, above). Any of the following uses produce undefined results: if these characters appear first in an ERE, or immediately following a vertical-line, circumflex or left-parenthesis if a left-brace is not part of a valid interval expression. The vertical-line is special except when used in a bracket expression (see RE Bracket Expression, above). A vertical-line appearing first or last in an ERE, or immediately following a vertical-line or a left-parenthesis, or immediately preceding a right-parenthesis, produces undefined results. Λ The circumflex is special when used: as an anchor (see ERE Expression Anchoring, below). as the first character of a bracket expression (see RE Bracket Expression, above). \$ The dollar sign is special when used as an anchor.

#### Periods in EREs

A period ( . ), when used outside a bracket expression, is an ERE that matches any character in the supported character set except NUL.

# **ERE Bracket Expression**

The rules for ERE Bracket Expressions are the same as for Basic Regular Expressions; see RE Bracket Expression, above).

### EREs Matching Multiple Characters

The following rules will be used to construct EREs matching multiple characters from EREs matching a single character:

- A concatenation of EREs matches the concatenation of the character sequences
  matched by each component of the ERE. A concatenation of EREs enclosed in
  parentheses matches whatever the concatenation without the parentheses matches.
  For example, both the ERE cd and the ERE (cd) are matched by the third and
  fourth character of the string abcdefabcdef.
- 2. When an ERE matching a single character or an ERE enclosed in parentheses is followed by the special character plus-sign (+), together with that plus-sign it matches what one or more consecutive occurrences of the ERE would match. For example, the ERE b+(bc) matches the fourth to seventh characters in the string acabbbcde; [ab] + and [ab] [ab] \* are equivalent.

- 3. When an ERE matching a single character or an ERE enclosed in parentheses is followed by the special character asterisk (\*), together with that asterisk it matches what zero or more consecutive occurrences of the ERE would match. For example, the ERE b\*c matches the first character in the string cabbbcde, and the ERE b\*cd matches the third to seventh characters in the string cabbbcdebbbbbcdbc. And, [ab] \* and [ab] [ab] are equivalent when matching the string ab.
- 4. When an ERE matching a single character or an ERE enclosed in parentheses is followed by the special character question-mark (?), together with that question-mark it matches what zero or one consecutive occurrences of the ERE would match. For example, the ERE b?c matches the second character in the string acabbbcde.
- 5. When an ERE matching a single character or an ERE enclosed in parentheses is followed by an *interval expression* of the format {*m*}, {*m*,} or {*m*,*n*}, together with that interval expression it matches what repeated consecutive occurrences of the ERE would match. The values of *m* and *n* will be decimal integers in the range 0 ≤ *m* ≤ {RE\_DUP\_MAX}, where *m* specifies the exact or minimum number of occurrences and *n* specifies the maximum number of occurrences. The expression {*m*} matches exactly *m* occurrences of the preceding ERE, {*m*,} matches at least *m* occurrences and {*m*,*n*} matches any number of occurrences between *m* and *n*, inclusive.

For example, in the string ababacccccd the ERE c(3) is matched by characters seven to nine and the ERE (ab)(2,) is matched by characters one to six.

The behavior of multiple adjacent duplication symbols (+, \*, ? and intervals) produces undefined results.

#### **ERE Alternation**

Two EREs separated by the special character vertical-line (1) match a string that is matched by either. For example, the ERE a((bc)|d) matches the string abc and the string ad. Single characters, or expressions matching single characters, separated by the vertical bar and enclosed in parentheses, will be treated as an ERE matching a single character.

# **ERE Precedence**

The order of precedence will be as shown in the following table:

ERE Precedence (from high to low)		
collation-related bracket symbols	[= =] [: :] []	
escaped characters	\ <special character=""></special>	
bracket expression	[]	
grouping	()	
single-character-ERE duplication	* + ? { <i>m,n</i> }	
concatenation		

anchoring	^\$
alternation	1

For example, the ERE abba | cde matches either the string abba or the string cde (rather than the string abbade or abbcde, because concatenation has a higher order of precedence than alternation).

# ERE Expression Anchoring

An ERE can be limited to matching strings that begin or end a line; this is called *anchoring*. The circumflex and dollar sign special characters are considered ERE anchors when used anywhere outside a bracket expression. This has the following effects:

- 1. A circumflex (^) outside a bracket expression anchors the expression or subexpression it begins to the beginning of a string; such an expression or subexpression can match only a sequence starting at the first character of a string. For example, the EREs ^ab and (^ab) match ab in the string abcdef, but fail to match in the string cdefab, and the ERE a^b is valid, but can never match because the a prevents the expression ^b from matching starting at the first character.
- 2. A dollar sign (\$) outside a bracket expression anchors the expression or subexpression it ends to the end of a string; such an expression or subexpression can match only a sequence ending at the last character of a string. For example, the EREs ef\$ and (ef\$) match ef in the string abcdef, but fail to match in the string cdefab, and the ERE e\$f\$ is valid, but can never match because the f prevents the expression e\$ from matching ending at the last character.

#### NAME

regexp, compile, step, advance – simple regular expression compile and match routines

#### SYNOPSIS

```
#define INIT declarations
#define GETC(void) getc code
#define PEEKC(void) peekc code
#define UNGETC(void) ungetc code
#define RETURN(ptr) return code
#define ERROR(val) error code

extern char *loc1, *loc2, *locs;

#include <regexp.h>

char *compile(char *instring, char *expbuf, const char *endfug, int eof);

int step(const char *string, const char *expbuf);

int advance(const char *string, const char *expbuf);
```

#### DESCRIPTION

Regular Expressions (REs) provide a mechanism to select specific strings from a set of character strings. The Simple Regular Expressions described below differ from the Internationalized Regular Expressions described on the regex(5) manual page in the following ways:

- only Basic Regular Expressions are supported
- the Internationalization features—character class, equivalence class, and multi-character collation—are not supported.

The functions step(), advance(), and compile() are general purpose regular expression matching routines to be used in programs that perform regular expression matching. These functions are defined by the <regexp.h> header.

The functions step() and advance() do pattern matching given a character string and a compiled regular expression as input.

The function compile() takes as input a regular expression as defined below and produces a compiled expression that can be used with step() or advance().

# Basic Regular Expressions

A regular expression specifies a set of character strings. A member of this set of strings is said to be matched by the regular expression. Some characters have special meaning when used in a regular expression; other characters stand for themselves.

The following *one-character REs* match a *single* character:

- 1.1 An ordinary character ( *not* one of those discussed in 1.2 below) is a one-character RE that matches itself.
- 1.2 A backslash ( \ ) followed by any special character is a one-character RE that matches the special character itself. The special characters are:

- a. ., \*, [, and \ (period, asterisk, left square bracket, and backslash, respectively), which are always special, *except* when they appear within square brackets ([]; see 1.4 below).
- b. ^ (caret or circumflex), which is special at the *beginning* of an *entire* RE (see 4.1 and 4.3 below), or when it immediately follows the left of a pair of square brackets ([]) (see 1.4 below).
- c. \$ (dollar sign), which is special at the end of an *entire* RE (see 4.2 below).
- d. The character used to bound (that is, delimit) an entire RE, which is special for that RE (for example, see how slash (/) is used in the g command, below.)
- 1.3 A period ( . ) is a one-character RE that matches any character except new-line.
- A non-empty string of characters enclosed in square brackets ([]) is a one-character RE that matches *any one* character in that string. If, however, the first character of the string is a circumflex (^), the one-character RE matches any character *except* new-line and the remaining characters in the string. The ^ has this special meaning *only* if it occurs first in the string. The minus (-) may be used to indicate a range of consecutive characters; for example, [0-9] is equivalent to [0123456789]. The loses this special meaning if it occurs first (after an initial ^, if any) or last in the string. The right square bracket (]) does not terminate such a string when it is the first character within it (after an initial ^, if any); for example, []a-f] matches either a right square bracket (]) or one of the ASCII letters a through f inclusive. The four characters listed in 1.2.a above stand for themselves within such a string of characters.

The following rules may be used to construct REs from one-character REs:

- 2.1 A one-character RE is a RE that matches whatever the one-character RE matches.
- 2.2 A one-character RE followed by an asterisk (\*) is a RE that matches 0 or more occurrences of the one-character RE. If there is any choice, the longest leftmost string that permits a match is chosen.
- 2.3 A one-character RE followed by  $\{m\setminus\}$ ,  $\{m,\setminus\}$ , or  $\{m,n\setminus\}$  is a RE that matches a *range* of occurrences of the one-character RE. The values of m and n must be non-negative integers less than 256;  $\{m\setminus\}$  matches *exactly* m occurrences;  $\{m,\setminus\}$  matches *at least* m occurrences;  $\{m,n\setminus\}$  matches *any number* of occurrences *between* m and n inclusive. Whenever a choice exists, the RE matches as many occurrences as possible.

	the strings matched by each component of the RE.
2.5	A RE enclosed between the character sequences $\setminus$ ( and $\setminus$ ) is a RE that matches whatever the unadorned RE matches.
2.6	The expression $\ n$ matches the same string of characters as was matched by an expression enclosed between $\ ($ and $\ )$ <i>earlier</i> in the same RE. Here $n$ is a digit; the sub-expression specified is that beginning with the $n$ -th occurrence of $\ ($ counting from the left. For example, the expression $\ ($ . * $\ )$ $\ 1$ \$ matches a

The concatenation of REs is a RE that matches the concatenation of

line consisting of two repeated appearances of the same string.

An RE may be constrained to match words.

2.4

- 3.1 \ < constrains a RE to match the beginning of a string or to follow a character that is not a digit, underscore, or letter. The first character matching the RE must be a digit, underscore, or letter.
- 3.2 \ > constrains a RE to match the end of a string or to precede a character that is not a digit, underscore, or letter.

An *entire RE* may be constrained to match only an initial segment or final segment of a line (or both).

- 4.1 A circumflex (^) at the beginning of an entire RE constrains that RE to match an *initial* segment of a line.
- 4.2 A dollar sign (\$) at the end of an entire RE constrains that RE to match a *final* segment of a line.
- 4.3 The construction  $^e$  to match the entire RE to match the entire line.

The null RE (for example, // ) is equivalent to the last RE encountered.

# Addressing with REs

Addresses are constructed as follows:

- 1. The character "." addresses the current line.
- 2. The character "\$" addresses the last line of the buffer.
- 3. A decimal number *n* addresses the *n*-th line of the buffer.
- 4. 'x addresses the line marked with the mark name character x, which must be an ASCII lower-case letter (a–z). Lines are marked with the k command described below.
- 5. A RE enclosed by slashes (/) addresses the first line found by searching *forward* from the line *following* the current line toward the end of the buffer and stopping at the first line containing a string matching the RE. If necessary, the search wraps around to the beginning of the buffer and continues up to and including the current line, so that the entire buffer is searched.

- 6. A RE enclosed in question marks (?) addresses the first line found by searching backward from the line preceding the current line toward the beginning of the buffer and stopping at the first line containing a string matching the RE. If necessary, the search wraps around to the end of the buffer and continues up to and including the current line.
- 7. An address followed by a plus sign (+) or a minus sign (-) followed by a decimal number specifies that address plus (respectively minus) the indicated number of lines. A shorthand for .+5 is .5.
- 8. If an address begins with + or -, the addition or subtraction is taken with respect to the current line; for example, -5 is understood to mean .-5.
- 9. If an address ends with + or -, then 1 is added to or subtracted from the address, respectively. As a consequence of this rule and of Rule 8, immediately above, the address refers to the line preceding the current line. (To maintain compatibility with earlier versions of the editor, the character ^ in addresses is entirely equivalent to -.) Moreover, trailing + and characters have a cumulative effect, so -- refers to the current line less 2.
- 10. For convenience, a comma (,) stands for the address pair 1,\$, while a semicolon (;) stands for the pair .,\$.

# Characters With Special Meaning

Characters that have special meaning except when they appear within square brackets ([]) or are preceded by \ are: ., \*, [, \ . Other special characters, such as \$ have special meaning in more restricted contexts.

The character ^ at the beginning of an expression permits a successful match only immediately after a newline, and the character \$ at the end of an expression requires a trailing newline.

Two characters have special meaning only when used within square brackets. The character – denotes a range, [c-c], unless it is just after the open bracket or before the closing bracket, [-c] or [c-] in which case it has no special meaning. When used within brackets, the character ^ has the meaning *complement of* if it immediately follows the open bracket (example:  $[^c]$ ); elsewhere between brackets (example:  $[^c]$ ) it stands for the ordinary character ^.

The special meaning of the  $\setminus$  operator can be escaped only by preceding it with another  $\setminus$  , for example  $\setminus\setminus$  .

#### Macros

Programs must have the following five macros declared before the #include <regexp.h> statement. These macros are used by the compile() routine. The macros GETC, PEEKC, and UNGETC operate on the regular expression given as input to compile().

GETC

This macro returns the value of the next character (byte) in the regular expression pattern. Successive calls to GETC should return successive characters of the regular expression.

PEEKC	This macro returns the next character (byte) in the regular
-------	---

expression. Immediately successive calls to PEEKC should return the same character, which should also be the next character

returned by GETC.

UNGETC This macro causes the argument c to be returned by the next call

to GETC and PEEKC. No more than one character of pushback is ever needed and this character is guaranteed to be the last

character read by GETC. The return value of the macro UNGETC (c)

is always ignored.

RETURN (ptr) This macro is used on normal exit of the compile() routine. The

value of the argument *ptr* is a pointer to the character after the last character of the compiled regular expression. This is useful to

programs which have memory allocation to manage.

ERROR (val) This macro is the abnormal return from the compile() routine.

The argument val is an error number (see ERRORS below for

meanings). This call should never return.

compile()

The syntax of the compile() routine is as follows:

compile(instring, expbuf, endbuf, eof)

The first parameter, *instring*, is never used explicitly by the compile() routine but is useful for programs that pass down different pointers to input characters. It is sometimes used in the INIT declaration (see below). Programs which call functions to input characters or have characters in an external array can pass down a value of (char \*) 0 for this parameter.

The next parameter, *expbuf*, is a character pointer. It points to the place where the compiled regular expression will be placed.

The parameter *endbuf* is one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in (endbuf-expbuf) bytes, a call to ERROR (50) is made.

The parameter *eof* is the character which marks the end of the regular expression. This character is usually a /.

Each program that includes the <regexp.h> header file must have a #define statement for INIT. It is used for dependent declarations and initializations. Most often it is used to set a register variable to point to the beginning of the regular expression so that this register variable can be used in the declarations for GETC, PEEKC, and UNGETC. Otherwise it can be used to declare external variables that might be used by GETC, PEEKC and UNGETC. (See EXAMPLES below.)

step(), advance()

The first parameter to the step() and advance() functions is a pointer to a string of characters to be checked for a match. This string should be null terminated.

The second parameter, expbuf, is the compiled regular expression which was obtained by a call to the function compile().

The function step () returns non-zero if some substring of *string* matches the regular expression in expbuf and 0 if there is no match. If there is a match, two external character pointers are set as a side effect to the call to step(). The variable loc1 points to the first character that matched the regular expression; the variable loc2 points to the character after the last character that matches the regular expression. Thus if the regular expression matches the entire input string, loc1 will point to the first character of *string* and loc2 will point to the null at the end of *string*.

The function advance () returns non-zero if the initial substring of *string* matches the regular expression in expbuf. If there is a match, an external character pointer, loc2, is set as a side effect. The variable loc2 points to the next character in *string* after the last character that matched.

When advance () encounters a \* or  $\{\ \}$  sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, advance () will back up along the string until it finds a match or reaches the point in the string that initially matched the \* or  $\setminus \{ \setminus \}$ . It is sometimes desirable to stop this backing up before the initial point in the string is reached. If the external character pointer locs is equal to the point in the string at sometime during the backing up process, advance () will break out of the loop that backs up and will return zero.

The external variables circf, sed, and nbra are reserved.

# **EXAMPLES**

**EXAMPLE 1** Using Regular Expression Macros and Calls

The following is an example of how the regular expression macros and calls might be defined by an application program:

```
#define INIT
                   register char *sp = instring;
#define GETC() (*sp++)
#define PEEKC() (*sp)
#define UNGETC(c) (--sp)
#define RETURN(c) return;
#define ERROR(c) regerr()
#include <regexp.h>
      (void) compile(*argv, expbuf, &expbuf[ESIZE],'\0');
      if (step(linebuf, expbuf))
                         succeed;
```

# **DIAGNOSTICS**

The function compile() uses the macro RETURN on success and the macro ERROR on failure (see above). The functions step() and advance() return non-zero on a successful match and zero if there is no match. Errors are:

```
11
                                  range endpoint too large.
              16
                                  bad number.
              25
                                   \ digit out of range.
              36
                                  illegal or missing delimiter.
              41
                                  no remembered search string.
              42
                                   43
                                  too many \ (.
              44
                                  more than 2 numbers given in \setminus \{ \ \setminus \}.
              45
                                   } expected after \.
              46
                                   first number exceeds second in \setminus \{ \setminus \}.
              49
                                   [ ] imbalance.
              50
                                   regular expression overflow.

# resource controls(5)

#### NAME

resource\_controls - resource controls available through project database

#### **SYNOPSIS**

resource controls

#### **DESCRIPTION**

The resource controls facility is configured through the project database. See project(4). You can set and modify resource controls through the following utilities:

- prctl(1)
- projadd(1M)
- projmod(1M)
- rctladm(1M)

In a program, you use setrctl(2) to set resource control values.

In addition to the preceding resource controls, there are resource pools, accessible through the pooladm(1M) and poolcfg(1M) utilities. In a program, resource pools can be manipulated through the libpool(3LIB) library.

The following are the resource controls available in the current release of the Solaris operating system.

```
project.cpu-shares
```

Number of CPU shares granted to a project for use with the fair share scheduler (see FSS(7)). The unit used is the number of shares (an integer).

```
project.max-device-locked-memory
```

Total amount of locked memory allowed, expressed as a number of bytes.

```
project.max-port-ids
```

Maximum allowable number of event ports, expressed as an integer.

```
project.max-shm-ids
```

Maximum number of shared memory IDs allowed for a project, expressed as an integer.

```
project.max-sem-ids
```

Maximum number of semaphore IDs allowed for a project, expressed as an integer.

```
project.max-msg-ids
```

Maximum number of message queue IDs allowed for a project, expressed as an integer.

```
project.max-shm-memory
```

Total amount of shared memory allowed for a project, expressed as a number of bytes.

```
project.max-lwps
```

Maximum number of LWPs simultaneously available to a project, expressed as an integer.

```
project.max-tasks
```

Maximum number of tasks allowable in a project, expressed as an integer.

```
project.max-contracts
```

Maximum number of contracts allowed in a project, expressed as an integer.

project.pool

Binds a specified resource pool with a project.

task.max-cpu-time

Maximum CPU time that is available to this task's processes, expressed as a number of seconds.

task.max-lwps

Maximum number of LWPs simultaneously available to this task's processes, expressed as an integer.

process.max-cpu-time

Maximum CPU time that is available to this process, expressed as a number of seconds.

process.max-file-descriptor

Maximum file descriptor index available to this process, expressed as an integer.

process.max-file-size

Maximum file offset available for writing by this process, expressed as a number of bytes.

process.max-core-size

Maximum size of a core file created by this process, expressed as a number of bytes.

process.max-data-size

Maximum heap memory available to this process, expressed as a number of bytes.

process.max-stack-size

Maximum stack memory segment available to this process, expressed as a number of bytes.

process.max-address-space

Maximum amount of address space, as summed over segment sizes, that is available to this process, expressed as a number of bytes.

process.max-port-events

Maximum allowable number of events per event port, expressed as an integer.

process.max-sem-nsems

Maximum number of semaphores allowed per semaphore set, expressed as an integer.

process.max-sem-ops

Maximum number of semaphore operations allowed per semop call (value copied from the resource control at semget () time). Expressed as an integer, specifying the number of operations.

process.max-msg-qbytes

Maximum number of bytes of messages on a message queue (value copied from the resource control at msgget () time), expressed as a number of bytes.

process.max-msq-messages

Maximum number of messages on a message queue (value copied from the resource control at msqqet () time), expressed as an integer.

# resource\_controls(5)

process.min-crypto-sessions

Number of sessions in fixed-sized session table when /dev/crypto is opened; value can only be changed by a privileged process. Expressed as an integer, specifying the number of sessions.

```
process.add-crypto-sessions
```

Number of additional sessions when session table is full and larger table is allocated. Expressed as an integer, specifying the number of additional sessions.

```
process.max-crypto-sessions
```

Maximum number of sessions in session table; value can only be changed by privileged process. Expressed as an integer, specifying the number of sessions.

```
process.crypto-buffer-limit
```

Number of bytes allocated for copying of user data; sizes of all buffers allocated for copying are added together and result checked against this resource control; limit applies to each instance of /dev/crypto; value can only be changed by privileged process. Expressed as a number of bytes.

In the current release, there are the following zone-wide resource controls:

```
zone.cpu-shares
```

Sets a limit on the number of fair share scheduler (FSS) CPU shares for a zone. CPU shares are first allocated to the zone, and then further subdivided among projects within the zone as specified in the project.cpu-shares entries. Expressed as an integer.

```
zone.max-lwps
```

Enhances resource isolation by preventing too many LWPs in one zone from affecting other zones. A zone's total LWPs can be further subdivided among projects within the zone within the zone by using project.max-lwps entries. Expressed as an integer.

See zones(5).

# Units Used in Resource Controls

Resource controls can be expressed as in units of size (bytes), time (seconds), or as a count (integer). These units use the strings specified below.

Category	Res Ctrl Type String	Modifier	Scale
Size	bytes	В	1
		KB	2^10
		MB	2^20
		GB	2^30
		TB	2^40
		PB	2^50
		EB	2^60
Time	seconds	s	1
		Ks	10^3
		Ms	10^6
		Gs	10^9
		Ts	10^12

		Ps Es	10 <sup>15</sup> 10 <sup>18</sup>
Count	integer	none K	1 10 <b>^</b> 3
		K	
		M	10^6
		G	10^9
		T	10^12
		P	10^15
		Es	10^18

Scaled values can be used with resource controls. The following example shows a scaled threshold value:

```
task.max-lwps=(priv,1K,deny)
```

In the project file, the value 1K is expanded to 1000:

```
task.max-lwps=(priv,1000,deny)
```

A second example uses a larger scaled value:

```
process.max-file-size=(priv,5G,deny)
```

In the project file, the value 5G is expanded to 5368709120:

```
process.max-file-size=(priv,5368709120,deny)
```

The preceding examples use the scaling factors specified in the table above.

Note that unit modifiers (for example, 5G) are accepted by the prctl(1), projadd(1M), and projmod(1M) commands. You cannot use unit modifiers in the project database itself.

# Resource Control Values and Privilege Levels

A threshold value on a resource control constitutes a point at which local actions can be triggered or global actions, such as logging, can occur.

Each threshold value on a resource control must be associated with a privilege level. The privilege level must be one of the following three types:

haaia

Can be modified by the owner of the calling process.

privileged

Can be modified only by privileged (superuser) callers.

svsten

Fixed for the duration of the operating system instance.

A resource control is guaranteed to have one system value, which is defined by the system, or resource provider. The system value represents how much of the resource the current implementation of the operating system is capable of providing.

Any number of privileged values can be defined, and only one basic value is allowed. Operations that are performed without specifying a privilege value are assigned a basic privilege by default.

# resource\_controls(5)

The privilege level for a resource control value is defined in the privilege field of the resource control block as RCTL\_BASIC, RCTL\_PRIVILEGED, or RCTL\_SYSTEM. See setrct1(2) for more information. You can use the prctl command to modify values that are associated with basic and privileged levels.

In specifying the privilege level of privileged, you can use the abbreviation priv. For example:

task.max-lwps=(priv,1K,deny)

#### Global and Local Actions on Resource Control Values

There are two categories of actions on resource control values: global and local.

Global actions apply to resource control values for every resource control on the system. You can use rctladm(1M) to perform the following actions:

- Display the global state of active system resource controls.
- Set global logging actions.

You can disable or enable the global logging action on resource controls. You can set the syslog action to a specific degree by assigning a severity level, syslog=level. The possible settings for level are as follows:

- debug
- info
- notice
- warning
- err
- crit
- alert
- emerg

By default, there is no global logging of resource control violations.

Local actions are taken on a process that attempts to exceed the control value. For each threshold value that is placed on a resource control, you can associate one or more actions. There are three types of local actions: none, deny, and signal=. These three actions are used as follows:

#### none

No action is taken on resource requests for an amount that is greater than the threshold. This action is useful for monitoring resource usage without affecting the progress of applications. You can also enable a global message that displays when the resource control is exceeded, while, at the same time, the process exceeding the threshhold is not affected.

#### deny

You can deny resource requests for an amount that is greater than the threshold. For example, a task.max-lwps resource control with action deny causes a fork() system call to fail if the new process would exceed the control value. See the fork(2).

#### signal=

You can enable a global signal message action when the resource control is exceeded. A signal is sent to the process when the threshold value is exceeded. Additional signals are not sent if the process consumes additional resources. Available signals are listed below.

Not all of the actions can be applied to every resource control. For example, a process cannot exceed the number of CPU shares assigned to the project of which it is a member. Therefore, a deny action is not allowed on the project.cpu-shares resource control.

Due to implementation restrictions, the global properties of each control can restrict the range of available actions that can be set on the threshold value. (See rctladm(1M).) A list of available signal actions is presented in the following list. For additional information about signals, see signal(3HEAD).

The following are the signals available to resource control values:

#### SIGABRT

Terminate the process.

#### SIGHUP

Send a hangup signal. Occurs when carrier drops on an open line. Signal sent to the process group that controls the terminal.

#### SIGTERM

Terminate the process. Termination signal sent by software.

#### SIGKILI

Terminate the process and kill the program.

# SIGSTOP

Stop the process. Job control signal.

#### SIGXRES

Resource control limit exceeded. Generated by resource control facility.

#### SIGXFSZ

Terminate the process. File size limit exceeded. Available only to resource controls with the RCTL\_GLOBAL\_FILE\_SIZE property (process.max-file-size). See rctlblk set value(3C).

#### SIGXCPU

Terminate the process. CPU time limit exceeded. Available only to resource controls with the RCTL\_GLOBAL\_CPUTIME property (process.max-cpu-time). See rctlblk\_set\_value(3C).

### Resource Control Flags and Properties

Each resource control on the system has a certain set of associated properties. This set of properties is defined as a set of flags, which are associated with all controlled instances of that resource. Global flags cannot be modified, but the flags can be retrieved by using either rctladm(1M) or the getrctl(2) system call.

# resource controls(5)

Local flags define the default behavior and configuration for a specific threshold value of that resource control on a specific process or process collective. The local flags for one threshold value do not affect the behavior of other defined threshold values for the same resource control. However, the global flags affect the behavior for every value associated with a particular control. Local flags can be modified, within the constraints supplied by their corresponding global flags, by the prctl command or the setrctl system call. See setrctl(2).

For the complete list of local flags, global flags, and their definitions, see rctlblk\_set\_value(3C).

To determine system behavior when a threshold value for a particular resource control is reached, use rctladm to display the global flags for the resource control. For example, to display the values for process.max-cpu-time, enter:

```
$ rctladm process.max-cpu-time
process.max-cpu-time syslog=off [ lowerable no-deny cpu-time inf seconds ]
```

The global flags indicate the following:

lowerable

Superuser privileges are not required to lower the privileged values for this control.

no-deny

Even when threshold values are exceeded, access to the resource is never denied.

cpu-time

SIGXCPU is available to be sent when threshold values of this resource are reached.

seconds

The time value for the resource control.

Use the prctl command to display local values and actions for the resource control. For example:

```
$ prctl -n process.max-cpu-time $$
process 353939: -ksh
NAME PRIVILEGE VALUE FLAG ACTION RECIPIENT
process.max-cpu-time
    privileged 18.4Es inf signal=XCPU -
    system 18.4Es inf none
```

The max (RCTL\_LOCAL\_MAXIMAL) flag is set for both threshold values, and the inf (RCTL\_GLOBAL\_INFINITE) flag is defined for this resource control. An inf value has an infinite quantity. The value is never enforced. Hence, as configured, both threshold quantities represent infinite values that are never exceeded.

#### Resource Control Enforcement

More than one resource control can exist on a resource. A resource control can exist at each containment level in the process model. If resource controls are active on the same resource at different container levels, the smallest container's control is enforced first. Thus, action is taken on process.max-cpu-time before task.max-cpu-time if both controls are encountered simultaneously.

NAME |

SEAM – overview of Sun Enterprise Authentication Mechanism

### DESCRIPTION

SEAM (Sun Enterprise Authentication Mechanism) authenticates clients in a network environment, allowing for secure transactions. (A client may be a user or a network service) SEAM validates the identity of a client and the authenticity of transferred data. SEAM is a single-sign-on system, meaning that a user needs to provice a password only at the beginning of a session. SEAM is based on the Kerberos™ system developed at MIT, and is compatible with Kerberos V5 systems over heterogeneous networks.

SEAM works by granting clients tickets, which uniquely identify a client, and which have a finite lifetime. A client possessing a ticket is automatically validated for network services for which it is entitled; for example, a user with a valid SEAM ticket may rlogin into another machine running SEAM without having to identify itself. Because each client has a unique ticket, its identity is guaranteed.

To obtain tickets, a client must first initialize the SEAM session, either by using the kinit(1) command or a PAM module. (See pam krb5(5)). kinit prompts for a password, and then communicates with a Key Distribution Center (KDC). The KDC returns a *Ticket-Granting Ticket* (TGT) and prompts for a confirmation password. If the client confirms the password, it can use the Ticket-Granting Ticket to obtain tickets for specific network services. Because tickets are granted transparently, the user need not worry about their management. Current tickets may be viewed by using the klist(1) command.

Tickets are valid according to the system *policy* set up at installation time. For example, tickets have a default lifetime for which they are valid. A policy may further dictate that privileged tickets, such as those belonging to root, have very short lifetimes. Policies may allow some defaults to be overruled; for example, a client may request a ticket with a lifetime greater or less than the default.

Tickets can be renewed using kinit. Tickets are also forwardable, allowing you to use a ticket granted on one machine on a different host. Tickets can be destroyed by using kdestroy(1). It is a good idea to include a call to kdestroy in your .logout file.

Under SEAM, a client is referred to as a principal. A principal takes the following form:

primary/instance@REALM

primary A user, a host, or a service.

instance A qualification of the primary. If the primary is a host

> — indicated by the keyword host— then the instance is the fully-qualified domain name of that host. If the primary is a user or service, then the instance is optional. Some instances, such as admin or root, are

privileged.

realm The Kerberos equivalent of a domain; in fact, in most

cases the realm is directly mapped to a DNS domain

name. SEAM realms are given in upper-case only. For examples of principal names, see the EXAMPLES.

By taking advantage of the General Security Services API (GSS-API), SEAM offers, besides user authentication, two other types of security service: *integrity*, which authenticates the validity of transmitted data, and *privacy*, which encrypts transmitted data. Developers can take advantage of the GSS-API through the use of the RPCSEC\_GSS API interface (see rpcsec gss(3NSL)).

## **EXAMPLES**

**EXAMPLE 1** Examples of valid principal names

The following are examples of valid principal names:

joe
joe/admin
joe@ENG.ACME.COM
joe/admin@ENG.ACME.COM
rlogin/bigmachine.eng.acme.com@ENG.ACME.COM
host/bigmachine.eng.acme.com@ENG.ACME.COM

The first four cases are *user principals*. In the first two cases, it is assumed that the user joe is in the same realm as the client, so no realm is specified. Note that joeand joe/admin are different principals, even if the same user uses them; joe/admin has different privileges from joe. The fifth case is a *service principal*, while the final case is a *host principal*. The word host is required for host principals. With host principals, the instance is the fully qualified hostname. Note that the words admin and host are reserved keywords.

Sun Enterprise Authentication Mechanism Guide

### **NOTES**

If you enter your username and kinit responds with this message:

Principal unknown (kerberos) you haven't been registered as a SEAM user. See your system administrator or the *Sun Enterprise Authentication Mechanism Guide*.

sgml(5)

NAME

sgml, solbook - Standard Generalized Markup Language

**DESCRIPTION** 

Standard Generalized Markup Language (SGML) is the ISO standard 8879:1986 that describes a syntax for marking up documents with tags that describe the purpose of the text rather than the appearance on the page. This form of markup facilitates document interchange between different platforms and applications. SGML allows the management of information as data objects rather than text on a page.

In an SGML document the main structural components are called elements. The organization and structure of a document and the meaning of elements are described in the Document Type Definition (DTD). Elements are the *tags* that identify the content. Element names may be descriptive of the content for ease of use. For example para> for paragraphs. Elements can have attributes which are used to modify or refine the properties or characteristics of the element. Within the DTD a valid context for each element is defined and a framework is provided for the types of elements that constitute a compliant document.

Another component of the DTD is entities. Entities are a collection of characters that can be referenced as a unit. Entities are similar to constants in a programming language such as C. They can be defined and referenced. An entity can represent one character or symbol which does not appear on a standard keyboard, a word or group of words, or an entire separate sgml marked-up file. Entities allow reuse of standard text.

There is no single standard DTD , but the de facto standard for the computer industry is the DocBook DTD , developed and maintained by the Davenport Group. Within Sun, the SolBook DTD , which is a proper subset of DocBook DTD , is used when writing reference manual pages. The SolBook DTD contains a number of tags that are designed for the unique needs of the reference pages.

**SolBook Elements** 

Elements are defined with a hierarchical structure that gives a structure to the document. The following is a description of some of the elements from the SolBook DTD which are used for reference pages.

**DOCTYPE** 

The first line in an SGML file that identifies the location of the DTD that is used to define the document. The <!DOCTYPE string is what the SGML -aware man(1) command uses to identify that a file is formatted in SGML rather than nroff(1).

RefEntry

The top layer element that contains a reference page is <refentry>. All of the text and other tags must be contained within this tag.

RefMeta

The next tag in a reference page is <refmeta>, which is a container for several other tags. They are:

<refentrytitle> This is the title of the reference page. It is equivalent to the name of

the reference page's file name, without the section number

extension.

<manvolnum> This is the section number that the reference page resides in. The

contents may be a text entity reference.

<refmiscinfo> There are one or more <refmiscinfo> tags which contain meta

information. Meta information is information about the reference page. The <refmiscinfo> tag has the class attribute. There are

four classes that are routinely used.

date This is the date that the file was last modified.

By consensus this date is changed only when the technical information on the page changes

and not simply for an editorial change.

sectdesc This is the section title of the reference page;

for example User Commands. The value of this attribute may be a text entity reference.

software This is the name of the software product that

the topic discussed on the reference page belongs to. For example UNIX commands are part of the SunOS x.x release. The value of this

attribute may be a text entity reference.

arch This is the architectural platform limitation of

the subject discussed on the reference page. If there are no limitations the value used is generic. Other values are sparc and x86.

copyright This attribute contains the Sun Microsystems

copyright. Any other copyrights that may pertain to the individual reference page file

should be entered as separate

<refmiscinfo> entries. The value of this
attribute may be a text entity reference.

RefNameDiv

This tag contains the equivalent information to the .TH macro line in an nroff(1) reference page. <refnamediv> contains three tags. These tags contain the text that is before and after the '-' (dash) on the NAME line.

<refname> These are the names of the topics that are discussed in the file.

There may be more than one <refname> for a page. The first

<refname> must match the name of the file and the

<refentrytitle>. If there are more than one <refname> tags,
each is separated by a ',' (comma). The comma is generated by the
publisher of sgml files, so it should not be typed. This is referred to

as auto-generated text.

<refpurpose> The text after the dash on the NAME line is contained in this tag.

This is a short summary of what the object or objects described on

the reference page do or are used for. The dash is also

auto-generated and should not be typed in.

# sgml(5)

<refdiscriptor> In some cases the <refentrytitle> is a general topic descriptor

of a group of related objects that are discussed on the same page.

In this case the first tag after the <refnamediv> is a

<refdiscriptor>. The <refname> tags follow. Only one <refdiscriptor> is allowed, and it should match the

<refentrytitle>.

# RefSynopsisDiv

The SYNOPSIS line of the reference page is contained by this tag. There is a <title> that usually contains an entity reference. The text is the word SYNOPSIS. There are several tags within <refsynopsisdiv> that are designed specifically for the type of synopsis that is used in the different reference page sections. The three types are:

Used for commands and utilities pages. <cmdsynopsis>

Used for programming interface pages. Used for pages that do not fall into the other two categories. <synopsis>

### RefSect1

<funcsynopsis>

This tag is equivalent to the .SH nroff macro. It contains a <title> element that is the title of the reference page section. Section names are the standard names such as DESCRIPTION, OPTIONS, PARAMETERS, SEE ALSO, and others. The contents of the <title> may be a text entity reference.

### RefSect2

This tag is equivalent to the .SS nroff macro. It contains a <title> element that contains the text of the sub-section heading. ct2> tags may also be used within a <refsynopsisdiv> as a sub-section heading for the SYNOPSIS section.

# **Block Elements**

There are a number of block elements that are used for grouping text. This is a list of some of these elements.

This tag is used to contain a paragraph of text. <para>

<variablelist> This tag is used to create two column lists. For example

> descriptions for command options, where the first column lists the option and the second column

describes the option.

<orderedlist> An list of items in a specific order.

<itemizedlist> A list of items that are marked with a character such as

a bullet or a dash.

Formatted program output as produced by a program literallayout>

> or command. This tag is a container for lines set off from the main text in which line breaks, tabs, and

leading white space are significant.

cprogramlisting> A segment of program code. Line breaks and leading

white space are significant.

This tag contains the layout and content for tabular

formatting of information. has a required

<title>.

sgml(5)

<informaltable> This tag is the same as the tag except the

<title> is not required.

<example> This tag contains examples of source code or usage of

commands. It contains a required <title>.

<informalexample> This tag is the same as the <example> tag except the

<title> is not required.

**Inline Elements** The inline elements are used for tagging text.

<command> An executable program or the entry a user makes to

execute a command.

<function> A subroutine in a program or external library.

cliteral> Contains any literal string.

function or routine.

<inlineequation> An untitled mathematical equation occurring in-line.

A hypertext link to text within a book, in the case of the

reference manual it is used to cross reference to another

reference page.

<oli>A hypertext link used to create cross references to

books other than the reference manual.

<xref> A cross reference to another part of the same reference

page.

smartcard(5)

NAME

smartcard – overview of smart card features on Solaris

### **DESCRIPTION**

The smart card framework provides a mechanism to abstract the details of interacting with smart cards and smart cardreaders (called card terminals). The framework is based on the OpenCard Framework V1.1 (OCF) with Sun extensions to allow OCF to operate in a multi-user environment. The core OCF software protocol stack is implemented as a system service daemon. This implementation allows smart cards and card terminals to be shared cooperatively among many different clients on the system while providing access control to the smart card and card terminal resources on a per-UID basis.

An event dispatcher is provided to inform clients of events occuring on the card and at the card terminal, such as card insertion and card removal.

A high-level authentication mechanism is provided to allow clients to perform smart card-based authentications without requiring knowledge of specific card or reader authentication features.

A set of applet administration tools is provided for JavaCards that support downloading Java applets (although applet build tools are not provided).

Administration of the smart card framework is provided with the smartcard(1M) command line administration utility and the smartcardguiadmin(1) GUI administration tool.

Support the following card terminal is provided:

■ Dallas iButton Serial Reader (see ocf\_ibutton(7D))

Additional card terminals can be supported by implementing smart card terminal interfaces in a shared library.

Support for several smart cards is provided:

- Schlumberger Cyberflex Access JavaCard
- Schlumberger MicroPayflex
- Dallas Semiconductor Java iButton JavaCard

Each of the supported cards has a complete set of OCF card services that implement the necessary functionality for authentication and secure storage of data. For the two supported JavaCards, an authentication and secure data storage applet is provided that can be loaded into these cards with the supplied applet administration tools. See smartcard(1M).

A PAM smart card module is provided to allow PAM clients to use smart card-based authentication. See  $pam\_smartcard(5)$ 

CDE is able to use the PAM smart card module for dtlogin and dtsession authentication. CDE also uses the smart card framework event dispatcher to listen for events on the card terminal and provide corresponding visual feedback to the user.

# $sma_snmp(5)$

**NAME** 

sma\_snmp, netsnmp – SNMP v1, v2c, v3 agent, tools, and modules

**DESCRIPTION** 

The Systems Management Agent (SMA) agent and tools are based on the open source NetSNMP project, published at http://www.net-snmp.org. The SNMP agent supports the v1, v2c and v3 protocols. Secure SNMP operations are provided through the use of USM and VACM. A set of tools that enable users to perform simple SNMP operations, monitor various variables, and perform configuration on the agent are available. Some value-added modules that provide monitoring information specific to Solaris platforms are also available.

**SNMP Agent** 

The agent (see snmpd(1M)) is capable of SNMP v3, v2c and v1 protocol operations. Details of the related RFCs can be found at

http://www.ietf.org/html.charters/snmpv3-charter.html. The agent supports these protocols over a variety of transports. Among these are TCP/UDP over IPv4/IPv6 and Unix domain sockets.

The agent and its modules, including USM and VACM, can be configured by making changes to /etc/sma/snmp/snmpd.conf. See snmpd.conf(4).

**USM** 

The User-based Security Model enables strong authentication of SNMP users as well as communication privacy, message integrity, and replay protection. SNMP users can be managed remotely through the use of SNMP operations. Details of USM can be found in RFC 3414. USM supports privacy of messages. Currently, DES encryption is supported on Solaris. In the future, more secure AES encryption might be added. The agent also provides the ability to manipulate user entries through local configuration files.

**VACM** 

The View-based Access Control Model enables access control to various parts of an SNMP MIB. Remote management of access control is possible through SNMP operations. Details of VACM can be found in RFC 3415. The agent provides the ability to manipulate access control entries through local configuration files.

Subagent

The agent supports subagents through the AgentX protocol and MIBs, as defined in RFCs 2741 and 2742. This enables the master agent to delegate population of different portions of the MIB tree to subagents. AgentX messages can be interchanged over a variety of transports including Unix Domain Sockets, TCP and UDP. Note that it is a possible security risk to expose the master agent listening address through TCP/UDP. See section 9 of RFC 2741 for more details.

**Tools** 

The following tools are available:

encode keychange

Collects information to build a KeyChange encoding, per the textual convention given in RFC 2274, Section 5. Computes the value and prints it to stdout as a hex string.

### fixproc

Fixes a process named "proc" by performing the specified action. The actions can be check, kill, restart, exist, or fix. The action is specified on the command line or is read from a default database, which describes the default action to take for each process.

### mib2c

A script that takes a MIB and converts it into C code. That C code can then be used as a template to implement your MIB.

### net-snmp-config

Net-SNMP configuration options.

### snmpbulkget

An SNMP application that uses the SNMP GETBULK request to efficiently query information on a network entity.

### snmpbulkwalk

An SNMP application that uses the SNMP GETBULK request to efficiently query a network entity for a tree of information.

A configuration file setup command for agent.

### snmpdelta

Monitors the specified integer valued OIDs, and report changes over time.

A networked version of the df(1M) command.

Invokes an SNMP GET request to query for information on a network entity.

# snmpgetnext

An SNMP application that uses the SNMP GETNEXT request to query information on a network entity.

### snmpinform

An SNMP application that uses the SNMP INFORM operation to send information to a network manager.

### snmpnetstat

Symbolically displays the values of various network-related information retrieved from a remote system using the SNMP protocol.

The SNMP SET request to set information on a network entity.

### snmpstatus

An SNMP application that retrieves several important statistics from a network entity.

### snmptable

An SNMP application that repeatedly uses the SNMP GETNEXT or GETBULK requests to query for information on a network entity.

# $sma\_snmp(5)$

An SNMP application that can monitor and manage information on a network entity.

### snmptranslate

An SNMP application that translates one or more SNMP object identifier values from their symbolic (textual) forms into their numerical forms (or vice-versa).

### snmptrap

An SNMP application that uses the SNMP TRAP operation to send information to a network manager.

### snmpusm

An SNMP application that can be used to do simple maintenance on an SNMP agent's User-based Security Module (USM) table.

### snmpvacm

An SNMP application that can be used to do simple maintenance on View-based Access Control (VACM) table.

### snmpwalk

An SNMP application that uses SNMP GETNEXT requests to query a network entity for a tree of information.

Some of these tools have common command line options which can be seen in the snmpcmd man page. Individual tools are described in their own man pages.

### Modules

The modules listed below are available. These enable detailed monitoring operations to be performed through SNMP.

## Host Resources MIB

Defines a uniform set of objects useful for the management of host computers. Host computers are independent of the operating system, network services, or any software application.

The Host Resources MIB defines objects which are common across many computer system architectures. For reference, see RFC 2790 at http://www.faqs.org/.

efines the second version of the Management Information Base for use with network management protocols in TCP/IP-based internets. It provides a simple, system for managing these internets. For reference, see RFC 1213 at http://www.ietf.org/.

### Sun MIB

An extension of the MIB II, this MIB contains Solaris-specific attributes. Adds a table that lists all the currently running processes on the monitored host and certain performance details on that host.

By default, the MIB files are located in /etc/sma/snmp/mibs.

# Module API Documentation

The module API documentation describes some of the Net-SNMP helper APIs as well as other APIs needed to develop SNMP modules. The default location is /usr/sfw/doc/sma snmp/html/modules.html.

# **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE	
Interface Stability	External	

# **SEE ALSO**

 $\label{eq:snmpstatus} snmpstatus(1), snmpconf(1M), snmpd(1M), snmpdf(1M), snmpget(1M), snmpgetnext(1M), snmpnetstat(1M), snmpset(1M), snmptrap(1M), snmpusm(1M), snmpvacm(1M), snmpvacm(1M), snmpvacm(4M), snmpvac$ 

See the section 1M man pages for each of the tools described under TOOLS, above.

smf(5)

### NAME |

smf – service management facility

### DESCRIPTION

The Solaris service management facility defines a programming model for providing persistently running applications called *services*. The facility also provides the infrastructure in which to run services. A service can represent a running application, the software state of a device, or a set of other services. Services are represented in the framework by *service instance* objects, which are children of service objects. Instance objects can inherit or override the configuration of the parent service object, which allows multiple service instances to share configuration information. All service and instance objects are contained in a *scope* that represents a collection of configuration information. The configuration of the local Solaris instance is called the "localhost" scope, and is the only currently supported scope.

Each service instance is named with a fault management resource identifier (FMRI) with the scheme "svc:". For example, the syslogd(1M) daemon started at system startup is the default service instance named:

```
svc://localhost/system/system-log:default
svc:/system/system-log:default
system/system-log:default
```

In the above example, 'default' is the name of the instance and 'system/system-log' is the service name. Service names may comprise multiple components separated by slashes (/). All components, except the last, compose the *category* of the service. Site-specific services should be named with a category beginning with 'site'.

A service instance is either enabled or disabled. All services can be enabled or disabled with the sycadm(1M) command.

The list of managed service instances on a system can be displayed with the svcs(1) command.

# **Dependencies**

Service instances may have dependencies on services or files. Those dependencies govern when the service is started and automatically stopped. When the dependencies of an enabled service are not satisfied, the service is kept in the offline state. When its dependencies are satisfied, the service is started. If the start is successful, the service is transitioned to the online state. Whether a dependency is satisfied is determined by its type:

require_all	Satisfied when all cited services are running (online or degraded), or when all indicated files are present.
require_any	Satisfied when one of the cited services is running (online or degraded), or when at least one of the indicated files is present.
optional_all	Satisfied when all of the cited services are running (online or degraded), disabled, in the maintenance state, or when cited services are not present. For files, this type is the same as require_all.
exclude_all	Satisfied when all of the cited services are disabled, in the maintenance state, or when cited services or files are not present.

Once running (online or degraded), if a service cited by a require all, require any, or optional all dependency is stopped or refreshed, the SMF considers why the service was stopped and the restart on attribute of the dependency to decide whether to stop the service.

I	resta	rt_on ·	value	
event	none	error	restart	refresh
+	 			
stop due to error	no	yes	yes	yes
non-error stop	no	no	yes	yes
refresh	no	no	no	yes

A service is considered to have stopped due to an error if the service has encountered a hardware error or a software error such as a core dump. For exclude all dependencies, the service is stopped if the cited service is started and the restart on attribute is not none.

The dependencies on a service can be listed with svcs(1) or svccfq(1M), and modified with svccfq(1M).

### Restarters

Each service is managed by a restarter. The master restarter, svc.startd(1M) manages states for the entire set of service instances and their dependencies. The master restarter acts on behalf of its services and on delegated restarters that can provide specific execution environments for certain application classes. For instance, inetd(1M) is a delegated restarter that provides its service instances with an initial environment composed of a network connection as input and output file descriptors. Each instance delegated to inetd(1M) is in the online state. While the daemon of a particular instance might not be running, the instance is available to run.

As dependencies are satisfied when instances move to the online state, svc.startd(1M) invokes start methods of other instances or directs the delegated restarter to do so. These operations might overlap.

The current set of services and associated restarters can be examined using svcs(1). A description of the common configuration used by all restarters is given in smf restarter(5).

### Methods

Each service or service instance must define a set of methods that start, stop, and, optionally, refresh the service. See smf method(5) for a more complete description of the method conventions for svc.startd(1M) and similar fork(2)-exec(2) restarters.

Administrative methods, such as for the capture of legacy configuration information into the repository, are discussed on the svccfg(1M) manual page.

The methods for a service can be listed and modified using the svccfg(1M) command.

### States

Each service instance is always in a well-defined state based on its dependencies, the results of the execution of its methods, and its potential receipt of events from the contracts filesystem. The following states are defined:

# smf(5)

UNINITIALIZED	This is the initial state for all service instances. Instances are moved to maintenance, offline, or a disabled state upon evaluation by $\verb"svc.startd"(1M)$ or the appropriate restarter.
OFFLINE	The instance is enabled, but not yet running or available to run. If restarter execution of the service start method or the equivalent method is successful, the instance moves to the online state. Failures might lead to a degraded or maintenance state. Administrative action can lead to the uninitialized state.
ONLINE	The instance is enabled and running or is available to run. The specific nature of the online state is application-model specific and is defined by the restarter responsible for the service instance. Online is the expected operating state for a properly configured service with all dependencies satisfied. Failures of the instance can lead to a degraded or maintenance state. Failures of services on which the instance depends can lead to offline or degraded states.
DEGRADED	The instance is enabled and running or available to run. The instance, however, is functioning at a limited capacity in comparison to normal operation. Failures of the instance can lead to the maintenance state. Failures of services on which the instance depends can lead to offline or degraded states. Restoration of capacity should result in a transition to the online state.
MAINTENANCE	The instance is enabled, but not able to run. Administrative action is required to restore the instance to offline and subsequent states. The maintenance state might be a temporarily reached state if an administrative operation is underway.
DISABLED	The instance is disabled. Enabling the service results in a transition to the offline state and eventually to the online state with all dependencies satisfied.
LEGACY-RUN	This state represents a legacy instance that is not managed by the service management facility. Instances in this state have been started at some point, but might or might not be running. Instances can only be observed using the facility and are not transferred into other states.
States can also hav	e transitions that result in a return to the originating state.

States can also have transitions that result in a return to the originating state.

# Properties and Property Groups

The dependencies, methods, delegated restarter, and instance state mentioned above are represented as properties or property groups of the service or service instance. A service or service instance has an arbitrary number of property groups in which to store application data. Using property groups in this way allows the configuration of the application to derive the attributes that the repository provides for all data in the facility. The application can also use the appropriate subset of the service\_bundle(4) DTD to represent its configuration data within the framework.

Property lookups are composed. If a property group-property combination is not found on the service instance, most commands and the high-level interfaces of <code>libscf(3LIB)</code> search for the same property group-property combination on the service that contains that instance. This feature allows common configuration among service instances to be shared. Composition can be viewed as an inheritance relationship between the service instance and its parent service.

Properties are protected from modification by unauthorized processes. See smf security(5).

### **Snapshots**

Historical data about each instance in the repository is maintained by the service management facility. This data is made available as read-only snapshots for administrative inspection and rollback. The following set of snapshot types might be available:

initial Initial configuration of the instance created by the administrator or

produced during package installation.

last import Configuration as prescribed by the manifest of the service that is

taken during svccfg(1M) import operation. This snapshot provides a baseline for determining property customization.

previous Current configuration captured when an administrative undo

operation is performed.

running The running configuration of the instance.

start Configuration captured during a successful transition to the online

state.

The svccfg(1M) command can be used to interact with snapshots.

# **Special Property Groups**

Some property groups are marked as "non-persistent". These groups are not backed up in snapshots and their content is cleared during system boot. Such groups generally hold an active program state which does not need to survive system restart.

# Configuration Repository

The current state of each service instance, as well as the properties associated with services and service instances, is stored in a system repository managed by svc.configd(1M). This repository is transactional and able to provide previous versions of properties and property groups associated with each service or service instance.

The repository for service management facility data is managed by svc.configd(1M).

### Service Bundles, Manifests, and Profiles

The information associated with a service or service instance that is stored in the configuration repository can be exported as XML-based files. Such XML files, known as service bundles, are portable and suitable for backup purposes. Service bundles are classified as one of the following types:

### smf(5)

at contain the complete set of properties associated with a
e set of services or service instances.

profiles Files that contain a set of service instances and values for the

enabled property on each instance.

Service bundles can be imported or exported from a repository using the <code>svccfg(1M)</code> command. See <code>service\_bundle(4)</code> for a description of the service bundle file format with guidelines for authoring service bundles.

A *service archive* is an XML file that contains the description and persistent properties of every service in the repository, excluding transient properties such as service state. This service archive is basically a 'svccfg export' for every service which is not limited to named services.

### Legacy Startup Scripts

Startup programs in the /etc/rc?.d directories are executed as part of the corresponding run-level milestone:

```
/etc/rcs.d milestone/single-user:default
/etc/rc2.d milestone/multi-user:default
/etc/rc3.d milestone/multi-user-server:default
```

Execution of each program is represented as a reduced-functionality service instance named by the program's path. These instances are held in a special legacy-run state.

These instances do not have an enabled property and, generally, cannot be manipulated with the svcadm(1M) command. No error diagnosis or restart is done for these programs.

### NAME

smf\_bootstrap – service management facility boot, packaging, and compatibility behavior

### DESCRIPTION

The service management facility defines a series of conventions for importing the configuration contained within a service manifest or profile into a repository.

# Manifest loading at boot

At system start, svc.startd(1M) run in default mode begins processing the manifests located in /var/svc/manifest and importing new or changed manifests into the repositorty.

The decision to import a service manifest is based on the existence of a property group in the svc:/smf/manifest service with the following characteristics:

- The name of the property group is the name of the imported manifest with non-alphanumeric characters replaced by underscore ( ) characters.
- The properties of the property group are set based on the manifest contents.

The manifest is not reimported in the event that configuration changes are made to the repository by an administrator. Such configuration changes might include the deletion of one or more services or service instances contained within the manifest. The /var/svc/manifest/site directory is provided for site-specific customizations.

The deletion of a property group by means of svccfg(1M) or libscf(3LIB) interfaces allows the manifest to be reimported on a subsequent system boot.

# Manifest handling during packaging operations

Service manifests within packages are identified with the class manifest. Class action scripts that install and remove service manifests are included in the packaging subsystem. When pkgadd(1M) is invoked, the service manifest is imported.

When pkgrm(1M) is invoked, instances in the manifest that are disabled are deleted. Any services in the manifest with no remaining instances are also deleted.

# Stability declarations

Each service group and each property group delivered in a manifest should declare a stability level based on attributes(5) definitions. With knowledge of the stability level, an application developer can determine the likelihood that feature development based on the existence or components of a service or object is likely to remain functional across a release boundary.

In an smf(5) context, the stability value also identifies the expected scope of the changes to properties within the property group across a release boundary for the service, which can include patches for that service. The following two sections discuss this in more detail.

### **Property overrides**

The service\_bundle(4) document type definition includes an override attribute that is applicable to each property in a service manifest. If set to true, the attribute instructs svccfg(1M) and other manifest import tools to replace the current value of a property in the repository with the one from the manifest. If the override attribute is absent or present but set to false, the current value in the repository is preserved.

# smf\_bootstrap(5)

Property groups declared as Stable do not contain override attributes on enclosed properties. Property groups declared as Evolving do so only to correct an erroneous setting. Property groups declared as Unstable can contain overrides on any property. The exception to this behavior is for the stability property itself, which can be modified to identify incipient change to the interface presented by the service.

# Property group deletion

The service\_bundle(4) document type definition includes a delete attribute, applicable to each property group in a service manifest. If set to true, the delete attribute instructs svccfg(1M) and other manifest import tools to delete this property group from the repository. If the delete attribute is absent or present but set to false, the property group in the repository is preserved.

Property groups declared as Stable or Evolving are not deleted. Property groups declared as Unstable can be deleted across any release boundary.

# Profile application

The first time the existence of each of the three service profiles listed below is detected, svc.startd(1M) automatically applies the profile.

/var/svc/profile/generic.xml /var/svc/profile/platform.xml /var/svc/profile/site.xml

The svc:/smf/manifest service is used in a similar fashion.

Additional service profiles that characterize the activation of various groups of service instances might be present in /var/svc/profile. None of the /var/svc/profile profiles are automatically applied to the repository. A profile can be manually applied or re-applied using svcadm(1M).

### **NOTES**

The present version of smf(5) does not support multiple repositories.

### NAME

smf\_method – service management framework conventions for methods

# DESCRIPTION

The class of services managed by svc.startd(1M) in the service management framework, smf(5), consists of applications that fit a simple fork(2)-exec(2) model. The svc.startd(1M) master daemon and other restarters support the fork(2)-exec(2) model, potentially with additional capabilities. The svc.startd(1M) daemon and other restarters require that the methods which activate, manipulate, or examine a service instance follow the conventions described in this manual page.

### **Invocation form**

The form of a method invocation is not dictated by convention. In some cases, a method invocation might consist of the direct invocation of the daemon or other binary executable that provides the service. For cases in which an executable script or other mediating executable is used, the convention recommends the form:

/path/to/method executable abbr method name

The  $abbr\_method\_name$  used for the recommended form is a supported method such as start or stop. The set of methods supported by a restarter is given on the related restarter page. The svc.startd(1M) daemon supports start, stop, and refresh methods.

A restarter might define other kinds of methods beyond those referenced in this page. The conventions surrounding such extensions are defined by the restarter and might not be identical to those given here.

### Environment Variables

The restarter provides three environment variables to the method that determine the context in which the method is invoked.

SMF FMRI The service fault management resource identifier (FMRI) of the

instance for which the method is invoked.

SMF METHOD The full method name of the method that is invoked

SMF RESTARTER The service FMRI of the restarter that invokes the method

These variables should be removed from the environment prior to the invocation of any persistent process by the method. A convenience shell function, smf\_clear\_env, is given for service authors who use Bourne-compatible shell scripting to compose service methods in the include file described below.

The method context may cause other environment variables to be set as described below.

# **Method Tokens**

A set of tokens are parsed and expanded with appropriate values from the method invocation by the restarter svc.startd. Other restarters might not support method tokens. The delegated restarter for inet services, inetd(1M), does not support the following method expansions.

%% %

%r Name of the restarter, such as svc.startd

# $smf_method(5)$

%m	Name of the method, such as start or stop
%S	Name of the service
%i	Name of the instance
%f	FMRI of the instance
%{prop[:,]}	Value(s) of a property. The prop might be a property FMRI, a property group name and a property name separated by a /, or a property name in the application property group. These values can be followed by a , (comma) or : (colon). If present, the separators are used to separate multiple values. If absent, a space is used. The following shell metacharacters encountered in string values are quoted with a \ (backslash):

An invalid expansion constitutes method failure.

Two explicit tokens can be used in the place of method commands.

:kill	Sends the specified signal, which is SIGTERM by default, to all
[-signal]	processes in the primary instance contract. Always returns
	SMF_EXIT_OK. This token should be used to replace common
	pkill invocations.
:true	Always returns SMF_EXIT_OK. This token should be used for methods that are required by the restarter but which are
	unnecessary for the particular service implementation.

# **Exiting and Exit Status**

The required behavior of a start method is to delay exiting until the service instance is ready to answer requests or is otherwise functional.

The following exit status codes are defined in  ${\tt <libscf.h>}$  and in the shell support file.

SMF_EXIT_OK	0	Method exited, performing its operation successfully.
SMF_EXIT_ERR_FATAL	95	Method failed fatally and is unrecoverable without administrative intervention.
SMF_EXIT_ERR_CONFIG	96	Unrecoverable configuration error. A common condition that returns this exit status is the absence of required configuration files for an enabled service instance.
SMF_EXIT_MON_DEGRADE	97	Monitor assesses service instance as operating in a degraded mode.

SMF_EXIT_MON_OFFLINE	98	Monitor assesses service instance as non-responsive and effectively offline.
SMF_EXIT_ERR_NOSMF	99	Method has been mistakenly invoked outside the $smf(5)$ facility. Services that depend on $smf(5)$ capabilities should exit with this status value.
SMF_EXIT_ERR_PERM	100	Method requires a form of permission such as file access, privilege, authorization, or other credential that is not available when invoked.
SMF_EXIT_ERR_OTHER	non-zero	Any non-zero exit status from a method is treated as an unknown error. A series of unknown errors can be diagnosed as a fault by the restarter or on behalf of the restarter.

Use of a precise exit code allows the responsible restarter to categorize an error response as likely to be intermittent and worth pursuing restart or permanent and request administrative intervention.

### **Timeouts**

Each method can have an independent timeout, given in seconds. The choice of a particular timeout should be based on site expectations for detecting a method failure due to non-responsiveness. Sites with replicated filesystems or other failover resources can elect to lengthen method timeouts from the default. Sites with no remote resources can elect to shorten the timeouts. Method timeout is specified by the timeout\_seconds property.

### Shell Programming Support

A set of environment variables that define the above exit status values is provided with convenience shell functions in the file /lib/svc/share/smf\_include.sh. This file is a Bourne shell script suitable for inclusion via the source operator in any Bourne-compatible shell.

To assist in the composition of scripts that can serve as SMF methods as well as /etc/init.d scripts, the  $\texttt{smf\_present}()$  shell function is provided. If the smf(5) facility is not available,  $\texttt{smf\_present}()$  returns a non-zero exit status.

One possible structure for such a script follows:

```
if smf_present; then
    # Shell code to run application as managed service
    ....
    smf_clear_env
else
    # Shell code to run application as /etc/init.d script
    ....
fi
```

This example shows the use of both convenience functions that are provided.

## **Method Context**

The service management facility offers a common mechanism set the context in which the fork(2)-exec(2) model services execute.

# smf method(5)

The desired method context should be provided by the service developer. All service instances should run with the lowest level of privileges possible to limit potential security compromises.

A method context may contain the following properties:

use profile A boolean that specifies whether the profile should be

used instead of the user, group, privileges, and

limit\_privileges properties.

environment Environment variables to insert into the environment

of the method, in the form of a number of

NAME=value strings.

profile The name of an RBAC (role-based access control)

profile which, along with the method executable,

identifies an entry in exec\_attr(4).

user The user ID in numeric or text form.

group The group ID in numeric or text form.

supp\_groups An optional string that specifies the supplemental

group memberships by ID, in numeric or text form.

privileges An optional string specifying the privilege set as

defined in privileges(5).

limit privileges An optional string specifying the limit privilege set as

defined in privileges(5).

working directory The home directory from which to launch the method.

: home can be used as a token to indicate the home directory of the user whose uid will be used to launch the method. If the property is unset, :home is used.

corefile pattern An optional string that specifies the corefile pattern to

use for the service, as per coreadm(1M). Most restarters supply a default. Setting this property overrides local customizations to the global core

pattern.

project The project ID in numeric or text form. :default can

be used as a token to indicate a project identified by getdefaultproj(3PROJECT) for the user whose uid

is used to launch the method.

resource pool The resource pool name on which to launch the

method. :default can be used as a token to indicate the pool specified in the project(4) entry given in the

project attribute above.

The method context can be set for the entire service instance by specifying a method\_context property group for the service or instance. A method might override the instance method context by providing the method context properties on the method property group.

Invalid method context settings always lead to failure of the method, with the exception of invalid environment variables that issue warnings.

In addition to the context defined above, many fork(2)-exec(2) model restarters also use the following conventions when invoking executables as methods:

Argument array The arguments in argv [] are set consistently with the

result /bin/sh -c of the exec string.

File descriptors File descriptor 0 is /dev/null. File descriptors 1 and

2 are recommended to be a per-service log file.

FILES /lib/svc/share/smf\_include.sh

Definitions of exit status values.

/usr/include/libscf.h

Definitions of exit status codes.

**NOTES** The present version of smf(5) does not support multiple repositories.

### smf restarter(5)

TA T		TA 4	
	Δ	IV/	ш

smf\_restarter – service management facility conventions for restarters

### DESCRIPTION

All service instances in the service management facility must be managed by a restarter. This manual page describes configuration, functionality, and reporting characteristics that are common to all restarters in the framework. Characteristics specific to a particular restarter are described in the restarter's manpage.

For each managed service, a restarter relies on retrieving properties on the service instance to determine configuration. The restarter manages a set of property groups to communicate the current disposition of a service with display tools such as svcs(1).

# Service configuration

The common restarter configuration for all services is captured in the general property group. This group includes the following required and optional property settings.

enabled This is a required property. If set, the restarter of an

instance attempts to maintain availability of the service.

restarter This is an optional property that allows the

specification of an alternate restarter to manage the service instance. If the restarter property is empty or absent, the restarter defaults to svc.startd(1M).

single instance This is an optional property. When set, only one

instance of the service is allowed to transition to an

online or degraded status at any time.

transient\_process This is an optional property. When specified, the

service does not contain objects that run indefinitely

### Service reporting

All restarters report status using the restarter property group, which includes the following properties:

next state The current state and next state, if currently in

transition, for instances stored in these properties. See

smf(5) for a description of the potential states.

auxiliary\_state An astring with no spaces that contains a precise term

to describe the full restarter-specific state in combination with the restarter state property. The auxiliary state may not always be set and is always cleared during transition out of any state. Each restarter must define the precise list of auxiliary states

it will use.

state timestamp The time when the current state was reached.

contract The primary process contract ID, if any, under which

the service instance is executing.

### **SEE ALSO**

svcs(1), svc.startd(1M), service bundle(4), smf(5), smf method(5)

### NAME

smf\_security – service management facility security behavior

# DESCRIPTION

The configuration subsystem for the service management facility, smf(5), requires privilege to modify the configuration of a service. Privileges are granted to a user by associating the authorizations described below to the user through user\_attr(4) and prof attr(4). See rbac(5).

The following authorization is used to manipulate services and service instances.

solaris.smf.modify Authorized to add, delete, or modify services, service instances, or their properties.

### Property Group Authorizations

The smf(5) configuration subsystem associates properties with each service and service instance. Related properties are grouped. Groups may represent an execution method, credential information, application data, or restarter state. The ability to create or modify property groups can cause smf(5) components to perform actions that may require operating system privilege. Accordingly, the framework requires appropriate authorization to manipulate property groups.

Each property group has a type corresponding to its purpose. The core property group types are method, dependency, application, and framework. Additional property group types can be introduced, provided they conform to the extended naming convention in smf(5). The following basic authorizations, however, apply only to the core property group types:

solaris.smf.modify.method

Authorized to change values or create, delete, or modify a property group of type method.

solaris.smf.modify.dependency

Authorized to change values or create, delete, or modify a property group of type dependency.

solaris.smf.modify.application

Authorized to change values or create, delete, or modify a property group of type application.

solaris.smf.modify.framework

Authorized to change values or create, delete, or modify a property group of type framework.

solaris.smf.modify

Authorized to add, delete, or modify services, service instances, or their properties.

Property group-specific authorization can be specified by properties contained in the property group.

modify authorization Authorizations allow the addition, deletion, or

modification of properties within the property group.

value authorization Authorizations allow changing the values of any

property of the property group except

modify authorization.

# smf\_security(5)

The above authorization properties are only used if they have type astring. If an instance property group does not have one of the properties, but the instance's service has a property group of the same name with the property, its values are used.

### Service Action Authorization

Certain actions on service instances may result in service interruption or deactivation. These actions require an authorization to ensure that any denial of service is a deliberate administrative action. Such actions include a request for execution of the refresh or restart methods, or placement of a service instance in the maintenance or other non-operational state. The following authorization allows such actions to be requested:

solaris.smf.manage Authorized to request restart, refresh, or other state modification of any service instance.

In addition, the general/action\_authorization property can specify additional authorizations that permit service actions to be requested for that service instance. The solaris.smf.manage authorization is required to modify this property.

### Defined Rights Profiles

Two rights profiles are included that offer grouped authorizations for manipulating typical smf(5) operations.

# Service Management

A service manager can manipulate any service in the repository in any way. It corresponds to the solaris.smf.manage and solaris.smf.modify authorizations.

The service management profile is the minimum required to use the pkgadd(1M) or pkgrm(1M) commands to add or remove software packages that contain an inventory of services in its service manifest.

### Service Operator

A service operator has the ability to enable or disable any service instance on the system, as well as request that its restart or refresh method be executed. It corresponds to the solaris.smf.manage and solaris.smf.modify.framework authorizations.

Sites can define additional rights profiles customized to their needs.

### Remote Repository Modification

Remote repository servers may deny modification attempts due to additional privilege checks. See NOTES.

### **NOTES**

The present version of smf(5) does not support remote repositories.

## **NAME**

standards, ANSI, C, C++, ISO, POSIX, POSIX.1, POSIX.2, SUS, SUSv2, SUSv3, SVID, SVID3, XNS, XNS4, XNS5, XPG, XPG3, XPG4, XPG4v2 – standards and specifications supported by Solaris

### **DESCRIPTION**

Solaris 10 supports IEEE Std 1003.1 and IEEE Std 1003.2, commonly known as POSIX.1 and POSIX.2, respectively. The following table lists each version of these standards with a brief description and the SunOS or Solaris release that first conformed to it.

POSIX Standard	Description	Release
POSIX.1-1988	system interfaces and headers	SunOS 4.1
POSIX.1-1990	POSIX.1-1988 update	Solaris 2.0
POSIX.1b-1993	realtime extensions	Solaris 2.4
POSIX.1c-1996	threads extensions	Solaris 2.6
POSIX.2-1992	shell and utilities	Solaris 2.5
POSIX.2a-1992	interactive shell and utilities	Solaris 2.5
POSIX.1-2001	POSIX.1-1990, POSIX.1b-1993, POSIX.1c-1996, POSIX.2-1992, and POSIX.2a-1992 updates	Solaris 10

Solaris 10 also supports the X/Open Common Applications Environment (CAE) Portability Guide Issue 3 (XPG3) and Issue 4 (XPG4); Single UNIX Specification (SUS, also known as XPG4v2); Single UNIX Specification, Version 2 (SUSv2); and Single UNIX Specification, Version 3 (SUSv3). Both XPG4 and SUS include Networking Services Issue 4 (XNS4). SUSv2 includes Networking Services Issue 5 (XNS5).

The following table lists each X/Open specification with a brief description and the SunOS or Solaris release that first conformed to it.

X/Open CAE		
Specification	Description	Release
XPG3	superset of POSIX.1-1988 containing utilities from SVID3	SunOS 4.1
XPG4	superset of POSIX.1-1990, POSIX.2-1992, and POSIX.2a-1992 containing extensions to POSIX standards from XPG3	Solaris 2.4
SUS (XPG4v2)	superset of XPG4 containing historical BSD interfaces widely used by common application packages	Solaris 2.6
XNS4	sockets and XTI interfaces	Solaris 2.6

### standards(5)

X/Open CAE		
Specification	Description	Release
SUSv2	superset of SUS extended to support POSIX.1b-1993, POSIX.1c-1996, and ISO/IEC 9899 (C Standard) Amendment 1	Solaris 7
XNS5	superset and LP64-clean derivative of XNS4.	Solaris 7
SUSv3	same as POSIX.1–2001	Solaris 10

The XNS4 specification is safe for use only in ILP32 (32-bit) environments and should not be used for LP64 (64-bit) application environments. Use XNS5 or SUSv3, which have LP64-clean interfaces that are portable across ILP32 and LP64 environments. Solaris releases 7 through 10 support both the ILP32 and LP64 environments.

Solaris releases 7 through 10 have been branded to conform to The Open Group's UNIX 98 Product Standard. Solaris 10 has been branded to conform to The Open Group's UNIX 03 Product Standard.

Solaris releases 2.0 through 10 support the interfaces specified by the System V Interface Definition, Third Edition, Volumes 1 through 4 (SVID3). Note, however, that since the developers of this specification (UNIX Systems Laboratories) are no longer in business and since this specification defers to POSIX and X/Open CAE specifications, there is some disagreement about what is currently required for conformance to this specification.

When Sun Studio C Compiler 5.6 is installed, Solaris releases 2.0 through 10 support the ANSI X3.159-1989 Programming Language - C and ISO/IEC 9899:1990 Programming Language - C (C) interfaces.

When Sun Studio C Compiler 5.6 is installed, Solaris releases 7 through 10 support ISO/IEC 9899:1990 Amendment 1:1995: C Integrity.

When Sun Studio C Compiler 5.6 is installed, Solaris 10 supports ISO/IEC 9899:1999 Programming Languages – C.

When Sun Studio C++ Compiler 5.6 is installed, Solaris releases 2.5.1 through 10 support ISO/IEC 14882:1998 Programming Languages - C++. Unsupported features of that standard are described in the compiler README file.

# Utilities

If the behavior required by POSIX.2, POSIX.2a, XPG4, SUS, or SUSv2 conflicts with historical Solaris utility behavior, the original Solaris version of the utility is unchanged; a new version that is standard-conforming has been provided in /usr/xpg4/bin. If the behavior required by POSIX.1–2001 or SUSv3 conflicts with historical Solaris utility behavior, a new version that is standard-conforming has been provided in /usr/xpg4/bin or in /usr/xpg6/bin. If the behavior required by POSIX.1–2001 or SUSv3 conflicts with POSIX.2, POSIX.2a, SUS, or SUSv2, a new version that is SUSv3 standard-conforming has been provided in /usr/xpg6/bin.

An application that wants to use standard-conforming utilitues must set the PATH (sh(1) or ksh(1)) or path (csh(1)) environment variable to specify the directories listed in the following table in the order specified to get the appropriate utilities:

Standard	Utility Directories	
SVID3, XPG3	<ol> <li>/usr/ccs/bin</li> <li>/usr/bin</li> <li>directory containing binaries for your compiler</li> <li>other directories containing binaries needed by the application</li> </ol>	
POSIX.2, POSIX.2a, SUS, SUSv2, XPG4	<ol> <li>/usr/xpg4/bin</li> <li>/usr/ccs/bin</li> <li>/usr/bin</li> <li>directory containing binaries for your compiler</li> <li>other directories containing binaries needed by the application</li> </ol>	
POSIX.1–2001, SUSv3	<ol> <li>/usr/xpg6/bin</li> <li>/usr/xpg4/bin</li> <li>/usr/ccs/bin</li> <li>/usr/bin</li> <li>directory containing binaries for your compiler</li> <li>other directories containing binaries needed by the application</li> </ol>	

When an application uses execlp() or execvp() (see exec(2)) to execute a shell file, or uses execlp(), the shell used to interpret the shell file depends on the standard to which the caller conforms:

Standard	Shell Used
1989 ANSI C, 1990 ISO C, 1999 ISO C, POSIX.1 (1990–2001), SUS, SUSv2, SUSv3, XPG4	/usr/xpg4/bin/sh
POSIX.1 (1988), SVID3, XPG3, no standard specified	/usr/bin/sh

### Feature Test Macros

Feature test macros are used by applications to indicate additional sets of features that are desired beyond those specified by the C standard. If an application uses only those interfaces and headers defined by a particular standard (such as POSIX or X/Open CAE), then it need only define the appropriate feature test macro specified by that standard. If the application is using interfaces and headers not defined by that standard, then in addition to defining the appropriate standard feature test macro, it

### standards(5)

must also define \_\_EXTENSIONS\_\_. Defining \_\_EXTENSIONS\_\_ provides the application with access to all interfaces and headers not in conflict with the specified standard. The application must define \_\_EXTENSIONS\_\_ either on the compile command line or within the application source files.

### 1989 ANSI C, 1990 ISO C, 1999 ISO C

No feature test macros need to be defined to indicate that an application is a conforming C application.

### ANSI/ISO C++

ANSI/ISO C++ does not define any feature test macros. If the standard C++ announcement macro \_\_cplusplus is predefined to value 199711 or greater, the compiler operates in a standard-conforming mode, indicating C++ standards conformance. The value 199711 indicates conformance to ISO/IEC 14882:1998, as required by that standard. (As noted above, conformance to the standard is incomplete.) A standard-conforming mode is not available with compilers prior to Sun WorkShop C++ 5.0.

C++ bindings are not defined for POSIX or X/Open CAE, so specifying feature test macros such as \_POSIX\_SOURCE, \_POSIX\_C\_SOURCE, and \_XOPEN\_SOURCE can result in compilation errors due to conflicting requirements of standard C++ and those specifications.

### **POSIX**

Applications that are intended to be conforming POSIX.1 applications must define the feature test macros specified by the standard before including any headers. For the standards listed below, applications must define the feature test macros listed. Application writers must check the corresponding standards for other macros that can be queried to determine if desired options are supported by the implementation.

POSIX Standard	Feature Test Macros	
POSIX.1-1990	_POSIX_SOURCE	
POSIX.1-1990 and POSIX.2-1992 C-Language Bindings Option	_POSIX_SOURCE and _POSIX_C_SOURCE=2	
POSIX.1b-1993	_POSIX_C_SOURCE=199309L	
POSIX.1c-1996	_POSIX_C_SOURCE=199506L	
POSIX.1–2001	_POSIX_C_SOURCE=200112L	

# SVID3

The SVID3 specification does not specify any feature test macros to indicate that an application is written to meet SVID3 requirements. The SVID3 specification was written before the C standard was completed.

# X/Open CAE

To build or compile an application that conforms to one of the X/Open CAE specifications, use the following guidelines. Applications need not set the POSIX feature test macros if they require both CAE and POSIX functionality.

XPG3 The application must define XOPEN SOURCE. If XOPEN SOURCE

is defined with a value, the value must be less than 500.

XPG4 The application must define XOPEN SOURCE and set

XOPEN VERSION=4. If XOPEN SOURCE is defined with a value,

the value must be less than 500.

SUS (XPG4v2) The application must define XOPEN SOURCE and set

XOPEN SOURCE EXTENDED=1. If XOPEN SOURCE is defined

with a value, the value must be less than 500.

SUSv2 The application must define \_XOPEN\_SOURCE=500.
SUSv3 The application must define XOPEN SOURCE=600.

# Compilation

A POSIX.1 (1988–1996)-, XPG4-, SUS-, or SUSv2-conforming implementation must include an ANSI X3.159-1989 (ANSI C Language) standard-conforming compilation system and the cc and c89 utilities. A POSIX.1–2001– or SUSv3–conforming implementation must include an ISO/IEC 99899:1999 (1999 ISO C Language) standard-conforming compilation system and the c99 utility. Solaris 10 was tested with the cc, c89, and c99 utilities and the compilation environment provided by Sun Studio C Compiler 5.6.

When cc is used to link applications, /usr/lib/values-xpg4.0 must be specified on any link/load command line, unless the application is POSIX.1–2001– or SUSv3–conforming, in which case /usr/lib/values-xpg6.0 must be specified on any link/load compile line. The preferred way to build applications, however, is described in the table below.

An XNS4- or XNS5-conforming application must include -1 XNS on any link/load command line in addition to defining the feature test macros specified for SUS or SUSv2, respectively.

If the compiler suppports the redefine\_extname pragma feature (the Sun Studio C Compiler 5.6 compilers define the macro \_\_PRAGMA\_REDEFINE\_EXTNAME to indicate that it supports this feature), then the standard headers use #pragma redefine\_extname directives to properly map function names onto library entry point names. This mapping provides full support for ISO C, POSIX, and X/Open namespace reservations.

If this pragma feature is not supported by the compiler, the headers use the #define directive to map internal function names onto appropriate library entry point names. In this instance, applications should avoid using the explicit 64-bit file offset symbols listed on the 1f64(5) manual page, since these names are used by the implementation to name the alternative entry points.

# standards(5)

When using Sun Studio C Compiler 5.6 compilers, applications conforming to the specifications listed above should be compiled using the utilities and flags indicated in the following table:

Specification	Compiler/Flags	Feature Test Macros
1989 ANSI C and 1990 ISO C	c89	none
1999 ISO C	c99	none
SVID3	cc -Xt -xc99=none	none
POSIX.1-1990	c89	_POSIX_SOURCE
POSIX.1-1990 and POSIX.2-1992 C-Language Bindings Option	c89	_POSIX_SOURCE and POSIX_C_SOURCE=2
POSIX.1b-1993	c89	_POSIX_C_SOURCE=199309L
POSIX.1c-1996	c89	_POSIX_C_SOURCE=199506L
POSIX.1-2001	с99	_POSIX_C_SOURCE=200112L
POSIX.1c-1996	c89	_POSIX_C_SOURCE=199506L
CAE XPG3	cc -Xa -xc99=none	_XOPEN_SOURCE
CAE XPG4	c89	_XOPEN_SOURCE and _XOPEN_VERSION=4
SUS (CAE XPG4v2) (includes XNS4)	c89	_XOPEN_SOURCE and _XOPEN_SOURCE_EXTENDED=1
SUSv2 (includes XNS5)	c89	_XOPEN_SOURCE=500
SUSv3	c99	_XOPEN_SOURCE=600

For platforms supporting the LP64 (64-bit) programming environment, SUSv2–conforming LP64 applications using XNS5 library calls should be built with command lines of the form:

```
c89 $(getconf XBS5_LP64_OFF64_CFLAGS) -D_XOPEN_SOURCE=500 \
   $(getconf XBS5_LP64_OFF64_LDFLAGS) foo.c -o foo \
   $(getconf XBS5_LP64_OFF64_LIBS) -lxnet
```

Similar SUSv3–conforming LP64 applications should be built with command lines of the form:

```
c99 $(getconf POSIX_V6_LP64_OFF64_CFLAGS) -D_XOPEN_SOURCE=600 \
   $(getconf POSIX_V6_LP64_OFF64_LDFLAGS) foo.c -o foo \
   $(getconf POSIX_V6_LP64_OFF64_LIBS) -lxnet
```

sticky(5)

**NAME** 

sticky - mark files for special treatment

# **DESCRIPTION**

The *sticky bit* (file mode bit 01000, see chmod(2)) is used to indicate special treatment of certain files and directories. A directory for which the sticky bit is set restricts deletion of files it contains. A file in a sticky directory can only be removed or renamed by a user who has write permission on the directory, and either owns the file, owns the directory, has write permission on the file, or is a privileged user. Setting the sticky bit is useful for directories such as /tmp, which must be publicly writable but should deny users permission to arbitrarily delete or rename the files of others.

If the sticky bit is set on a regular file and no execute bits are set, the system's page cache will not be used to hold the file's data. This bit is normally set on swap files of diskless clients so that accesses to these files do not flush more valuable data from the system's cache. Moreover, by default such files are treated as swap files, whose inode modification times may not necessarily be correctly recorded on permanent storage.

Any user may create a sticky directory. See chmod for details about modifying file modes.

**SEE ALSO** 

chmod(1), chmod(2), chown(2), mkdir(2), rename(2), unlink(2)

**BUGS** 

The mkdir(2) function will not create a directory with the sticky bit set.

#### NAME

tecla, teclarc – User interface provided by the tecla library.

#### **DESCRIPTION**

This man page describes the command-line editing features that are available to users of programs that read keyboard input via the tecla library. Users of the tcsh shell will find the default key bindings very familiar. Users of the bash shell will also find it quite familiar, but with a few minor differences, most notably in how forward and backward searches through the list of historical commands are performed. There are two major editing modes, one with emacs-like key bindings and another with vi-like key bindings. By default emacs mode is enabled, but vi(1) mode can alternatively be selected via the user's configuration file. This file can also be used to change the bindings of individual keys to suit the user's preferences. By default, tab completion is provided. If the application hasn't reconfigured this to complete other types of symbols, then tab completion completes file names.

#### **Key Sequence Notation**

In the rest of this man page, and also in all tecla configuration files, key sequences are expressed as follows.

^A or C-a This is a 'CONTROL-A', entered by pressing the CONTROL key at

the same time as the 'A' key.

\\E or M- In key sequences, both of these notations can be entered either by

pressing the ESCAPE key, then the following key, or by pressing the META key at the same time as the following key. Thus the key sequence M-p can be typed in two ways, by pressing the ESCAPE key, followed by pressing 'P', or by pressing the META key at the

same time as 'P'.

up This refers to the up-arrow key.

down This refers to the down-arrow key.

Ieft This refers to the left-arrow key.

This refers to the right-arrow key.

a This is just a normal 'A' key.

## The Tecla Configuration File

By default, tecla looks for a file called .teclarc in your home directory (ie. ~/.teclarc). If it finds this file, it reads it, interpreting each line as defining a new key binding or an editing configuration option. Since the emacs keybindings are installed by default, if you want to use the non-default vi editing mode, the most important item to go in this file is the following line:

edit-mode vi

This will re-configure the default bindings for vi-mode. The complete set of arguments that this command accepts are:

vi Install key bindings like those of the vi editor.

emacs Install key bindings like those of the emacs editor. This is the

default.

none

Use just the native line editing facilities provided by the terminal driver.

To prevent the terminal bell from being rung, such as when an unrecognized control-sequence is typed, place the following line in the configuration file:

nobeer

An example of a key binding line in the configuration file is the following.

```
bind M-[2~ insert-mode
```

On many keyboards, the above key sequence is generated when one presses the insert key, so with this key binding, one can toggle between the emacs-mode insert and overwrite modes by hitting one key. One could also do it by typing out the above sequence of characters one by one. As explained above, the M- part of this sequence can be typed either by pressing the ESCAPE key before the following key, or by pressing the META key at the same time as the following key. Thus if you had set the above key binding, and the insert key on your keyboard didn't generate the above key sequence, you could still type it in either of the following 2 ways.

- 1. Hit the ESCAPE key momentarily, then press '[', then '2', then finally '~'.
- 2. Press the META key at the same time as pressing the '[' key, then press '2', then '~'.

If you set a key binding for a key sequence that is already bound to a function, the new binding overrides the old one. If in the new binding you omit the name of the new function to bind to the key sequence, the original binding becomes undefined.

Starting with versions of libtecla later than 1.3.3 it is now possible to bind key sequences that begin with a printable character. Previously key sequences were required to start with a CONTROL or META character.

Note that the special keywords "up", "down", "left", and "right" refer to the arrow keys, and are thus not treated as key sequences. So, for example, to rebind the up and down arrow keys to use the history search mechanism instead of the simple history recall method, you could place the following in your configuration file:

```
bind up history-search-backwards
bind down history-search-backwards
```

To unbind an existing binding, you can do this with the bind command by omitting to name any action to rebind the key sequence to. For example, by not specifying an action function, the following command unbinds the default beginning-of-line action from the ^A key sequence:

```
bind ^A
```

If you create a ~/.teclarc configuration file, but it appears to have no effect on the program, check the documentation of the program to see if the author chose a different name for this file.

## Filename and Tilde Completion

With the default key bindings, pressing the TAB key (aka. ^I) results in tecla attempting to complete the incomplete file name that precedes the cursor. Tecla searches backwards from the cursor, looking for the start of the file name, stopping when it hits either a space or the start of the line. If more than one file has the specified prefix, then tecla completes the file name up to the point at which the ambiguous matches start to differ, then lists the possible matches.

In addition to literally written file names, tecla can complete files that start with ~/ and ~user/ expressions and that contain \$envvar expressions. In particular, if you hit TAB within an incomplete ~user, expression, tecla will attempt to complete the username, listing any ambiguous matches.

The completion binding is implemented using the cpl\_complete\_word() function, which is also available separately to users of this library. See the cpl\_complete\_word(3TECLA) man page for more details.

#### Filename Expansion

With the default key bindings, pressing ^X\* causes tecla to expand the file name that precedes the cursor, replacing ~/ and ~user/ expressions with the corresponding home directories, and replacing \$envvar expressions with the value of the specified environment variable, then if there are any wildcards, replacing the so far expanded file name with a space-separated list of the files which match the wild cards.

The expansion binding is implemented using the ef\_expand\_file() function. See the ef\_expand\_file(3TECLA) man page for more details.

#### Recalling Previously Typed Lines

Every time that a new line is entered by the user, it is appended to a list of historical input lines maintained within the GetLine resource object. You can traverse up and down this list using the up and down arrow keys. Alternatively, you can do the same with the ^P, and ^N keys, and in vi command mode you can alternatively use the k and j characters. Thus pressing up-arrow once, replaces the current input line with the previously entered line. Pressing up-arrow again, replaces this with the line that was entered before it, etc.. Having gone back one or more lines into the history list, one can return to newer lines by pressing down-arrow one or more times. If you do this sufficient times, you will return to the original line that you were entering when you first hit up-arrow.

Note that in vi mode, all of the history recall functions switch the library into command mode.

In emacs mode the M-p and M-n keys work just like the  $^P$  and  $^N$  keys, except that they skip all but those historical lines which share the prefix that precedes the cursor. In vi command mode the upper case 'K' and 'J' characters do the same thing, except that the string that they search for includes the character under the cursor as well as what precedes it.

Thus for example, suppose that you were in emacs mode, and you had just entered the following list of commands in the order shown:

```
ls ~/tecla/
cd ~/tecla
ls -1 getline.c
emacs ~/tecla/getline.c
```

#### If you next typed:

ls

and then hit M-p, then rather than returning the previously typed emacs line, which doesn't start with "ls", tecla would recall the "ls -l getline.c" line. Pressing M-p again would recall the "ls ~/tecla/" line.

Note that if the string that you are searching for, contains any of the special characters, \*, ?, or '[', then it is interpretted as a pattern to be matched. Thus, cotinuing with the above example, after typing in the list of commands shown, if you then typed:

```
*tecla*
```

and hit M-p, then the "emacs ~/tecla/getline.c" line would be recalled first, since it contains the word tecla somewhere in the line, Similarly, hitting M-p again, would recall the "ls ~/tecla/" line, and hitting it once more would recall the "ls ~/tecla/" line. The pattern syntax is the same as that described for file name expansion, in the ef expand file(3TECLA).

#### **History Files**

Authors of programs that use the tecla library have the option of saving historical command-lines in a file before exiting, and subsequently reading them back in from this file when the program is next started. There is no standard name for this file, since it makes sense for each application to use its own history file, so that commands from different applications don't get mixed up.

#### International Character Sets

Since libtecla version 1.4.0, tecla has been 8-bit clean. This means that all 8-bit characters that are printable in the user's current locale are now displayed verbatim and included in the returned input line. Assuming that the calling program correctly contains a call like the following,

```
setlocale(LC CTYPE, "");
```

then the current locale is determined by the first of the environment variables LC\_CTYPE, LC\_ALL, and LANG, that is found to contain a valid locale name. If none of these variables are defined, or the program neglects to call setlocale, then the default C locale is used, which is US 7-bit ASCII. On most unix-like platforms, you can get a list of valid locales by typing the command:

```
locale -a
```

at the shell prompt.

#### Meta Keys and Locales

Beware that in most locales other than the default C locale, META characters become printable, and they are then no longer considered to match M-c style key bindings. This allows international characters to be entered with the compose key without unexpectedly triggering META key bindings. You can still invoke META bindings, since there are actually two ways to do this. For example the binding M-c can also be invoked by pressing the ESCAPE key momentarily, then pressing the c key, and this will work regardless of locale. Moreover, many modern terminal emulators, such as gnome's gnome-terminal's and KDE's konsole terminals, already generate escape pairs like this when you use the META key, rather than a real meta character, and other emulators usually have a way to request this behavior, so you can continue to use the META key on most systems.

For example, although xterm terminal emulators generate real 8-bit meta characters by default when you use the META key, they can be configured to output the equivalent escape pair by setting their EightBitInput X resource to False. You can either do this by placing a line like the following in your ~/.Xdefaults file,

```
XTerm*EightBitInput: False
```

or by starting an xterm with an -xrm '\*EightBitInput: False' command-line argument. In recent versions of xterm you can toggle this feature on and off with the 'Meta Sends Escape' option in the menu that is displayed when you press the left mouse button and the CONTROL key within an xterm window. In CDE, dtterms can be similarly coerced to generate escape pairs in place of meta characters, by setting the Dtterm\*KshMode resource to True.

#### **Entering International Characters**

If you don't have a keyboard that generates all of the international characters that you need, there is usually a compose key that will allow you to enter special characters, or a way to create one. For example, under X windows on unix-like systems, if your keyboard doesn't have a compose key, you can designate a redundant key to serve this purpose with the xmodmap command. For example, on many PC keyboards there is a microsoft-windows key, which is otherwise useless under Linux. On a laptop, for example, the xev program might report that pressing this key generates keycode 115. To turn this key into a COMPOSE key, do the following:

```
xmodmap -e 'keycode 115 = Multi_key'
```

Type this key followed by a "character to enter an 'I' with a umlaut over it.

### The Available Key Binding Functions

The following is a list of the editing functions provided by the tecla library. The names in the leftmost column of the list can be used in configuration files to specify which function a given key or combination of keys should invoke. They are also used in the next two sections to list the default key bindings in emacs and vi modes.

user-interrupt Send a SIGINT signal to the parent process.

suspend Suspend the parent process. stop-output Pause terminal output.

start-output Resume paused terminal output.

literal-next Arrange for the next character to be treated

as a normal character. This allows control

characters to be entered.

cursor-right Move the cursor one character right.

cursor-left Move the cursor one character left.

insert-mode Toggle between insert mode and overwrite

mode.

beginning-of-line Move the cursor to the beginning of the

line.

end-of-line Move the cursor to the end of the line.

delete-line Delete the contents of the current line.

kill-line Delete everything that follows the cursor.

backward-kill-line Delete all characters between the cursor and

the start of the line.

forward-word Move to the end of the word which follows

the cursor.

forward-to-word Move the cursor to the start of the word

that follows the cursor.

backward-word Move to the start of the word which

precedes the cursor.

goto-column Move the cursor to the 1-relative column in

the line specified by any preceding digit-argument sequences (see Entering

Repeat Counts below).

find-parenthesis If the cursor is currently over a parenthesis

character, move it to the matching parenthesis character. If not over a

parenthesis character move right to the next

close parenthesis.

forward-delete-char Delete the character under the cursor.

backward-delete-char Delete the character which precedes the

cursor.

list-or-eof This is intended for binding to ^D. When

invoked when the cursor is within the line it displays all possible completions then

redisplays the line unchanged. When
invoked on an empty line, it signals
end-of-input (EOF) to the caller of

gl\_get\_line().

del-char-or-list-or-eof This is intended for binding to ^D. When

invoked when the cursor is within the line it invokes forward-delete-char. When invoked at the end of the line it displays all possible completions then redisplays the line unchanged. When invoked on an empty line, it signals end-of-input (EOF) to

the caller of gl get line().

forward-delete-word Delete the word which follows the cursor.

backward-delete-word Delete the word which precedes the cursor.

upcase-word Convert all of the characters of the word

which follows the cursor, to upper case.

downcase-word Convert all of the characters of the word

which follows the cursor, to lower case.

capitalize-word Capitalize the word which follows the

cursor.

change-case If the next character is upper case, toggle it

to lower case and vice versa.

redisplay Redisplay the line.

clear-screen Clear the terminal, then redisplay the

current line.

transpose-chars Swap the character under the cursor with

the character just before the cursor.

set-mark Set a mark at the position of the cursor.

exchange-point-and-mark Move the cursor to the last mark that was

set, and move the mark to where the cursor

used to be.

kill-region Delete the characters that lie between the

last mark that was set, and the cursor.

copy-region-as-kill Copy the text between the mark and the

cursor to the cut buffer, without deleting the

original text.

yank Insert the text that was last deleted, just

before the current position of the cursor.

append-yank Paste the current contents of the cut buffer, after the cursor. Recall the next oldest line that was entered. up-history Note that in vi mode you are left in command mode. Recall the next most recent line that was down-history entered. If no history recall session is currently active, the next line from a previous recall session is recalled. Note that in vi mode you are left in command mode. history-search-backward Recall the next oldest line who's prefix matches the string which currently precedes the cursor (in vi command-mode the character under the cursor is also included in the search string). Note that in vi mode you are left in command mode. history-search-forward Recall the next newest line who's prefix matches the string which currently precedes the cursor (in vi command-mode the character under the cursor is also included in the search string). Note that in vi mode you are left in command mode. history-re-search-backward Recall the next oldest line who's prefix matches that established by the last invocation of either history-search-forward or history-search-backward. history-re-search-forward Recall the next newest line who's prefix matches that established by the last invocation of either history-search-forward or history-search-backward. complete-word Attempt to complete the incomplete word which precedes the cursor. Unless the host program has customized word completion, file name completion is attempted. In vi commmand mode the character under the cursor is also included in the word being completed, and you are left in vi insert mode. expand-filename Within the command line, expand wild cards, tilde expressions and dollar expressions in the file name which immediately precedes the cursor. In vi

commmand mode the character under the cursor is also included in the file name being expanded, and you are left in vi insert mode.

list-glob List any file names which match the

wild-card, tilde and dollar expressions in the file name which immediately precedes the cursor, then redraw the input line

unchanged.

list-history Display the contents of the history list for

the current history group. If a repeat count of > 1 is specified, only that many of the most recent lines are displayed. See the

Entering Repeat Counts section.

read-from-file Temporarily switch to reading input from

the file who's name precedes the cursor.

read-init-files Re-read teclarc configuration files.

beginning-of-history Move to the oldest line in the history list.

Note that in vi mode you are left in

command mode.

end-of-history Move to the newest line in the history list

(ie. the current line). Note that in vi mode

this leaves you in command mode.

digit-argument Enter a repeat count for the next key

binding function. For details, see the Entering Repeat Counts section.

newline Terminate and return the current contents of

the line, after appending a newline

character. The newline character is normally '\', but will be the first character of the key sequence that invoked the newline action, if this happens to be a printable character. If the action was invoked by the '\' newline character or the '\\r' carriage return

character, the line is appended to the history

buffer.

repeat-history Return the line that is being edited, then

arrange for the next most recent entry in the history buffer to be recalled when tecla is next called. Repeatedly invoking this action

	causes successive historical input lines to be re-executed. Note that this action is equivalent to the 'Operate' action in ksh.
ring-bell	Ring the terminal bell, unless the bell has been silenced via the nobeep configuration option (see The Tecla Configuration File section).
forward-copy-char	Copy the next character into the cut buffer (NB. use repeat counts to copy more than one).
backward-copy-char	Copy the previous character into the cut buffer.
forward-copy-word	Copy the next word into the cut buffer.
backward-copy-word	Copy the previous word into the cut buffer.
forward-find-char	Move the cursor to the next occurrence of the next character that you type.
backward-find-char	Move the cursor to the last occurrence of the next character that you type.
forward-to-char	Move the cursor to the character just before the next occurrence of the next character that the user types.
backward-to-char	Move the cursor to the character just after the last occurrence before the cursor of the next character that the user types.
repeat-find-char	Repeat the last backward-find-char, forward-find-char, backward-to-char or forward-to-char.
invert-refind-char	Repeat the last backward-find-char, forward-find-char, backward-to-char, or forward-to-char in the opposite direction.
delete-to-column	Delete the characters from the cursor up to the column that is specified by the repeat count.
delete-to-parenthesis	Delete the characters from the cursor up to and including the matching parenthesis, or next close parenthesis.
forward-delete-find	Delete the characters from the cursor up to and including the following occurence of the next character typed.

backward-delete-find Delete the characters from the cursor up to

and including the preceding occurence of

the next character typed.

forward-delete-to Delete the characters from the cursor up to,

but not including, the following occurence

of the next character typed.

backward-delete-to Delete the characters from the cursor up to,

but not including, the preceding occurence

of the next character typed.

delete-refind Repeat the last \*-delete-find or \*-delete-to

action.

delete-invert-refind Repeat the last \*-delete-find or \*-delete-to

action, in the opposite direction.

copy-to-column Copy the characters from the cursor up to

the column that is specified by the repeat

count, into the cut buffer.

copy-to-parenthesis Copy the characters from the cursor up to

and including the matching parenthesis, or next close parenthesis, into the cut buffer.

forward-copy-find Copy the characters from the cursor up to

and including the following occurence of the next character typed, into the cut buffer.

backward-copy-find Copy the characters from the cursor up to

and including the preceding occurence of the next character typed, into the cut buffer.

forward-copy-to Copy the characters from the cursor up to,

but not including, the following occurence of the next character typed, into the cut

buffer.

backward-copy-to Copy the characters from the cursor up to,

but not including, the preceding occurence of the next character typed, into the cut

buffer.

copy-refind Repeat the last \*-copy-find or \*-copy-to

action.

copy-invert-refind Repeat the last \*-copy-find or \*-copy-to

action, in the opposite direction.

vi-mode Switch to vi mode from emacs mode.

emacs-mode Switch to emacs mode from vi mode.

mode.

vi-overwrite From vi command mode, switch to

overwrite mode.

vi-insert-at-bol From vi command mode, move the cursor

to the start of the line and switch to insert

mode.

vi-append-at-eol From vi command mode, move the cursor

to the end of the line and switch to append

mode.

vi-append From vi command mode, move the cursor

one position right, and switch to insert

mode.

vi-replace-char From vi command mode, replace the

character under the cursor with the next

character entered.

vi-forward-change-char From vi command mode, delete the next

character then enter insert mode.

vi-backward-change-char From vi command mode, delete the

preceding character then enter insert mode.

vi-forward-change-word From vi command mode, delete the next

word then enter insert mode.

vi-backward-change-word From vi command mode, delete the

preceding word then enter insert mode.

vi-change-rest-of-line From vi command mode, delete from the

cursor to the end of the line, then enter

insert mode.

vi-change-line From vi command mode, delete the current

line, then enter insert mode.

vi-change-to-bol From vi command mode, delete all

characters between the cursor and the beginning of the line, then enter insert

mode.

vi-change-to-column From vi command mode, delete the

characters from the cursor up to the column that is specified by the repeat count, then

enter insert mode.

vi-change-to-parenthesis Delete the characters from the cursor up to

and including the matching parenthesis, or next close parenthesis, then enter vi insert

mode.

vi-forward-change-find From vi command mode, delete the

characters from the cursor up to and including the following occurence of the next character typed, then enter insert

mode.

vi-backward-change-find From vi command mode, delete the

characters from the cursor up to and including the preceding occurence of the next character typed, then enter insert

mode.

vi-forward-change-to From vi command mode, delete the

characters from the cursor up to, but not including, the following occurence of the next character typed, then enter insert

mode.

vi-backward-change-to From vi command mode, delete the

characters from the cursor up to, but not including, the preceding occurence of the next character typed, then enter insert

mode.

vi-change-refind Repeat the last vi-\*-change-find or

vi-\*-change-to action.

vi-change-invert-refind Repeat the last vi-\*-change-find or

vi-\*-change-to action, in the opposite

direction.

vi-undo In vi mode, undo the last editing operation.

vi-repeat-change In vi command mode, repeat the last

command that modified the line.

Default Key Bindings In emacs Mode The following default key bindings, which can be overriden by the tecla configuration file, are designed to mimic most of the bindings of the unix tcsh shell shell, when it is in emacs editing mode.

This is the default editing mode of the tecla library.

Under UNIX the terminal driver sets a number of special keys for certain functions. The tecla library attempts to use the same key bindings to maintain consistency. The key sequences shown for the following 6 bindings are thus just examples of what they will probably be set to. If you have used the stty command to change these keys, then the default bindings should match.

^C user-interrupt
^\\ abort
^Z suspend
^Q start-output
^S stop-output
^V literal-next

The cursor keys are refered to by name, as follows. This is necessary because different types of terminals generate different key sequences when their cursor keys are pressed.

right cursor-right
left cursor-left
up up-history
down down-history

^F

The remaining bindings don't depend on the terminal setttings.

cursor-right

**^**B cursor-left Μ-i insert-mode ^A beginning-of-line ^E end-of-line ^U delete-line ^K kill-line forward-word M-fM-b backward-word ^D del-char-or-list-or-eof ^H backward-delete-char ^? backward-delete-char forward-delete-word M-dM-^H backward-delete-word

M-^?	backward-delete-word
M-u	upcase-word
M-1	downcase-word
M-C	capitalize-word
^R	redisplay
^L	clear-screen
^T	transpose-chars
<b>^</b> @	set-mark
^x^x	exchange-point-and-mark
^W	kill-region
M-w	copy-region-as-kill
^Y	yank
^P	up-history
^N	down-history
М-р	history-search-backward
M-n	history-search-forward
^I	complete-word
^X*	expand-filename
^X^F	read-from-file
^X^R	read-init-files
^Xg	list-glob
^Xh	list-history
M-<	beginning-of-history
M->	end-of-history
\	newline
\\r	newline
M-0	repeat-history
M-^V	vi-mode
M-0, M-1, M-9	digit-argument (see below)

Note that  $^{\text{I}}$  is what the TAB key generates, and that  $^{\text{@}}$  can be generated not only by pressing the CONTROL key and the  $^{\text{@}}$  key simultaneously, but also by pressing the CONTROL key and the space bar at the same time.

#### Default Key Bindings in vi Mode

The following default key bindings are designed to mimic the vi style of editing as closely as possible. This means that very few editing functions are provided in the initial character input mode, editing functions instead being provided by the vi command mode. The vi command mode is entered whenever the ESCAPE character is pressed, or whenever a key sequence that starts with a meta character is entered. In addition to mimicing vi, libtecla provides bindings for tab completion, wild-card expansion of file names, and historical line recall.

To learn how to tell the tecla library to use vi mode instead of the default emacs editing mode, see the earlier section entitled The Tecla Configuration File.

Under UNIX the terminal driver sets a number of special keys for certain functions. The tecla library attempts to use the same key bindings to maintain consistency, binding them both in input mode and in command mode. The key sequences shown for the following 6 bindings are thus just examples of what they will probably be set to. If you have used the stty command to change these keys, then the default bindings should match.

^C	user-interrupt
^\\	abort
^Z	suspend
<b>^</b> Q	start-output
^s	stop-output
<b>^</b> V	literal-next
M-^C	user-interrupt
M-^\\	abort
M-^Z	suspend
M- <b>^</b> Q	start-output
M-^S	stop-output

Note that above, most of the bindings are defined twice, once as a raw control code like ^C and then a second time as a META character like M-^C. The former is the binding for vi input mode, whereas the latter is the binding for vi command mode. Once in command mode all key sequences that the user types that they don't explicitly start with an ESCAPE or a META key, have their first key secretly converted to a META character before the key sequence is looked up in the key binding table. Thus, once in command mode, when you type the letter i, for example, the tecla library actually looks up the binding for M-i.

The cursor keys are refered to by name, as follows. This is necessary because different types of terminals generate different key sequences when their cursor keys are pressed.

```
right
          cursor-right
```

left cursor-left
up up-history
down down-history

The cursor keys normally generate a key sequence that start with an ESCAPE character, so beware that using the arrow keys will put you into command mode (if you aren't already in command mode).

The following are the terminal-independent key bindings for vi input mode.

	· ·
<b>^</b> D	list-or-eof
<b>^</b> G	list-glob
^H	backward-delete-char
^I	complete-word
\\r	newline
\	newline
^L	clear-screen
^N	down-history
^P	up-history
<b>^</b> R	redisplay
<b>^</b> U	backward-kill-line
^W	backward-delete-word
^X*	expand-filename
^X^F	read-from-file
^x^R	read-init-files
^?	backward-delete-char

The following are the key bindings that are defined in vi command mode, this being specified by them all starting with a META character. As mentioned above, once in command mode the initial meta character is optional. For example, you might enter command mode by typing ESCAPE, and then press 'H' twice to move the cursor two positions to the left. Both 'H' characters get quietly converted to M-h before being compared to the key binding table, the first one because ESCAPE followed by a character is always converted to the equivalent META character, and the second because command mode was already active.

M-\\	cursor-right (META-space)
M-\$	end-of-line
M-*	expand-filename

M-+	down-history
M	up-history

Note that 'I is what the TAB key generates.

### **Entering Repeat Counts**

Many of the key binding functions described previously, take an optional count, typed in before the target key sequence. This is interpreted as a repeat count by most bindings. A notable exception is the goto-column binding, which interprets the count as a column number.

By default you can specify this count argument by pressing the META key while typing in the numeric count. This relies on the digit-argument action being bound to 'META-0', 'META-1' etc. Once any one of these bindings has been activated, you can optionally take your finger off the META key to type in the rest of the number, since every numeric digit thereafter is treated as part of the number, unless it is preceded by the literal-next binding. As soon as a non-digit, or literal digit key is pressed the repeat count is terminated and either causes the just typed character to be added to the line that many times, or causes the next key binding function to be given that argument.

For example, in emacs mode, typing:

M-12a

causes the letter 'a' to be added to the line 12 times, whereas

M-4M-c

Capitalizes the next 4 words.

In vi command mode the meta modifier is automatically added to all characters typed in, so to enter a count in vi command-mode, just involves typing in the number, just as it does in the vi editor itself. So for example, in vi command mode, typing:

4w2>

moves the cursor four words to the right, then deletes two characters.

You can also bind digit-argument to other key sequences. If these end in a numeric digit, that digit gets appended to the current repeat count. If it doesn't end in a numeric digit, a new repeat count is started with a value of zero, and can be completed by typing in the number, after letting go of the key which triggered the digit-argument action.

term(5)

NAME

term – conventional names for terminals

#### **DESCRIPTION**

Terminal names are maintained as part of the shell environment in the environment variable TERM. See sh(1), profile(4), and environ(5). These names are used by certain commands (for example, tabs, tput, and vi) and certain functions (for example, see curses(3CURSES)).

Files under /usr/share/lib/terminfo are used to name terminals and describe their capabilities. These files are in the format described in terminfo(4). Entries in terminfo source files consist of a number of comma-separated fields. To print a description of a terminal term, use the command infocmp -I term. See infocmp(1M). White space after each comma is ignored. The first line of each terminal description in the terminfo database gives the names by which terminfo knows the terminal, separated by bar (|) characters. The first name given is the most common abbreviation for the terminal (this is the one to use to set the environment variable TERMINFO in \$HOME/.profile; see profile(4)), the last name given should be a long name fully identifying the terminal, and all others are understood as synonyms for the terminal name. All names but the last should contain no blanks and must be unique in the first 14 characters; the last name may contain blanks for readability.

Terminal names (except for the last, verbose entry) should be chosen using the following conventions. The particular piece of hardware making up the terminal should have a root name chosen, for example, for the AT&T 4425 terminal, att4425. This name should not contain hyphens, except that synonyms may be chosen that do not conflict with other names. Up to 8 characters, chosen from the set a through z and 0 through 9, make up a basic terminal name. Names should generally be based on original vendors rather than local distributors. A terminal acquired from one vendor should not have more than one distinct basic name. Terminal sub-models, operational modes that the hardware can be in, or user preferences should be indicated by appending a hyphen and an indicator of the mode. Thus, an AT&T 4425 terminal in 132 column mode is att4425—w. The following suffixes should be used where possible:

Suffix	Meaning	Example
-w	Wide mode (more than 80 columns)	att4425-w
-am	With auto. margins (usually default)	vt100–am
-nam	Without automatic margins	vt100-nam
<i>−n</i>	Number of lines on the screen	aaa-60
-na	No arrow keys (leave them in local)	c100-na
-np	Number of pages of memory	c100-4p

-rv Reverse video att4415-rv	-rv	Reverse video	att4415-rv
------------------------------	-----	---------------	------------

To avoid conflicts with the naming conventions used in describing the different modes of a terminal (for example, -w), it is recommended that a terminal's root name not contain hyphens. Further, it is good practice to make all terminal names used in the terminfo(4) database unique. Terminal entries that are present only for inclusion in other entries via the use= facilities should have a '+' in their name, as in 4415+n1.

Here are some of the known terminal names: (For a complete list, enter the command ls -C /usr/share/lib/terminfo/?).

2621,hp2621	Hewlett-Packard 2621 series
2631	Hewlett-Packard 2631 line printer
2631-c	Hewlett-Packard 2631 line printer, compressed mode
2631-е	Hewlett-Packard 2631 line printer, expanded mode
2640,hp2640	Hewlett-Packard 2640 series
2645,hp2645	Hewlett-Packard 2645 series
3270	IBM Model 3270
33,tty33	AT&T Teletype Model 33 KSR
35,tty35	AT&T Teletype Model 35 KSR
37,tty37	AT&T Teletype Model 37 KSR
4000a	Trendata 4000a
4014,tek4014	TEKTRONIX 4014
40,tty40	AT&T Teletype Dataspeed 40/2
43,tty43	AT&T Teletype Model 43 KSR
4410,5410	AT&T $4410/5410$ in $80$ -column mode, version $2$
4410-nfk,5410-nfk	AT&T $4410/5410$ without function keys, version 1
4410-nsl,5410-nsl	AT&T 4410/5410 without pln defined
4410-w,5410-w	AT&T 4410/5410 in 132-column mode
4410v1,5410v1	AT&T $4410/5410$ in $80$ -column mode, version $1$
4410v1-w,5410v1-w	AT&T $4410/5410$ in 132-column mode, version 1
4415,5420	AT&T 4415/5420 in 80-column mode
4415-nl,5420-nl	AT&T 4415/5420 without changing labels

#### term(5)

4415-rv,5420-rv	AT&T 4415/5420 80 columns in reverse video
4415-rv-nl,5420-rv-nl	AT&T $4415/5420$ reverse video without changing labels
4415-w,5420-w	AT&T 4415/5420 in 132-column mode
4415-w-nl,5420-w-nl	AT&T $4415/5420$ in 132-column mode without changing labels
4415-w-rv,5420-w-rv	AT&T 4415/5420 132 columns in reverse video
4418,5418	AT&T 5418 in 80-column mode
4418-w,5418-w	AT&T 5418 in 132-column mode
4420	AT&T Teletype Model 4420
4424	AT&T Teletype Model 4424
4424-2	AT&T Teletype Model 4424 in display function group ii
4425,5425	AT&T 4425/5425
4425-fk,5425-fk	AT&T 4425/5425 without function keys
4425–nl,5425–nl	AT&T $4425/5425$ without changing labels in $80$ -column mode
4425-w,5425-w	AT&T 4425/5425 in 132-column mode
4425-w-fk,5425-w-fk	AT&T $4425/5425$ without function keys in 132-column mode
4425–nl–w,5425–nl–w	AT&T $4425/5425$ without changing labels in 132-column mode
4426	AT&T Teletype Model 4426S
450	DASI 450 (same as Diablo 1620)
450–12	DASI 450 in 12-pitch mode
500,att500	AT&T-IS 500 terminal
510,510a	AT&T 510/510a in 80-column mode
513bct,att513	AT&T 513 bct terminal
5320	AT&T 5320 hardcopy terminal
5420_2	AT&T 5420 model 2 in 80-column mode
5420_2-w	AT&T 5420 model 2 in 132-column mode
5620,dmd	AT&T 5620 terminal 88 columns
5620–24,dmd–24	AT&T Teletype Model DMD 5620 in a 24x80 layer
5620-34,dmd-34	AT&T Teletype Model DMD 5620 in a 34x80 layer
<del> </del>	

(40, (40)	ATTATE (401
610,610bct	AT&T 610 bct terminal in 80-column mode
610-w,610bct-w	AT&T 610 bct terminal in 132-column mode
630,630MTG	AT&T 630 Multi-Tasking Graphics terminal
7300,pc7300,unix_pc	AT&T UNIX PC Model 7300
735,ti	Texas Instruments TI735 and TI725
745	Texas Instruments TI745
dumb	generic name for terminals that lack reverse line-feed and other special escape sequences
hp	Hewlett-Packard (same as 2645)
lp	generic name for a line printer
pt505	AT&T Personal Terminal 505 (22 lines)
pt505–24	AT&T Personal Terminal 505 (24-line mode)
sync	generic name for synchronous Teletype Model 4540-compatible terminals

Commands whose behavior depends on the type of terminal should accept arguments of the form -Tterm where term is one of the names given above; if no such argument is present, such commands should obtain the terminal type from the environment variable TERM, which, in turn, should contain *term*.

#### threads(5)

**NAME** 

threads, pthreads – POSIX pthreads and Solaris threads concepts

#### **SYNOPSIS**

**POSIX** 

cc -mt [ flag... ] file... -lpthread [ -lrt library... ]

#include <pthread.h>

Solaris

cc -mt [ flag . . . ] file . . . [ library . . . ]

#include <sched.h>
#include <thread.h>

#### DESCRIPTION

POSIX and Solaris threads each have their own implementation of the threads library. The libthread library is associated with POSIX; the libthread library is associated with Solaris. Both implementations are interoperable, their functionality similar, and can be used within the same application. Only POSIX threads are guaranteed to be fully portable to other POSIX-compliant environments. POSIX and Solaris threads require different source, include files and linking libraries. See SYNOPSIS.

#### **Similarities**

Most of the functions in the libpthread and libthread, libraries have a counterpart in the other corresponding library. POSIX function names, with the exception of the semaphore names, have a "pthread" prefix. Function names for similar POSIX and Solaris have similar endings. Typically, similar POSIX and Solaris functions have the same number and use of arguments.

#### Differences

POSIX pthreads and Solaris threads differ in the following ways:

- POSIX threads are more portable.
- POSIX threads establish characteristics for each thread according to configurable attribute objects.
- POSIX pthreads implement thread cancellation.
- POSIX pthreads enforce scheduling algorithms.
- POSIX pthreads allow for clean-up handlers for fork(2) calls.
- Solaris threads can be suspended and continued.
- Solaris threads implement interprocess robust mutex locks.
- Solaris threads implement daemon threads, for whose demise the process does not wait.

### Function Comparison

The following table compares the POSIX pthreads and Solaris threads functions. When a comparable interface is not available either in POSIX pthreads or Solaris threads, a hyphen (–) appears in the column.

LOCKING		

#### **Synchronization**

POSIX (libpthread) Solaris (libthread) Multi-threaded behavior is asynchronous, and therefore, optimized for concurrent and parallel processing. As threads, always from within the same process and sometimes from multiple processes, share global data with each other, they are not guaranteed exclusive access to the shared data at any point in time. Securing mutually exclusive access to shared data requires synchronization among the threads. Both POSIX and Solaris implement four synchronization mechanisms: mutexes, condition variables, reader/writer locking (optimized frequent-read occasional-write mutex), and semaphores.

Synchronizing multiple threads diminishes their concurrency. The coarser the grain of synchronization, that is, the larger the block of code that is locked, the lesser the concurrency.

#### MT fork()

If a POSIX threads program calls fork(2), it implicitly calls fork1(2), which replicates only the calling thread. Should there be any outstanding mutexes throughout the process, the application should call pthread atfork(3C) to wait for and acquire those mutexes prior to calling fork().

#### **SCHEDULING**

#### **POSIX**

Scheduling allocation size per thread is greater than one. POSIX supports the following three scheduling policies:

SCHED_OTHER	Timesharing (TS) scheduling policy. It is based on the timesharing scheduling class.
SCHED_FIFO	First-In-First-Out (FIFO) scheduling policy. Threads scheduled to this policy, if not pre-empted by a higher priority, will proceed until completion. Threads whose contention scope is system (PTHREAD_SCOPE_SYSTEM) are in real-time (RT) scheduling class. The calling process must have a effective user ID of 0. SCHED_FIFO for threads whose contention scope's process (PTHREAD_SCOPE_PROCESS) is based on the TS scheduling class.
SCHED_RR	Round-Robin scheduling policy. Threads scheduled to this policy,

if not pre-empted by a higher priority, will execute for a time period determined by the system. Threads whose contention scope is system (PTHREAD SCOPE SYSTEM) are in real-time (RT) scheduling class and the calling process must have a effective user ID of 0. SCHED RR for threads whose contention scope is process (PTHREAD SCOPE PROCESS) is based on the TS scheduling class.

#### Solaris

Only scheduling policy supported is SCHED OTHER, which is timesharing, based on the TS scheduling class.

#### **ERRORS**

In a multi-threaded application, linked with libpthread or libthread, EINTR may be returned whenever another thread calls fork(2), which calls fork1(2) instead. To ensure proper library linking order, use this option, rather than -lthread, to link with libthread.

#### USAGE

#### threads(5)

## -mt compiler option

The -mt compiler option compiles and links for multithreaded code. It compiles source files with -D\_REENTRANT and augments the set of support libraries to include -lthread in the required order.

To ensure proper library linking order, use this option rather than -lthread to link with libthread.

#### **ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Linker and Libraries Guide

**NAME** 

vgrindefs - vgrind's language definition data base

**SYNOPSIS** 

/usr/lib/vgrindefs

#### **DESCRIPTION**

vgrindefs contains all language definitions for vgrind(1). Capabilities in vgrindefs are of two types: Boolean capabilities which indicate that the language has some particular feature and string capabilities which give a regular expression or keyword list. Entries may continue onto multiple lines by giving a \ as the last character of a line. Lines starting with # are comments.

#### Capabilities

The following table names and describes each capability.

Name	Туре	Description
ab	str	Regular expression for the start of an alternate form comment
ae	str	Regular expression for the end of an alternate form comment
bb	str	Regular expression for the start of a block
be	str	Regular expression for the end of a lexical block
cb	str	Regular expression for the start of a comment
се	str	Regular expression for the end of a comment
id	str	String giving characters other than letters and digits that may legally occur in identifiers (default '_')
kw	str	A list of keywords separated by spaces
lb	str	Regular expression for the start of a character constant
le	str	Regular expression for the end of a character constant
oc	bool	Present means upper and lower case are equivalent
pb	str	Regular expression for start of a procedure
pl	bool	Procedure definitions are constrained to the lexical level matched by the 'px' capability
рх	str	A match for this regular expression indicates that procedure definitions may occur at the next lexical level. Useful for lisp-like languages in which procedure definitions occur as subexpressions of defuns.
sb	str	Regular expression for the start of a string
se	str	Regular expression for the end of a string
tc	str	Use the named entry as a continuation of this one
tl	bool	Present means procedures are only defined at the top lexical level

#### vgrindefs(5)

#### Regular Expressions

vgrindefs uses regular expressions similar to those of ex(1) and lex(1). The characters '^', '\$', ':', and '\' are reserved characters and must be 'quoted' with a preceding \ if they are to be included as normal characters. The metasymbols and their meanings are:

\$	The end of a line
^	The beginning of a line
\d	A delimiter (space, tab, newline, start of line)
\a	Matches any string of symbols (like '.*' in lex)
<b>\</b> p	Matches any identifier. In a procedure definition (the 'pb' capability) the string that matches this symbol is used as the procedure name.
()	Grouping
1	Alternation
?	Last item is optional
\e	Preceding any string means that the string will not match an input string if the input string is preceded by an escape character (\). This is typically used for languages (like C) that can include the string delimiter in a string by escaping it.

Unlike other regular expressions in the system, these match words and not characters. Hence something like '(tramp | steamer)flies?' would match 'tramp', 'steamer', 'trampflies', or 'steamerflies'. Contrary to some forms of regular expressions, vgrindef alternation binds very tightly. Grouping parentheses are likely to be necessary in expressions involving alternation.

#### **Keyword List**

The keyword list is just a list of keywords in the language separated by spaces. If the 'oc' boolean is specified, indicating that upper and lower case are equivalent, then all the keywords should be specified in lower case.

#### **EXAMPLES**

**EXAMPLE 1** A sample program.

The following entry, which describes the C language, is typical of a language entry.

```
C|c|the C programming language:\
    :pb=^{d?*?}d?^{p}d?(\a?))(\d|\{):bb=\{:be=\}:cb=/*:ce=*/:sb=":se=\e":\align{center}
    :le=\e':tl:\
    :kw=asm auto break case char continue default do double else enum\
    extern float for fortran goto if int long register return short\
    sizeof static struct switch typedef union unsigned void while #define\
    #else #endif #if #ifdef #ifndef #include #undef # define endif\
    ifdef ifndef include undef defined:
```

Note that the first field is just the language name (and any variants of it). Thus the C language could be specified to vgrind(1) as 'c' or 'C'.

### wbem(5)

### **NAME**

wbem – Web-Based Enterprise Management

### DESCRIPTION

Web-Based Enterprise Management (WBEM) is a set of management and Internet-related technologies intended to unify the management of enterprise computing environments. Developed by the Distributed Management Task Force (DMTF), WBEM enables organizations to deliver an integrated set of standards-based management tools that support and promote World Wide Web technology. The DMTF has developed a set of standards that make up WBEM. This set of standards includes:

 Common Information Model (CIM) - an object-oriented data model that describes the overall management of information in an enterprise network environment.
 CIM consists of a CIM specification and a CIM schema:

CIM Specification Consists of the language and methodology that

describes management data.

CIM Schema Provides actual model descriptions of systems,

applications, large area networks, and devices. The CIM Schema enables applications from different developers on different platforms to describe management data in a standard format. As a result, a variety of management applications can share this

information.

 CIM Operations Over HyperText Transport Protocol (HTTP) 1.1 is a transport mechanism that maps CIM operations to HTTP to allow implementations of CIM to interoperate in an open, standardized manner.

CIM Operations Over HTTP 1.1 uses eXtensible Markup Language (XML), which is a markup language that represents management information in textual form. In addition to the XML representation, CIM information is also represented

textually by the managed object format (MOF). These MOF representations are typically stored as text files that developers compile into a CIM Object Manager.

### EXTENDED DESCRIPTION WBEM Tools and Services

Tools and services that enable developers to create and Services management applications and instrumentation that manage heterogeneous computer environments include:

- Solaris WBEM Services 2.5
- Solaris WBEM Software Development Kit 2.5

### Solaris WBEM Services 2.5

These services consist of a set of value-added Services 2.5 components. These services make it easier for developers to create management applications that run in the Solaris operating environment. They also make the Solaris operating environment easier to manage. Solaris WBEM Services 2.5 consists of:

■ CIM Object Manager, CIM Repository, and MOF Compiler

- CIM and Solaris Schema, which is an extension schema of CIM. CIM and Solaris Schema is a collection of CIM classes that describe managed elements in the Solaris operating environment. These classes are available from the CIM Object Manager at start up.
- Solaris Providers, which are programs that communicate information between the Solaris operating environment and the CIM Object Manager (providers get and set "dynamic" information about managed elements, acting as an intermediary between the CIM Object Manager and the managed elements).
  - Solaris software providers have been developed for a variety of areas: users, roles, file systems, and network configuration, for example. A remote provider is also available to distribute agents away from the CIM Object Manager when required. Because of the incremental development capabilities of the WBEM instrumentation framework, developers can progressively and consistently add more providers for additional Solaris software services.
- SNMP Adapter for WBEM, which enables Simple Network Management Protocol (SNMP) management applications to access system management information that is provided by Solaris WBEM Services. Used with the Solstice Enterprise Agent (SEA) Master Agent snmpdx(1M), the SNMP Adapter for WBEM maps SNMP requests into equivalent WBEM Common Information Model (CIM) properties or instances.

The SNMP Adapter for WBEM also remaps the response from the CIM Object Manager into an SNMP response, which is returned to the management application.

A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation One (ASN.1) type for each object. Developers can create their own mapping files.

SNMP Provider, which enables WBEM services to deliver SNMP information.

# Solaris WBEM Software Development Kit

This kit consists of a set of key application Software development tools that make it easier for developers to write management applications that can communicate with any WBEM-enabled management device. The Solaris WBEM Software Development Kit includes examples, documentation, and CIM Workshop, a graphical user interface through which developers can view and create classes and instances, through the remote method invocation (RMI) or the XML/HTTP protocol.

Developers can also use this kit to write providers, which are programs that communicate with managed elements to access data.

All management applications that developers create with the Solaris WBEM Software Development Kit run on the Java platform. The Solaris 9 WBEM Software Development Kit installs and runs in version 1.4 of the Java environment. Developers can use the kit to write standalone applications or applications that run in conjunction with Solaris WBEM Services.

# wbem(5)

The Solaris WBEM Software Development Kit is described in the *Solaris WBEM SDK Development Guide*. Javadoc for the WBEM application programming interface is located at /usr/sadm/lib/wbem/doc/index.html.

### Compatibility of Solaris WBEM Services with Existing Protocols

Adapters and converters enable Solaris WBEM Services of Solaris to work compatibly with existing protocols by mapping WBEM information to these protocols. One such protocol is Simple Network Management Protocol (SNMP).

Legacy management applications can administer WBEM-enabled software in the Solaris operating environment. Developers can write agents or providers that convert information from these protocols to WBEM, and they can write adapters that convert WBEM information into these protocols.

### **ATTRIBUTES**

### NAME

zones – Solaris application containers

### DESCRIPTION

The zones facility in Solaris provides an isolated environment for running applications. Processes running in a zone are prevented from monitoring or interfering with other activity in the system. Access to other processes, network interfaces, file systems, devices, and inter-process communication facilities are restricted to prevent interaction between processes in different zones.

The privileges available within a zone are restricted to prevent operations with system-wide impact. See privileges(5).

You can configure and administer zones with the zoneadm(1M) and zonecfg(1M) utilities. You can specify the configuration details a zone, install file system contents including software packages into the zone, and manage the runtime state of the zone. You can use the zlogin(1) to run commands within an active zone. You can do this without logging in through a network-based login server such as in.rlogind(1M) or sshd(1M).

An alphanumeric name and numeric ID identify each active zone. Alphanumeric names are configured using the <code>zonecfg(1M)</code> utility. Numeric IDs are automatically assigned when the zone is booted. The <code>zonename(1)</code> utility reports the current zone name, and the <code>zoneadm(1M)</code> utility can be used to report the names and IDs of configured zones.

A zone can be in one of several states:

CONFIGURED	Indicates that the configuration for the zone has been completely specified and committed to stable storage.
INCOMPLETE	Indicates that the zone is in the midst of being installed or uninstalled, or was interrupted in the midst of such a transition.

INSTALLED	Indicates that the zone's configuration has been
	instantiated on the system: packages have been
	installed under the zone's root path.

I	ndicates that the "virtual platform" for the zone has
b	been established. Network interfaces have been
ŗ	plumbed, file systems have been mounted, devices
Ī	have been configured, but no processes associated with

the zone have been started.

RUNNING Indicates that user processes associated with the zone

application environment are running.

SHUTTING DOWN

READY

DOWN Indicates that the zone is being halted. The zone can

become stuck in one of these states if it is unable to tear down the application environment state (such as mounted file systems) or if some portion of the virtual platform cannot be destroyed. Such cases require

### operator intervention.

### Process Access Restrictions

Processes running inside a zone (aside from the global zone) have restricted access to other processes. Only processes in the same zone are visible through /proc (see proc(4) or through system call interfaces that take process IDs such as kill(2) and priocntl(2). Attempts to access processes that exist in other zones (including the global zone) fail with the same error code that would be issued if the specified process did not exist.

### Privilege Restrictions

Processes running within a non-global zone are restricted to a subset of privileges, in order to prevent one zone from being able to perform operations that might affect other zones. The set of privileges limits the capabilities of privileged users (such as the super-user or root user) within the zone. The list of privileges available within a zone can be displayed using the ppriv(1) utility. For more information about privileges, see privileges(5).

### Device Restrictions

The set of devices available within a zone is restricted, to prevent a process in one zone from interfering with processes in other zones. For example, a process in a zone should not be able to modify kernel memory using /dev/kmem, or modify the contents of the root disk. Thus, by default, only a few pseudo devices considered safe for use within a zone are available. Additional devices can be made available within specific zones using the zonecfg(1M) utility.

The device and privilege restrictions have a number of effects on the utilities that can run in a non-global zone. For example, the eeprom(1M), prtdiag(1M), and prtconf(1M) utilities do not work in a zone since they rely on devices that are not normally available.

### File Systems

Each zone has its own section of the file system hierarchy, rooted at a directory known as the zone root. Processes inside the zone can access only files within that part of the hierarchy, that is, files that are located beneath the zone root. This prevents processes in one zone from corrupting or examining file system data associated with another zone. The chroot(1M) utility can be used within a zone, but can only restrict the process to a root path accessible within the zone.

In order to preserve file system space, sections of the file system can be mounted into one or more zones using the read-only option of the lofs(7FS) file system. This allows the same file system data to be shared in multiple zones, while preserving the security guarantees supplied by zones.

NFS and autofs mounts established within a zone are local to that zone; they cannot be accessed from other zones, including the global zone. The mounts are removed when the zone is halted or rebooted.

### Networking

Zones can be assigned logical network interfaces, which can be used to communicate over the network. These interfaces are configured using the <code>zonecfg(1M)</code> utility. The interface is removed when the zone is halted or rebooted. Only logical interfaces can be assigned to a zone.

parameters, 184	me — macros to format technical papers, 255
live_upgrade, 215	mech_spnego — Simple and Protected GSS-API
locale — subset of a user's environment that	Negotiation Mechanism, 260
depends on language and cultural	mm — macros to format articles, theses and
conventions, 219	books, 262
localedef extensions description file —	ms — macros to format articles, theses and
extensions, 57	books, 269
lp_cap_1000fdx — Ethernet mii kstat and ndd	MT-Level — attributes of interfaces, 18
parameters, 184	mutex — concepts relating to mutual exclusion
lp_cap_1000hdx — Ethernet mii kstat and ndd	locks, 274
parameters, 184	Caveats, 275
lp_cap_100fdx — Ethernet mii kstat and ndd	Initialization, 274
parameters, 184	
lp_cap_100hdx — Ethernet mii kstat and ndd	
lp_cap_100hdx — Ethernet mii kstat and ndd	N
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184	
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd	native instruction sets known to Solaris —
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  O openssl — OpenSSL cryptographic & Secure
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  O openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  O openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  O openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  O openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278 overview of concepts related to POSIX thread
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  O openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  Openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278 overview of concepts related to POSIX thread cancellation — cancellation, 30 Overview of Kerberos V5 authorization —
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184  M macros to format articles, theses and books —	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  Openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278 overview of concepts related to POSIX thread cancellation — cancellation, 30 Overview of Kerberos V5 authorization — krb5_auth_rules, 194
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184  M macros to format articles, theses and books — mm, 262	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  Openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278 overview of concepts related to POSIX thread cancellation — cancellation, 30 Overview of Kerberos V5 authorization —
lp_cap_100hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10fdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_10hdx — Ethernet mii kstat and ndd parameters, 184 lp_cap_asmpause — Ethernet mii kstat and ndd parameters, 184 lp_cap_autoneg — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_cap_pause — Ethernet mii kstat and ndd parameters, 184 lp_rem_fault — Ethernet mii kstat and ndd parameters, 184  M macros to format articles, theses and books —	native instruction sets known to Solaris — isalist, 192 NFS and sticky bits — sticky, 396 nfssec — overview of NFS security modes, 276  Openssl — OpenSSL cryptographic & Secure Sockets Layer toolkit, 278 OpenSSL cryptographic & Secure Sockets Layer toolkit — openssl, 278 overview of concepts related to POSIX thread cancellation — cancellation, 30 Overview of Kerberos V5 authorization — krb5_auth_rules, 194

to format Manual pages — man, 247

# PAM account management module for UNIX pam\_unix\_account, 313 pam\_authtok\_check — authentication and password management module, 279 pam\_authtok\_get — authentication and password management module, 281 pam\_authtok\_store — password management module, 283 pam\_dial\_auth — authentication management for dialups, 289 pam\_krb5 — authentication, account, session and password management for Kerberos V5, 290 pam\_krb5 — authentication, account, session, and password management PAM modules for Kerberos V5, 290 pam\_krb5\_migrate — authentication PAM module for the KerberosV5 auto-migration of users feature, 297 pam\_passwd\_auth — authentication module for password, 304 pam\_projects — account management PAM module for projects, 306 pam\_rhosts\_auth — authentication management using ruserok(), 307 pam\_sample — sample module for PAM, 310 pam\_unix\_account — PAM account management module for UNIX, 313 pam\_unix\_cred — PAM user credential authentication module for UNIX, 317 pam\_unix\_session — session management PAM module for UNIX, 319 PAM user credential authentication module for UNIX — pam\_unix\_cred, 317 password management module pam\_authtok\_store, 283 PKCS#11 interface to Kernel Cryptographic Framework — pkcs11\_kernel, 320 pkcs11\_kernel — PKCS#11 interface to Kernel Cryptographic Framework, 320 POSIX — standards and specifications supported by Solaris, 389 POSIX pthreads and Solaris threads concepts pthreads, 424 POSIX pthreads and Solaris threads concepts —

threads, 424

POSIX.1 — standards and specifications supported by Solaris, 389
POSIX.2 — standards and specifications supported by Solaris, 389
privileges — process privilege model, 326
process privilege model — privileges, 326
profiling utilities, profile within a function — prof, 334
pthreads — POSIX pthreads and Solaris threads concepts, 424

### R

rbac — role-based access control, 335
realtime conversion of Solaris audit data to
syslog messages — audit\_syslog, 27
regex — internationalized basic and extended
regular expression matching, 338
regular expression compile and match routines
— advance, 347
— compile, 347
— regexp, 347
— step, 347

role-based access control — rbac, 335
